COMPOSITION, ELECTROTYPING, PRESSWORK, BINDING

BY

J. B. Lyon Company, Albany, New York
PARTIAL LIST OF CONTRIBUTORS TO VOLUME X

ALDEN, RAYMOND M., Ph.D., Litt.D.
Professor of English, Leland Stanford Junior University

ESSAY

BERRY, GEORGE R., Ph.D., D.D.
Professor of Old Testament Interpretation and Semitic Languages, Colgate University

ESTHER, BOOK OF

BOGART, ERNEST L., Ph.D.
Professor of Economics, University of Illinois

FACTORY SYSTEM, THE

BOTHNE, GISLE, A.B.
Professor of Scandinavian Languages and Literature, University of Minnesota

ERASMUS MONTANUS

BREWSTER, WILLIAM T., A.M.
Professor of English, Columbia University

ENGLISH LITERATURE, VICTORIAN PERIOD—POETRY AND PROSE

ESSAY ON MAN, THE

BUCK, H. W., E.E., Ph.D.
Consulting Electrical Engineer, New York

ELECTRICAL ENGINEERING

BUELL, MARCUS D., S.T.B., D.D.
Professor of New Testament Greek and Exegesis, Boston University School of Theology

EPHESIANS, EPISTLE TO THE

BUTLER, AMOS W., A.M., LL.D.
Zoologist and Anthropologist, Indianapolis

ETHNOLOGY

CAIRNS, WILLIAM B., Ph.D.
Associate Professor of American Literature, University of Wisconsin

ELSIE VENNER

FALL OF THE HOUSE OF USHER

CAJORI, FLORIAN, Ph.D., LL.D., Sc.D.
Professor of History of Mathematics, University of California

EQUATIONS, GENERAL THEORY OF

CANFIELD, ARTHUR G., Ph.D.
Professor of Romance Languages, University of Michigan

ELLE ET LUI

CHAMBERLAIN, CHARLES J., Ph.D.
Professor of Morphology and Cytology, University of Chicago

EMBRYOLOGY OF PLANTS

CHANDLER, FRANK W., Ph.D.
Professor of English and Comparative Literature, University of Cincinnati

ELECTRA

EXEMPLARY NOVELS

CHEYNEY, A. R.

ELECTRIC ALTERNATING CURRENT MACHINERY

CHITTENDEN, FRANK H., Sc.D.
Entomologist, in Bureau of Entomology, United States Department of Agriculture, Washington, D.C.

ENTOMOLOGY

CHUBB, PERCIVAL
Leader of the Ethical Society of Saint Louis

ETHICAL MOVEMENT AND ETHICAL SOCIETIES

CLARK, L. PIERCE, M.D.
New York City

EPILEPTIC CONSTITUTION

COCHRANE, CHARLES H.
Author of "Modern Industrial Progress"

ENGINE

ENGINEERING TERMS

COOPER, LANE, Ph.D.
Professor of English Language and Literature, Cornell University

ENGLISH MAIL COACH, THE

COUMBE, CLEMENT W.
Technical Art Expert

*(prime), *(secondary) accents, to indicate syllabic stress
EGYPT. - Greek, Aiguptos; Hebrew, אֵיֵגֶּפֶּ טֹסְסָא, Physos; Arabic, مَازُرَ مَازُرَ, Ma'asar; also called مَازُرَ, Pathros (Is. xi. 11) and نُفْسُ, Eres-Ham, "The land of Ham" (Ps. cvi. 22). Assyrian, مَازُرُ, Mursi; Arabic مَازُرُ, Misr or مَازُرَ.

In Hieroglyphics, 𓊠𓊞 (Komi). Its present name is derived from the Greek, Aiguptos (meaning obscure). The Hebrew name Mizrām is the dual form of Mazor (a fortified or walled-in place or country), viz., two Mazors, "Upper and Lower Egypt." But its principal name upon the monuments and in the papyri is Komi or Komi "Black land," an appropriate name, owing to the black alluvial soil in the Nile Valley, in contradistinction to the reddish soil of the neighboring land on both sides of the Nile.

Modern Egypt is a vast country extending from the Mediterranean Sea, lat. 31° 35' to parallel 22° N. I., called Egypt Proper, thence southward to the British possessions in equatorial Africa, which latter region (known as the Egyptian Soudan) is jointly governed by Great Britain and Egypt. The eastern boundary is the Red Sea, and on the extreme northeast, Wady-el-Arish, Syria. The western boundary runs northwest to Tripoli, and thence southeast through the Libyan desert, to a point 200 miles west of Wady-Halfa. The area of Egypt (exclusive of the Soudan) is about 363,181 square miles, the country extending 675 miles north and south, and 500 miles east and west.

Topography.—In modern as in ancient times Egypt was always divided into the Upper and the Lower, or the Southern and Northern countries. At a very early period it was further subdivided into a number of departments, called nomes, varying in different ages; 42 was probably the usual number. A third great division, the Heptanomion, "seven nomes," preserved in the modern (Wustani) "Middle Egypt," was introduced at the time of the geographer Ptolemy (first half of the 2d century A.D.). Each nome had a separate local government. In the 5th century A.D., Egypt was divided into six eparchies. Augusta Prima and Secunda on the east, Egyptiaca on the west, Arcadia (the former Heptanomion), Thebais Proxima as far as Panapolis, and Thebais Supra to Philæ. Under the Mohammedans, the triple division, Misr-el-Bahri (Lower Egypt); el-Wustani (Middle); and es-Said (Upper) has prevailed, but the number of subdivisions has varied. At present there are altogether five governments of principal towns, and 14 provinces subdivided into districts.

Egypt is connected with Asia by the Isthmus of Suez, across which runs the great canal, about 100 miles long. The inhabited portion of Egypt is mainly confined to the valley and delta of the Nile, the widest part of which does not exceed 120 miles, while in many parts of the valley it is only from 3 to 15 miles wide, and at the southern frontier of Egypt proper, only two miles. West of the Nile are several oases. Two ranges of lofty mountains, the Arabian Hills on the east and the Libyan on the west, enclose this valley. The delta of the Nile is traversed by a network of primary and secondary channels and is also intersected by numerous canals.

Seven principal channels or mouths were usually recognized in ancient times, the names of which, going from east to west, were the Pelusiac mouth, the Tanitic, the Mendesian, the Pithomitic, the Sebennytic, the Bubastian, and the Canopic. Now only the Bolbitine (called Rosetta) and the Pathmetic (Damietta), are in existence. The Nile has a current running seaward at the rate of 2½ or 3 miles an hour and the stream is always deep enough for navigation. The water becomes a reddish-brown during the annual overflow; it is esteemed highly salubrious. Near the sea are the lakes Menzaleh, Birket-el-Mariut and other extensive but shallow lagoons.

The openings or lateral valleys of the hills confining the valley of the Nile are comparatively few, or, being little frequented, are not well known. Those on the east side with which we are best acquainted are the Wady-el Tifi, "Valley of the Wanderings" (of the children of Israel), leading from the neighborhood of Cairo to the head of the Gulf of Suez, and that through which passes the road from Koptos to Kosseir on the Red Sea. A short distance west of the Nile and above the Delta is the fertile valley of Fayyum, in the northwest and lowest part of which is the Birket-el-Kerum Lake, fed by a canal or branch from the Nile. The level of the lake is now 130 feet below that of the
Mediterranean. This lake, formerly known as Lake Moeris, covered a far larger area, and by means of sluices and other works was utilized for irrigation purposes. The deserts on the west bank of the Nile generally present to view plains of gravel or of fine drifting sand; on the east, the scene is varied by rocks and mountains.

Climate.—The atmosphere in Egypt is extremely clear and dry, the temperature regular and hot, though the heat is tempered during the daytime for seven or eight months of the year by the strong wind which blows from the north and which enables sailing vessels to ascend the river against the stream. The winter months are the most delightful of the year, the air being cool and balmy and the ground covered with verdure; later, the ground becomes parched and dry, and in spring the suffocating khamsin, or simoom, frequently blows into the Nile valley from the desert plains on each side of it, raising lofty clouds of fine sand and causing great annoyance, until the rising of the river again comes to bless the land. It rains but rarely, except near the sea shore.

In this rain falls perhaps three or four times in the course of a year, and in Upper Egypt only once or twice, if at all; showers of hail sometimes reach the borders of Egypt, but the formation of ice is very uncommon. Earthquakes are occasionally felt and thunder and lightning are neither frequent nor violent. Egypt is not remarkably healthy, especially in the delta, where ophthalmia, diarrhea, dysentery and smallpox are somewhat prevalent. Many invalids now winter in Egypt, especially in the neighborhood of Cairo, or higher up the river, where the air is dry and pure.

The Nile, Irrigation and Agriculture.—The great historic river Nile, Greek Nilus; Latin Nilus; Hebrew Yeor or Shihor; Arabic Eni-Neel (black), is 3,400 miles in length, the longest in Africa and one of the great rivers of the world. It divides at lat. 30° 15', just below Cairo, into two main streams, the one entering the sea by the Rosetta mouth on the west, the other by the Damietta mouth on the east. These two streams carry the bulk of the Nile water to the Mediterranean and enclose a large portion of the territory known as the delta, from its resemblance to the Greek letter Δ and which owes its existence to the deposits of alluvial matter brought down by the stream. The most remarkable phenomenon connected with the Nile is its annual regular increase, arising from the periodical rains which fall within the equatorial regions and the Abyssinian Mountains. As rain rarely falls in Egypt, the prosperity of the country entirely depends on this overflowing of the river. On the subsiding of the water the land is found to be covered with a brown slimy deposit, which so enriches the soil that with a sufficient inundation, it produces two crops a year, while beyond the limits of the inundation there is no cultivation. The Nile begins to rise about the middle of June and continues to increase until about the end of September, overflowing the lowlands along its course and forming canals or irrigation channels by artificial courses where natural channels fail. After remaining stationary for a short time, the river rises again but subsequently begins to subside, showing a markedly lower level in January, February and March and reaching its lowest in April, May and early June. The overflow water is now to a great extent managed artificially by means of an extensive system of reservoirs and canals, so that after the river subsides it may be used as required. A certain proportion of the fields, after receiving the overflow and being sown, can ripen the crop without further moisture; but many others always require artificial irrigation. Steam pumps are now largely used in northern Egypt. Latterly the government has tried to make the farmers less and less directly dependent on the inundation, and the great barrage of the Nile below Cairo, the largest weir in the world, is one means to this end, the great dam or barrage at Assouan being another.

The native methods of raising water for irrigation are chiefly by the sabtah, or water wheel, and the shaddouf. The first consists of a horizontal wheel turned by one or two oxen, which sets in motion a vertical wheel, around which are hung a number of earthen jars, this wheel being sunk into a reservoir connected with the river. The jars that form the reservoir are brought to a trough on a level with the top. Into this trough each jar empties itself in succession and the water is conducted by an inclined channel into the cultivated ground adjoining, which may have been previously divided into compartments of 1 or 2 yards square by raising the mold into walls or ridges of 5 or 6 inches in height. Into these compartments the cultivator forms an entrance for the water by depressing a little space in the ridge or wall with the sole of his foot; and this overlying of the channels of irrigation and adjustment of the openings from one compartment to the other with the foot is continued till the cultivator is assured by the growth of the plants that each compartment is daily and duly supplied with its proper quantity of water. The second means of raising water, namely, the shaddouf, consists of a leather bucket slung at one end of a pole which has a weight at the other and sways up and down on a vertical support, a continuous basin being enabled to scoop up the water considerably below his feet and raise it with comparative ease to the mouth of a channel on a level with his breast. The latter mode of raising water is of great antiquity and is depicted on the walls of the ancient tombs of Egypt and also in the sculptures of Nineveh. A sufficient rise of the river (the rise varies at different points) is essential to secure the prosperity of the country; and as the water subsides, the chaflet of buckets on the sabtah is lengthened, or several shaddoufs, rising one above the other on the river bank, are required. Should the Nile rise above the requisite height it may do great damage; on the other hand if it should not attain the ordinary height, there is a deficiency of crops; but with rare exceptions, the inundations are regular and nearly uniform. See Delta; Irrigation.

The Nile Barrage.—One of the greatest wonders of modern times, rivaling the Pyramids of the ancients, is the Nile Barrage. Thanks to Lord Kitchener the difficulties presented by the stupendous work at Assouan and Assiat of taming the Nile, is an accomplished fact. Egypt is no more subject to the caprices of the Nile. The precious fertilizing fluid coming down from
equatorial Africa by way of Bahr-el-Ghazal and Bahr-el-Abiyad are halted and stored in an immense reservoir 200 miles long, with, since 1912, a holding capacity of 9,000,000 cubic feet. By the giving of perpetual irrigation two or three crops may be raised annually. This is found on both sides of the river have been reclaimed. Other works have been constructed within the past 10 years, showing equally marvelous results. Egypt's prosperity is always dependent upon the Nile. This "seven year famine" recorded in Scripture was the result of insufficient irrigation, and there is an earlier instance of a similar character recorded in hieroglyphics on the rocks of Assouan. After many centuries of inactivity and decay, Egypt lifts up her head and promises to become again the storehouse of the East.

Oases.—The fertile spots peculiar to the deserts of Africa are found in Egypt along the hollow region of the Libyan Desert, parallel to the Nile. By leaning against the valley of the Nile, and above 80 miles west of it. The Great Oasis or Wah-al-Khargeh, lies immediately west of the Thebaid, and has a length of 100 miles. About 50 miles west of the northern extremity of the oasis lies the oasis of Siwa, which is 24 miles long and 10 miles broad. West by south from the Fayum the date groves of the Little Oasis, or Wah-al-Bahariteh, display their unusual verdure. In this fertile spot arsained wells are numerous and some of ancient construction have been discovered which have a depth exceeding 400 feet. On the road between this oasis and that of El Dakhileh, inclining to the west, occurs half way the Wah-al-Parahfrah of small extent. West of the Fayum and about 200 miles from the Nile, lies the oasis of Siwa. The inhabitants of this settled spot, though tributary to Egypt, are in language and manners wholly Libyuan. The region of the oases terminates toward the north in the desert of the Natron lakes. See Oases.

Owens.—Owing to the absence of forests in Egypt there are few wild animals, the principal species being the fox, jackal, hyena, the wild ass, the ibex in the Red Sea hills and several kinds of antelope. The chief domestic animals are camels, cattle, goats, sheep and goats. The hippopotamus is no longer found in Egypt, though it is met with in the Nile above the cataracts and the crocodile is found in Upper Egypt. Among the birds are three species of vultures (one of which is very large, individuals sometimes measuring eight feet across the wings), eagles, falcons, hawks, buzzards, kites, crows, linnets, larks, sparrows and the beautiful hoopoe, which is regarded with superstitious reverence. Pigeons, quail and various kinds of poultry are very abundant and numerous aquatic birds and pelicans. The ostrich is found in the deserts. Among the reptiles are the horned viper (cerastes) and the asp (naja haja), both poisonous. Fishes abound in the Nile and lakes and furnish a favorite article of food. Water-fowl are plentiful and were formerly prepared and salted like fish. The sacred ibis is still a regular visitor during the inundation and the pelican is found in the northern lagoons. Among the countless insects are the sacred beetle (Alcathous sacer) and the migratory locust.

Flora.—The few trees found in Egypt include the date-palm, tamarisk, sycamore, Christ's- thorn, carob and two species of acacia. Many trees have been planted in recent times, especially about Cairo, such as the lebbek (Albizia Lebbek) and the eucalyptus. The papyrus plant, once so important, is now to be found only in one or two spots. And the productivity of the soil is increased by 50 per cent. Millions of acres on both sides of the river have been reclaimed. Other works have been constructed within the past 10 years, showing equally marvelous results. Egypt's prosperity is always dependent upon the Nile. This "seven year famine" recorded in Scripture was the result of insufficient irrigation, and there is an earlier instance of a similar character recorded in hieroglyphics on the rocks of Assouan. After many centuries of inactivity and decay, Egypt lifts up her head and promises to become again the storehouse of the East.

Geology and Mineralogy.—Granite, cocenite limestone and sandstone are the principal rock formations found in Egypt. But in the Nile Valley from 25° North Latitude to the Fayum, sandstone predominates. At Syene, the southern extremity of Egypt proper, granite predominates. Its quarries have supplied the materials for the obelisks and many colossal statues of Ancient Egypt. A great extent of the country is covered with moving sands; the soil bordering the Nile, owing to the encroachment of the shifting sands of the desert, consists of an argilaceous earth or loam, more or less mixed with sand. In addition to those already mentioned, there are various other minerals, which were employed in architecture, sculpture, etc. These include syenite, basalt, alabaster, breccia and porphyrite and the famous Egyptian products of Ancient Egypt were emeralds, gold from the mines in Upper Egypt, iron from the desert plains of Nubia and natron from the lakes in the Oasis of Ammon (hence named Ammonia, Latin sal-ammoniacum). Bitumen, salt and sulphur are also among the minerals of Egypt.

Government.—Egypt in modern times has been held as a suzerain of Turkey under the rule of a Khedive. In 1879 it came under the joint control of Great Britain and France as surety for the European bondholders. During the rebellion organized by Arabi Pasha in 1882 France refused to intervene and after his defeat and the restoration of the Khedive's authority the dual control came to an end and the government of the country was effectively controlled by the British authorities, but still under Turkish suzerainty. Since the beginning of the British occupation great reforms have been carried through in every department of the public service; the finances have been placed on a sound basis; extensive public works have been carried through; the
Sudan (q.v.) has been reconquered and the fear of incursions from the south brought to an end. In 1883 an organic law was promulgated by the Khedive creating a number of representative institutions whose functions were almost wholly consultative. In July 1913 this law was repealed by an act bringing into being a legislative assembly consisting of 85 members, 66 of whom are elective and in which the ministers sit. Provincial councils have been organized with powers of regulation over markets, local administration and elementary vernacular education and trade schools.

Justice.—The administration of Egyptian justice is extremely complicated. There are four classes of courts: (1) The mukammels, or Mohammedan courts, conducted according to the precepts of the Koran and the principles of the Mohammedan religion, and retaining jurisdiction in matters of personal law only. (2) The so-called native tribunals, composed of 90 summary tribunals, 8 central tribunals and a court of appeals at Cairo. These deal with crimes committed by natives and civil actions between natives. The most recent addition in this category has been the creation of village or cantonal courts, having powers analogous to those possessed by English justice of peace courts. (3) The consular courts, which deal with civil cases between foreigners of the same nationality and also try criminal cases in which the accused are foreigners not within the jurisdiction of the mixed tribunals. (4) The mixed tribunals, dating from 1876, which have jurisdiction in all matters civil and criminal between natives and foreigners or between foreigners of different nationalities. These courts are admittedly successful. A code of laws has been published for the greater systematization of native jurisprudence.

Education.—The chief seat of Koranic education is the famous University of El Azhar, founded by Saladin about 1170 and still employing the same methods of instruction that were originally in use. The faculty numbered in 1819 about 300 moulahs or priests, many having wide reputation for scholarship; the students numbered 3,600. Other institutions of learning are found in Egypt, Syria, Afghanistan and other Mohammedan countries. There is no regular university organization nor arrangement for the endowment of departments or founding of chairs. Anyone who can collect a class is allowed to lecture. Frequently the professors practise law, hold clerkships or are connected with mosques in Cairo. There is no charge for instruction. Three-fourths of the students study theology, though other "ologes" and geography, philosophy and astronomy are also taught. There are also in Cairo eight colleges and professional schools of excellent grade. The Egyptian Ministry of Public Instruction has under its direction schools for engineering, medicine, law and agriculture, technical schools and normal training schools for teachers. A military school is under the management of the war office. The number of indigenous schools under control of the provincial councils on 31 Dec. 1915 was 3,666, with a total enrolment of 250,575 (225,073 boys). Higher educational institutions under the authority of the secretary of education are: 26,662 (20,507 boys, 6,115 girls). Of native Egyptians, according to the census of 1907, 85 per 1,000 males were able to read and write and three per 1,000 females.

Technical Training.—In 1907 the authorities introduced a new system of technical education in Egypt under the direction of Mr. Sidney Wells, which has made remarkable progress despite peculiar difficulties in a country where a technical or an industrial vocation is carried with it a social stigma. It was divided into three branches—industrial, agricultural, commercial. In the first two branches, obviously the most important three sections have been organized, corresponding with the social grades of the people and the needs of the various classes of either branches. In the general educational scheme are the Kiftab or village schools, the primary and the secondary schools. The new plan provides for manual workers, foremen and managers and skilled professional workers. Under industrial education are comprised trade schools, a technical school and a school of engineering; under agricultural are included farm schools, intermediate schools and a school for agriculture. The trade schools—some called model—provide a system of apprenticeship in trades that are in demand and of local interest; the apprentices, all of the poorer classes and from the age of 12 and with but a very rudimentary knowledge, are taught a four years' course in carpentry, furniture-making, plumbing, shoe-making, tailoring, saddlery, etc. They accept outside work, and in 1914 17 such workshops executed orders valued at $150,000. The 11 farm schools afford practical training in elementary agricultural matters to the poorer class.

Demanding primary certificates the Boulaq technical and the intermediate agricultural schools deal with the middle classes. The first has three sections in a four-year course—mechanical and electrical engineering, building trades and scavenging, artistic crafts. The second, in a three-year course, creates in the first case draftsmen, architects, assistant engineers, builders, clerks and lecturers on technical topics; and also to improve the knowledge of landed proprietors and to train pupils to fill managers' positions. The highest schools—those of engineering and agriculture—form, with the schools of medicine and law, the nucleus for the future university. The course is four years and conditioned on the secondary certificate. Irrigation, engineering and architecture, with very advanced agricultural education, are taught. Graduates are fitted to fill vacancies in the ministries of public works and agriculture, to become expert lecturers and occupy higher technical posts outside government service. Besides more instruction the department encourages local industries and introduces modern methods in carpet making or weaving and will provide new industries after the present war. A specialty has been made in Upper Egypt of the manufacture out of natural colored wools of carpets of much beauty and unique design.

Commercial education, the third branch of technical training, is more recent. Evening classes for shorthand and then in typewriting, commercial arithmetic and bookkeeping (in English, French and Arabic) were established in Cairo, Alexandria and Mansura. Last two
schools of commerce were opened, to include specializing in accountancy, secretarial work and general commerce. The authorities, too, co-operate with the training of girls at the Cairo Trade School where dressmaking, embroidery and stock-making are taught, the attending being sold at an adjacent shop. Further five economic schools are operated. In the 51 schools imparting various kinds of instruction are over, 5,500 pupils; nine years ago there were 1,029 pupils in eight such schools. Efforts will be made not to neglect the many native industries. The cotton trade, is of great importance, and the cultivators of the sugar-cane received a great impulse from the viceroy, Ismail, who, at a great expense, erected a number of mills. Goods carried by the Suez Canal do not form part of the commerce of the country, and the transit trade proper is of little importance. In 1915, 4,590 steamers of registered tonnage of 12,553,573 cleared at Egypt of vessels (foreign and coastal) of 85,726 tons. The produce of cotton had increased from 5,001,000 kantars (1 kantar = 99.05 lbs.) in 1909-10 to 6,878,000 kantars in 1914-15. In 1915 the area sown and yield of wheat were 1,592,085 acres and 1,060,000 tons; barley 462,577 acres and 300,000 tons; maize and millet, 2,194,031 acres; rice, 330,923 acres. In the same year the sugar exports amounted to 26,257 tons, valued at $2,668,075, and of these, 70,000 tons and of exports to 6,899,122 landed valued at $95,728,220. The imports for 1915 were valued at $96,644,965 (of which Great Britain sent $43,692,990) and exports at $135,234,360 (of which Great Britain took $69,678,125).

Finance.—The unfortunate financial situation under the former khedives, becoming bankrupt in the time of Ismail Pasha, was in reality a blessing in disguise for the laboring classes, since it led to the reform of conditions which had become well-nigh intolerable. The taxes were exacted with brutal rigor, even torture being resorted to in their collection and they were moreover excessive. The principal taxes were the Kharagh or territorial tax, Werka or income tax and Himi or tax on commerce. From the start the property of the khedive and his higher officials were exempted. The English régime has lowered the imports by over £2,000,000 ($10,000,000) annually and has abolished altogether the hated tax on salt, also the bridge and port tolls on the Nile and those collected from trade and fishing vessels. The registration tax on land sales has been reduced from 5 to 2 per cent, also those on water transport, and the customs duties on coal, combustible liquids, building wood, petroleum, meat and food-stuffs. The inland fisheries have been relieved of the vexatious restrictions under which they formerly labored. The postal, telegraph and railway rates have also undergone a material reduction. Thus it may be said that at present the Egyptians, especially those dwelling in the cities and towns, are unburdened by imports of any kind. Up to 1888 the finances of the country were piling up a yearly deficit. This condition has been remedied until there is now an annual surplus and each year there appears less and less necessity of imposing special taxes for the viceroy's works while the country needs imperatively and the government's reserve fund has increased and also the sum set aside for the amortization of the foreign debt. There has been established a Farmers' Bank which has advanced over 10,000,000 to the cultivators of the soil through the medium of co-operative societies under the patronage of the government. Until 1885 resident Europeans were exempt from taxes, occupying a privileged situation, thanks to the capitulation privileges granted at the time the
Turks were defeated. In the year mentioned, however, the several powers interested declared resident Europeans subject to several taxes, such as the house tax, stamps and licenses, etc., but an Army was not enforced until 1891. The 1913 budget estimated the revenues from all sources at $8,065,000 and the disbursements at $78,150,000. The chief sources of revenue are land taxes, about $27,500,000 annually, railways ($19,000,000), customs ($11,000,000), postal and telegraph receipts ($10,000) and other items ($400,000). The chief items of disbursement are: administration costs ($25,000,000 yearly), the debt service ($17,500,000 yearly) and the railways ($10,000,000 yearly). The foreign debt of Egypt dates from 1862 when loans were made to wipe out the floating debt. Other loans followed and finances were subject to the joint direction of France and England until 1879. In 1876 the several issues were consolidated into one debt of $455,000,000. The administration of the finances is almost entirely in British hands. In 1912 the foreign debt consisted of the 3 per cent guaranteed loan of $36,592,500, the 3½ per cent privileged debt of $155,638,900, the unfranked 4 per cent debt of $279,889,800 and the 4½ per cent dominion loan of $1,017,100, a total foreign debt of $747,780,600, with a guaranteed interest of $17,803,475. Reserve fund established in 1880—90 amounted in 1911 to $25,238,060. At the beginning of 1913 the foreign debt was reduced to $471,748,400. The revenue for 1911—12 was $713,730,000, and the expenditure $79,500,000. In January 1915 the public debt stood at $470,144,200, the charges for interest and sinking fund amounting to $17,756,330.

Money, Weights and Measures.—By decree of 14 Nov. 1883 the monetary unit of Egypt is the Egyptian pound, divided into 100 piastres, weighing 8.5 grammes, .875 fine and containing therefore 7.4375 grammes of pure gold. Therefore £ E = £1 = 0s. = 6½ = $5.00. The piastre (kush or kurush) equals 5 cents, and is divided into 10 parts called ochrel guerche.

The principal pieces in circulation are the pound: 20, 10, 5, 2 and 1 piastre pieces (silver); 1, ½, 1/5 and 1/10 of a piastre (nickel), and ½ and 1/10 of a piastre (brass). The unit of capacity is the arbeh, equal to 43.759 English gallons or 5.44739 bushels. Its approximate weight is 315 rolls for wheat and maize, 320 rolls for beans, 250 rolls for barley and 260 rolls for cotton seed. Weights are the akheb = 1.326 English ounces, the roll = 0.99069 English pounds, the Oke = 2.7513 pounds and the Kantor = 100 rolls or 36 okes or 99.0492 pounds. Linear measures are the дираа balad = 22.8350 inches, the дираа mimar = 29.5281 inches, and the kasab = 139.7653 inches. For square measure: the feddan = 7.468 square pics; pic = 0.562 square metres = 0.936 inches.

Railways, Telegraphs and the Post-Office.

—On 1 Jan. 1915 there were 2,065 miles of railway under state control (exclusive of the Sudan Military Ration and not owned or occupied by railways privately owned. In 1914, 3.594,049 tons of freight were carried, and 24,215,000 passengers, with net receipts of $1,061,912. Telegraphs and telephones belonging to the Egyptian government on 1 Jan. 1915 had a total length of 9,240 kilometers, the length of the wires being 21,882 kilometers. The Eastern Telegraph Company has (by concessions) lines across Egypt from Port Said to Suez and from Alexandria (via Cairo) to Suez. There were in 1914 1,937 post-offices and stations in Egypt. On 19 Sept. 1882, the organization of the Egyptian Army was placed in the hands of a British officer, with the title of Sirdar. Military service is compulsory, but since a very small army is maintained only a very small portion of the men of military age are in the ranks. The term of service is three years. The forces consist of administration officials, music corps, four squadrons of cavalry, nine Egyptian and seven Sudanese battalions of infantry, a camel corps, artillery and sanitation corps, engineers and railway corps, and a veterinary corps. There is a total of 138 English officers, 709 Egyptian officers and 18,381 English soldiers. The Army of occupation, or the English garrison, consists of a cavalry regiment, a battery of artillery, a mountain battery, a company of engineers and four battalions. It is stationed in the Delta. Moreover, in the west, there is a battalion of infantry and a detachment of artillery. The total English force numbers 6,067 men of all arms. The Egyptian government makes an annual budget provision of $750,000 for the upkeep of the force. The navy consists of a steamer for coast and lighthouse service, five revenue cutters, two of which are steam vessels, five skiffs, 11 schooners and one school ship. On the Upper Nile are three steamers and eight gunboats. No details are available since the outbreak of the European War, when the defense of the country was undertaken largely by troops from the overseas Dominions, aided by British warships in the Suez Canal. See section History—Egypt during the European War.

Ethnology.—The origin of the Egyptians is unknown. Ethnologists have endeavored to establish a relationship with the peoples of the south, any differences being accounted for by variations of environment. Philologists have looked to the East for their next regards descent as well as speech. It has been thought by some that an Eastern origin is indicated by the fact that the Egyptian oriented himself by looking to the south, but this is rather due to the direction of trade between the results thus reached there is an evident conflict, with no obvious means of harmonizing them. It has been suggested that the facts can best be reconciled upon the theory, not of a migration of a whole people, but of an incursion of a smaller band who succeed in establishing their rule over the original people and in gradually forcing their own language, as that of a ruling class, upon those whom they had subjugated, while still the ancient ethnological type persisted. This theory is merely a working hypothesis, and it has reference to a time long anterior to any historical monuments or traditions, for long before the earliest extant inscription Egypt was a united country under the rule of native kings, and possessed miles of land; and the present government and of well-defined classes of society. Judging from the language and the physical condition of the mummies of ancient Egypt, the population appears to have been of mixed origin, part Asiatic and part Nigritic; and there seems also to have been an abnormal race of copper color, with rather thin legs,
large feet, high cheek-bones and large lips; both types are represented on the monuments.

A national name for the people as such never seems to have existed. Among themselves they were Romet, men, par excellence; all others were inferior races, miserable Cushites, Libyans, Asatics, Semi. They themselves were the wards of the great gods, and Pharaoh was descended from Ra, who had himself once ruled in Egypt. Other peoples were descended from the enemies of their deities, and when Ra had overthrown them at Edfu a portion escaped, those southward became Ethiopians, northward Asatics, westward Libyans, eastward Bedouin.

Personal experience has warped the judgment of observers as to their character. Herodotus praises the cleverness of the Egyptians and their excellence of memory; Diodorus declares them to be the most grateful of people; the Emperor Hadrian characterized them as "thoroughly frivolous, unstable, following every rumor, refractory, idle and licentious." The modern notion is that they were so occupied with the thoughts of the future as to be oblivious of the present. They regarded the Pyramids, still the wonder of the world, possessed of sufficient skill to perform the task of numbers laborers who would test modern mechanics severely, practical in their methods of utilizing the forces of nature; peaceable as compared with other nations, and little given to love of novelty; artistic in their execution and accurate in their proportions, keen to realize, universal in literary arts, devoted to agricultural pursuits, developed within narrow limits, and little affected by external and foreign influences.

The peasant class, or Fellahin, is the most numerous class in the population of the present day and is indigenous. They are to a certain extent descendants of the ancient Egyptians, but they have been subjected to crossings and have embraced Mohammedanism. Next in number are the Copts, the descendants of the ancient Egyptians who embraced Christianity. The Copts are very few in number, and little affected by the Christian religion. (See Copts.) Though comparatively few in number (about 600,000), their education and useful talents enable them to hold a respectable position in society filling the posts of clergymen, accountants, etc. With these aboriginal inhabitants are mingled various proportions Turks, Arabs (partly Bedouins), Armenians, Berbers, negroes, and a considerable number of Jews, Greeks and other Europeans. The Turks hold many of the principal offices under the government. The great bulk of the people are Mohammedans, the Christians being only about 7.5 per cent. The Egyptians in the mass are quite illiterate, but under the supervision of the Ministry of Public Instruction progress is being made.

The Fellahin, the most superior type of the Egyptian, are a fine race, handsome, of excellent physique, and courteous in their manners. In northern Egypt they are of a yellowish complexion, growing darker toward the south, until the hue becomes a deep brown. Mr. Lane, the best authority upon the subject, speaks highly of their mental capacity, and gives them credit for uncommon quickness of apprehension and readiness of wit. They are highly religious, and are generally honest, cheerful, humane and hospitable. But these are exceptions in a mixed population of Bedouins, negroes, Abyssinians, Turks, Syrians, Greeks, Armenians, Jews and Europeans.

Population.—The population, according to the census of 1907, was 11,189,978, and is estimated at present to be about 12,500,000. Of this total 5,567,074 were males, and 5,620,285 females. The population was divided by nationality as follows: Egyptians, 10,903,677; Ottomans, 69,725; Sudanese at 65,162; Greeks, 62,973; Italians, 34,926; English, 20,653; French, 14,591; Austro-Hungarians, 7,704; Russians, 2,410; Germans, 1,847; Persians, 1,385; all others, 4,925. In 1800 the French estimated the population at 2,460,000. In 1821 the census returns showed 2,536,400; that of 1846, 4,476,440; of 1882, 6,831,131; 1897, 9,734,405; 1907, 11,189,978. According to its religious beliefs the population is divided as follows: Musulmans, 10,269,445; Copts, 708,322; Orthodox Greeks, 76,953; Roman Catholics, 17,741; Jews, 15,385; Greek Catholics, 38,635; others, 28,143. Of the Egyptian population over 10 years 62.65 per cent was engaged in agriculture and of the foreign element less than 1 per cent; 16.27 per cent of the natives engage in commerce and industry, in which are employed 47.85 per cent of the foreigners.

History.—The history of Egypt and its civilization covers a period that the most recent studies estimate as extending over 10,000 years. From this, according to Petrie, should be deducted the 3,500 years that witnessed the first stumbling prehistoric efforts at expression, and in addition the centuries of Greco-Roman domination, and the period from the beginning of Christianity down to our days. This leaves a period of over 50 centuries during which the religious, artistic, social and political ideas of the people underwent little change, and did not absorb any elements of the civilization of Asia and the rest of the Mediterranean littoral. Egyptian chronology, to which reference is constantly made in treating of the monuments executed during the 30 dynasties, deemed historical, arrises only at exact historical certitude from the period of the conquest of Alexander the Great (about 340 B.C.). The divisions established by historians and archaeologists are based chiefly on the fragments of Egyptian history written in Greek in the 3rd century B.C. by Manetho, priest of Heliopolis. It contained the lists of the kings, from the 1st dynasty down to Alexander. But unfortunately only about one-third of the original was come down to us. (The fragments and lists of kings were published in Müller's 'Fragmenta historicae graecorum' Paris 1848). The exactitude of the periods at which began the several dynasties varies greatly. The Egyptians divided the solar day into 24 hours, the latter they subdivided into minutes, seconds, and thirds of seconds; 10 days formed a week, and 3 weeks one month, 12 months (360 days) and 5 complementary days formed the Egyptian year. In remote times the year consisted of 360 days, but the premature arrival of the seasons being noticed, 5 days were added (6th dynasty), the five complementary days were added. The year was divided into three
seasons: the first (Skhat), commenced 19 July, terminated about 15 November and corresponded to the period of the inundation of the Nile; the second (Peri) from 15 November to 15 March, and the third (Shmu) from 15 March to 19 July. There is as we have noted above considerable rivalry among Egyptologists in regard to fixing the dates of the various dynasties. Myer and Sethy have assigned the beginning of the 1st dynasty to a date corresponding approximately to the year 3400 B.C. Breasted, Erman and Stein dorff also favor this date. A notable circumstance in this connection is the complete lack of any reference to eclipses in the Egyptian texts so far interpreted. The history proper divides itself into six great periods: (1) The Pharaohs or native kings; (2) the Persians; (3) the Ptolemies; (4) the Romans; (5) the Arabs; (6) the Turks.

The Pharaohs.—The main sources of his history under the Pharaohs are the Scriptures, the Greek writers Herodotus, Diodorus and Eratosthenes, and fragments of the writings of Manetho (an Egyptian priest in the 3d century B.C.). From Herodotus' account we learn that the Hebrew patriarch Abraham went into Egypt because of a famine that prevailed in Canaan. He found the country ruled by a Pharaoh, Egyptian per as, meaning "Great house," the Egyptian term for a capital. The capital was called the Per-Neteru, and according to the chronology of the Hebrew text of the Bible, was 1920 B.C.; according to the Septuagint, 2551; while Bunsen fixed it at 2876. Nearly two centuries later Joseph, a descendant of Abraham, was sold into Egypt, as a slave to Potiphar, the captain of Pharaoh's guard. In a district called the land of Goshen. There they remained until their numbers had multiplied to two or three millions, when under the lead of Moses they revolted and quitted Egypt.

Ptolemaic Period.—When Alexander's army occupied Memphis the numerous Greeks who had settled in Lower Egypt found themselves the ruling class. Egypt became at once a Greek kingdom, and Alexander showed his wisdom in the regulations by which he guarded the prejudices and religion of the Egyptians. He founded Alexandria as the Greek capital, which became the emporium of commerce and centre of learning for several centuries. Ptolemy I was succeeded by Ptolemy II, Philadephus. He was successful in his external wars, built the Museum, founded the famous library of Alexandria, purchased the most valuable manuscripts, engaged the most celebrated professors, and had ordered 70 Hebrew sages to translate the Hebrew Scriptures into the Greek language, under the direction of the famous Greek grammarian, known as the Septuagint, and the Egyptian history to be written by Manetho. His successor Ptolemy III, Euergetes, pushed the southern limits of his empire to Axum. Ptolemy IV, Philopator (221-204 B.C.) warred with Antiochus, persecuted the Jews and encouraged learning. Ptolemy V, Epiphanes (204-180 B.C.) experienced repeated rebellions, and was succeeded by Ptolemy VII, Philometor (180-145 B.C.) and Euergetes (145-116 B.C.) by Ptolemy X, Soter II and Cleopatra, till 106 B.C. and by Ptolemy XI, Alexander I (87 B.C.) under whom Thebes rebelled; then by Cleopatra, Berenice, Ptolemy XII, Alexander II (80 B.C.), and Ptolemy XIII, Neos Dionysius (51 B.C.), and finally by the celebrated Cleopatra. After the battle of Actium (31 B.C.) Egypt passed into the condition of a province of Rome, governed always by a Roman governor of the equestrian, not senatorial, rank.

The Egyptians had continued building temples and covering them with hieroglyphic inscriptions as of old; but on the spread of Christianity the older religions lost their sway. Then the Christian catechistical school arose in Alexandria, which produced Clemens and Origen. Monasteries were built all over Egypt; Christian monks took the place of the pagan hermits, and the Bible was translated into Coptic. See Egyptian Archaeology and Exploration; Egyptian Architecture; Egyptian Arts; Egyptian Language and Writing; Egyptian Literature; Egyptian Music; Egyptian Religion and Society; Moses; Pharao; Ptolemy; Cleopatra.

Christian Era.—On the division of the great Roman empire by Theodosius (337 A.D.) into the Western and Eastern empires, Egypt became a province of the latter. It was a land of fertile soil and a great deep in barbarism and weakness. It then became the prey of the Saracens, 'Amr ibn el-Asr, their general, under the Caliph Omar, taking Alexandria, the capital, by assault. This happened 641 A.D., when Heraclius was the emperor of the East. As a province of the caliphs it was under the government of the celebrated Abbassides—Harun al-Rashid and Al-Mamon and that of the famous Sultan Saladin. The last dynasty was, however, overthrown by the Mamelukes (1240), and under those formidable despots the last shadow of former greatness and civilization disappeared. Selim, Sultan of the Turks, eventually (1516-17) conquered the last Mameluke sultan, and Egypt became a Turkish province, governed by a pasha. After this it was the theatre of innumerable Mameluke boys against the Turkish domination, which was several times nearly extinguished. Confusion and civil war between the different factions of the Mamelukes continued to prevail till 1798, when the French invasion under Napoleon Bonaparte united their chiefs in self-defense; but the Mameluke army was all but annihilated in the battle of the Pyramids. The French then conquered the whole of Egypt and held it till 1801, when they were driven out by the British under Abercromby and Hutchinson. On the expulsion of the French the Ottoman Porte effectually urged its claim to sovereignty, and the accession of the Albanian soldier Mohammed 'Ali to the pashalic in 1805 imparted to the galvanic prosperity to Egypt by the merciless destruction of the Mamelukes (who, when a disastrous British expedition in 1807 vainly sought to restore), the formation of a regular army, the increase of security, the improvement of the irrigation and the introduction of the elements of European civilization. Mohammed 'Ali reduced the turbulent Mamelukes (whom a disastrous British expedition in 1807 vainly sought to restore), the formation of a regular army, the increase of security, the improvement of the irrigation and the introduction of the elements of European civilization. Mohammed 'Ali, reduced the turbulent Mamelukes (whom a disastrous British expedition in 1807 vainly sought to restore), the formation of a regular army, the increase of security, the improvement of the irrigation and the introduction of the elements of European civilization. Mohammed 'Ali reduced the turbulent Mamelukes (whom a disastrous British expedition in 1807 vainly sought to restore), the formation of a regular army, the increase of security, the improvement of the irrigation and the introduction of the elements of European civilization.
his troops, under Ibrahim, occupied various points in the Morea and Crete, to aid the Turks in their war with the insurgent Greeks. The Egyptian fleet was annihilated at Navarino, and Ibrahim remained in the Morea till for his life he was tried by the French army under Maitson, in 1828. In 1831 Ibrahim began the conquest of Syria, and in the following year totally routed the Ottoman army at Komiyah, after which the Porte ceded Syria to Mohammed 'Ali on condition of his being the victor over the Egyptians again. The victory of Nisib in 1839 would perhaps have elevated him to the throne of Constantinople; but the quadruple alliance in 1840, the fall of Saint Jean d'Acre to the British and the consequent evacuation of Syria, compelled him to limit his ambition to the pashalie of Egypt. In 1848 Mohammed 'Ali became imbécile (he died in 1849), and his son Ibrahim sat on his throne for two months, when he died, and Abbas Pasha, Mohammed Ali's grandson, succeeded him and his successors in turn: 1853 Sa'id Pasha, youngest son of Mohammed 'Ali. M. de Lesseps then obtained the co-operation, hitherto withheld, of the Egyptian government in his scheme of the Suez Canal, which was opened in 1869. Sa'id was killed in battle (1863) by his nephew, Ismail, son of Ibrahim, who by a firman purchased from the Sultan (1866) the hereditary title of Khedive. He obtained the hereditary title of Khedive to the throne of Egypt, direct from father to son, instead of descending, according to Turkish law, to the eldest male of the family, and in 1872 the Sultan granted to the Khedive the rights (withdrawn in 1879) of concluding treaties and of maintaining an army, and virtually gave him sovereign powers. Thus secure on an hereditary throne, Ismail began a series of vast internal reforms, built roads, bridges, lighthouses, railways and telegraphs, reorganized the postal service, improved the harbors at Suez, Port Said and Alexandria, supported education, and introduced mixed courts of law. His possessions southward, he annexed Dar-For in 1874, and in that and the following year further conquests were made. The condition of the finances led to the establishment of "dual control" by Great Britain and France, and in 1879 Ismail was forced to abdicate under pressure of the British and French governments, and was replaced by his son, Tewfik. His position was soon threatened by the so-called National party with Arabi Pasha at its head, who aimed at his deposition and the abolition of European intervention. In May 1879, a rising took place in Alexandria, when many Europeans were killed and their houses pillaged. The Khedive fled from Cairo, where Arabi remained autocrat. The French refusing to interfere, Great Britain demanded, and on 31 July a British fleet bombarded the forts at Alexandria, causing the rebels to retreat. In August a force under Sir Garnet (afterward Lord) Wolseley landed at Ismailia, and on 13 September Arabi's forces were totally defeated at Tel-el-Kebir and the rebellion crushed. Arabi and his associates, being harrassed, retired against Egyptian rule had broken out in the Sudan under the leadership of Mohammed Ahmed, who professed to be the Mahdi or divinely-sent Mohammedan conqueror. His followers soon became numerous, defeated Egyptian troops that opposed them, and threatened the existence of all the Egyptian garrisons in the Sudan. In 1883 they annihilated an Egyptian force under General Sir H. Graham, Meantime Obeid in Kordofan, and in 1884 Osman Digna, as representing the Mahdi, defeated another force under Baker Pasha near Suakim. British troops were now dispatched to Suakim, and at El Teb and Tamai severe defeats were inflicted on the Arabis breaking out again. General Gordon had been sent to Khartum to withdraw the garrisons from the Sudan, but he was shot up in the town for nearly a year, and perished before the relief expedition under Sir Garnet Wolseley could reach him (January 1885). The Sudan was then given up, and the southern boundary of the Egyptian dominions fixed at Wady-Halfa.

In 1892 Tewfik died, and was succeeded by his son, Abbas Hilmi, who is the seventh vice-roy and third khedive of Egypt. In 1896 an Anglo-Egyptian expedition for the reconquest of the lost provinces was dispatched under Sir Herbert (afterward Lord) Kitchener. Dongola was soon occupied. Abu Hamed was captured in the following year, and (8 April 1898), the Egyptian insurgents were defeated near the confluence of the Atbara. Finally (2 Sept. 1898) the forces of the Khalifa, as the Mahdi's successor was called, were defeated with great slaughter at Omdurman, near Khartum. The territory thus reconquered was placed under a governor-general, and was rapidly organized. A subsequent attempt of France to occupy Fashoda and enforce a claim to the Bahr-el-Ghazal "Blue River" Valley led to some friction with Great Britain.

Egypt During the European War.—Owing to the entrance of Turkey into the war on the side of the Central Powers, and to the adhesion of the khedive to the king's enemies, a British protectorate was declared and the Khedive Abbas Pasha deposed on 18 Dec. 1914. Prince Hussein Kaimed, a living relative of the family of Mohammed 'Ali, a former viceroy of Egypt, was appointed in his stead, under the title of Sultan of Egypt. Two unsuccessful attempts at his assassination have been made (8 April and 9 July 1915). Sir Arthur McMahon was appointed British high commissioner. Turkish armies under German leadership have made successive attempts to attack the Suez Canal as preliminaries to an invasion of Egypt. The most dangerous of these incursions were: (1) On 2 Feb. 1915 the Turks attempted to cross near Toussoum, 35 miles north of Suez; (2) on 23 April 1916 an attempt was made at the Quatia Oasis, 2 miles east of the canal, on the road to El Kastara; (3) the most formidable effort was made on 4 Aug. 1916 when 14,310 Turks, under General d'Istria, with four battalions, 22 miles west of Port Said, 6 miles west of Port Said, and just north of Kalia, on a front of seven or eight miles. The British troops, under the command of Sir Archibald Murray, and composed mainly of Australians and New Zealanders, succeeded by a strategic retirement in involving the Turks, which fell upon their rear, and succeeded in taking 2,500 unwounded Turkish and German prisoners. EGYPTIAN ARCHEOLOGY AND EXPLORATION. The attention of the world was drawn to Egypt, as a scientific field for the scientific exploration in the early part of the 19th century. M. Boussard, a French officer under Bonaparte (1799), discovered at Fort Julien, near Rosetta, a large block of black granite, with the remains of three inscriptions, the two in hieroglyphics, the third in demotic characters, the third in Greek. This Rosetta Stone was taken to England after the capitulation of Alexandria (1801), and presented by George III to the British Museum. It contains a decree promulgated at Memphis, in honor of Ptolemy V, Epiphanes, by the priesthood of Egypt in synod assembled, thanking that sovereign for the benefits which he had conferred on them. They ordered it to be sent to all the temples of the first, second and third rank, there to be preserved on stelae in the three forms of writing then used throughout the land. When found, half of the hieroglyphic portion of the Rosetta copy was wanting, but the demotic and Greek were nearly complete, and the work of decipherment began with them. The French orientalist. Champollion, made out the demotic some of the proper names mentioned in the Greek (‘Lettre au Citoyen Chaptal sur l’inscription egyp
tienne du monument de Rosette’ Paris 1802); and the Swede Akerblad, following in his steps, ascertained the hieroglyphic values to most of the signs employed in the proper names (‘Lettre sur l’inscription egyp
tienne de Rosette adressee au Citoyen S. de Sacy’, Paris 1802). In 1814 Thomas Young, the English mathematician, succeeded in isolating a number of groups which express common names, and even in translating some fragments of demotic phrases. Turning to the hieroglyphs he tried to determine the power of the characters, which being enclosed in cartouches or rings, were known to indicate the names of time. Thus he read the names of Ptolemy and Berenice, but he failed to analyze them exactly; five only of the values which he proposed for the signs turned out to be true. The problem with which Young had such poor success was solved forty years later by Champollion, who had felt attracted to the study of the Oriental languages from his early youth and published at 24 the famous work ‘L’Egypte sous les Pharaons’ (2 vols., Paris 1814), on the civilization and history of Egypt. Guided by his thorough knowledge of the Coptic, he applied himself to the decipherment of the inscriptions, and ascertained very soon that the three kinds of characters found in the monuments, far from representing three independent systems, were three successive developments of one system of writing, of which the hieroglyphs were the prototype, the hieratic and demotic the cursive forms. (‘De l’ecriture hieratique et demotique (1816); ‘Egypte et les Nubiens’ (Grenoble 1821). He then dissected the cartouches which had been studied by Young and proved that the hieroglyphs in them were always taken alphabetically, and that the alphabet thus employed for the rendering of the Greek royal names was used at the same time of the first dynasties, not only for proper names, but for the common parts of the language. He gave a general outline of his system to the Academie des Inscriptions on 22 Sept., 1822, a day famous as marking the foundation of Egyptology. He completed his revelations, and explained fully his method in his ‘Precis du systeme hieroglyphique des anciens Egyptiens’ (Paris 1824; 1828). He spent the last eight years of his life in working out the principles which he had established for the reconstruction of the old Egyptian writing. In 1828-30 he searched Egypt from Alexandria to Wady-Halfa with the help of other French and Italian archaeologists. Upon his return he was made professor of Egyptian literature at the College de France in 1832, and having overtaxed his strength during the journey to Egypt. His rapid success had raised up a host of detractors and opponents. Klaproth criticized his work with a bad faith and virulence which even death did not abate; Spohn and Seyffarth stated that the work he had so well begun. Nestor Lhote, Charles Lenormant and Dulauffer in France; Salvolini, Rosellini, Ungarelli, in Italy; Seemans in the Netherlands; Wilkinson, Birch and Osborn in England. Champollion’s Figurae dea humana to the memory of his younger brother, and published the most important of his unfinished books, his ‘Lettres ecrives d’Egypte’ (Paris 1833); and his ‘Grammaire Egyptienne’ (ib. 1836-41); his ‘Dictionnaire Egyptien et ecrivien hieroglyphique’ (ib. 1841-46); ‘Monuments de l’Egypte et de la Nubie’ (ib. 1835-75), completed by Maspero. Since then the story has been a perpetual record of success and discoveries. Lepsius analyzed critically in his ‘Lettre a M. Rosellini sur l’alphabet hieroglyphique’ (Rome 1837) the structure of the old language and elucidated the origin and mechanism of the syllabic characters, the existence of which had only been surmised by Champollion. Lepsius, however, early left philological for historical and archaeological researches. From 1837 to 1885 nearly every year was marked by the appearance of some important work from his pen: ‘Das Todtenbuch der Agypter’; ‘Uber die XII. aegyptische Konigsdynastie’; ‘Einleitung in die Chronologie’; ‘Uber den ersten aegyptischen Gotterkranz’; ‘Koenigsbuch der alten Agypten’, etc. Large portions of these have become anti-
TOMB IN THE VALLEY OF EL ASSASSIF, THEBES, EGYPT
quated, but they formed the solid ground upon which the chronology and history of ancient Egypt have been built up. His three years' stay in the Nile Valley at the head of a commission of German scientists (1842-45) has created the gigantic "Denkmäler aus Ägypten und Äthiopien" (12 vols., Berlin 1849-89), in which all the historical texts known at the time were reproduced by the skilful hand of Weidenbach. Bunsen popularized the ideas of Lepsius in his "Ägypten und seine Philologen" (Hamburg 1849); Brugsch applied himself to the demotic texts ("Scriptura Aegyptiorum demotica", Berlin 1848); "Grammaire démotique" (ib. 1885). While things went thus in Germany, Emmanuel de Rougé commenced his labours in France with his "Examen critique de l'ouvrage de M. le Chevalier de Bunsen," in which the merits of Bunsen's and Lepsius' work were fully recognized, while their errors and fallacious hypotheses were pointed out with a vigor of method and a certainty which placed the young savant among the first of Egyptologists. He remodelled the grammar in his "Chrestomathie Egyptienne" (Paris 1867-76), he called back to life the first dynasties in "Recherches sur les monuments qu'on peut attribuer aux six premières dynasties de Manthoni" (ib. 1886), and his pamphlets, he was the first who really translated whole Egyptian books and inscriptions, both hieroglyphic and hieratic. He gave a new impulse to the study not only in France, where Chabas, Devriera, Pierrert and Maspero followed him, but also in England, where the young Egyptologists were sent every year to Egypt to excavate, draw, copy and publish the monuments. They are helped in the work of finding and preserving the remains of antiquity by an Anglo-American society, the Egypt Exploration Fund, the first secretary and real promoter of which was Amelia B. Edwards (1882-92). In 1883 they sent out their first agent, E. Naville of Geneva, and he cleared the site of Pithom in the land of Goshen. Since then Naville, Flinders Petrie, Griffith, Gardner and Newberry have been at work. Naucratites has come to light, Tanis and Babastis, the Pyramids of the Fayum, the tombs of Beni-Hasan and El-Amarna have yielded unexpected treasures of archaeological and historical lore. The last few years have seen wonderful discoveries in Egypt, for the tombs of the kings of Abydos have been opened and the treasures which have been found bring us face to face with archaic history. Among the remarkable finds were a carved slate slab showing King Nár-mer slaying his enemy, an ebony table, a bar of gold, gold jewelry, inlaid with turquoise and amethyst. The oldest group of jewelry in the world is undoubtedly the four bracelets of the queen of King Zer or Tet (4366 B.C.), which was discovered with a portion of the mummy in a hole in a wall. This is 1,500 years earlier than any other jewelry thus far identified. The bracelets show a wonderful perfection in the soldering of gold. They also give a glimpse of the development of Egyptian art; the finest bracelets are formed of alternate plaques of gold and turquoise, each surmounted with a royal hawk. The turquoise hawks are clumsy, of a more archaic form than those on the gold pieces.

An American archaeologist, Theodore M. Davies, has made one of the most interesting discoveries of recent years in excavating the tomb of Thothmes IV of the 18th dynasty. The tomb contained the chariot in which he rode at Thebes. Like other royal tombs it consisted of a gallery cut in the heart of the mountain. After sloping downward for a considerable distance it is interrupted by a deep square well; on one of the walls is a band of paintings. On the farther side of the wall the passage turns back and finally opens into a large chamber, at the extreme end of which is a magnificent sarcophagus of granite covered with texts from "The Book of the Dead." On either side are smaller chambers; the floor of one of them was covered with the offerings made to the dead king, consisting of mumifed meat, fish, fowl, mutton and trussed ducks and geese. Clay seals with the name of the Pharaoh had been attached to the doors of the chambers, and it is stated that the raised portions of the seals had been smeared with blue ink before being pressed on the clay. A great many of the objects in the tomb of Thothmes were found to be broken, and this was explained by a hieroglyphic inscription on one of the paintings which add to the walls of the vestibule to the chamber in which the sarcophagus was found. The inscription states that the tomb was plundered by robbers, but that it had been restored as far as possible to its original condition by Hor-em-heb, the reigning Pharaoh. The floor was covered with vases, dishes, symbols of life and other objects in blue faience. Unfortunately, nearly all of them had been wantonly broken, though it is possible that the breakage had been repaired in the time of Hor-em-heb. Equally interesting is a piece of textile fabric into which hieroglyphic characters of different colors have been woven with such wonderful skill as to present the appearance of painting on linen. The chariot is one of the finest specimens of art that have come down to us from antiquity. Along with the chariot was found the leather gauntlet with which the king protected his hand and wrist when using the bow or reed. Later excavations at Abydos have brought to light the royal tomb of Menes, of the first dynasty, in which was found a large globular vase of green glaze, with Menes' name inlaid in purple. Thus polychrome glazing is taken back thousands of years before it was previously known to exist. There are also several pieces of delicately carved ivory of that age. One represents the figure of an aged king, which, for subtility of character, stands in the first rank of such work, and ranks with the finest work of Greece and Italy. The old pottery takes back its relation to Egypt some 4,000 years. Hitherto no trace of the camel had appeared before Greek times. The ivory carv-
EGYPTIAN ARCHITECTURE.

The most ancient monuments of the world's architecture in stone are those of the Nile Valley. The ruins of some ancient Chaldean buildings are probably of earlier date, but they are almost entirely of sun-dried brick, while the tombs and pyramids of the early Egyptian dynasties are many of them in excellent preservation. The people who built them were probably of Asiatic origin but long-settled along the Nile, and were a highly civilized race thousands of years B.C. It is customary to divide the history of ancient Egyptian art into five periods: (1) the Old Kingdom (or Memphite Empire, c. 3100-2680 B.C.), comprising ten dynasties of kings; (2) the Middle Empire, with Thebes as capital, 2150-1788 B.C., two dynasties; (3) the Second Theban or New Empire (1588-1150 B.C.), comprising the dynasties xvii-xx., and separated by instances and periods of art, the artistic interregnum of the Hyksos or Shepherd kings (Arabs); (4) the Decadence or Saitic period of six dynasties, 1150-324 B.C., which includes the Persian conquest in 525 B.C., and (5) the Ptolemaic and Roman period (324 B.C.-A.D.).

Then followed a period of over three centuries during which the only architectural works were Coptic churches and monasteries. The Arabs conquered Egypt in 642 A.D., since which date the architecture has been of the Arabo-Moslem or "Saracenic" style, an architecture of mosques, tombs, palaces, baths, fountains and city gates. As this last period, with its infiltrations of Turkish influence since 1517, is treated of under Moslem Art (q.v.), the present article will be confined mainly to the ancient art of Egypt from which brief reference to the Coptic development.

Materials and Character.—There is evidence that the primitive architecture of the Egyptians was of mud ("crude" or sun-dried brick) and wood, but the monuments that have survived to our time are of stone, except for some scanty remains of brick. The stones employed were granite of various kinds and limestone; the coarser stone being often furnished with a thin layer of stucco to receive painted decoration. The architecture was almost entirely of tombs and temples, although remains of palaces of the New Empire have been excavated, and there are vestiges of fortifications at Semneh and Gournah. The civilization of Egypt was distinctively monarchical and religious and this is clearly shown in the number and type of the monuments. The Roman Emperors continued the constructions and the reigns of the Flavians and Antonines are recorded by many monuments. The impulse died out about 250 A.D.; Philippus is the last emperor whose name is engraven officially in the hieroglyphic character. The English have recognized French intervention in the direction of the Cairo Museum which has a right to one-half of all discoveries of antiquities, etc., made in Egypt. Gaston Maspero was appointed director in 1889 of the Service of Antiquities, as this branch is known, and was succeeded in October 1914 by Pierre Lecou. Several permanent commissions are at work in various parts of the country. Consult Champollion, 'Monuments de l'Egypte' (1843); Mariette, 'Monuments of Upper Egypt' (1861); Petrie, 'History of Egypt' (1881); Rawlinson, 'History of Ancient Egypt' (1881).

EGYPTIAN ARCHITECTURE.

The most ancient monuments of the world's architecture in stone are those of the Nile Valley. The ruins of some ancient Chaldean buildings are probably of earlier date, but they are almost entirely of sun-dried brick, while the tombs and pyramids of the early Egyptian dynasties are many of them in excellent preservation. The people who built them were probably of Asiatic origin but long-settled along the Nile, and were a highly civilized race thousands of years B.C. It is customary to divide the history of ancient Egyptian art into five periods: (1) the Old Kingdom (or Memphite Empire, c. 3100-2680 B.C.), comprising ten dynasties of kings; (2) the Middle Empire, with Thebes as capital, 2150-1788 B.C., two dynasties; (3) the Second Theban or New Empire (1588-1150 B.C.), comprising the dynasties xvii-xx., and separated by instances and periods of art, the artistic interregnum of the Hyksos or Shepherd kings (Arabs); (4) the Decadence or Saitic period of six dynasties, 1150-324 B.C., which includes the Persian conquest in 525 B.C., and (5) the Ptolemaic and Roman period (324 B.C.-A.D.).

Then followed a period of over three centuries during which the only architectural works were Coptic churches and monasteries. The Arabs conquered Egypt in 642 A.D., since which date the architecture has been of the Arabo-Moslem or "Saracenic" style, an architecture of mosques, tombs, palaces, baths, fountains and city gates. As this last period, with its infiltrations of Turkish influence since 1517, is treated of under Moslem Art (q.v.), the present article will be confined mainly to the ancient art of Egypt from which brief reference to the Coptic development.

Materials and Character.—There is evidence that the primitive architecture of the Egyptians was of mud ("crude" or sun-dried brick) and wood, but the monuments that have survived to our time are of stone, except for some scanty remains of brick. The stones employed were granite of various kinds and limestone; the coarser stone being often furnished with a thin layer of stucco to receive painted decoration. The architecture was almost entirely of tombs and temples, although remains of palaces of the New Empire have been excavated, and there are vestiges of fortifications at Semneh and Gournah. The civilization of Egypt was distinctively monarchical and religious and this is clearly shown in the number and type of the monuments. The Roman Emperors continued the constructions and the reigns of the Flavians and Antonines are recorded by many monuments. The impulse died out about 250 A.D.; Philippus is the last emperor whose name is engraven officially in the hieroglyphic character. The English have recognized French intervention in the direction of the Cairo Museum which has a right to one-half of all discoveries of antiquities, etc., made in Egypt. Gaston Maspero was appointed director in 1889 of the Service of Antiquities, as this branch is known, and was succeeded in October 1914 by Pierre Lecou. Several permanent commissions are at work in various parts of the country. Consult Champollion, 'Monuments de l'Egypte' (1843); Mariette, 'Monuments of Upper Egypt' (1861); Petrie, 'History of Egypt' (1881); Rawlinson, 'History of Ancient Egypt' (1881).
Tombs.—The religion of Egypt, with its insistence on a future life, assigned an enormous importance to the arts of sepulture, and the tombs are far more numerous than the temples. They are of two chief kinds: the hypogeum or excavated tomb, cut in the rock of the western bank of the Nile, with many passages, chambers and shafts; and the structure built up. These two chief types, the pyramid (see PYRAMID) and the mastaba or "bench." This latter type, rectangular in plan, had usually sloping walls and a flat top, and contained a variety of chambers and passages, with one or more serdabs or secret chambers, and wells or shafts leading to deep chambers, in one of which the sarcophagus was deposited. Statues of the deceased ("ka-statues") were secreted in the serdabs in order to assist in preserving the life and identity of the "ka" or spirit while in the tomb, while the walls were painted with pictures of his daily life and sports in order that the "ka" might by their help enjoy the same pleasures until admitted by Osiris and his assessors to the final home in the underworld. The tombs of this type have been taken down and re-erected in the Metropolitan Museum at New York.

Temples.—The fundamental scheme of the Egyptian temple was early developed and remained unchanged in essentials for over 3,000 years. It appears to have had an expansion of the ancient Oriental house-plan, with its enclosing wall, gate, fore-court, reception-hall and living rooms. These became respectively the enclosing wall (sometimes of crude brick) the pylon-gate with its twin truncated pyramid towers, the fore-court or temple court flanked or surrounded with colonnades, the hypostyle or colonnular hall for the princes and magnates, and the sekos or sanctuary, with its shrine or "holy of holies" and its surrounding rooms for the priests. These various parts might be duplicated or increased, but they are to be found in all the temples, large or small.

Historic Monuments.—From the Ancient or Memphite Empire there have been preserved to us innumerable tombs and a few temple-ruins. The Coptic Architects the pyr-mid-tombs, of which there are nearly a hundred in six groups. They are all royal tombs, but vary in size and shape, some having stepped sides, some being built with two slopes—the lower part steeper than the upper; the remainder are built with a single slope from the square base to the apex. Three of these, at Ghizeh, are far larger than the rest; they belong to the 4th dynasty. The largest is that of Cheops or Khufu, with a base 764 feet square and an original height of 482 feet. The second, of Chephren or Khafr, is slightly smaller; the third, of Mycerinus or Menkhaura, rises 218 feet from a base 254 feet square. The stepped pyramid of Saqqara is older, dating possibly from the First dynasty; it is about 350 by 250 by 200 feet; its base is 213 feet high. All of these, and most of the others, were built of limestone with a facing of granite which, however, has in most cases disappeared; they all contain corridors and chambers of elaborate construction. There are also many mastabas at Memphis and many excavated tombs cut in the rock of the cliffs; the ka-paintings of some of these (e.g., the tomb of Ti) are extraordinarily detailed and interesting. The temples of this period are all connected with or adjacent to the tombs, to which they served as chapels. The best preserved is that of Chephren, known as the Sphinx Temple, having square piers instead of columns.

The Middle Empire has left us only scanty monuments, of which the most interesting are tombs cut in the cliffs with columnar porches whose columns somewhat resemble the Greek Doric, hence called "proto-Doric." There have been found scanty remains of temples of this period at Bubastis and at Karnak.

The New Empire was the great age of Egyptian architecture as well as of political greatness under a succession of mighty rulers—the Thutmoses, Amenhotep, Setis, Rameses and others of the 18th dynasty, of whom Rameses II was the greatest builder. The tombs of this period are all, or nearly all, deep tunnels cut in the rock, with many chambers and corridors; the temples are the largest in Egypt, especially that of Karnak, over 1,200 feet long and 340 wide, whose hypostyle hall with 16 rows of colossal columns. is the greatest hall in Egypt. Not far away is the great temple of Luxor, next to which in size and splendor is the Ramesseum. Others of almost equal extent and splendor are at Abydos and at Medinet Abu; while at Deir-el-Bahari are the remains of the stupendous hemicycle of Queen Hatshepsout, a sepulchral temple partly excavated and partly structural. At Ipsambul (Abu Simbel) are two colossal temples of Rameses II and III, entirely hewn into the rocky cliff. Many smaller temples, as of Khonsu at Karnak, are in good preservation.

The Ptolemaic-Roman age created the two temples of Hathor and Isis at Denderah, built by Cleopatra; the temple of Edfu and the superb group at Philae; and the Roman-built temples of Esneh and Koom Ombo, with others in Nubia. All these late temples have screen-walls between the front columns of the hypostyle hall, crested with carved serpents—a new feature; and the capitals of columns are very complex and elaborate.

This is unimportant except in its relations to later Arabo-Egyptian art and to the architecture of Christian Europe and Asia of the same period (4th-7th century). The Copts are the Christian descendants of the ancient Egyptians, and erected, during the above period, many churches and monasteries, mostly of small size. These are interesting chiefly for their use of the arch, of the dome over the sanctuary, and of minutely-detailed surface carving and elaborate wooden screens. It was the Copts who built the earliest Arab mosques in Cairo, and the Arabo-Egyptian style owes much of its character to their work. See ARCHITECTURE; OBELISK; PYRAMID; SPHINX.

EGYPTIAN ARTS.

SCULPTURE, PAINTING, AND MINOR ARTS.—Sculptors were numerous and very prolific. Several great collections of extant works have been made in modern times; of these the greatest is that of the Louvre Museum of Grisez, next to which the four great gilt and painted groups of the New Empire of the Louvre, the British Museum, the Vatican, Florence, Turin, The Hague and Berlin. Many works, however, are still in situ in the temples and tombs, both colossal statuary and seated figures. Of all the sculptures they have been found in tombs. They are realistic and of value as portraits. In the Middle Empire the official and colossal style was developed in connection with temple architecture reaching its greatest period under the Rameses and Setis of the New Empire. Plastic art was early employed to illustrate the daily life of the subject. Each tomb contained a representation in detail of the person, family and occupation of the deceased, and near the tomb were statues of him or her as they appeared in life. The New Empire sunk into relief and outline relief come into vogue. Methods of quarrying, carving, polishing and finishing sculptures are represented in these styles together with others. Wood was used in sculpture as it is testified by the number of statues and statuettes remaining, some dating from the Old Empire, the most noteworthy being the famous figure, Sheik-El-Beled. Red granite and basalt were favorite material for statuary, while limestone and sandstone were used more in relief. Red porphyry was especially popular in the later periods. The representation was purely conventional, for the purpose of conveying an idea and not creating an illusion. Perspective was avoided in scenes where several planes of figures appear, the rows being raised one above another. Despite their lack of realism the sculptors were careful of detail. The earliest work of sculpture is the famous Sphinx of Gizeh now disintegrating under the changed climate. A common portrait is the seated group of husband and wife, found throughout all the tombs of the Old Empire. The representation of divinities was usually effected by placing an animal's head on a human body, a jackal's head for Anubis; a hawk's for Horus, etc. The gods were worshipped on the opposite walls of a temple and the image of the god was repeated several hundred times on the walls and columns and on the outer pylons. There were also small images of the gods in bronze, glazed earth, etc., used for objects of devotion. Another theme might be termed the political; consisting of the giant king, at whose feet cower many captives. There was little variation in the several representations during long periods. Of particular interest are the reliefs and paintings on the tombs of private persons. A tomb of the Middle Empire represents the migration of a tribe in a single scene showing how traveling was done in the age of Moses. Under the New Empire there was a change to the stiff and colossal. Greek art was introduced into the Ptolemaic and had a profound influence on Egyptian forms. Painting in ancient Egypt can hardly be called an independent art, being largely an adjunct to architecture. Wall paintings were popular from the 5th to the 13th dynasty and closely resemble the reliefs of the same period in theme and treatment. In portrait sculpture the Egyptians attained extraordinary perfection at an early date, the skill with which they worked in hard stone, such as diorite and basalt, being surprising. Some of the early statues are of colossal size, but a higher style of art is shown in those of ordinary size. The treatment is always apparent. The most usual kind of mural sculpture, a kind peculiar to the Egyptians, is that known as hollow or sunk relief (cavo-rilievo). The general outline of the object intended to be represented is cut into the smooth surface of the stone, while at the same time the minor forms and rotundity are represented within the incised outline. By this contrivance the details of the sculptures are protected. Sometimes the outline is excessively deep, at others the surface of the figures is altogether much lower than the general surface of the wall, and in others the outline is but slightly incised with a corresponding flatness within. Wherever the Egyptians practised the true bas-relief the sculpture is almost invariably in very low relief. The head division of the Phœnician figure is never represented in the sculptures excepting in the case of an enemy, and then rarely; the figure is generally represented in profile, and there are but few attempts at delineating the front view of the form, or of the face; however, whether the face be represented in conventional side view, a profile eye is never found. The figures of the king in battle-pieces, and of the landed proprietor in domestic scenes, are always on a much larger scale than the other actors in the piece. Statues and reliefs were always painted, and when wall painting is employed it is always as a substitute for sculpture. There is no proper perspective, and certain conventionalities of color are employed. The Egyptians are represented with red and yellow complexes, red ochre for the men; yellow for the women. The hair of the king is frequently painted blue, but that of ordinary men black. In representing the various nations with whom Egypt had intercourse, the artists seem to have endeavored to imitate the complexes peculiar to each. Ammen-Ra, the face division of the Phœnician figure is always painted blue, and he is further distinguished by two high feathers which he wears in his cap. The inferior divinities are not uncommonly of the complexes of mortals. The sky or heavens are invariably indicated by a strip of blue coming downward at the lower side of each extremity, and occasionally having upon it a row of five-pointed stars. Water, seas and rivers are represented by zigzag lines of a blue or green color. Mountains have a yellow color, with red spots upon it. Egyptian art was at its highest during the period between the 4th and 6th dynasties, and notwithstanding its defects it was superior to that of Nineveh and Babylon. Gold and enamel jewelry with rich necklaces and pectorals of a very early period have come down to us. Artistic design was skilfully applied by the Egyptians to articles of furniture, ornament and articles of domestic use—mirrors, spoons, chairs, etc. Wood, ivory and various metals were used. The Phœnicians and Greeks spread these works along the Mediterranean littoral where they exerted a very great influence on design. (See Art; Sculpture.) Consult Lepsius, 'Denkmäler' (1874); Perrot and Chipiez, 'History of Art in Ancient Egypt' (1883).

EGYPTIAN BEAN—EGYPTIAN LANGUAGE AND WRITING

EGYPTIAN BEAN, a name sometimes given to the bean-like fruits of the *Netumumum speciosum*, the sacred lotus, found in Asia and Africa.

EGYPTIAN BLUE, a brilliant pigment consisting of the hydrated protocate of copper mixed with a minute quantity of iron.

EGYPTIAN LANGUAGE AND WRITING. To formulate an opinion in regard to the group to which the ancient language of Egypt belonged, it is best to follow step by step the gradual process of interpretation and secondly the translation of the numerous texts existing in inscriptions and papyri. By so doing one is led to the conclusion that the language of old Egypt belonged to the Semitic family, an opinion objected to until quite recently. The first modern studies tending to elucidate the mysterious tongue locked up in the Egyptian hieroglyphics were those of the learned Jesuit Athanasius Kircher (1601-80), but they, like those of other savants of the 17th and 18th centuries, were without result until the discovery of a tablet inscribed in three languages furnished the key to the history of an ancient civilisation, whose annals extended over 40 centuries. A French military officer, Captain M. Boussard, found in 1798 or 1799 in the fort of Saint Julien de Rosetta an inscription drawn up by the priests of Egypt gathered at Memphis, in honor of Ptolemy Epiphan (196 B.C.). The first inscription was carved in hieroglyphics, the second in demotic characters and the third in Greek. The inscriptions were copied and copies sent to several academies. The Rosetta tablet came into the hands of the British in 1801 and now rests in the British Museum. The first Greek translation was that of Du Theil and Weston in 1801-02, and about the same time Akerblad, a Swedish Orientalist connected with the embassy at Paris, deciphered several demotic phrases, identifying the equivalents of the names of Alexander, Alexandria, Ptolemy and others, being guided principally by the position they occupied in the Greek text. Subsequently Thomas Young published in 1819 the result of his labors in this field, formulating the phonetic code of an Egyptian vocabulary from the Rosetta Stone and from other monuments. Warburton, Barthélemy, Zega and others indicated the possibility of the existence of a hieroglyphic alphabet. Finally Champollion the Younger, prepared by his studies of history and philology, brought an almost complete light to bear on the subject, revealing the contents of hieroglyphic writing on many inscriptions. His "Précis du système hieroglyphique" was followed, after his death in 1832, by the publication of a grammar and dictionary of the Egyptian tongue. Lepsius, Birch, Rouge, Chabas and others continued the work but without success in establishing the grammatical structure of the works on a solid basis. Gaston Maspero and Revilloud added considerably to the collection of translated inscriptions and the decipherment of the modern translations was first reached in 1880 when Louis Stern published his Coptic grammar, and when Erman published his in 1902. This last-named work is based on the style and linguistic variations during the time that the ancient Egyptian tongue was a living idiom. It shows the changes of different periods and permits that those who study this old tongue may now do so with as great security as those who undertake the study of Latin or of Greek. The investigations of the German school, which counts illustrious members in England, Denmark, the United States, Italy and France, are published in the annals of the Berlin Academy of Sciences. From the most recent studies it appears that the ancient Egyptian belonged to the Semitic branch. Until recently and because of the bilateral roots of the Coptic, it was supposed that the Egyptian language should be classified with the three sub-families of the Hamite group previous to the formation of the Semitic, of which the triliteral root is characteristic. But it was shown that the bilateral roots of the Coptic had originated from triliteral roots of the early Egyptian and other similarities were shown which prove conclusively that ancient Egyptian belonged to the Semitic branch. The ancient language had four periods: (1) that of the Ancient Empire, employed until some centuries previous to our era; (2) colloquial Egyptian, employed by merchants and artisans; (3) the alphabet course, and which existed from the 6th to the 17th or 18th dynasty; (3) the popular tongue from the 18th dynasty to the end of the period of Roman domination, and (4) the language of the country from the propagation of Christianity until it centred three centuries ago, except in the liturgy of the Coptic Christians.

Ancient Egyptian writing had three forms: (1) the Hieroglyphic, the most ancient, employed on inscriptions on temples, tombs, pillars and statues; (2) the Hieratic, the abbreviated form of the former. It was employed by the priests from the 4th to the 16th dynasty; (3) the Demotic or popular form, which began about the end of the 22nd dynasty and consisted of conventional signs. The hieroglyphic writing was employed with small variants from the 4th dynasty until the 3rd century of our era. The signs were employed in three ways—1st, representing in themselves an object, idea, a word or root; 2nd, representing a syllable or part of a word; 3rd, socializing the sense of a word already expressed by other or many signs. Phonograms were few, about 100 in all, of which 70 or 80 were in current use. The most important signs are those representing a single letter; in the Old Empire there were 24 of these. Signs representing two letters were about 50, and those which represented three letters were formed by combinations of this and the first group. Ideographic signs were represented by hieroglyphs symbolizing an idea, viz.: V a scepter signified prince or ruler; ☼ the moon; ☯ the sun; an inclined wall represented the action of falling, etc., etc. Hieroglyphs were written horizontally or perpendicularly, reading in the direction in which the signs figuring birds were faced, which was generally from right to left of the reader, except in cases where the horizontal order was changed to conform with the sides of a door, pylon, etc. To preserve a symmetrical appearance the scribes were accustomed to group the signs in squared areas and by adopting syllabic notation when the signs hindered such symmetrical order. Consonants were thus added materially to the difficulty of interpretation, which
EGYPTIAN LITERATURE

is also complicated by the fantastic writing of various sources and their errors. See Hieroglyphic Egyptian Literature.

EGYPTIAN LITERATURE. The advance that has been made in recent years in the decipherment of the ancient writings of the world enables us to deal in a very matter-of-fact way with the Egyptian inscriptions. Their chief mysteries are solved, their philosophy is almost fathomed, their general nature is understood. They have to tell us is seldom startling to the modern mind when they were written. The heart of man was given to devious ways then, as now and in the days of Solomon,—that we can affirm full well; but his mind was simpler; apart from knowledge of the conduct of affairs, the educated Egyptian had no more subtlety than a modern boy of 15, or an intelligent English rustic of a century ago.

To the Egyptian by profession the inscriptions have a wonderful charm. The writing in its heading form is the most attractive that has ever been seen. Long rows of clever little pictures of things in heaven and earth compose the sentences; every sign is a plaything, every group a pretty puzzle, and at present almost every phase well understood brings a tiny addition to the sum of the world's knowledge. But these inscriptions, so rich in facts that concern the history of man and the progress of civilization, seldom possess any literary charm. If pretentious, as many of them are, they combine bald exaggeration with worn-out simile, in which ideas that may be poetical are heaped together in defiance of art. Such are the priestly laudations of kings by whose favor the temples prospered. Take, for instance, the dating of a stela erected under Ramesses II on the route to the Nubian gold mines. It runs:

On the fourth day of the first month of the season of winter, in the third year of the Majesty of Horus, the Strong Bull, beloved of the Goddess of Truth, lord of the vulture and of the rich lands of Egypt and restraining the barbarian, the Golden Horus, rich in years, great in victory, beloved of Amen, King of Upper and Lower Egypt, Mighty in Truth of Ra, Chosen of Ra, the son of Ra, Ramesses Beloved of Amen, granting life for ever and ever, beloved of Amen, Lord of the Throne of the Two Lands in Abydos, appearing glorious on the throne of Horus among the gods. Young as his father Ra; the good god, lord of the South Land, Him of Edfu Horus bright of plumage, the majestic spear-bearer of hawk of peace that hath protected Egypt with his wing, making a shade for men, fortress of strength and of victory; he who came forth terrible from the womb to take himself his strength, to extend his borders, to whose body color was given of the strength of Mentu; the god Horus and the god Set. There was exaltation in heaven on the day of his birth; the gods said, "We have begotten him"; the goddesses said, "He came forth from us to rule the kingdom of Ra"; Amen spoke, "I am he who have made him, whereby I have created him in his place; the earth is established, heaven is well pleased, the gods are satisfied by reason of him. The Strong Bull against the vile Ethiopians, which uttereth his roaring against the land of the negroes while his hoofs trample the Tvetodjet, his horn thrusteth at them; his spirit is mighty in Nubia and the terror of him reacheth to the land of the Kari; his name circulates in all lands because of the victory which his arms have won; at his name gold cometh forth from the mountain as at the name of his father, the god Horus of the land of Baka; beloved is he in the Lands of the South even as Horus at Memphis, the god of the Land of Baken, King of Upper and Lower Egypt, Mighty in Truth of Ra, Chosen of Ra, the son of Ra, Lord of Didaema, Ramesses Beloved of Amen, giving life for ever and ever like his father Ra, day by day. (Revised from the German translation of Professor Erman.)

As Professor Erman has pointed out, the courtly scribe was most successful when taking his similes straight from nature, as in the following description, also of Ramesses II:

A vociferous lion putting forth his thunderous roaring loudly and uttering its voice in the Valley of the Osirides. . . . A jackal swift of foot seeking what it may find, prancing round the circuit of the tempest, in the storm, his mighty will seeth on his enemies like a flame catching the li-ka plant with the storm beating it, like a destructive flame which hath tasted the fire, destroying, until everything that is in it becometh ashes; a storm howling terribly over the sea, its waves like mountains, the one can enter it, every one that is in it is engulfed in Dust.

Here and there among the hieroglyphic inscriptions are found memorials of the dead, in which the praises of the deceased are neatly strung together and balanced like beads in a necklace, and passages occur of picturesquely narrative writing in which to rank as literature of the oldest time. We may quote in this connexion from the biographical epitaph of Amen, who was governor of a province in middle Egypt for 25 years during the long reign of Usertesen I (about 2716 B.C.). This inscription not only recounts the achievements of Amen and the royal favor which was shown him, but also tells us in detail of the capacity, goodness, charm, discretion and insight by which he attached to himself the love and respect of the whole court, and of the people over whom he ruled and for whose well-being he cared. Amen says:

I was a professor of favor, abounding in love, a ruler who loved his city. Moreover I passed years as ruler in the house of the 3,000 bulls of their draught stock. I was praised for it in the house of the King each year of stock-taking. I rendered all their works to the King's house; there were no arrears to me in any of his offices.

The entire Oryx nome served me in numerous attendances. There was not the daughter of a poor man that I wronged, nor a widow that I oppressed. There was not a farmer that I chastised, nor a herdsman whom I drove away, not a foreman of whose men I took away for the works. There was not a pauper around me, there was not a hungry man in my time. When there came years of famine, I arose and ploughed all the fields of the Oryx nome to its boundary south and north, giving life to its inhabitants, making its provisions. There was not a hungry man in it. I gave to the widow as to her who possessed a husband, and I favored those beyond measure, in favor as I gave. Thereafter great rises of the Nile took place, producing wheat and barley, and producing all things abundantly, but I did not exact the annual tribute.

Elsewhere in his tomb there are long lists of the virtues of Amenemhat, and from these the following may be selected both on account of picturesqueness of expression and the appreciation of fine character which they display:

Superintendent of all things which heaven gives and earth produces, overseer of the granaries, fishponds and shrines. . . . Master of the art of causing writing to speak. . . . Caring of heart to all people, making to prosper the timid man, hospitable to all, escorting (travelers) up and down the river. . . . Knowing how to aid, arriving at the name of need; have set truth, planing evil, without greediness in his body, speaking words of truth. . . . Unique as a mighty hunter, the abode of the heart of the King. . . . Speaking the right thing when he desires to decorate his mouth with speaking fraud, knowing how to proceed in the council of the elders. . . . In the house of the King the worship of the king's favors in the house of the King, contenting the heart on the day of making division, careful of his going to his equals, obtaining reward and the day of weighing words, beloved of the officials of the palace.

The cursive forms of writing—hieratic from the earliest times, demotic in the latest—were those in which records were committed to papyrus. This material has preserved to us documents of every kind, from letters and ledgers to works of religion and philosophy. To these, again, "literature" is a term rarely
to be applied; yet the tales and poetry occasionally met with on papyri are perhaps the most pleasing of all the productions of the Egyptian scribe.

It must be confessed that the knowledge of writing in Egypt led to a kind of primitive pedantry, and a taste for unnatural and to us childish formality; the free play and naïveté of the original spirit was too often stilted, and the ideal finish was little understood. Simplicity and truth to nature alone gave lasting charm, for though adornment was often attempted, their rude arts of literary embellishment were seldom otherwise than clumsily employed.

A word should be said about the strange condition in which most of the literary texts have come down to us. It is rare that monumental inscriptions contain serious blunders of orthography; the peculiarities of late archaic inscriptions which sometimes produce a kind of "dog Egyptian" can hardly be considered as blunders, for the scribe knew what meaning he intended to convey. But it is otherwise with copies of literary works on papyrus. Sometimes these were the productions of schoolboys copying from dictation as an exercise in the writing school, and the blank edges of these papyri are often decorated with essays at executing the more difficult signs. The master of the school would seem not to have cared what nonsense was produced by the pupil misunderstanding of his dictation, so long as the signs were well formed. The composition of new works on the model of the old, and the accurate understanding of the ancient works, were taught in a very different school, and few indeed attained to skill in them. The boys turned out of the writing school would read and write a little; the clever ones would keep accounts, write letters, make out reports as clerks in the government service, and might ultimately acquire considerable proficiency in this kind of work. Apparently men of the official class sometimes amused themselves with puzzling over an ill written copy of some ancient tale, and with trying to copy portions of it. The work, however, was beyond them; they were attracted by it, and occasionally made a discovery of old age and those which were "written by the finger of Thoth himself?"; but the science of language was unborn, and there was little or no systematic instruction given in the principles of the ancient grammar and vocabulary. Those who desired to attain eminence in scholarship after they had passed through the writing school had to go to Heliopolis, Hermopolis or wherever the principal university of the time might be, and there sit at the feet of priestly professors; who we flattery were revered as demigods, and who in mysterious fashion and with rigorously hard imparted scraps of knowledge to their eager pupils. Those endowed with special talents might after almost lifelong study become proficient in the ancient language. Whether that we might one day discover the hoard of rolls of such a copyist and writer!

There must have been a large class of hack-copyists practised in forming characters both uncial and cursive. Sometimes their copies of religious works are models of deft writing, the embellishments of artist and colorist being added to those of the calligrapher; the magnificent rolls of the 'Book of the Dead' in the British Museum and elsewhere are the admiration of all beholders. Such manuscripts satisfy the eye, and apparently neither the multitude in Egypt nor even the priestly royal undertakers questioned their efficacy in the tomb. Yet are they very apples of Sodom to the hieroglyphic scholar, fair without but too often marked, and the text of literary finish was little understood. Simplicity and truth to nature alone gave lasting charm, for though adornment was often attempted, their rude arts of literary embellishment were seldom otherwise than clumsily employed.

In the 8th century B.C. the new and the old were definitely parted, to the advantage of each. On the one hand the transactions of ordinary life were more easily registered in the cursive demotic script, while on the other the sacred writings were more thoroughly investigated and brought into order by the priests. Hence, in spite of absurdities that had irremediably crept in, the archaic texts copied in the 20th dynasty are more intelligible than the same class of work on the 19th and 20th dynasties. Nor is it only in the later papyri that these blunders are met with. The hieroglyphic system of writing, especially in its cursive forms, lends itself very readily to perversion by ignorant and inattentive copyists; and even monumental inscriptions, so long as they are mere copies, are usually corrupted. The most ridiculous perversion of all date from the Rameses epoch when the dim past had lost its charm, for the glories of the 18th dynasty were still fresh, while new impulses and foreign influences had broken down adherence to tradition and isolation.

In reading translations from Egyptian, it must be remembered that uncertainty still remains concerning the meanings of multitudes of words and phrases. Every year witnesses a great advance in accuracy of rendering; but the translation even of an easy text still requires here and there some close and careful guess-work to supply the connecting links of passages or words that are thoroughly understood, or the resort to some conventional rendering that has become current for certain ill understood but frequently recurring phrases. The copyist is now to a great extent himself aware whether the ground on which he is treading is firm or treacherous, and it seems desirable to make a rule of either giving the public only what can be warranted as sound translation, or else of warning them where accuracy is doubtful. A few years ago such a course would have curtailed the area for selection to a few of the simplest stories and historical inscriptions; but now we can range over almost the whole field of Egyptian writing, and gather from any part of it warranted samples to set before the reading public. The labor, however, involved in producing satisfactory translations for publication, not mere hasty readings which may give something of the sense, is very great; and at present few texts have been well rendered.

We may now sketch briefly the history of Egyptian literature, dealing with the subject in periods:

1. The Ancient Kingdom, About 4400 B.C.—3000 B.C.—The earlier historic period from the 1st dynasty to the 5th, about 3766 B.C.
—has left no inscriptions to any extent. Some portions of the ‘Book of the Dead’ (q.v.) profess to date from these or earlier times, and probably much of the religious literature is of external date. The first book of ‘Proverbs’ in the Prieze Papyrus is attributed by its writer to the end of the 3d dynasty (about 3765 B.C.). From the 4th dynasty to the end of the 6th (3100 B.C.) the number of the inscriptions increases; tablets set up to the end of the 4th dynasty in memory of warlike raids are found in the peninsula of Sinai, and funerary inscriptions abound. The pyramids raised at the end of the 5th and during the 6th dynasties are found to contain interminable religious inscriptions, forming almost complete rituals for the deceased kings. Professor Maspero, who has published these texts, states that they contain much verbiage, many pious platitudes, many obscure allusions to the affairs of the other world, and among all this rubbish some passages full of movement and wild energy, in which poetical inspiration and religious emotion are still discernible through the veil of mythological expressions. The funerary and biographical inscriptions are not remarkable. Of the 1st, 2nd, and 3rd dynasties it is only of the 4th dynasty, and the 5th dynasty, that can be considered, as the others are too fragmentary to be of much use to the scholar. The funerary inscriptions of the 5th dynasty are of very great importance, as they contain a great number of prayers and incantations intended to ensure the security of the soul in the other world, and to serve it as a sort of passport in the travels it was compelled to undertake before reaching the Hall of Judgement. The Hymn to Osiris, the Thoth, and the Elysian Fields. Several copies of this book have been reproduced in facsimile by Lepsius (‘Das Todtenbuch der alten Ägypter,’ Berlin 1842) and by E. de Rouge (‘Rituel funéraire des Anciens Égyptiens,’ Paris 1861–64) but the standard edition is that projected by the International Commission of Orientalists in London (1874) and executed in part by Naville in ‘Das thebanische Todtenbuch der XVIII bis XX Dynastie’ (Berlin 1886). It gives, however, only those chapters which are to be found in the manuscripts of the Theban period. Translations of the whole book exist in English, prepared by Birch (in Bunsen’s ‘Egypt’s Place in Universal History,’ Vol. V, 1866) and by Le Page-Renouf in ‘Proceedings of the Society of Biblical Archaeology.’ Rituals and the ceremonies of prayers performed in the temples and tombs — are very numerous; such are the ritual for the cult of the Theban Amon. The Opening of the Mouth and the other rites performed on the day of burial have been preserved to us in the pyramids of the 5th and 6th dynasties and in the private and royal vaults of the Theban tombs.

Here we might end. Greek authors in Egypt were many; some were native, some of foreign birth or extraction, but they all belong to a different world from the ancient Egyptian. With the adaptation of the Greek alphabet to the spelling of the native dialects, Egyptian came again to the front in Coptic, the language of Christian Egypt. Coptic literature, if such it may be called, was almost entirely produced in Egyptian monasteries and inscribed in stone or papyrus. Let us hope that it served its end in its day. To us the dull, extravagant and fantastic ‘Acts of the Saints,’ of which its original works chiefly consist, are tedious and ridiculous except for the scholar or the linguist or the antiquary. They certainly display the adjustment of the ancient Egyptian mind to new conditions of life and belief.

Some Modern Texts and Translations.—The bulk of the Egyptian literature has been preserved in papyri, nearly all of which are scattered in the various museums of Europe. Nine papyri out of 10 contain the religious books and rituals which were placed with the mummmies in the coffins or in the sepulchral chambers. The most famous of them is the Book of the Dead, a compilation of prayers and magical incantations intended to ensure the security of the soul in the other world, and to serve it as a sort of password in the travels it was compelled to undertake before reaching the Hall of Judgement. The 9th and 10th dynasties. Several copies of this book have been reproduced in facsimile by Lepsius (‘Das Todtenbuch der alten Ägypter,’ Berlin 1842) and by E. de Rouge (‘Rituel funéraire des Anciens Égyptiens,’ Paris 1861–64) but the standard edition is that projected by the International Commission of Orientalists in London (1874) and executed in part by Naville in ‘Das thebanische Todtenbuch der XVIII bis XX Dynastie’ (Berlin 1886). It gives, however, only those chapters which are to be found in the manuscripts of the Theban period. Translations of the whole book exist in English, prepared by Birch (in Bunsen’s ‘Egypt’s Place in Universal History,’ Vol. V, 1866) and by Le Page-Renouf in ‘Proceedings of the Society of Biblical Archaeology.’ Rituals and the ceremonies of prayers performed in the temples and tombs — are very numerous; such are the ritual for the cult of the Theban Amon. The Opening of the Mouth and the other rites performed on the day of burial have been preserved to us in the pyramids of the 5th and 6th dynasties and in the private and royal vaults of the Theban tombs.
EGYPTIAN MUSIC—EGYPTIAN RELIGION AND SOCIOLOGY

18

Rome 1889-90) Books of magic abound, though they are not as numerous as the ritualistic or religious works. Most of them are unpublished as yet, but the translation of Chabas ("Le papyrus magique Harris," Chalons-sur-Saône 1861); Pleyte ("Etude sur un rouleau magique, etc."), and Lefebure ("Un chapitre des papyrus de l'Egypte") give a sufficient idea of the ways in which Pharaoh's magicians were wont to conjure the demons. That they were sometimes prosecuted as adepts in the black art is proved by the proceedings of a trial for high treason at Thebes during the reign of Rameses III. Magicians are by no means rare among the physicians, surgeons, and no remedy could be properly applied without their help. About 20 treatises on medicine are known to exist, of which a few have been published ("Papyrus médical de Berlin"). Ebers studied and published comments on portions of his papyrus which relate to the diseases of the eye. No papyrus treating of astronomy has yet been discovered, but the calendars, zodiacs, astronomical and astrological tables which abound on the walls of temples and tombs at Ombos, Esneh, Edfu, Denderah the Round Temple, the Memnonium, etc., furnish a large quantity of material. Three mathematical papyri have been found, one of Roman times and one from the 12th dynasty and one at Thebes. There are several works on physiology, which was limited to a rendition of moral precepts and aphorisms on the conduct of life. Some are very ancient—the "Papyrus Prisse" seems to have been written in the 12th dynasty and has been called "the oldest book in the world." Poems and songs are by no means rare in the music of ancient Egypt. The remains of two collections of love-songs have been studied by Maspero ("Etudes Égyptiennes," Vol. 1) and the poem on the battle of Kadesh, in which Rameses II is made to describe how he fought against the Hittites, is likewise worthy of notice. There was a whole literature of stories akin to the "Arabian Nights." De Rouge discovered the first of them in 1852 and entitled it "A Tale of Two Brothers" and since then about 20 have been published; the most curious among them is the "Wicked Mariner" (Golenischeff, "Sur un ancien conte égyptien," (Leipzig 1881) and the "Tale of Khonfoui and the Magicians" (Erman, "Der Papyrus Westcor," Berlin 1891). They have been collected by Maspero in his "Contes populaires de l'ancienne Égypte," (2d ed. Paris 1890).

Even fables were current in Egypt which the Greeks attributed to Æsop; the fable of "The Lion and the Mouse" (Lauth, "Their nabel in Ägypten," Munich 1868) and "Dispute of the Members and the Stomach" (Maspero, op. cit., Vol. 1) have found their way into many of them sealed and unopened, others preserved in anthologies, where teachers of the 19th and 20th dynasties had inserted specimens of descriptions and poetical epistles, official reports on administrative subjects, as models of elegant style for the young scribes, their pupils. Several of these have been published by the trustees of the British Museum in the first volume of the "Select Papyri" (London 1841-44). The Old Egyptian language has been the subject of continuous research and there are many excellent grammars but lexicography is not so well advanced. For the constant progress in this field of uncovering the ancient literature of Egypt consult the notes, pamphlets, papers, etc., inserted in the various journals of Europe and America. Consult also "Transactions and Proceedings" of the Society of Biblical Archaeology and "Memoirs of the Egyptian Exploration Fund," in England; the "Zeitschrift der Deutschen Morgenländischen Gesellschaft" and the "Zeitschrift für Ägyptische Sprache und Alterthumskunde," in Germany; and the "Journal Asiatique, Revue de l'histoire des Religions, the Revue Égyptologique," in France; (Prince) Ibrahim-Hilmy, "The Literature of Egypt and the Soudan" (2 vols., London 1886-88). See HIEROGLYPHICS.

SAMUEL AUGUSTUS BINION,
Author of "Ancient Egypt or Misraim."

EGYPTIAN MUSIC. Our knowledge of the music of ancient Egypt is very meagre. We have short accounts of it in Greek authors and we find specimens of their musical instruments and there have survived numerous illustrations of others, together with scenes representing the singing of various gods and heroes, funeral dirges, and we know that musicians and dancers formed a part of all entertainments. In general their instruments are of the same character as those of the Hebrews and Assyrians, from which we infer that their music was of the same general type as that of these neighboring civilized peoples. Their first music was merely an accompaniment to the dance, as we find representations of singers clapping their hands in rhythm to the motions of the dance. Vocal music was made up of solos and choruses. Women often sang without musical accomplishment, but it appears that men rarely did so. Many songs have been preserved, one of the oldest being that of the oxen threshing out the corn. The Egyptians had no clear or fixed ideas of harmony and possessed no system of notation although they had many treatises on music. The harp, lyre, flute, trumpet, drum, cymbals and tambourine were their principal instruments. We find notices of the harp prior to 30 of a string. The harp had about 7 strings increasing gradually to 22. The strings were of catgut. It had no pedals and could be played in but one key. The lyre was also a popular instrument of from 6 to 20 strings. Flutes were in use at an early period. About 500 B.C. the "tek-bou" a kind of banjo, came into use. It generally had but one string, although some specimens have two or three. A shoulder harp was also in vogue about this time; it was played when resting on the shoulder. It was a medium between the harp and guitar. All these instruments underwent considerable development in the course of time and there were also a number of derived instruments. Both women and men played on these, although certain instruments appear to have been peculiar to each sex. Consult Engel, "Musik der alten Ägypter" (London 1864); Mathews, "Popular History of Music" (Chicago 1894); Smith, "World's Earliest Music" (London 1904).

EGYPTIAN RELIGION AND SOCIOLOGY. Religion.—No satisfactory treatment of ancient Egyptian religion has appeared, though the subject was one of the first to awaken interest in modern times. The names
of the deities of the Pantheon are well known and their general characteristics are sufficiently defined, but the gradations between them and the conceptions which gave them force are obscured not only by the most curious inconsistencies but by the fog of mythology which is for the most part unknown to us. Religious conceptions existed during all periods, but never a religion in any true sense. It is plain enough that the differences in religious belief and practice corresponded to the primitive condition of the land and each district had its object of veneration. It was a condition of Monotheism out of which, in consequence of the closer contact produced by the union of the *nomoi* under a central government, there grew up a system of national polytheism in which the principal god of the capital gained pre-eminence. The original deities were objects of nature, but their development was various in the different *nomoi*. Only at a later date did gods appear who represented abstract or cosmogonical ideas. Within limits these contacts occurred there was a resultant confusion of attributes and names. The hegemony of the god of the capital contained in itself the motives of Monotheism, but there is no indication that Monotheism was the original form of the Egyptian religion or that it applied to a period before the priests of separate deities proved that a determined resistance was made to any attempt to introduce monotheism, such as is actually seen in the case of Amenophis IV. Ptah was the god of Memphis; Neith, the warlike goddess of Libyan Sais; Chnum of Elephantine was the deity of the cataract regions; Nechet was goddess of the south in general; Min was the desert god; Osiris of Abydon supplanted an earlier deity; Amon of Thebes, Anubis of Tyreopolis, Tutu of Thebes, and their mates, Teker of the Fayum, Hathor of Denderah, Horus of Edfu, Thoth of Hermopolis, Mont of Hermocrates are examples of the local gods.

The forms of many of the deities are extraneous to the land or to man; Sekhmet, for instance, has the animal shape but frequently it is a mixture of the two; the human trunk being surmounted by an animal head. Thus Ptah appears as the Apis-Bull; Hapi, Amon and Chnum as rams; Sebek as a crocodile-headed man; Nechet as a serpent; Mut as a vulture; Anubis as a jackal-headed man; Bast as a cat-headed woman; Sechet and Tefnut as lion-headed; Hathor as a cow; Horus as a hawk, or hawk-headed man; Thoth as an ibis. The Phmonix is possibly derived from Benu of Hieropolis, which appears as a heron.

In various periods of the history certain deities appear as deifications of the powers of nature: Ra, the sun, the ruler of the world, having his sanctuary at Heliopolis, was even in predynastic times. He was the bringer of light, is represented in conflict with Set, the god of darkness; Ra-Harmachis was the rising sun; Ra-Tum the sun at evening. Thoth was also worshipped as the moon. The number of mythological beings, such as Nun, the original ocean, out of which Ra proceeded, is beyond number. Mat, the goddess of truth, represents a large class which symbolizes abstract notions. Deities are also portrayed in pairs, such as Aeb, god of earth, and Hut, goddess of Heaven, Shut and Tefnut, Osiris and Isis. In these pairs is seen the family relation which is carried out in numerous ways, not without great confusion. Much of the religion has its explanation only in connection with the future life. When the soul or "double" *(ka)* left the body, the latter was preserved with extreme care. An object of the personal existence of the disembodied spirit depended upon the absolute preservation of the mummy. The future of the individual was determined by a judgment which is represented as weighing of the heart by Horus, who counterbalances it with the symbol of the truth. Mat, the goddess of truth, watches the operation, and Thoth, scribe of the gods, registers the result. In the earliest periods specific beliefs as to their nature, qualities and powers, clustered about the idea of action, but later, when they became a true mythology till the amalgamation of variant views under the influence of the national union of the *nomoi*. The confusion which resulted led to attempts at harmony. But little is known of this mass of mythology, which must have been very extensive if one is to judge by the allusions abounding in every religious text.

The ancient Egyptian religion was, therefore, a kind of philosophical pantheism, the various attributes of the deity being divided among the different gods of the Pantheon. Unlike the Greek, where a god was honored in a separate temple, each Egyptian divinity was accompanied by a *paout*, or "company" of companion-gods.

A few foreign deities became at the close of the 18th dynasty engraven upon the religious system— as Bar, Baal; Ashikara, Ashratth; Ania, Anaitis; Ken, Kiun; Reshpenu, Reseph; Set, or Sutekh, sometimes identified with Baal. All the gods had human passions and affections, and their moods, either as they walked on earth, or sailed through ethereal space in boats. First among the deities comes Ptah, the opener, represented as the creator of the world, the sun and moon, out of chaos *(ka)* or matter, the sea, and the planets. Baal and Bast, Bubastis, lion-headed goddesses presiding over fire, and Nefer-Tum, his son, a god wearing a lotus on his head. Next in the cosmic order is Chnum—worshipped at Elephantine—the ram-headed god of the liquid element, who also created the matter of which the gods were made; and connected with him are the goddesses Heka the Frog, or "primveal formation," Sati, or "sunbeam* and Anuka, alluding to the genesis of the cosmos. The Theban triad comprised Amen-ra, "the hidden," power of the "sun," the Jupiter; Mut, the "Mother" goddess of "Mater* the Juno; Nit, the "Shuttle," the Minerva; and Khons, "Force* is Hercules, a lunar type. A subordinate type of Amon is Khem or Amsu, "the enshrined," who, as Harnekh, or Powerful person; Horus, the bringer of light, is represented in conflict with Set, the god of darkness; Ra-Harmachis was the rising sun; Ra-Tum the sun at evening. Thoth was also worshipped as the moon. The number of mythological beings, such as Nun, the original ocean, out of which Ra proceeded, was very extensive if one is to judge by the allusions abounding in every religious text.
mals, birds and reptiles were held sacred by the Ancient Egyptians; whoever killed a sacred animal, an ibis or a hawk, was put to death. The Egyptians had a conception that every person in the house shaved his eyebrows; if a dog died, the whole body and the head were shaved. The cats were sacred to the goddess Bast and were buried at Bubastis and the dogs in the vaults of their own cities, field-mice and hawks at Buto, the ibis at Hermopolis, and other animals where they were found lying. Of all animals the sacred bull, Apis, was the most revered. His chief temple was at Memphis. The cow, being sacred to Isis, was thrown into the Nile, which was considered sacred; and the Apis bull was buried in the Serapeum near Memphis.

Of the doctrines of the Egyptian religion little is accurately known. The existence of the spirit after death was believed and a future state of rewards and punishments inculcated, in which the wicked were consigned to fiery torments amid perpetual darkness. It was believed that after the lapse of ages the spirit would return to the body, which was therefore carefully embalmed. The organs were removed and placed in Canopic jars. The body was then embalmed;黄金 beating, damascening, engraving, casting, inlaying, enameling, wire drawing and other processes were practised. Weapons and other instruments of war, shields, cuirasses of quilted leather, helmets, spears, clubs, maces, daggers, bows, battle-axes, pole-axes, hatchets and falchions are shown. The testudo, ladders, torches and lanterns were also in use. In agriculture the plow, hoe, sickle and other implements were employed. The processes of growing and preparing flax and making it into thread, string, ropes and cloth, as well as the looms employed, are all depicted. Mats and baskets were beautifully made, either of the halfa grass or palm leaves, or of the outer rind of the papyrus plant, which was used in making paper. Coffins or wooden sarcophagi were chiefly of sycamore or cedar, covered with stucco and richly painted. The ordinary boats of the Nile were planks of the acacia and had two rudders or large oars, with a sail of cloth frequently painted or worked in gold. The beams and masts of the vessels of burden were of great size. The boats made of papyrus were mostly punts for fishing, or for gliding through the canals of the Delta. Implements for painting ladies, bells, crucibles and surgical instruments have also been found. The commerce of the Egyptians with neighboring nations enriched the country with slaves, cattle, gems, metals, rare animals and objects of curiosity. The Egyptians expended enormous wealth on the tombs and furniture of the dead, and the king and his queen occupied them fully with the various ceremonies followed. In embalming they excelled. Each administrative department had its own troop of laborers under its own overseer, who kept minute tally of work performed, rations distributed and of absentees. The troops, not the individual, were the unit. All artisans as well as the slaves were regarded superciliously by the scribes and held in lower repute than the agriculturists, though the products of their skill still command admiration. Weavers working with papyrus reeds or with linen thread, produced baskets, boats, mats, or the finest linen cloths; joiners though handicapped by lack of good raw material, nevertheless produced creditable work
by the use of instruments most simple in their character. Potters through all periods reproduced the same shapes with little variation, but attuned for the rudeness of much of their work by the fineness of their products in faience, the glazing of stone objects being especially noteworthy. Metal workers used gold, silver, bronze, iron and tin, the source whence tin was derived being probably in the desert. A bronze bell is mentioned which was an alloy of six metals. Objects in bronze and iron have been found among the remains of the Old Empire, though the earliest bronze statue is one of Rameses II. The sources of most metals were the mines of Nubia and Sinai. In value silver exceeded gold and a mixture of the two is frequently mentioned. The processes of agriculture are well portrayed on the walls of the tombs. The plow was simply a sharpened stick dragged through the ground by oxen; the hoe a broad blade fastened to a handle in such a way of each preventing too great a strain. The seed once scattered was trampled in by animals. Harvesting was done by a short sickle; the grain was carried in sheaves to the threshing floor, where the hoofs of cattle performed the labor. The floor and shovel and wind and the grain was stored in conical receptacles open at the top, to which the bearers mounted on ladders. Supplementary irrigation was by a well sweep similar to the modern shadoof. These labors were so essential a part of Egyptian life that the future life was portrayed under exactly the same circumstances, happiness consisting essentially in the degree in which personal performance could be avoided. Cattle of all sorts, asses, sheep, pigs and goats existed in great herds and were tended by slaves and peasants whose occupations in marshy districts so far removed them from civilization that they were regarded with detestation. Their disrepute is the more remarkable in view of the evident pride with which landed proprietors enumerated their flocks.

The schools, "bookhouse" or "house of instruction" presided over by a scribe, was an institution of the Old Empire, which received all classes alike and prepared them for the technical education of the special bureau. In the New Empire both branches were combined in the departmental schools. Orthography, calligraphy, style and the formulae of etiquette comprised the known curriculum; the rest was learned by practice. Many corrected school exercises have survived, containing various specimens of literature, tales, religious and magical texts, poems, codes of rules, or "instruction," of ancient sages for the proper regulation of daily life and statements of the unlively condition of soldiers and laborers as contrasted with the beauty of the scribe's life, at once inciting to industry on the part of the pupil and to profound respect for the teacher. These papyri are of great value in affording a knowledge of orthography, language and literature. The tombs of the Old and Middle Empires represent the various operations of large landed estates with the complexity. The ownership of the soil, of large tracts and even of whole villages, seems to have been a survival from the time when the princes of the nomor were at the head of the independent districts which collectively constituted Egypt. A decided change is seen in the New Empire when the title to land was held by the individual. The lands were vested in the king and when it was worked for the state by slaves or let out at an annual rate per cent. The change came about during the Hyksos period or in the transition to the revived native dynasties. The biblical account of Joseph and that of his people in connection. The dwellings of the common people probably resembled those of the fellahin of to-day, being mud hovels, whose destruction accounts for the formation of the tells which mark city sites. The dwellings of nobles and kings were more pretentious, but no remains have survived. The only models by which to judge are some ancient sarcofagi of house-like form and some mural representations. Record has survived of a palace which stood 300 cubits square.

Family Life.—The position occupied by woman was quite extraordinary. In the household there was generally only one wife, though there might be several concubines or female slaves. Actual polygamy was infrequent, though the royal harem often contained 200 women. Private polygamy was done, with number of inmates depending on the financial ability of the individual. Inheritance and genealogy were reckoned by the mother, not the father, and while a man's possessions might descend to his son, the line might also pass through the daughter to his son. Sometimes marriages were contracted upon these considerations. It was a father's ambition to hand down his official position to his sons, and the title of "hereditary prince" is often met with. The practice of marriage with a sister is met with in early periods, but under the Ptolemies it was quite the rule, and the marriage contracts specified the amounts which the husband engaged to give annually to his wife for family purposes.

Costume.—There is a constant development observable in the dress of the upper classes. Royally set the fashions, and they were followed at intervals by those standing on the various social levels. There was a distinction between king and noble, and between noble and plebeian. The simple apron bound about the loins was always the essential garment. To this the king added a lion's tail, and the noble a panther's skin during the period of the Old Empire. During the Middle Empire the apron took a pointed triangular shape and became longer; next comes a double apron, a short one beneath, opaque, and a long and transparent one outside. The priest continued to wear the short apron, however, while the king had advanced to a mode of dress which covered the whole body and was complex in structure. That which before was holiday attire became the garb of every day. The dress of women was of a different kind; it consisted at first of a close-fitting garment which extended from the breasts to the ankles, and was fastened by straps over the shoulders. Only in the latest periods were sleeves or sleeveless mantles worn. Transparent cloth was used for female wear, and the apron of males, but without the inner garment. The dress of peasants consisted simply of the apron, which in some cases amounted only to a band with pendant ends. These simple articles were made of papyrus mats, leather or cloth.
The hair was worn short, but the shaving of the head does not appear to have been practised daily. Wigs of various forms and sizes were used as ceremonial head coverings. Specimens of them are not infrequent. Natural beards were not worn except by shepherds and similar persons. A typical Semitic beard was one of the marks of royalty and divinity in the tombs. Sandals of various sorts completed the costume. Egyptian garments of the better class were of linen, wool being regarded as filthy. The food of the lower classes consisted largely of lentils and barley. The principal vegetables were kidney beans, lentils, turnips, radishes, carrots and spinach. Milk and cheese were also common articles of food. Pomegranates, dates, figs and grapes were plentiful. The flesh of the goat, ox, gazelle, antelope and other animals formed part of the diet of the middle classes. The flesh of the hog was not in use, this animal being considered unclean. Geese, ducks, turtle doves and hens were abundant and even to-day are a source of considerable late. Salt was extracted from the coast marshes and from some deposits in the Libyan desert. The national beverage was beer, seasoned with various plants. The wealthy classes drank wine of the grape and the common people the fermented juice of certain palms.

Recreations.—The dance to the accompaniment of the lute was a popular diversion. Acrobat and clowns performed in the royal and princely palaces. Checkers and chess much in the form of our day were also popular amusements. As regards furniture chairs and tables resembled closely those of the present day. Other articles appear to have been of simple construction. The hunting of wild animals was by coursing with dogs and the use of lasso and spear. The bow and arrow were seldom employed. Fishing was with line or net. Fowling was done in the marshy districts in boats, the weapon used being the boomerang. Traps and nets were also used. Wrestling matches and the game of hide and juggling are often represented in paintings. Singing and music were the accompaniment of work and play, and at feasts, music and dancing, performed by members of the harem, enlivened the scene. The instruments used were the flute, a sort of whistle, the guitar, the harp, the lyre, the last two having sometimes nearly 20 strings. Assistants beat time by hand-clapping. Bow practice was engaged in and a game similar to quoits is represented, along with other games which cannot be understood in their details. T-shaped boards divided into squares like checker-boards have been found, but how they were used is uncertain. The children were not forgotten, for the tombs have yielded several specimens of their toys.

When the king was simply the first among equals, Upper Egypt was divided into 30 administrative departments of different grades, each having its nomarch or governor who stood as the head in everything—chief judge, district chief, military commander, tax collector, city overseer, etc. As judge he was also chief priest of Mat, the goddess of truth. So long as the king retained supreme power this arrangement continued, but upon the decay of royal prestige each district chief aspired to leadership. This probably explains the periods of confusion in the history indicated by the blanks between the 7th and 11th and the 13th and 17th dynasties. A new order came in during the period of the New Empire. The nomarch surrendered all his functions to the military official appointed by the king to look after his interests and to gather the taxes in kind, peaceably or forcibly as the case might be. Royal stewards and messengers, the "mouths" or "speakers" of the king appear as intermediaries. Some of the more important additional offices were those of chief judge, governor, building-master, treasurer, scribe, engineer, priest, etc. The chief judge was a man of high standing, a prince or noble, or perhaps a priest. Beneath him were several grades in the office. Several sat as a court and before them complaint was made, prosecution and defense heard and judgment pronounced or referred to the king, according to the gravity of the complaint. The prosecutor might be a private person or a public official with whom the complaint was lodged. Confessions were forced with the bastinado. The sentences pronounced were the loss of ears and nose, or death by impaling, compulsory suicide, or poisoning. Accounts of trials are frequent, but no legal code has survived. In the earliest periods there was no standing army. Each nom, nomitia and each temple its soldiers, who appear rather to have been police. This arrangement continued through the Middle Empire. The chief service rendered by soldiers in these periods was to escort expeditions to the quarries of Syene and Harsomut and to the mines of Sinai and Nubia. They also rendered service as laborers. Under Pepi (6th dynasty) a military expedition was undertaken against the Bedouin of the east. Ethiopian mercenaries formed the bulk of this force. Under Amenemha III (12th dynasty) expeditions to Nubia were undertaken and a stele of the period, now in Berlin, records the wailing which attended the visits of the conscript officer, the "military scribe" who came to "choose out the likely youth." About this time the king came to have a body guard and during the contest with the Hyksos the armies were increased. Mercenaries, however, were constantly employed as conscription was little employed. Bowmen formed the principal arm of the pharaonic forces coming into use after the Hyksos wars, was constructed to contain two persons, driver and warrior. Border garrisons were maintained to the east and south. The native weapons were the spear and shield, the axe, lance, dagger and sling. Naval warfare was little practised.

EGYPTIAN SUDAN. See Sudan.

EGYPTIAN VULTURE (Neophron percnopterus), a well-known bird which frequents
both shores of the Mediterranean, southern India and, during the winter, South Africa. It is the scavenger of Egyptian villages, collecting in numbers where carrion or garbage is deposited. It feeds also on frogs, lizards and small mammals found in cultivated fields. The birds usually go in pairs, however, and add to themselves to particular localities, being only drawn together in numbers by abundance of their favorite food. The name, as also that of Pharaoh's hound, is given because of the frequent representation of this bird in Egyptian sculpture. See Vulture.

EGYPTIANIZED CLAY is the name invented for the purpose of describing a certain treatment of clay by which a clay weak in strength and in plasticity is made stronger and more plastic. In this process the clay is treated with extract of straw, tannin and other plant products. The treatment reduces the particles of clay to a state so fine that they will pass through ordinary filter paper, and will remain permanently suspended in water. The employment of the extract of straw to make the clay stronger, suggested to Edward G. Acheson (q.v.), the discoverer of the process, the name "Egyptianized clay" because of the Biblical story of the use of straw in the making of bricks.

EGYPTOLOGY, the science of Egyptian antiquities. See Egypt.

EHREBERG, är-bärj, Karl Theodor von, German political economist: b. Munich 1855. He received his education at the University of Munich and in 1882 was appointed professor of political economy at Erlangen. He is best known through his masterly presentation of the subject of finance in his "Finanzwissenschaft" (3d ed., 1891; new ed., 1909). He also wrote "Über das ältere deutsche Münzweisen und die Hausgenossenschaften besonders in volkswirtschaftlicher Beziehung" (1879), and "Das Reichsmünzwesen" (1908).

EHLERs, är-ters, Ernst Heinrich, German zoologist: b. Lüneburg 1835. He received his education at Göttingen and Munich and in 1860 became professor of zoology at Erlangen. In 1874 he became professor of zoology and comparative-anatomy at the University of Göttingen. With A. von Kölliker he edited the "Zeitschrift für wissenschaftliche Zoologie." He wrote "Zoolgische Beiträge" with W. Keferstein (1861); "Die Borstenwürger" (1868); "Hypophorella Expana" (1876); "Florida-Anneliden" (1887); "Zur Kenntnis der Medusen" (1890); "Magellansche Anneliden Gesammelt während der Schwedischen Expedition nach der Magellansländern" (1900); "Neuseelandische Anneliden" (1904).

EHLEs, Otto Ehrenfried, German traveler: b. Hamburg 1855; d. 1895. He studied at the universities of Jena, Heidelberg and Bonn. In 1887 he went to East Africa, and later traveled through India, the Andaman and Nicobar islands, Siam, French Indo-China, Korea, Japan, the Hawaiian Islands and the United States. In a second tour he again visited India, and went to Samoa, Kaiser Wilhelm's Land and New Guinea. In an effort to traverse the latter country he was slain by his guides. He wrote "An indischen Fürstenhöfen" (2 vols., 1883; 5th ed., 1898); "Im Sattel durch Indochina" (1894); "Samoa, die Perle der Südsee" (3d ed., 1896); "Im Osten Asiens" (4th ed., 1900).

EHLERS, Rudolf, German theologian: b. Hamburg 1834; d. 1908. He received his education at the universities of Heidelberg, Berlin and Göttingen. For some time he was professor at Stolberg, near Aachen, and in 1864 removed to the Protestant Reformed Church at Frankfort-on-the-Main, where he exercised a wide influence as a theologian. In 1876 he was made consistorial councilor, and in the following year became one of the editors of the "Zeitschrift für praktische Theologie." He published, among other works, "Evangelische Predigten" (1873); "Das alte Gesetz und die neue Zeit" (1877); "Bilder aus dem Leben des Apostels Paulus" (1886); "Richard Rothe" (1906), and a philosophical work in Latin.

EHNINGER, åning-ér, John Whetton, American artist: b. New York 1827; d. 1889. He studied under Couture in Paris and later studied at Düsseldorf. He left a number of portraits, and landscapes and figure subjects, including "Peter Stuyvesant" (1850); "Death and the Gambler"; "Autumn Landscape" (1867); "Twilight from the Bridge of Pau" (1878); illustrations for Longfellow's "Miles Standish" (1858) and for Irving's "Dolph Heylinger" and "Ye Legend of St. Gwendauny" (1867).

EHRENBerg, är-ren-bärj, Christian Gottfried, German scientist: b. Delitzsch, 19 April 1795; d. Berlin, 27 June 1870. After studying theology, medicine and natural history at Leipzig and Berlin, he joined in 1820 an expedition to Palestine, Egypt and Abyssinia, returning to Berlin in 1825. In 1829 he accompanied Humboldt to the Urals and Altai ranges and to central Siberia. In 1839 he was appointed full professor of medicine, at Berlin. His great work on "Infusoria" ("Die Infusionstierchen als vollkommene Organismen") appeared in 1838, and was at once recognized as the highest authority on the subject. It was followed in 1854 by his "Microgeologie." Ehrenberg's work gave an enormous impetus to the study of microscopic organisms. He was the first to show that the phosphorescence of the sea is due to the presence of hosts of animalcules. Consult Lane, "Life" (1895).

EHERNBREITSTEIN, är-ren-brít-stin, Prussia, town and fortress on the right bank of the Rhine, opposite Coblenz with which it is connected by a bridge of boats and a railroad bridge. Tobacco, flour, leather, soap, bricks and wine are manufactured and there is a large trade in corn, wine and iron. There are several large fairs held annually. The fortress is on a steep rock, 385 feet above the river. It has massive fortifications and until the advent of heavy siege artillery was deemed impregnable. In 1799 after repeated assaults had failed and after a siege of 14 months the French succeeded in capturing it. In 1801 they destroyed the fortifications and retired. In 1826 new fortifications were completed. Pop. 5,302.

EHRELE, är-le, Francis, German Catholic scholar: b. Isny, Württemberg, 17 Oct. 1845. He was educated at the Jesuit College, Münster, Westphalia, at the Maria-Laach in Freiburg, and at Ditton Hall, Lancashire, having been ad-
mitted to the Society of Jesus in 1861. After several years in mission work he was transferred to Rome, where he devoted himself to historical studies. In 1890 he became a member of the administrative council of the Vatican Library, of which he was appointed prefect in 1895. He retired in 1914. He received honorary degrees, not only from Münster (1902) and Louvain (1909), but from Oxford (1899) and Cambridge (1905). His 'History of the Church and its Literature in the Middle Ages' (in German) is based on extensive researches in the archives of Germany, England and Italy. It is on this work that his reputation largely rests; but he has further written a Latin history of the Papal Library from 1200 to 1417, and (with Stevenson) a history of the Vatican. He was placed in charge of the Papal exhibit at the Louisiana Purchase Exposition, Saint Louis. His principal works are monographs on the frescoes of Pinturicchio in the Borgia Chambers at the Vatican Palace (French 1897; Italian 1899); edition of the more important documents in the Vatican Library and 'Beiträge zur Geschichte und Reform der Armenpfege' (1881).

EHRLICH, är'likh, Heinrich, German writer on music: b. Vienna 1822, d. 1899. He studied under Henselt and Thalberg, and for a time was court pianist to George V of Hanover. He removed to Berlin in 1862 and taught the pianoforte at the Stern Conservatory there in 1864-72 and 1886-98. He also wrote musical criticisms and other articles in the Berliner Tageblatt, Die Gegenwart and the Neue Berliner Musikzeitung. He published 'Wie üb't man am Klavier' (2d ed., 1884; Eng. trans.), 'Die Ornamentik in Sebastian Bachs Klavierwerken', 'Dreissig Jahre Künstlerlebens 1862-92' (1893); 'Schlacherl und Schlachsgatten aus der Musikwelt' (1872); 'Aus alle Tonarten' (1888); 'Die Ornamentik in Beethoven's Sonaten' (1896); 'Musik-Aesthetik von Kant bis auf die Gegenwart' (1881); 'Modernes Musikleben' (1895).

EHRLICH, Paul, German medical scientist: b. of Jewish parents at Strehlen, Silesia, 14 March 1854; d. Homburg, 20 Aug. 1915. He was educated at the universities of Breslau, Strassburg, Freiburg and Leipsig. After graduating in medicine in 1878 he began his researches into the relationship existing between scientific medicine and chemistry, experimenting on the effects of various chemicals upon living tissue. He first chose the aniline dyes, on account of their effects being visible when injected into animals. With these dyes and their derivatives his whole life's work was concerned and his most brilliant triumphs were gained through their employment. By staining the tubercle bacillus with dyes he found that certain of them possessed a peculiar affinity for this bacillus and this accorded with the view on which he based his whole philosophy—that of the specific affinity of particular chemical substances for particular tissues, more especially for the organisms which cause disease. He next discovered a method of testing the potency of the anti-diphtheria serum by experimenting on guinea-pigs, which made it possible to standardize the serum and accurately measure the dosage. Ehrlich then found a dye called 'trypan red' which cured fatal trypanosoma in-
1837. He served in the War of Liberation, 1813-15, and held a position (1831-45) in the Prussian Ministry of Education. He was one of the most gifted and original romantic lyricists of Germany. His principal works are 'Presagio und Freundschaft,' 'Waage, to the Philippines,' a dramatic story; 'The Life of a Good-for-Nothing;' idealizing vagabondage; the tragedies 'Erzeln von Romano,' 'The Last Hero of Marienburg'; and other plays, and a number of histories of German literature, including 'The Ecclesiastical and Religious Manuals of the New Romantic Poetry in Germany' (1847); 'German Romance of the Eighteenth Century in Relation to Christianity' (1851); 'History of German Poetry' (1857).

EICHHORN, Hr. E. Gottfried
German theologian and Orientalist: b. Dorrenzimmern, 16 Oct. 1752; d. Göttingen, 25 June 1827. In 1775 he became professor of Oriental languages at Jena, and in 1788 at Göttingen. He is considered the founder of scientific criticism of the literary and historical aspects of the biblical Scriptures. He edited a 'Repertory of Biblical and Oriental Literature' (1797-85); 'Universal Library of Biblical Literature' (1787-1803); and wrote 'Historico-Critical Introductions' to the Old and to the New Testament, and to the Apocryphal Books of the Old Testament; a 'Latin Commentary on the Apocalypse.'

EICHHORST, Hr. Hermann Ludwig
German physician: b. Königsberg 1849. He received his education at the university of his native city and in 1877 became director of the Medical Polyclinical Institute at Göttingen. Seven years later he was appointed to the chair of pathology and therapy at the University of Zürich. He has published many important works, including 'Lehrbuch der physikalischen Untersuchungsmethoden innerer Krankheiten' (3d ed., 1889); 'Handbuch der speziellen Pathologie und Therapie' (5th ed., 1895-96); 'Handbuch der Allgemeinen Pathologie und Therapie innerer Krankheiten' (1904); 'Hygiene des Herzens und der Blutgefäße im Gesunden und Kranken Zustande' (1906); 'Pathologie und Therapie der Nervenkrankheiten' (1907).

EICHLER, Hr. August Wilhelm
German botanist: b. Neukirchen 1839; d. 1887. He was educated at the University of Marburg and in 1871 was appointed professor of botany and director of the Botanical Garden at Graz. Two years later he became professor of botany at Kiel and in 1878 was appointed to a similar chair at the University of Berlin. He wrote extensively on the Coniferae, Cycadaceae and other plant groups of Brazil. His principal work is 'Blütenwölkchen' (1875-78), a description of the comparative study of flowers. Other important works are 'Syllabus der Vorlesungen über spezielle und Medizinisch-pharmazeutische Botanik' (1883); 'Beiträge zur Morphologie und Systematik der Marantaceae' (1884); 'Zur Entwicklungsgeschichte der Palmblätter' (1885).

EICHRÖDT, Hr. Ludwig
German poet: b. Durlach, Baden, 2 Feb. 1827; d. Lahr, 2 Feb. 1892. He studied at Heidelberg and Freiburg and published in 1848 in Fliegende Blätter his comic songs, 'Wanderlust,' which had great popularity. Among his works are 'Gedichte in allerlei Humoren' (1853); 'Leben und Liebe' (1856); 'Hortus Deliciarum' (1875); 'Gold' (1880). His collected works were published in 1890 at Stuttgart.

EICHSTÄTT, Hr. E. EICHSTÄDT,
Middle Franconia, Bavaria, an old town in a deep valley of the Altmühl, 67 miles north-northwest of Munich. Its principal edifice is a fine Gothic cathedral, founded in 1259. It has a number of very interesting monuments in marble and bronze and here also is the tomb of Saint Wilibald. Saint Walpurgis' Church is renowned as a place of pilgrimage, great numbers congregating there annually on 1 May. Other noteworthy features are the town-hall, the ancient episcopal palace, now converted into barracks, the episcopal lyceum, seminary, and municipal theatre. It has manufactures of shoes, matches, lithographic stone, etc. It is said that the city grew up about a military station of the Romans. In 908 it was chartered as a city. It suffered greatly in the many wars of the 18th and 19th centuries, being burned repeatedly by the French. The episcopal see was secularized in 1803, and the see of Eichstätt was annexed to the Diocese of Bavaria but was re-established in 1817.

EIDER, Hr. E. EIDER, a river of Prussia, in Schleswig-Holstein, which rises about 12 miles from Kiel, flows generally northwest, and after a course of 112 miles, of which 69 are navigable, empties into the North Sea at Tönning, where it forms a bay. It is connected with Kiel by the Schleswig-Holstein Canal.

EIDER DUCK, a bird of the sub-family Fuligulinae, or sea ducks, genus Somateria, distinguished by the peculiar form and feathering of the bill, and closely allied to the scoter ducks. The several species are confined to the northern regions. The American eider (S. dresseri) and the European eider (S. mollissima) are closely similar species which breed on solitary rocky shores and islands from Maine and the Farne Islands, respectively, northward, the former species wintering as far south as the Delaware River. They are most abundant in Labrador, Newfoundland, Greenland, Iceland and Norway, where they are strongly protected by law. Both species breed gregariously and in particular spots their nests are so abundant that a person can scarcely walk without treading on them. Their nests are usually formed of grass, dry sea-weed, etc., lined with a quantity of down which the female plucks from her own breast. In this soft bed she lays five eggs, which she covers over with a layer of down; then the natives, who watch her operations, take away both the eggs and the down, and this removal is repeated as often as she lays until the close of the season, when the last lot of eggs is allowed to hatch and the down removed from the nest only after the young have left. The drake does not, as is often stated, furnish any of the down. One female generally furnishes a few ounces of down. This down, from its superior warmth, lightness and elasticity, is preferred by the luxurious to every other article of clothing, and, from the great demand for it, those districts in Norway, Greenland and Iceland where these birds abound are regarded as the most valuable property and are guarded with the greatest vigilance. Proprietors endeavor to attract them by supplying artificial nests and otherwise, and when they settle in
an island off shore, cattle and herdsmen are
reminded to allow them to breed undisturbed.
The down from dead birds is little valued, hav-
ing lost its elasticity.

The length of the eider duck is about two
feet three inches, extent of the wings three feet,
weight from six to seven pounds; the head is
large and the bill of singular structure, being
three inches in length, forked at the base of
the upper mandible in a remarkable manner,
rising high up on the forehead, and having the
feathers on each side descending nearly to the
nostrils; the whole of the bill is of a dull, yel-
lowish horn color, somewhat dusky in the mid-
dle. The male is black beneath, head and back
white, with a black crown. The female is red-
dish drab, spotted with black, with two white
bands across the wings. Eiders associate in
flocks, diving to great depths for shell-fish,
which constitute their principal food. They
live much on the water, returing to the shores
to rest, particularly on the appearance of an
approaching storm. Their flesh is eaten, but
tastes strongly of fish. The eggs, however, are
extremely desirable, and the down is both fre-
quently obtained at the hazard of life by people
let down by ropes from craggy steeps.

Other species are the Pacific eider (S.
v-nigrus), and the remarkable king eider (S.
leucophrys) of high Arctic regions. The now
extinct Labrador duck (q.v.) is closely related.

**EIFFEL.** îfél, The, a barren and bleak
plateau of Rhenish Prussia, between the Rhine,
Moselle and Roer rivers, showing extensive
traces of volcanic action. Its surface is diver-
sified by crater-like depressions and volcanic
pits. It is 40 miles long and 20
wide, averaging from 1,500 to 2,000 feet in
height.

**EIFFEL, **à-fé or i-fél, Alexandre Gusta-
tave, French engineer; b. Dijon, 15 Dec. 1832.
He was educated at Dijon and Sainte-Barbe,
and at the Central School of Arts and Manu-
facture. In 1858 he was entrusted with the con-
struction of the large iron bridge over the
Garonne at Bordeaux, and was one of the first
to introduce caissons worked with compressed
air. The bridge over the Douro at Oporto, the
great viaduct at Garabit, in Corrèze, and that
over the Tardes, near Montluçon, are all the gigan-
tic locks designed and partly prepared for
the Panama Canal are among later triumphs of
his engineering skill; while in the huge frame-
work erected for Bartholdi's "Statue of Lib-
erty" may be seen the germ of the idea which
afterward assumed the form of the colossal
iron structure (1887–89) on the Champs-de-Mars
in Paris, with which his name is identified. He
also constructed the Aerodynamic Laboratory at
Auteuil. He is a member of the Legion of
Honor and has received decorations from Russia,
Austria, Portugal and Spain. See Eiffel Tower.

**EIFFEL TOWER.** A notable structure
in Paris. The plans for the exposition of 1889
included a monstrous iron tower, to be raised on
the site of the Exposition. The designer, Gustave Eiffel,
constructed it of iron lattice-
work, with three elevators giving access to
the summit. The uses of so stupendous an
undertaking are many, and it became one of the
chief permanent ornaments of the city. Its im-
portance from a meteorological point of view
cannot be overestimated, the tower enabling
meteorologists to study the decrease of tempera-
ture at different heights, to observe the vari-
ations of winds, and to find out the quantity of
rain that falls at different heights, and the den-
sity of the clouds. **EIGENMANN, i-gen-man, Carl H., Ameri-
can zoologist; b. Plochingen, Germany, 1863.
He was graduated at Indiana University in
1886 and studied at Harvard 1887–88. Between
1888 and 1892 he continued his scientific inves-
tigations in San Diego Biological Laboratory,
the Woods Hole Marine Stations, and in the explora-
tions undertaken for the British Mu-
seum in California, Oregon, Idaho, Montana,
Dakota and western Canada. He was ap-
pointed professor of zoology in Indiana Uni-
versity in 1891 and in 1895 founded and assumed
the direction of the Biological Station of Indi-
ana University. He made scientific explora-
tions in Cuba in 1902–04 and in British Guiana
in 1908. He has contributed more than 100
papers to the proceedings of scientific societies
and to scientific journals, including 'Catalogue of Fresh-Water Fishes of Central America and
Southern Mexico' (1893); 'The Ghizeh Inscrip-
tions of America' (1909); 'Egg and Develop-
ment of Conger Eel' (1901); 'Fresh-Water Fishes of Western Cuba' (1903); 'Fresh-Water Fishes of British Guiana' (1911).

**BIGG.** See Egg.

**BIGHT-HOUR DAY.** In the struggle for
the shortest hours of labor compensation with the
highest efficiency, begun in Great Britain early
in the 19th century, the first great landmark
was the Ten Hours' Bill of 1847, enforcing in
all trades what had come about in many.
But the golden ideal since 1824 (announced as such
by Robert Owen in 1817) has been eight hours;
possibly in remembrance that such was the rule
in mediaeval England; partly perhaps from the
tempting threefold division of the day into
equal parts, as in the rhyme "Eight hours for
work, eight hours for play, eight hours for
sleep, eight 'bob' a day. The eight-hour
movement began in America in 1856; by 1877
the short day was established for women work-
ers in factories, for miners working under-
ground and for public service employees.
The movement on the Continent received
the foundation of the "International" in 1864,
and as a world-demand of the social reformers,
from the Paris Trades-Union Congress of
1883. In 1916 Ecuador enacted an eight-hour
law, of universal application, with exemption
from labor on Sundays and legal holidays. Ex-
tra work is to be paid 25 per cent overtime, 50
per cent for overtime from six in the evening
to midnight, and 100 per cent after that hour.
In the United States, till recently, the subject
was left to the States and to private contests,
the government aiding by making a "donor in
its own works. In 1840 President Van Buren
reduced the working day in the government
navy yards to 10 hours. The first State 10-
hour law, for textile workers only, was of 1849,
in Pennsylvania. The first Massachusetts law
was in 1874, and was due largely to the
"Knights of Saint Crispin." But the eight-hour
movement had long before become general:
in 1866 the demand was formulated at a gen-
eral workingmen's congress at Baltimore, and
at other meetings; and the National Labor
EIGHT-HOUR LAW—EIGHTEENTH CENTURY

Union was organized to secure an eight-hour day. A six weeks' strike in New England and New York, April—May 1866, attempted to secure it, but failed. In 1867 Connecticut and Illinois passed laws making eight hours a legal day "unless otherwise agreed." Pennsylvania followed New York in railway. On 24 June 1869 the United States enacted an eight-hour day for its establishment; but the managers reduced wages correspondingly, allowing those who wished to work 10 hours at the old wages, which aroused such wrath that the President revoked the order. All these laws were rendered nugatory by the contracting-out clauses. In 1872 eight-hour leagues were formed in various places, and in Connecticut and New York a mass of strikes among the wood-working trades won this goal for a while; but the great depression from 1873 on prevented pressing such questions. Since 1880 nearly all the States have enacted eight-hour laws, subject to conditions, usually restricted to work for the State, county or municipality. The first great concerted effort for eight hours was when in 1901 20,000 workmen went on strike; it was at an eight-hour meeting in Haymarket Square, Chicago, that the anarchist bomb was thrown. A general strike was announced for this object in 1890, but was only partially successful; several hundred thousand workmen struck, and many employers yielded, but soon advanced the hours. The first really efficient national law was of 1 Aug. 1892, enforcing eight hours upon all laborers, mechanics or contractors in the District of Columbia or places of public works, under pain of fine and imprisonment.

Unquestionably the shorter workday movement, which began in Britain because of the same time as in America, had its inception in the desire to protect women and children from being overworked. Soon the labor unions recognized that it was better to ask for shorter hours than for higher wages, and so in various industries there has been a steady persistent effort for an eight-hour day, at the same wages paid for 9 or 10 hours. Widespread strikes in the building trades, the printing industry, etc., were won by the employees, and the numbers in the unions steadily increased. By 1912 it was popularly understood, both in Great Britain and America, that eight hours was a fair day's work, and liberal employers granted it very generally without pressure. However, some large industries continued to work 10 hours, notably the railways and common carriers.

In 1916 the various unions of railway workmen, affiliated through the American Federation of Labor, made a concerted demand for eight hours at the same wages that were being paid for 10 hours, and threatened a general strike and tie-up of the railways of the entire United States unless their demands were acceded to. After several months of discussion, and endeavor to obtain settlement by arbitration, no agreement was reached, and President Wilson held conferences with leaders on both sides. He finally succeeded in getting a promise from the unions that the strike would be declared off if Congress passed a law fixing an eight-hour day, and a bill was hastily prepared and rushed through both houses with very little discussion, being passed by the Democrats, by a nearly strictly party vote. It was signed 3 Sept. 1916 by the President, but its constitutionality was promptly challenged by the railway interests. The law provides: (1) An eight-hour day from 1 Jan. 1917, by common carriers and railways, excepting street railways, short independent railways and interurban railways; (2) a commission of three to be appointed to study conditions and report to the President; (3) that, pending the report of the commission, it shall be unlawful for the railways to reduce wages because of the shortened hours, in other words, they shall pay the 10-hour price for the eight-hour day; (3) a fine of $100 to $1,000 or imprisonment not to exceed a year or both are the penalties provided for violation. See LABOR LEGISLATION.

EIGHT-HOUR LAW, an act adopted in 1868 by the United States Congress, providing that in all government employment eight hours shall constitute a day's work. It originated in the agitation which had begun in England in 1833 by the proposition of eight hours as a legitimate working day. The agitation spread itself among the industrial classes throughout the civilized world, and first bore fruit in Australia in 1856, where it was adopted by several trades. The National Labor Union of the United States demanded it in 1866, and it came into effect in the government navy yards in 1869, and shortly afterward in all departments of government work. Its universal adoption, however, is still unrealized, and it is the source of persistent agitation among the labor organizations and parties throughout the United British Empire and on the continent of Europe. Consult Rae, 'Eight Hours for Work' (1894). See Eight-Hour Day.

EIGHTEENTH CENTURY. The. Carlyle made the 18th century for readers who accepted his ideas, and they were legion, a period of extreme decadence and even degeneration of interest in all that was best for humanity. He called it the age of prose, of lying sham, the fraudulent bankrupt century, the reign of Beezlebub, the peculiar era of Cant. Frederic Harrison came in defense of the period with the suggestion that indictments against a century are more unprofitable than indictments against a nation, and pointed out that almost all of Carlyle's heroes of the modern times apart from Oliver Cromwell are children and representatives of that epoch from Frederick of Prussia, Mirabeau, Danton and George Washington to Samuel Johnson, Burns, Watt, Arkwright and others. The century was so low in its interest in architecture that it is not surprising that Ruskin thundered against it that "Satan must have had a hand in the designing of the churches of the Georgian era," and there is no doubt that its art and education were far below the standards of preceding centuries, but on the other hand it is the greatest of musical centuries, the pioneer in physical science throughout, and its sad history of utter neglect for the poor is redeemed to a great extent by the upward movements which made themselves felt very widely at the end of the century in politics, economics, and literature, especially as regards the insane, prisoners and the defectives.

The last 25 years brought about more social
Changes than any other corresponding period in human history. Perhaps the reason for this was, as has often been suggested, that about the middle of the 18th century a great many of the highest and best human interests, especially those concerning fellow-men who needed sympathy and aid, were better than they had ever been before. Humanity had reached a nadir in social life from which there had to be an ascent and fortunately the reaction against the lamentable conditions which existed was strong enough to set up a humanitarian movement toward the end of the century which made itself felt during the course of the 19th century and has not been lost even yet. This makes the 18th century a pivotal period in modern history and therefore of ever so much more interest than many another century that represents greater immediate achievements.

What is particularly notable in the history of the 18th century is its wars in almost unbroken succession dictated by royal ambition or for money, and for political reasons. The time king’s mistresses or licentious women monarchical courts ruled the internal affairs of kingdoms. The war of the Spanish succession (1701-14) began with the century. The same first year of the new century saw the active carrying on of what had been the Northern War, lasting from 1700 to 1721. In 1718 war broke out between Spain and Austria, in the midst of which there was a formal declaration of war by England against Spain, and peace was not made until 1720. In the meantime the rebellion in favor of the Pretender, as he was called, the heir of the Stuarts who assumed the name of James III, came in Scotland in 1715 and was not suppressed until the following year. The Treaty of Utrecht (1714), which concluded the War of the Spanish Succession, changed the map of Europe as no previous treaty, not even that of Westphalia at the end of the Thirty Years War (1648), had done, but instead of settling the politics of Europe established a number of foci of irritation eminently calculated to unsettle them. Naples and Milan were given to Austria and the Austrian rule in Italy thus began to continue for a century and a half, always the subject of serious disturbance from within and without. Austria regained the Northern Netherlands which was called the Austrian Netherlands and to be a similar focus of disturbance. The Bourbon Philip V was allowed to rule in Spain on condition that the French and Spanish possessions should never be under the rule of a single individual. Great Britain received Nova Scotia and Newfoundland and the Hudson Bay region, thus precluding the expulsion of French from North America, and Gibraltar which brought with it the command of the Straits but has been a frequent subject of political irritation ever since. These wars of the first quarter of the century were only typical of the period. There was scarcely a year during the century when two important European powers were not at war; there were long series of years when a number of states were embroiled with each other. The War of the Spanish Succession had its counterpart in what is known as the War of the Polish Succession (1733), between Austria, Russia and Denmark, with France, Spain and Sardinia becoming involved. When the Emperor Charles VI of Austria died (1740), he left no sons, but had negotiated a treaty, the Pragmatic Sanction (1731), to secure the succession of his daughter Maria Theresa. The very year of his death saw the War of the Austrian Succession. In 1739 England and Spain were at war and in 1745 Charles Edward Stuart, the Young Pretender, as he was called, encouraged by France, led an insurrection of the Highlanders. This was terminated by the bloody battle of Culloden under “the butcher” Cumberland. In 1748 the peace of Aix-la-Chapelle was signed and the various countries of Europe made mutual restitution of their conquests so as to assure future peace, only Spain and Prussia being the gainers. It was to no purpose, for France and England became embroiled in war in the early 1750s; in 1756 came the Seven Years War involving most of the important countries of Europe; in 1775 the American Revolution broke out, Spain and France becoming involved in it before the end, and in 1792 the French Revolutionary wars began and for more than 40 years practically always at war, and over and over again the various nations of Europe were drawn into the Napoleonic wars. This by no means tells the tale of all the wars of the century, but at least it will serve to give an idea of the ever-recurring vain rivalry to arms.

The monarchs of the century whose names are best known are the Georges I, II, III, in England and Louis XV in France. The English were ruled for nearly 100 years by kings who could not speak their language, or but as a foreign tongue, and whose interests were much more in their German Hanoverian dominions and mistresses than their English people. Perhaps the political conditions of the time are best illustrated by the fact that their rule caused comparatively little dissatisfaction in England itself, though fortunately it provoked the American Revolution, which brought independence to the United States. Louis XV, succeeding to the magnificent dominions created by the genius of Louis XIV, whose personality had subjugated the French people and set an unfortunate example for other European monarchs, proved utterly unworthy of his great position and allowed himself to be ruled by designing mistresses. His reign increased the debt and the taxes of the French. Yet the young Louis XVI fell heir to an impossible situation. In spite of Louis XV’s weakness, France at the end of his reign (1774) had even more territory than at the death of his grandfather, Louis XIV (1715). Special conditions had however sunk to a level almost indescribable and the reaction against them was inevitable and could not be long delayed.

Certain great political changes which took place in the 18th century had far-reaching effects on subsequent generations, some of which are only working out to legitimate conclusions in our own time. Apart from the creation of the American Republic, itself of greatest significance for the course of civilization, the three most important political changes were the establishment of Prussian absolutism (1701), the rise of Russia to be a great European power which began under Peter the Great (d. 1725), and the establishment of British power in India which led eventually to the erection of the British Empire. In the light of recent events probably the first of these must be considered the most
important. The electorate of Brandenburg, whose ruler was one of those privileged to elect the emperor, came under the Hohenzollern family late in the Middle Ages. It was a narrow strip of territory less than 50 miles east and west of the little town of Berlin. It is the special pride of the family that each one of the reigning heads added something to his ancestral territory. The ruler was known only as Margrave and was considered of no special importance in German life. Prussia which fell to them by inheritance at the beginning of the 17th century had been originally ruled by the Teutonic Knights who had conquered its pagan inhabitants in a Crusade in the 13th century and continued to rule it through their grand masters. At the time of the religious revolt in Germany in the early 16th century the Teutonic Order was dissolved, and their lands were secularized and out of them the duchy of Prussia erected. The grand master of the time occupying what had hitherto been an elective office now becoming the Duke of Prussia with the right of inheritance. He was a relative of the Elector of Brandenburg and when this branch of the House of Holstein the Hohenzollerns now ruling over such distant provinces as Cleves and Mark in the Rhineland and Prussia far to the east. The great elector as he is called succeeded in welding these widely separated territories into a strong state. His son, Frederick I, obtained from the emperor, for military aid rendered, permission to change his title from elector to king though he was but king in Prussia as he did not rule over the whole of Prussia, but he preferred this title because his Prussian dominions were outside the Imperial limits and he was more independent. After the partition of Poland his title became King of Prussia.

His son, Frederick William I, though noted more for his eccentricities and for his rude boorish manners than for interest in anything higher, consolidated the Prussian dominions, created an army of nearly 100,000 men, drilled and trained probably better than any other soldiers of the time. He was himself a sanctimonious ascetic with regard to anything except military expenses, reduced the number of his court servants, coined the family silver and sold most of the royal jewels at auction. He left his son, Frederick II, a magnificent army and a well-filled military chest. Frederick II, to be known in history as the Great, whose interest in literature and the arts had disgusted his father in his youth, had no sooner ascended the throne (1740), at the age of 28, than he proceeded to develop the military advantages which his father had secured for him to the utmost. Maria Theresa having ascended the throne in Austria the same year, Frederick, taking advantage of the expected weakness of a female ruler, without any reasonable grounds laid claim to Silesia and began the War of the Austrian Succession. He enlarged his territories in every way that he could, showed great military genius in his campaigns and devoted himself to the encouragement of arts and sciences, the building of public structures for music and libraries and the building of a series of palaces, not all of them in good architectural taste, but not behind that of the century in which he lived. He especially enriched the city of Berlin with public buildings and though he encouraged French more than German literature did much for the intellectual life of the Prussian people. Under him Prussia became an important power in Europe.

The second of these great political changes of the century was the rise of Russia. This was mainly due to one man, Peter, to whom history has given the title of Great. The house of Romanoff came to the throne of Russia on the extinction of the dynasty of Rurik 1598. The 17th century was spent in breaking the power of the nobles, encouraging mining, manufactures and commerce and increasing Russian territory in the west at the expense of Poland. Peter the Great came to the throne in 1699 and reigned till 1725. He insisted on introducing the ways of European civilization, shaving off the beards of his nobles and cutting short their long gowns when they refused to obey his order he himself when they refused to obey his order he himself. He declared that people so dressed and bearded could not be good soldiers. He made war on the Turks and conquered Azov. Just at the beginning of the 18th century, Peter made his way to Poland on the Rhine and Prussia. He must have an outlet to the sea and that Holland could teach her lessons in shipbuilding. He worked as a ship carpenter for a while at Zaandam in Holland and studied the shipbuilding methods of the English on the Thames. He returned to put down an insurrection in Russia and the Cossacks under Mazeppa (1707), and then proceeded to take territory away from Sweden which would allow him an outlet to the Baltic Sea. He established nearby his capital, Petersburg, his desired "window into Europe," at immense expense, setting it up on piles in the swamps. In spite of the fact that Peter was succeeded by his wife, Catherine, who reigned for several years, and that between Elizabeth and Catherine II for most of the rest of the 18th century Russia was ruled by women of the most licentious personal character, whose favorites had much to do at least with the internal affairs of the empire, the country continued to gather strength and importance in Europe until about the latter part of the century it was one of the strong factors against Napoleon on many occasions. German intrigue riddled the country, however, and especially under Elizabeth and Catherine II succeeded in Germanizing the nobility to a great extent, especially the bureaucracy and keeping the Russian people in the worst possible condition of servitude and subjection.

The third important political event of the 18th century was the subjection of India to England. About the middle of the century the French, owing to the genius of Duplex who had been governor of Pondicherry since 1741, came into prominence in Indian affairs. Duplex dreamed of a French empire in India following the lines of the old Mogul Empire which had fallen at the beginning of the 18th century. Robert Clive who went to India as a clerk took on himself to make head against Duplex who was unsupported by his own government. In the midst of the wars between England and France which occurred around 1750, the American events of which are Braddock's defeat and the French and Indian War, and during the Seven Years War, Clive gradually built up the Indian Empire, often under
conditions that would not have been approved at home but that once concluded were accepted as accomplished facts. As a result at the beginning of the 19th century some 300,000,000 people in India were under English rule.

The American Revolution beginning appears to its full and the fall of scattered rather disconnected colonies with less than 3,000,000 of inhabitants and even those by no means strongly welded together, and with a very large party among them who remained loyal to England, its conclusion seemed almost impossible, ended with a triumph that gave genuine democracy almost its first great opportunity in the world's history. In a new land far from the disturbing political conditions of European countries and with magnificent resources to develop, the American Republic proceeded to exemplify what government of the people, by the people and for the people may mean. De Tocqueville's 'American Democracy,' written 50 years later, is the tribute of a wise and sensitive European republican to America's success. Undoubtedly the colonists owed their successful termination of the Revolution to the aid of the French, though the kingdom of France under Louis XVI was tottering, so its fall and the sure victory by the very success of the spirit of democracy in America. From Lexington to Yorktown represented seven long years of the severest trials borne with magnificent courage and persistency by the colonists, hampered by a large loyalist contingent among them, and these virtues had their own reward. The result was a solidarity of feeling owing to sympathy and union in suffering which more than all else served to bring the colonists together. The 13 colonies had been anything but homogeneous in race and character and they were almost infinitely dissimilar in attitude toward religion and life. The Puritan of New England and the Cavalier of the Virginias and Carolinas represented opposite poles of feeling in almost every way. It was hard enough indeed after the Revolution to bring them together or secure a working modus vivendi for their government, but it would have been quite impossible only for the long years of bloodshed and the severe victory with which the had passed in the period of travail from which the new Republic of the West was eventually born. It has well been called the greatest fact in modern history; the greatness of that fact has been enhanced by the part which the American Republic, now one of the largest of the nations, has taken in the War World for democracy.

The greatest man of the 18th century was beyond all doubt George Washington. It was the custom sometimes to speak of him as owing his reputation to a series of happy accidents rather than to innate genius. Having been chosen the general of the Colonial forces, it was said that he succeeded in holding out against the British whose mistakes were so great as to facilitate this until the alliance with France. Consequently, he wisely brought the combination of regular military strength and organization which made Yorktown possible and brought a happy ending to the Revolution. Any such view, however, is contradicted by detailed knowledge of the facts. Just as much more than a youth he had saved Braddock from total defeat in spite of that general's utter errors. The campaign around Boston added further to his military reputation. The battles of Princeton and Trenton have been acknowledged by modern military experts as one of the greatest series of strategical combinations under the most discouraging circumstances that have ever been made. The official documents of Washington show clearly how large and noble was his mind. His advice is still the best policy of the republic in spite of its broad extension beyond anything that he could have imagined in his wildest dreams. His declamation of the presidency for the third time and the consequent tradition of but two presidential terms was a precious heritage for the nation, and the final proof of his magnanimity. Time instead of lessening his prestige has added to his reputation and made it clear that he was a great man raised up to fit a great occasion.

The saddest chapter of the 18th century is that of the social conditions. In order to explain the French Revolution so much attention has been devoted to social conditions in France that there has come to be a very general impression that social abuses were at the worst in that country. As a matter of fact with the exception of England the poorer classes were better off in France than anywhere else in Europe. The awful picture of the Ancien Régime is true, but it should be remembered that the German lower classes were in still worse condition and the Russian serfs were quite literally slaves and life and death was practically in the hands of their masters. The nobility in all the countries apparently felt themselves to be of quite different clay from the human beings below them in the social order and treated them accordingly. With the coming of the capitalist class as the result of the industrial revolution something of this same feeling was to develop on the part of rich employers to employees. Whenever human nature has the chance it imposes on those below it and it must not be forgotten that the Declaration of Independence in the last quarter of the century was written and most strongly upheld by men who thoroughly believed in the institution of negro slavery and insisted on maintaining it for nearly a full century.

The most shocking element in social conditions was the utter neglect of the wards of the state, prisoners, the insane, feeble-minded and the poor. The awful conditions which existed in prisons and hospitals were described by John Howard toward the end of the century who brought about a beginning of reform. The prisoners were huddled together utterly regardless of their influence on each other, the young and the old, the first offender and the hardened criminal, and the treatment of women was almost worse than that of men. Hundreds of women in London prisons were crowded together, some of them women of the streets and some accused of little thefts to keep their children alive, and with many of the prisoners children were allowed to be there because there was no one else to care for them. Nearly 250 crimes were called felonies and were subject to punishment by hanging. Poor women were often hanged for having passed a counterfeit pound note when in fact they themselves did not know was a counterfeit and the fact that they had children at their breast or were
in an early stage of pregnancy was no mitigation of their offense. The insane who had ever shown any sign of violence were shackled and were seldom allowed to be free again. The quarters in which they were cared for were filthy beyond description and they were often confined in cells underground or chained to the walls of dark rooms into which the sunlight never penetrated. Quaker philanthropists in England began a crusade for the reform of the asylum which the eighteenth century had been slow to gain ground and the movement spread to America. It had been the custom to permit visitors in search of amusement to stand at windows where they could view the antics of the insane, a small sum of money being collected for this privilege. This amusement became so popular that many thousands indulged in it every year and the fee constituted an important source of revenue. Pinel in France dared to strike the shackles off the insane in the great asylum and hospital at Bicêtre though a great many even of his medical colleagues were convinced that it was a dangerous proceeding. The care for the defectives and for the poor in the poorhouses continued to be almost unpeachably bad until well on into the 19th century, and indeed in some cases until our own time. The serious idea of reform in the matter of care began to take hold of thinking people before the end of the 18th century. The United States was a leader in these reforms. When de Tocqueville visited America and gathered the material for his book on Democracy he was here as a member of a commission to investigate our prison system in order to secure the reform of French prisons.

Personal liberty on the Continent had sunk to a very low ebb indeed. Most of the rulers were absolute monarchs and there being no written guarantee of rights men had almost no redress against the monarch’s ill will in their regard if he wished to exercise it. In France particularly the king might order the imprisonment of a subject no matter what his rank and keep him in prison for any length of time that he wished. This process was accomplished under a sealed document issued by the king called a Lettre de Cachet. This mode of imprisonment had been very much abused under Louis XIV, but the abuse reached a climax under Louis XV when it is said that over 130,000 sealed orders were issued. Sometimes men thus imprisoned would be entirely forgotten and the reason for their imprisonment be quite unknown. A clause of Magna Charta made any procedure a violation of the rights of Englishmen, but in other countries the practice was quite common. When the Bastille fell (1789) some of these prisoners were found for whose imprisonment no reason could be discovered.

A profound reaction in social matters was due in Europe. It came with the French Revolution when the attempt to distribute the burdens of taxation more equally on the French, or indeed to solve the problem of the bankruptcy of the country, it developed into a great outburst of the oppressed classes. As Hilaire Belloc who probably knows the period of history he is writing, says in his book on the Middle Ages, it was an organized effort to win back for men some of the privileges which they had enjoyed in the Middle Ages. In that sense it continued to make itself felt all during the 19th century and down to our own time. It is this aspect of the movement that has until now not been properly appreciated. Hailed by all the liberal thinkers of Europe as a great step forward, the Revolution degenerated into the saddest of butcheries, and gave place to utter anarchy until the French people themselves, tired of bloodshed, welcomed a military dictator with power to maintain public order. In 1789 the States-General were summoned by the words of the Declaration of 1614. This was changed shortly into the National Assembly. A new constitution was proclaimed in 1790. In 1792 the monarchy was abolished and the next year the well-meaning but unfortunate Louis XVI was put to death and Marie Antoinette, his queen, Maria Theresa’s beautiful but imprudent daughter who had been the admiration of Europe, followed. These events alienated all Europe and the new republic fought them all in combination and won battles that enabled her to extend her territory but finally brought her under the heels of a military despot. The most compelling figure of the 18th century is Napoleon Bonaparte and his career is the index that French affairs had reached a point where reaction was inevitable. This product of the time was a man of genius, nearer to being the master of Europe than any other man had been before. He called himself consul and an old Greek would have said that he had made himself tyrant, but he was a more absolute ruler than ever Louis XIV had been. One of the last reflections made by Gibbon, the historian of the Roman Empire, whose wide knowledge of world history would seem to give him a right to an opinion on the subject, was that the world would never again see a great conqueror arise who like Augustus or Caesar might threaten to have the world under his domination. Gibbon died in 1794. Had he lived but a scant 10 years more he would have been able to witness the utter contradiction of this opinion, though there is no doubt now that most of the learned men of his time and especially those familiar with history would have accepted his reflection as almost so obvious as to be an axiom. In this after all Gibbon differed very little from many a serious student of history of a century later who would not have hesitated to say that he never felt that a great prolonged European war was shared by most of the civilized nations of the world was an utter impossibility.

Bonaparte was carried to the height of power on a flood of military success. Arrived there he proved to have a genius for administration that enabled him to maintain himself and that has stamped his influence on all modern legislation. He came to the front in the Italian campaigns of the wars of the French Revolution when his victories in Italy forced the Emperor Francis of Austria to surrender the Austrian Netherlands to France and to withdraw from northern Italy with the result that Piedmont and Savoy were annexed to France. France was a republic, but there was no republicanism in the spirit of French conquests once the man was seized. Tyrants were sacrificed quite as readily to French ambition, or rather to the ambition of French military leaders, as were monarchies. In return
for his surrender to France of these large territories the Austrian emperor was permitted to join the French in destroying the ancient commonwealth of Venice, which with all that was oligarchical in its government had at least some show of self-ruling about it. The French and the Austrians divided the Venetian territory. While Bonaparte planned his expedition to Egypt and the French needed money to finance it the Directory of France calmly proceeded to attack Switzerland, for some six centuries a republic, for no better reason than because the town of Berne was known to take her duties as a treasure. The French Revolution would seem then utterly to have failed in its purpose, but it was only an eclipse for a time and in spite of many vicissitudes its spirit was to work for good for more than a century later. Napoleon came to be the hammer by which a great many of the presumably most firmly established things of the old order in Europe were smashed upon the anvil of war to be made over for the better, though the betterment was often not immediate.

The era of the century in the best sense of the word was Maria Theresa, queen of Austria or "king," as her Magyar subjects loved to call her, and finally Austrian empress. Her father had anticipated trouble for his daughter's rule and made the treaty called the Pragmatic Sanction to secure it, but his worst portents were confirmed and Maria Theresa was scarcely seated on the throne before she became embroiled in a series of wars for the preservation and integrity of her states. Probably no woman in history has ever taken her duties as a treasure more seriously. On the other hand as the mother of 17 children she took her domestic duties quite as seriously and was a model wife and mother. Her letters to Marie Antoinette during the French troubles show her maternal solicitude at its best and her wisdom as a ruler and administrator. She treated her subjects very much as she did her family, with the most loving care and profound wisdom. She practised strict economy, encouraged manufactures and trade, and was in favor of the idea of preventing bloodshed by being prepared for war, and organized a system of military colonies on the frontiers so as to prevent invasion and save her subjects from the worst hardships of war, that of having the enemy in their midst. Above all Maria Theresa won the love of all the different peoples who composed her multilingual kingdom. It has always been a historical mystery why the heterogeneous peoples who constitute the Austrian Empire have hung together and it has often been supposed that it was a mere question of armed force and repression. There can be no doubt, however, that there was real attachment to the house of Hapsburg and that above all Maria Theresa's long reign of nearly 50 years had much to do with creating a spirit of solidarity among these peoples. Her readiness to do for the suffering among her people was literally unbounded. It is said that once she was driving through a part of the country where famine was rife and people were starving. Passing by a mother seated at the roadside trying to nurse her child and evidently unable to supply it with food, the empress threw a piece of money into her lap and told her to get something to eat, but the mother, with tears in her eyes insisted that it would be too late to save her baby. The mother of 17 children might well be expected to be in a condition to supply for lack of infant food, and so the starving baby nursed at the Imperial breast and its life was saved. It is easy to understand that among peoples who had traditions of acts of this kind on the part of their empress queen, deep feelings of affection would be aroused to become a tradition in favor of the family of which she was a member.

The one thing that stains the reign of Maria Theresa is the partition of Poland. There is no doubt at all that she entered upon it with great unwillingness and felt that she was forced to take part lest there should be such a disturbance of frontiers and the balance of power in central Europe as would leave her kingdom and people open to attack under unfavorable conditions. Perhaps another fault was the association of her son Joseph II in the government. Maria Theresa was a woman of heart and high administrative ability. Joseph was an intellectual prig who was quite sure that humanity could be made better by rules and regulations and that men could be governed by sweet reasonableness and intellectual reform. His career as a ruler was an utter failure. He tried to make himself a benevolent autocrat for the benefit of his subjects and was so terribly disappointed by his failure that he died a broken-hearted man before he was 50.

Women were destined to play an extremely important role in 18th century history. The reign of Queen Anne is a great period in English history but unfortunately unworthy women were to be the most influential characters of the time. The most noteworthy of these whose career is typical in many ways of the lamentable political influences that were at work was Catherine II, the empress of Russia, who reigned from 1762 to 1796. She was not a native Russian, but a princess of Anhalt-Zerbst in upper Saxony. Her name Sophia Augusta was changed to Catherine upon admission into the Greek Church just before her marriage with Peter who had been selected to succeed his aunt, the Empress Elizabeth, on the throne of Russia. She was not the first thus to be lifted from obscurity to the high position of empress of the Russians, for her earliest predecessor in the 18th century, Catherine I, the wife of Peter the Great, who reigned for two years after his death, 1725 to 1727, was the natural daughter of a country girl in Livonia. The first Catherine, after having been the mistress of a series of Russian generals, attracted the attention of the tsar and became his mistress and subsequently his wife. She died at the early age of 40, her end being hastened by dissipation. She never learned to read or write, but she knew how to please men. The second Catherine was quite as dissipated, and had even more administrative ability, but she had devoted herself to her own education until she came to be looked up to as one of the scholars of the time. She was a friend of Voltaire and of the Encyclopedists. She was a great believer in the new social philosophy which they preached, and maintained cor-
EIGHTEENTH CENTURY

respondence with them. Her husband frittered away his life in senseless dissipation, but while the Empress Elizabeth lived, Catherine maintained some show of respectability and acquired deep influence over her. Her mode of life, however, soon became such as to make the patience of her child of grace a matter of grave doubt. With the death of Elizabeth the half-imbecile Peter, her husband, soon got into serious difficulty with his people and his nobles, and Catherine through her lovers took advantage of this to secure the throne.

All during her life Catherine continued to live most licentiously. One lover succeeded another, though one favorite, Potemkin, maintained his influence over Catherine for some 15 years, supplying her with new favorites when his mistress's personal inclination for himself suffered an interval or ceased entirely. Catherine's lovers are said to have cost Russia over $100,000,000 at a time and under circumstances when money was worth at least five times as much as it is now. In spite of this utterly deplorable rule, Russia for Russia's advantage though not for the benefit of her subjects. She pursued relentlessly the policy of giving Russia an egress for its commerce by sea. She succeeded in bringing Courland with its Baltic coast line into the Russian Empire, had Pomerania, an old over, elected to the throne of Poland, and finally brought about the infamous division of Poland — Catherine obtaining about two-thirds of the Polish territory. An inscription of the people under Kosciusko, the Polish hero of the American Revolution, on the Russian army stormed Warsaw and the last trace of Poland as an independent country was obliterated (1794). It was the foulest deed in history.

War with the Turks led to Catherine's conquest of Bessarabia and other countries down to the Caspian and came near realizing the Russian empress' dream of driving the Turks entirely from Europe and the establishment of her own empire at Constantinople. She was completely alienated from all sympathy for French ideas by the progress of the French Revolution and prohibited the publication of French works in Russia. French admirers used to call her the Semiramis of the North and her career, political and moral, amply justifies the comparison, with the moral balance in favor of the ancient ruler who anticipated Catherine by some 2,500 years. It was the presence of such rulers as herself and Louis XV during the 18th century that brought about the reaction against monarchical government which was to attract so much attention during the 19th century.

This century contains the most important chapter in the history of music. Scarlatti (1659-1725) who wrote some hundred operas, a number of oratorios and an immense amount of ecclesiastical music, introduced three novelities destined to make important changes in the form of opera and oratorio. These three novelities are the Simfonia or Overture and the accompanied recitative. Every country in Europe took up music and made distinct contributions to it. Purcell's work in the 17th century in England had finely prepared the public mind, and Handel and Bach contributed to the organization of the art of music on a firm footing. It has been said that these two great composers of the 18th century, wrote every combination of musical notes that down to our latest times has ever been employed with good effect. The more the works of these masters are studied the more they are found to foreshadow the supposed novelties in harmony, employed by subsequent artists. (MacFarren, 'The History of Music in Britain and America'). The period includes also the life and works of Gluck who did so much to unite music and plot in opera into one harmonious whole. Piccini, Gluck's rival in the famous musical war in Paris, was a much less important musician, but he had dramatic power and real musical talent. Haydn, often spoken of as the father of the symphony, contributed greatly to the development of music and some of the sons of the great Sebastian Bach have an enduring place in the history of musical art. Mozart whose untimely death at the age of 35 cut him off in the flower of his achievement was one of the greatest musicians of all time. Before the end of the century Beethoven had rounded the symphony into its modern form and Catherine the Great had died. The death of Gluck marks his marvelous command over notes. The opera comique of the French which dates from early in the 18th century, the distinction from grand opera being that there was spoken dialogue interspersed with the music, provided opportunity for the development of lighter music that was to occupy so much attention in modern times. What is noteworthy, however, in the 18th century is the depth and seriousness of interest of even the general public in music. Handel's oratorios to crowded houses and as Frederic Harrison has said "the ill designed churches of the period were often crowded with people who were deeply touched by the sacred music given and whose emotions were heartfelt and not at all the result of any fashionable or conventional feeling."

The literature of the 18th century, opening with 'The Rape of the Lock' and closing with Goethe's 'Faust,' must surely be considered as of significant import in the history or literature. It includes in Germany the work of Winckelmann, Lessing and Herder, as well as the youth of Schiller; in France the writings of Montesquieu, of Voltaire and the Encyclopedists, and in England such historians as Hume, Robertson and Gibbon, as well as such potent writers of English prose and verse as Addison, Steele, Samuel Johnson, young Wordsworth and Robert Burns. Frederic Harrison has suggested that it is the first age since that of Augustus which ever left imitable pictures of its own daily home existence. The Spectator, Walpole's and Fanny Burney's letters and the novels of Richardson, Fielding and Smollett have given a picture of the times that has probably never been equalled. What is interesting above all about the literature of the 18th century was the trust in ordinary human beings. The problems of men as men were here first stated in literature and sympathy aroused for even the lowest of mortals. Gay's 'Beggars Opera,' Crabbe's 'Tales' and Defoe's and Swift's romances are representative in this regard. Defoe and Swift wrote from so close to the heart of human nature that their best works are forever popular.

Education reached a very low ebb in the
18th century so that Cardinal Newman suggests the middle of the century as representing probably the lowest period in the history of university education, when the students at Oxford and Cambridge scarcely more than use their terms, that is, lived in residence to receive their degrees, while Winkelmann, wanting to teach Plato at the end of the century, had to have manuscript copies of the author because no Greek edition had been issued in Germany for over 100 years. Philosophy, however, was subject of a good deal of attention and exploitation usually on the part of men not directly connected with the universities. It is the age of Locke, of Hume and of Bishop Berkeley in England, whose stay in America influenced Jonathan Edwards, of Voltaire and the Encyclopedists in France and of Kant in Germany. The work of these men lived to influence the 19th century. Religion was at a low ebb and it was an age of skepticism. The work devoted to John Wesley in England, which proved the incentive for the Oxford movement of the century, was the first index of reaction. French philosophy in its atheistic aspects was curiously enough a child of English skepticism. Voltaire and the French Encyclopedists (see Encyclopaedia) attracted attention rather by the brilliancy of their style, the chemistry of their satire than by depth of thought. Voltaire himself pronounced the period an age of trivialities. Rousseau suggested the abandonment of artificial culture and refinement and the going back to the primitive state of nature because it seemed hopeless to guide men otherwise. Adam Smith's Wealth of Nations represented the English philosophy of independent morality applied to practical life.

The 18th century was the century of the fundamental organization of the sciences, in their modern form. The period crystallized the data of scientific information, till then held in solution, and gave the physical sciences the form they have maintained since. Physics, chemistry, botany, zoology, comparative anatomy, geology, were the elements of social science both in history and in statics took shape. Lancisi at the beginning of the century in Italy and at the end of the century Hunter and Bichat in England and France revolutionized methods and results in the sciences related to medicine. Morgagni founded pathology. Jenner's discovery of vaccination marked the dawn of a new era in therapeutics. Auenbruger initiated clinical diagnosis, and the example of such men as Percival Pott, after whom Pott's disease (q.v.), and Pott's fracture are named, gave a new impetus to accuracy of surgical diagnosis. The Vienna School of Medicine began its work as an inheritance from some great students of Boerhaave at the beginning of the century, and such men as Cullen, Hermitage, Huxham left an indelible impress upon medical history. Franklin, Galvani, Volta laid the foundations of the science of electricity while Priestley, Lavoisier and Scheele were doing similar work in chemistry. St. Helier, La Grange and others were adding to the literature all that Newton had accomplished at the beginning of the 18th century, recognizing very clearly the surpassing value of their predecessor's work. La Grange declared that Newton, whose Princ.
work long hours in unsanitary, ill-ventilated factories, compelling them to live in crowded slums not far from the factories because their long working day did not allow them the time to go or come farther to their work. The industrial revolution worked an immense amount of social harm, led to the employment of women and children for such long hours and under such unsuitable conditions as proved seriously detrimental to health, and it took more than a century before humanity wakened up to the need for regulating industry in such a way as to conserve the rights of man.

JAMES J. WALSH,
Author of 'The Thirteenth and Greatest of Centuries.'

PRINCIPAL EVENTS OF THE 18TH CENTURY.

1701. Frederick (III) Elector of Brandenburg is crowned first King of Prussia, 18 Jan.
1702. Anne, Queen of Great Britain, begins her reign.
1708. Peter the Great is crowned by Peter the Great.
1709. Charles XII of Sweden is defeated at Parnawa, 30 June.
1710. The union of Scotland with England is ratified and the parliament of Great Britain assembled.
1711. The British defeat the French at Oudenarde.
1712. An alliance of Sweden is defeated at Pultowa, 30 June. Battle of Malplaquet, 11 Sept.
1713. Treaty of Utrecht signed, 30 March.
1714. Hugo Stenbock becomes King of Great Britain.
1715. Scotland revolt; the Stuart Pretender appears, but his supporters are defeated at Sheriffmuir. Louis XIV of France dies.
1716. The Turks are defeated at Belgrade.
1718. Charles XII of Sweden is killed at the siege of Fredrikshald, Norway.
1720. The South Sea Scheme, 7 April—29 September, collapses. Victor Amadus, duke of Savoy, becomes King of Sardinia.
1722. Peter the Great assumes the title of Czar of Russia.
1723. Death of Peter the Great. Persecution of Protestants in France.
1727. George II becomes King of Great Britain.
1733. France and Poland at war.
1735. Kien-Lung ascends the throne of China. He receives embassies from Russia, Holland, and Great Britain.
1739. Nadir, Shah of Persia, conquers the greater part of the Mogul Empire.
1740. Frederick the Great begins to reign. Maria Theresa becomes Queen of Hungary.
1741. The Allies defeat the French at Dettingen.
1744. Great Britain declares war against France, 31 March. Commonerre Anson completes his voyage around the world.
1750. Seven Years' War begins. Rupture between Great Britain and France.
1757. Damien's conspiracy against Louis XV. Prussian victory at Dettingen over French and Austrians. 5 Nov. King of Prussia becomes master of Silesia.
1759. France loses Canada in the final battle of the Heights of Abraham.
1760. George III begins his reign.
1767. Seven Years' War ends with Frederick victorious. Peace ratified at Paris between Great Britain, France and Spain.
1764. The British Parliament grants Mr. Harrison $50,000 for discovering the longitude by his chronometer.
1766. American Stamp Act repealed.
1769. Captain Cook makes discoveries in the Pacific Ocean.
1772. First Partition of Poland by Russia, Prussia and Austria. First Partition.
1773. Captain Cook's voyage to the Antarctic, reaching 10° south latitude.
1774. Louis XIV of France begins his reign.
1776. The Declaration of Independence proclaimed, 4 July.
1778. Siege of Gibraltar. Captain Cook killed at Hawaii.
1781. The surrender of Cornwallis at Yorktown, 18 Oct.
1790. Titles of nobility suppressed in France in such a way as to conserve the rights of man.
1795. Holland invaded by the French. Belgium annexed to the French Republic. The remainder of Poland partitioned between Russia, Austria and Prussia. Jay's treaty between the United States and Great Britain.
1796. Bonaparte's campaign in Italy.
1799. The siege of Acre. Bonaparte made First Consul.

EIGHTH CENTURY, The. The 8th century is a cardinal epoch in modern history because it witnessed the culmination of the struggle in the east and west of Europe by which it was decided that European civilization should be Christian rather than Mohammedan in character. The failure of the Saracens to capture Constantinople in the early part of the century (718) and the decisive defeat inflicted upon the Moors at Tours (732) by Charles Martel followed by Charlemagne's successful campaign (777) which pushed Moorish dominion below the Ebro in Spain definitely settled that Christianity was to have an opportunity for free development in Europe. It was the fashion a generation or two ago to suggest the possibility that civilization might have increased more rapidly under Mohammedan dominion than actually proved to be the case under Christianity. The opinion was dictated primarily by the love of paradox though undoubtedly supported by the tendency to minimize the real progress of the Middle Ages through ignorance of their genuine achievement and to exaggerate the place of the Moors in education, literature, and, especially, in science. What actually happened in the Mohammedan countries in spite of the magnificent incentives afforded them by the close touch with Greek civilization in the East is the historical demonstration that their definite repulse in the 8th century was for the benefit of humanity.
medan power and reunion never took place. The raising of the siege of Constantinople (718) was due more to one man, Leo, known as the Isaurian, than to any other factor. Leo was the son of a shoemaker who rose by military and administrative genius to be emperor and founded a dynasty. Like self-made men at all times he was confident that he could solve all problems since he had solved so many, and his interference in Church matters separated Christianity into two parts that in spite of many administrative attempts have not united again. Leo and his son Constantine Copronymus declared against the worship of images in religion and encouraged the so-called iconoclasts or image breakers who did so much to disturb both religion and art in the East during this century.

Defeated in their attempts on Constantinople the Mohammedans forced their way along the northern shore of Africa, crossed the Straits of Gibraltar and succeeded in conquering, in 711 they had won over the Visigoths which made them masters of the country, and by the end of the first quarter of the century they had overran the peninsula and were crossing the Pyrenees to menace Gaul. The Duke of Aquitaine held them in check for a time, but they defeated him near Bordeaux in 732 and advanced toward Tours. Between Tours and Poitiers their immense host was met by Charles Martel (the Hammer) and completely defeated in one of the decisive battles of history. There are few authentic details of the battle though it would seem to have been, as far as we know, the conflict with the greatest numbers engaged ever fought between men at any time in history except in our present Great War. Charles Martel was the mayor of the palace of the western Frankish king. The Merovingians had ruled since Clovis' time, but weaklings ascended the throne and the Prime Minister, who was called the mayor of the palace, became the real ruler. Charles' son Pepin, surmounted the Short, acquired even more power than his father and finally put to the Pope the question whether the king should reign when his power was gone, received the answer that it seemed better that he who had the power in the state should be king, and so Pepin began the Carolingian dynasty. Pepin was the father of Charles the Great, who was destined to consolidate France, conquered the surrounding countries, including a portion of Spain from the Moors, put down the barbarians on the north and acquired dominion over northern Italy.

Charlemagne is the heart of the 8th century. The only man in history with whose name the adjective great has become so thoroughly incorporated that most people think of it as an essential part of his name, and he thoroughly deserves that distinction. At his accession Charlemagne's kingdom was the bulwark of the Christianity of the West. At his death his empire included most of western and southern Europe. Thought of usually as a warrior his greatness is reflected much more in his successful pursuit of a far-reaching constructive policy. He put an end to the process of political disintegration which had been at work in Europe since long before the fall of the Roman Empire, and he made it possible for men to think of progress and civilization in place of being constantly occupied with resistance to barbarian aggression which for three centuries had been their one preoccupation. It was a fitting consummation of his work that he crowned the emperor of the Romans by the Pope at Rome on Christmas Eve of the year 800. It was a striking omen of the new outlook for Europe when in the first year of the 9th century and of the Imperial reign an embassy arrived with precious Oriental presents from the great caliph of the East whose lot it was as well known in history and romance as Charlemagne's own—Haroun al Raschid.

Charlemagne lives in romance through his expedition into Spain, whither he went to put an end to the menace of the Moors to his kingdom by attacking them in their own stronghold. After some years of war, begun at the instance of an embassy from Spain, in the year of the mystical number 777, he succeeded in conquering all the district north of the Ebro, and established there the Spanish March, a name given to outlying districts of his domain whose rule was committed to special officials called margraves, or counts of the marches, or marks, from which our word marquis. Charlemagne's defeat of the Moors was the first step in the gradual expulsion of the Mohammedans from Spain which was not to be accomplished in its entirety for over 700 years. On the return from his victorious expedition to Spain the rear guard of Charlemagne's army was attacked and cut to pieces by the Basques in the pass of Roncesvalles, in the Pyrenees. The battle of that name, fought by Roland and his Paladins with surpassing courage to the bitter end, was celebrated in song and story for many centuries afterward. The prodigies of valor there done tinged even the tales of chivalry which were to occupy so much Spanish attention in the later Middle Ages and whose influence was felt until Cervantes laughed the romances of chivalry away.

Charlemagne lives in history much more as a lawyer, an organizer of the civil functions of his great empire and of education and opportunities for intellectual development than even for his success in arms. At his invitation Alcuin, called a Saxon monk by Charlemagne's earliest biographers, but claimed an Irishman (Albinus) by many writers, was invited to organize the schools all over Charlemagne's dominions. He was given the powers of Imperial Minister of Education. He well deserved Charlemagne's confidence. As Duruy says: "Alcuin was truly a scholar; he was familiar with Pythagoras; often cites Aristotle, Homer, Plato, Virgil and Pliny, and is one of the most noticeable instances of the union of those elements so difficult to harmonize, the spirit of ancient literature with the spirit of Christianity." It is interesting indeed to note that this founding of the palace of Charlemagne an academy in which the emperor and all his family and all the nobility at court were members. In this academy the emperor bore the name of David, Alcuin took the name of Plato, while the other members took such names as Homer, Plato and Virgil. We have some 300 of his letters addressed by this modern Aristotle to the Alexander of the West.

Charlemagne's efforts for the provision of
EIGHTH CENTURY

education for his people included women as well as men. His own daughters as well as those of the nobility attended the Palace School, and there are letters of Alcuin which show that they were deeply interested in the intellectual problems of the time. The emperor also recognized the social obligations of the ruler and ordered that there should be hospital ships in connection with all cathedrals and monasteries. At this time the word hospital included also refuges for the infirm, the old, the deformed and defective, and even the insane as well as for the homeless wayfarer.

In spite of many vicissitudes, wars, political disturbances, and accidental traditions, Charlemagne's work for civilization bore fruit down the generations, though his empire broke up and internal dissections arose mainly through the custom of dividing the realm among his sons which Charlemagne also followed. He disparaged such expressions as that of John Fiske: "When we think of all the work big with promise that went on in those centuries which modern writers in their ignorance used once to set apart and stigmatize as the Dark Ages, when we think of the various works of Gregory, a Benedict, a Boniface, an Alfred, a Charlemagne, we feel that there is a sense in which the most brilliant achievements of pagan antiquity are dwarfed in comparison with these."

While Charlemagne was reigning gloriously in Europe at the end of the 8th century a ruler in many ways scarcely less worthy than he and equally famous, Haroun Al Raschid (Aaron the orthodox), occupied the Eastern caliphate. Haroun was the fifth of the Abbaside caliphs, an accomplished scholar, a poet of distinction, who gathered wits, poets and musicians around him. It is for this reason that he is so widely and favorably known for it is to the Arabian Nights rather than to history that his fame is due. How much of the real greatness of his reign was due to Yafa, his vizier of the Barmecide family, is difficult to say. Haroun's personal character is revealed by his murder of his sister and his nephews when he learned of her marriage to the brother of his vizier. While all his life he occupied a position of bitter hostility to the Greek emperors, there is a well-established tradition that he sent presents to Charlemagne and endeavored to cultivate his friendship though perhaps only with the idea of thus making less of the rulers of the Eastern Empire.

Europe had freed herself from the danger of Mohammedanism attacking from the east and South, but before the end of the century was to witness an invasion of almost more serious nature from the opposite quarter. The Vikings or Norsemen invaded Britain in the last decade of the century and were to prove a serious foe to civilization for the next three centuries in many countries of Europe. Britain and Ireland had succeeded in developing education and culture, and Gael had made a magnificent beginning under Charlemagne, but the Danes were to prove a serious detriment and obstacle. Alfred overcame them in the next century for a time in Britain, but the northern coast of France had to be given over to them and they obtained a foothold in Sicily and southern Italy. They represent a much more serious impediment to the evolution of civilization at this time than any internal factor.

The 8th century was the scene of the career of one of these men who, forgetting himself in life, are never willingly forgotten. This was Boniface, the apostle of Germany. His name was Winfrid (A. S., *win-peace*), and he received the surname of Bonifacius from the Latin signifying "good face or the benevolent." Born of noble parents in Devonshire, England, he insisted on devoting himself to the spiritual and intellectual life in a monastery at Exeter, and when his talents assured his advancement, he obtained permission to become a missionary to the old Saxons. Some 40 years were spent in missions to the Saxons, and Boniface has been in honor ever since as the apostle of civilization as well as of Christianity to the German people. Distinction came to him unsought and Boniface was made a bishop and subsequently archbishop of Mainz and prince-bishop of Germany. Having solved some of the serious problems of ecclesiastical jurisdiction by his genius in the management of men as well as his kindliness of disposition he gave up his archbishopric to become a missionary to the Frisians by whom he died. His letters which have been preserved show us the interests of the time better, perhaps, than almost any other set of documents of the period that we possess.

One of the most interesting of Boniface's developments in Germany was his invitation to English nuns to help him in his mission. He recognized that the German women still swayed that influence in the communities which has been described by Tacitus and realized that women auxiliaries would be of great help on the mission. Thecla and Lioba, to whom the title of Saints has been accorded, accepted this invitation and exercised great influence. Boniface's letters show how thoroughly he appreciated the nuns as intelligent fellow-laborers in his apostolate. The education of the children of the Germans was confided to them and a greater influence was thus brought to bear on the Teuton women than could otherwise have been exercised. It was to the rising generation that Boniface looked for the exhibition of genuine Christianity. "It was extremely difficult to bend the savage natures of the Germans to the milder virtues of the Gospel. Saint Thecla particularly did much to organize the rising generation of young German women to carry on her missionary work.

The 8th century is usually considered one of the low periods of intellectual life in history and yet it contains the careers of three men famous ever after for their intellectual work. The great prose writer is Boethius, who, within two generations of his death, came to bear the title of Venerable Bede, by which he has been known ever since. Something of the place that he secured for himself in Christian scholarship will probably be best appreciated from the fact that in November 1899 Pope Leo XIII decreed to him the title of Doctor of the Church. Bede's influence was very great in his own time, not only in England but throughout all of western Europe, and in spite of the invasions of the Danes which disturbed English Christianity and its influence so
much, Bede's work came to be widely known. He has come to be recognized as the greatest scholar of his time—a writer whose style and critical judgment have made him a favorite among even modern students of a literary propriety seldom exhorted in his time. He referred all his materials to their sources and insisted on copists giving all the references. His critical, historical judgment has given him a distinct place among the historians. His life was the one of middle ages with occasional visits for a few days to friends and is the ideal scholarly writer's life at all times. The surprise is to find it so well exemplified in the England of the first half of the 8th century.

The second of these great scholars, John of Damascus, or Saint John Damascene, also had the distinction of being enrolled among the Doctors of the Church by Pope Leo XIII. His intellectual distinction is that of being the first of the scholastic philosophers and his De Fide, the great leader of the Christian work of scholasticism. He undoubtedly had a deep influence upon the Arabians scholars of his time, and their philosophy owes much to his inspiration for they admired him as much as his ideas. The most important of his works is that one known as the Fountain of Wisdom. It has a special significance in the history of theology because it is the first attempt at a Summa Theologica that has come down to us, though there were to be many such in the course of the Middle Ages afterward. Damascus's work for the Church is due to Leo the Isaurian's attempt to be head of both Church and state and to dictate the beliefs of his people in the matter of the veneration of images. When Leo issued his first edict, John was chief councillor of the city of Damascus and not a cleric, but he took up the defense of Church traditions, and then, recognizing his lack of knowledge for Christian apologetics, he entered a monastery, gave himself to study and became the great leader of the Christian thought of the time. He suffered bitter persecution at the hands of the emperor and his satellites, but he was vindicated by the Seventh General Council of Nice (787) and came to be known after the Greek fashion of adding a title of admiration as John Chrysostomos, that is, "John of the Golden Stream," because of his golden flow of words in defense of Christianity. Damascus is besides one of the world's great writers of hymns, and modern hymnologists have even spoken of him as the prince of Greek hymnologists. Three of his hymns, 'Those Eternal Bowers,' 'Come Ye Faithful, Raise the Strain' and 'Tis The Day of the Resurrection,' are widely known and admired in their English version.

The third of the scholars of the 8th century was another of Saint Peter's bishop of Salzburg, who had been an Irish missionary of the name of Fergal or Ferghil. He was received with great favor by Pepin, then mayor of the palace, and his talents and learning led to his being made abbot of Saint Peter's at Salzburg. He was deeply interested in mathematics and astronomy and his teachings that there were antipodes led to his being tried in the ecclesiastical courts, not, however, because of the scientific doctrine, but because it was said that this involved the denial that men had all come from a single origin. Vergilius succeeded in showing that his teaching was not contrary to Scripture and it was after this that he was made bishop of Salzburg. He was canonized in the 13th century by Gregory IX. There seems no doubt that his belief in the existence of people on the other side of the earth and that the earth itself was a sphere was due to his knowledge of the accounts of some of the Irish expeditions that had probably found their way in times of storm if not voluntarily across the Atlantic.

The century closed with a woman, Irene, the only woman who ever occupied the position of empress, in the fullest sense of the word, Basiliscus, in the Eastern Empire. While she had taken a determined stand against the Iconoclastic party which was disturbing both Church and State, she is distinctly one of the least worthy rulers of history. French historians have not hesitated to declare that she was as given to intrigue as Catherine de Medicis, and spared not even her own son in her ambition. She schemed against his marriage to Rotrud, a daughter of Charlemagne, and forced him to marry an Armenian totally unsuitable to become his consort. She sanctioned his bigamy with a woman of the court in the hope of ruining his career, and is even said to have blinded him before confining him to prison where he died. She did not long enjoy the fruit of her ambition (797–802), but was deposed by Nicephorus and passed the end of her life on the island of Lesbos in poverty and contempt.

The Pope and the people of Rome took advantage of the accession of Irene as the formal empress to repudiate the Eastern Empire and to make a formal break with Constantinople. They declared that a woman could not sit with Cesar and Augustus, and thus the path was laid open for a new era and a Western Empire. Pepin, as king of France, had come at the request of Pope Stephen III to save Italy from the Lombards, and was hailed as ruler though he received only the name of patrician which Charles inherited from him. This office was changed to that of emperor, and Pope Leo crowned Charlemagne as emperor in the last days of the 8th century.

JAMES J. WALSH,
Author of 'The Thirteenth the Greatest of Centuries.'

principal events of the 8th century.

710. The Saracens conquer Spain.
714. Charles Martel, natural son of Pepin the "major domo," or chief of the Franks, succeeds his father.
719. Boniface of England begins his civilizing mission in Germany.
721. The Saracens invade France.
726. Leo the Isaurian interdicts the worship of images.
731. Bede the Anglo-Saxon scholar completes his great work 'Historia Ecclesiastica Gentis Anglorum.'
732. Charles Martel defeats the Saracens at the Battle of Tours, and compels their retreat to Spain, which they almost entirely occupy, driving the Goths to the Asturias.
737-741. Charles Martel, having also subjected several German tribes, becomes duke and prince of the Franks.
752. Pepin the Shorts, son of Charles Martel, succeeds him and is made King of the Franks.
754. Constantine V of the Eastern Empire suppresses monasteries.
755. Archbishop Boniface, apostle of Germany, is murdered by pagan Frisians at a sacrifice.
756. The Lombards of Baltic origin, occupying the north of Italy, are defeated by Pepin, son of Charles Martel and father of Charlemagne.
768. Charlemagne begins to reign in Western Europe.
EIGHTH NERVE—EINHORN

774. Charlemagne conquers the Lombards; and Upper Italy is united by the Franks; Middle Italy by the Pope; Lower Italy by the Greeks.
775. Charlemagne invades Spain.
776. The battle of Roncesvalles.
794. Charlemagne holds a great Council at Frankfort.
799. Pope Leo III is acknowledged first bishop of the West.
797. Irene begins her short reign as Empress of the East.

EIGHTH NERVE. See AUDITORY NERVE.

EIKON BASILIKE, εἰκών βασιλική, (Gr. "the royal image"), a work the full title of which is Εἰκών μαζική ("The Pourtraiture of His Sacred Majesty in His Solitudes and Sufferings"). It was published 9 Feb. 1649, 10 days after the execution of Charles I, and within 12 months ran through 50 editions in various languages. It professes to be Charles' own composition in the form of a diary. It is written in an alt. in the Academy (1883), and contains numerous assertions of love for his misguided and ungrateful people. At the Restoration, Gauden, afterward bishop of Worcester, laid claim to the authorship, and a memorandum in the copy of the Earl of Anglesea, lord privy seal, under Charles II, affirms that claim with the authority of Charles II and the Duke of York. Milton's answer to it, 'Eikonoklastes' (that is, "imagebreaker") appeared the same year by order of Parliament. Gauden professed to have begun the work in or about the year 1637, and to have submitted a MS. copy of it to the king. On the other hand, those who maintain that the work was by Charles, assert that he had written the first six of its 28 chapters before the battle of Naseby (1645). The question is one of much complexity. Historians generally, from Lingard to Green, have pronounced against Charles; while some of those who have sifted his claims are in his favor. (See GAUDEN, JOHN.). Consult Almack, "Bibliography of the King's Book" (1890); Dobson in the Academy (1883); Scott E. (1857), "Comments on Edition of the Work" (1880); Wordsworth, Christopher, 'Who Wrote Icon Basilike?' (1824–25); Tucker, 'On the Author of Icon Basilike' (Berlin 1874).

EILDON, e'ldon, HILLS, three peaks belonging to a single mass, south of Melrose, in Roxburghshire, Scotland. The highest has an elevation of 1,385 feet above sea-level, and all command a splendid prospect and are rich in historic and legendary associations.

EILENBERG, t'len-boorg, Germany, town of Prussian Saxony, mainly situated on an island of the Mulde, 14 miles northwest of Leipzig. It has manufactures of calico, woolen cloth, yarn, dyes, stuffs, vehicles, basketwork, tobacco, chemicals, celluloid, beer and agricultural implements. Franz Abt, the song writer, and M. Rinckert, the poet, were born here. Pop. 17,403. Consult Gundermann, 'Chronik der Stadt Eilenburg' (Eilenburg 1879).

EILETHYIA (hieroglyph, Nekheb; city of Lucina, now called El-Ibn, a city of ancient Egypt, situated on the right bank of the Nile, a little below Edfu. The present ruins consist of the temple dedicated by Amenophis III to the local deities. The names of other monarchs are also found in the ruins; but the most interesting and important remains are the rock-tombs, some as early as the 13th dynasty, excavated in the hills. That of Aahmes, the 'captain of the sailors,' records his services in the wars of the early monarchs of the 18th dynasty against the Hyksos or Shepherds, and the Nubian and Nigratic races. Another, that of Pahir, is decorated with rich and elaborate paintings, representing the pursuits of agriculture, fishing, etc. The city was an outpost against the southern tribes, and its fort, a large enclosure of crude brick, was of importance as early as the Shepherd War. The goddess Suben (Eilethiya or Lucina) was a special protectress of Upper Egypt. Consult Brugsch, 'Reiseberichte' (Leipzig 1855), and 'Egypt Under the Pharaohs'; Wilkinson, 'Ancient Egyptians'; Mariette, 'Ancient Egyptian History'; Quibell, 'El Kab' (London 1897).

EIMBECK, im'beck, William, American geodesist: b. Brunswick, Germany, 29 Jan. 1841. He was for two years professor of mechanics and engineering, Washington University, and a member of the government commissions to the expeditions to Illinois 1869 and to Italy 1870. After 1871 he was an assistant on the United States Coast and Geodetic Survey. He has been a Fellow of the American Association for the Advancement of Science since 1875, is the inventor of the invariable reversible pendulum and the duplex base apparatus of coast and geodetic survey. His chief work has been in connection with the western divisions of the 39th parallel triangulation across the continent.

EINBECK, in'beck, or EIMBECK, Germany, town of Prussia, in the province of Hanover, on the Ilme, near its junction with the Leine, 40 miles south of Hanover. In the Alexander-kirche are remarkable old choir stalls, a bronze baptismal font of exquisite design and the tombs of the Prinzen-Grubenhagen. The town has vocational departments attached to its school system and maintains a school for police. Belts, linen, carpets, felt, sugar and tobacco are the principal articles of manufacture. The formerly celebrated Eimbecker beer ("bock" beer) is still highest in the hierarchy of malt liquors and of importance in the 15th century. It was a member of the Smalkaldic League and it figured prominently in the Thirty Years' and the Seven Years' wars. There are still remains of its old walls and towers. Pop. 9,431.

EINHARD. See EINHARD.

EINHORN, in'horn, David, American rabbi: b. Disperck, Bavaria, 10 Nov. 1809; d. New York, 2 Nov. 1879. His first rabbinical position was at Hopstaden, Bavaria, and shortly afterward he became chief rabbi of the grand duchy of Mecklenburg-Schwerin. In 1851 he was called to Peuth, but his progressive tendencies aroused sharp opposition and his temple was closed by order of the government. In 1855 he was invited to become rabbi of the Har Sinai Congregation, of Baltimore, Md. His activity was now to be rapidly developed, for he issued his "Essays of Leading Men," which was widely received by many reformed Jewish congregations, and he began the publication of a scholarly monthly magazine in German, entitled Sinai, in the interests of advanced reform.
His vigorous onslaughts on slavery in 1861 led to his removal from Baltimore to Philadelphia, where he became rabbi of the Keneseth Israel Temple and published his catechism. In 1866 he was appointed rabbi of the Adas Jeshurun Temple in New York, where he continued a zealous, impassioned and scholarly advocate of reform and the leader of the then radical school, until his retirement in July 1879.

EINSIEDLEN, in Zél döl, Switzerland (place of the solitary or hermit), a small town at an imposing depth of 2,895 feet above sea-level and 26 miles southeast of Zürich, seat of a renowned abbey of Benedictine monks since the middle of the 9th century. It is a famous resort of pilgrims who visit the place in thousands to venerate an ancient miraculous image of the Blessed Virgin. For the accommodation of the pilgrims the little town has more than 50 inns or houses of entertainment. Those pilgrimages are made throughout the year, but the great annual pilgrimage culminates on the anniversary of the dedication of the abbey's church, 14 September. The present abbey is the successor of four previous edifices which were destroyed by fire; it was erected in the first quarter of the 18th century and is an imposing pile in the Italian style. The place was visited by Edward Gibbon, the historian, 1755, who writes that he was astonished by the profane ostentation of riches in the poorest corner of Europe; amidst a savage scene of woods and mountains a palace appears to have been erected by magic, and it was erected by the potent magic of religion. The abbey which Gibbon then saw is still in existence and is annually visited by more than 150,000 pilgrims. It was plundered of its vast treasures of silver and gold and precious stones by the French (1798), but it is still very rich, especially in literary monuments, possessing a library of 61,000 volumes, 1,190 manuscripts and more than 1,000 productions of the printing press in its early period. The leading industry is the manufacture and sale of religious objects, statues, crucifixes, altar vessels, etc. The monastery has many historical and religious associations; a great chandelier was donated by Napoleon III. The monastery was founded by an English lady chapel here to house the statue of the Virgin given him by Hildegard. Pop. 8,438. Consult Rintholtz, O., Geschicht der fürstlichen Benediktinerstifts Einsiedeln (Einsiedeln 1904).

EISELEN, Ižé-lén, Wilhelm Bernard, German gymnast: b. Berlin, 27 Sept. 1792; d. Misdroy, 22 Aug. 1846. His early studies began in Berlin and he was the pupil of the eminent gymnast Jahns. He soon became prominent among the young gymnasts of Berlin and in 1819 began to teach gymnastics at a school in Berlin. He opened a fencing school in 1825 in which he and a musician in 1828, and had a large number of pupils. The first gymnasia for young girls was instituted by him in 1832. He published many works on gymnastics and fencing, including 'Deutsche Turnkunst' (in collaboration with Jahns, 1816), 'Abriss des deutschen Stossichtens' (1826).

EISENACH, Ižé-näkt, Germany, town in the grand duchy of Saxe-Weimar, at the north-west end of the Thuringian Forest, at the confluence of the Nesse with the Hörself, 17 miles west of Gotha. The neighborhood is remarkably picturesque, being ornamented with splendid gardens and residences. In the market-place there is a statue of Frederick the Great, erected by the inhabitants of the town, which was removed in 1870-71, and in the Karlsplatz stands the Luther memorial, unveiled in 1895. It contains many old buildings of historical and architectural importance. Among the educational institutions of Eisenach, the most prominent is the gymnasium formerly a Latin school, which Luther and Bach once attended, a school of forestry, a school of design and a teachers' seminary. It has some well-developed manufacturing interests which comprise coloring materials, white-lead, woolens, beer, leather, pottery, tobacco, cigars, cement pipe, alabaster ware, cabinet-work, lumber, oil, machinery, etc. The town has many interesting historical associations. Luther was at school here, and Sebastian Bach, to whom there is a statue, was born here. Near it is the Wartburg, where Luther resided for a time. Eisenach was formerly the capital of a principality of the same name. Consult Scheller, 'Eisenach und Umgebung,' ed. by Kühner (Eisenach 1898). Pop. 38,362.

EISENACH CHURCH CONGRESS. See Evangelical Church Congress.

EISENBERG, Ižé-nér, Germany, town in the province of Saxe-Altenburg, of great antiquity, birthplace of the philosophers Kranse, whose statue is set up there. It is near the junction of the Saale and Elster, 36 miles southwest of Leipzig. It possesses a famous castle, Christiansburg, and is the seat of many manufactures, including woolens, velvet, pottery, furniture, pianos, porcelain and agricultural machines. Statues have been erected to Bismarck and to Duke Christian of Saxe-Eisenberg, in addition to that of the philosopher Karl Friedrich Krause. Pop. 10,749. Consult 'Chronik der Stadt und des Amtes Eisenberg' (Eisenburg 1843).

EISENBERG, Ižé-nérz, Austria, mining town in the north of Styria, 20 miles northwest of Bruck. It stands in a narrow mountain valley at the foot of the Erzberg (5,000 feet), a mountain so rich in iron ore that the miners, instead of cutting mines into it and following the metal in veins, quarry the rock from the outside. About 3,000 miners are employed in the quarries on the mountain in summer and 2,800 in winter, the annual output being about 1,000,000 tons, of which about 40 per cent is metal. The Gothic church of Saint Oswald, founded in 1279, is an excellent example of the fortified type of ecclesiastical architecture, and its frescoes are in the Aragonite of the purest white, and resembling coral branches in form, and of the most beautiful white is found in caves in the mountain. Pop. 6,494.

EISENMENGER, Ižé-meng-ér, August, Austrian fresco painter. He was born at Vienna in 1830. He studied in the Vienna Academy and early gained the first prize in painting (1845). In 1863 he was appointed teacher of drawing in the Protestant Real-schule of Vienna. His first work of importance was the fresco which he executed in the hall of the Musical amateurs (Musik Freunde), 'Apollo with the Muses'; but he has painted many notable frescoes in other public buildings. He was
appointed professor of the Vienna Academy in 1872, remaining until 1901, and at the same
time opened a private school of fresco painting.
His more important works included the frieze
medallions in the Museum of Art and Industry, Viennia; a series of historical pictures illustra-
tive and in the reign of Emperor Maximilian I, in
Castle Hohenzollern, near Vienna (1872-79), and the
decorative painting in the session room of the
Chamber of Deputies in the Reichsrat
building at Vienna (1885).

EISENSTADT, i-sen-stat, or KISMAR-
TON, Hungary, town in the County of Oden-
burg, at the foot of the Leitha Mountains,
and 25 miles southeast of Vienna. It contains
the magnificent palace of Prince Esterhazy,
erected in 1683 and restored in 1805. Fine
grounds surround the palace, in the library of
which is housed a fine collection of musical
manuscripts. Nearby is the pilgrim shrine of
Maria-Einsiedel, also the burial place of the
composer Joseph Haydn. Pop. 3,073.

EISLEBEN, i-lä-ben, Germany, town in
Prussian Saxony, 18 miles to the west of Halle
famous as the place where Martin Luther was
born and died. The royal gymnasium, origin-
ally founded by Luther, was rebuilt in 1883.
The house in which Luther died has been re-
cently restored. In 1883, on the occasion of the
celebration of the 400th anniversary of
Luther's birth, a statue of him was unveiled
in the market-place. In the church of Saint
Andrew are busts of Luther and Melanchthon,
the tombs of the counts of Mansfeld, and
Luther's pulpit. Other Lutheran relics are in
the church of Saints Peter and Paul. Copper
and silver are mined in the neighborhood of
Eisleben, which has several smelters. A con-
siderable trade in flower and vegetable seeds
is carried on. In the 10th century the place
was called Iselben. Soon after the year 1100
it fell to the counts of Mansfeld, in whose
possession it remained until 1780, when it was
given to Saxony. In 1815 it was transferred to
Prussia. Pop. 24,629.

EISTEDDFOD, i-stê'd-fôd, the name of an
assembly of Welsh bards for the purpose of
musical and poetical contests. They were held
at Caerwys, at Aberfrau in Anglesea and
at Mathrelav in Powys. The judges were ap-
pointed by commissions from the native
princes, and, after the conquest, from the Eng-
lish kings. The last was issued in 1568 by
Queen Elizabeth, but the ancient custom has
been again revived by the Gwyneddigion and
Cambrian societies, and annual meetings for
the recitation of prize poems and performances
of the harp are now held under the name of Eist-
edydd Eisteddfod. Eisteddfod was an-
ounced a year and a day beforehand at an
assembly called a gorsedd, at which prizes
for the previous competition were awarded.
At the present time yearly eisteddfods are held
at several points in the north and south of
Wales, and in some parts of the United States,
especially throughout Pennsylvania, and other
sections settled by the Welsh people. Annual
meetings take place, in every way similar to
the rite in their native land. During the Co-
lumbian Exposition at Chicago probably the
most notable Eisteddfod held in this country
took place there.

EJECTMENT AND EVICTION. Eject-
ment in law is a mixed action, as it is
resorted to in order to recover the possession
of land and damages for the wrongful with-
holding of it, though the damages are nominal.
Originally, it was a possessory action—that is,
adapted to the recovery of the possession of
land. It ultimately became a convenient means
of testing the title by a series of actions. The
supposition was (and this was the substance
of the fiction) that a lease for a certain num-
ber of years had been made to a tenant, "John
Doe," who had entered into possession and had
been ejected by a person supposed to represent
the party to be finally made defendant. This
person was called "a casual ejector," and was
usually represented as "Richard Roe." An
action was then brought, substantially under
the following title: "Doe, as tenant of
Edward, (claiming the land), against Roe. A
written notice was thereupon served in the
name of Roe by Edwards' attorney to the opposing
claimant (Jones), who is the person in pos-
session. By this notice Jones was advised to
defend the action, otherwise Roe would permit
judgment to be taken against him, and the
possession would be lost. Jones, on making
application to be made defendant, was allowed
to defend on condition that he would admit the
validity of the fictitious portion of these pro-
ceedings, so that the matter was narrowed
down to a trial of the merits of the case. The
action was now deemed to be between Ed-
wards and Jones, although Doe still remained
plaintiff on the records of the court. It was
a rule in this action that the plaintiff can only
recover upon a legal title, as distinguished
from a title in a court of equity. He can suc-
cceed upon the strength of his own title, and of
its validity, and not upon the weakness of that
of his adversary. He must also have a right
of entry. Where that does not exist another
form of action must be resorted to. This
method of procedure was defective in one par-
cular. Any number of successive actions of
ejectment could be brought by the plaintiff,
although he had been defeated. The only
check upon suits of this kind was a resort
to a court of equity for an injunction to pre-
vent harassing litigation. In England the fi-
citious portion of the proceeding was abolished
by the Common Law Procedure Act of 1852,
and the action placed upon satisfactory
grounds. In New York and some other States
the same result had been accomplished as early
as 1830. In 1875 the law in England was modi-
fied to the extent of making an action for the
recovery of land similar to other actions, all
of which were simplified to conform to a unified
plan. This legenon was copied by many States
of the Union, but in many jurisdictions the
ancient forms survive. In general, it may be
stated that an ejectment action may be brought
by any person having a legal right to possession,
whatever be the character of his interest in it,
against any person or persons who are holding
it against one having an estate therein. Title
must be proven by the plaintiff. Substan-
tial damages to the plaintiff are now allowed
in most jurisdictions. Consult Blackstone, 'Com-
mentaries on the Laws of England'; Stephen,
EKATERINBURG—EL GRAN GALEOTO

New Commentaries (1903); Powell, 'The Law of Ejectment' (1911).

Eviction.—Depriving a person of his lands or tenements. Technically, the dispossession made by judgment of law; if otherwise it is an ouster. Eviction may be total or partial. Total eviction takes place when the possessor is entirely deprived of his rights in the premises. Partial eviction takes place when the possessor is deprived of a portion of them, as if a third person comes in and ejects him from a portion of his land, or establishes a right to some easement over it, by an older title than that under which he holds. See Dispossess.

EKATERINBURG, екатеринбург, also Iekaterinburg, Russia, town, in the government and 170 miles southeast of Perm, on the east side, and in the mining district of the Ural Mountains. It was founded in 1723 by Peter the Great and was named after Empress Catharine I. It has a mint, arsenal, customhouse, military academy, school, hospital, meteorological observatory and botanical garden. The art of cutting, polishing and engraving gems, which are found in the neighboring mountains, is here carried to great perfection, and, together with mining and metallurgy, and commerce in cattle and cutlery forms the chief occupation of the inhabitants. In the neighborhood are several platinum mines and also the famous gold mines of Beresov and Niviansk. Pop. 32,230.

EL BURRITO (N. M.), Battle of (Doniphan's name Brazito, Mexican Temascalitos), 24 Dec. 1846, in the Mexican War. Colonel Doniphan, marching from California to Chihuahua, was assailed at a bend of the Rio Grande, some 25 miles from El Paso, by a battalion of Mexicans under Antonio Ponce. The Mexicans fired at long range as they charged; the Americans waited till they came close, then broke them with a destructive volley, and a company of 20 horse scattered their cavalry, which fled to the mountains. American loss, 4 wounded; Mexicans, 43 killed and 150 wounded.

EL BURLADOR DE SEVILLA. Tirso de Molina's drama, 'El Burlador de Sevilla y Convidado de Piedra' ('The Gay Scoffer of Seville and Feast of the Statue'), is the parent source in literature of the famous legend of Don Juan Tenorio, the unscrupulous gallant and blasphemer, subsequently presented variously by Molière and Byron as Don Juan, by Mozart as Don Giovanni, and, in Spain itself at a more recent date, by José Zorrilla as Don Juan Tenorio in the most popular of all Spanish plays. Few characters in the history of letters have attracted the attention of so many writers, or have been reproduced so universally and in such multiplicity of styles. In itself, however, Tirso's play is a structureless aggregation of unrelated adventures, in the course of which the hero seduces a Neapolitan lady, a fisher-girl, a young peasant, and, by a base deception, Doña Ana de Ulloa, whose father he slays. The blasphemous feast which follows, at which the statue of the Commander Don Gonzalo de Ulloa dined with Don Juan, dragging him down afterward with the tomb from which it has descended and the chapel containing it to perdition, is wholly distinct from the other episodes, which Tirso conceives after the manner of the chronicle play in a succession of loosely related incidents, without regard either to consistency of character or to dramatic action. Hence in this comic tragedy, Don Juan is a mere vulgar seducer, by after-thought a blasphemer, whose overthrow does not rise above the sphere of melodrama. Although Tirso must be held to rank with Lope de Vega and Calderón at the head of the Spanish romantic theatre, even the pastoral elements in this play are devoid of picturesqueness and lack the author's customary mellowness and sober imaginative charm. The story had been utilized previously by Juan de Cueva. While of uncertain origin, prevailing Spanish authority traces it to Seville, where Don Juan Tenorio is said to have died at the foot of the statue of the Commander, whom he had killed, as in the play, The Feast of the Statue is derived from independent sources. The play was first printed in 1630, but has never been translated into English. Consult Cotarelo y Morí, E., in his introduction to the 'Obras de Tirso de Molina' (in the Nueva Biblioteca de Autores Españoles, Vols. IV and IX, Madrid 1906-07); Menéndez Pidal, E., 'Sobre el Burlador de Sevilla y el Convidado de piedra' (in Cultura Española, Madrid, May 1906).

EL CANEY, el cañe, Cuba, town, on the main road, four miles northeast of Santiago de Cuba. During the Spanish-American War it was the scene of a battle between 525 Spaniards under General Vara del Rey, and 4,400 Americans under General Lawton. The Spaniards made a desperate resistance, but were finally overcome by the American infantry. The Spaniards lost 320, and 100 were taken prisoners; the Americans lost 440. This battle occurred 1 July 1898. In 1901 the United States government purchased the battlefield and approaches for a public reservation. See United States—Spanish-American War.

EL DORADO. See Eldorado.

EL DORADO, Ark., city and county-seat of Union County, 30 miles southeast of Camden, on the Chicago, Rock Island and Pacific, the El Dorado and Wesson, and the Iron Mountain and Southern railroads. It has cotton oil and planing mills, railroad repair shops, an iron foundry and bottling works. It contains also a courthouse and a county jail. In 1898 it was chartered as a city. The surrounding district is devoted to cotton and peach growing.

EL DORADO, Kan., city, county-seat of Butler County; on the Walnut River; the Atchison, Topeka and Santa Fé, the Missouri Pacific, and other railroads; about 25 miles east of Wichita. The city is situated in an agricultural region, and its principal trade is in grain, livestock and farm and dairy products. The city has machine shops, wagon works and quarries of limestone. It was settled in 1858 and was first incorporated in 1870. The city has a Carnegie library, and the water supply system is the property of the municipality.

EL GRAN GALEOTO. José Echegaray's 'The Great Galeoto,' certainly the most famous Spanish play of the 19th century beyond the
of about 40,000 tons of ore a month. The monthly payment to miners for ores brought in averages $11,310,000, which finds its way into the stores and factories of the city; the monthly pay-roll of the smelters and other manufactures and the railways centering in the city is nearly $300,000; and these, together give to the financial interests a stability that few little mining operations in other parts of the country have. It has one of the largest custom smelters in the world, giving employment to from 2,500 to 3,000. Other industrial establishments are a wood-finishing and box factory, foundries and machine shops, cement plant, railroad repair shops, brick and tile works, saw and door, macaroni and cigar factories, brass works and flour mills. The United States Census of Manufactures for 1914 showed within the city limits 117 industrial establishments of factory grade, employing 2,815 persons, 2,347 being wage-earners, receiving annually $1,663,000 in wages. The capital invested aggregated $8,660,000 and the year's output was valued at $6,135,000; of this, $3,325,000 was the value added by manufacture. Eastern manufacturers, especially of machinery, have large warehouses here. The city carries on an extensive trade in copper, silver and lead, machinery, livestock, wool and hides and has important wholesale and jobbing interests. El Paso has 10 national banks, with resources amounting to over $27,660,719, and deposits over $22,660,485, as contrasted with $1,500,000 and $750,000 respectively 30 years ago. El Paso is pre-eminently a city of homes. The streets are lighted by gas and electric light, and a well-planned electric street railway system places all parts of the city within easy reach of the business section. The more notable buildings are the Federal building, county courthouse, city hall, post-office, high school, the State School of Mines, Fort Bliss, Carnegie library, Knights of Columbus Home, Masonic Temple. There are 13 public parks. The city has several public schools and parochial (Roman Catholic) schools, a business college, and is the seat of the Saint Joseph's Academy and of the Rio Grande Congregational Training School and Theological Seminary. There are several handsome churches and two well-equipped hospitals. El Paso is a noted health resort, having many excellent hospitals, some of which are open during the entire year. The assessed valuation in 1916 amounted to $48,736,645. There are within the city limits nearly 60 miles of asphalt streets, 82 miles of concrete sidewalks and 97 miles of sewers. The city adopted the commission form of government in 1885. Its receipts amount annually to about $2,000,000, while its payments reach about $1,800,000. The waterworks system, costing $1,500,000, is owned by the city. The Spanish explorers visited the site at an early time. The first settlement was made in 1827, and the town incorporated in 1889. During the Civil War it was occupied alternately by Federal and Confederate troops and for a time was the base for operations against New Mexico and Arizona. The present charter dates from 1889 with revisions of 1891 and 1907.

EL-PASO, Ei pa'so, Texas, city, port of entry and county-seat of El Paso County; on the northern fringe of the Atchison, Topeka and Santa Fe, the Texas and Pacific, the Rock Island, Southern Pacific and other railways; on the Rio Grande River in the extreme western part of the State. It is opposite Ciudad Juarez, Mexico, the most important of the Mexican Central Railway. El Paso is about midway between the tide water of the Atlantic (Gulf of Mexico) and the Pacific oceans, about 3,800 feet above sea-level and is central to the rich tributary regions of western Texas, New Mexico, Arizona and the northern section of old Mexico; it is 600 miles from any railroad center that may compete with it. It is the center of a rich fruit and vegetable growing region, the great Elephant Butte Dam (q.v.), costing nearly $10,000,000, furnishing ample water for irrigation. By it 200,000 acres are reclaimed. El Paso's unequaled railway facilities, the proximity in New Mexico of inexhaustible supplies of fuel coal and the demand for supplies and machinery from the mines, ranches and growing town make it one of the most important manufacturing cities of the Southwest. Its most important industry is smelting the valuable ores of the neighboring region. The El Paso smelters have a capacity
the development of the natural resources of the country tributary to the city. The total imports in 1915 had an appraised value of $9,149,410, of which cotton, cattle, copper, silver, zinc and lumber formed the principal items imported. Exports were valued in 1915 at $4,146,655, of which wool, flour and coke, short, blankets, cotton and cotton prints comprised the bulk. Pop. 7,700.

EL RENO, Okla., city and county-seat of Canadian County; on the Rock Island Lines, junction main lines north and south, and east and west, being operating headquarters for the second district of the system; terminal for Saint Louis, El Reno and Western Railway, and also for Oklahoma Railway Company and Intercity. Near the geographical centre of State, it exploits a rich agricultural district producing alfalfa, corn, kafir, wheat, oats, broom corn, fruits and vegetables. The industries of the city are varied and growing rapidly. They include five lumber yards, two flour mills (daily capacity 3,000 bbls.), vitrified brick and tile factory, two ice plants, incubator factory, washing machine factory, broom factory, cigar factories, foundries, machine shops, tent and awning factory, granite and stone works, plumbing mill, gas and electric plants, ice cream factory, steam laundry, wholesale groceries, etc. El Reno has 15 churches and 7 public schools, the new High School costing $100,000; school enrollment of 1,600 and a teaching force of 45. The Sacred Heart Institute (Catholic) has an enrollment of 200, with graded, high school and music courses. There is also a business college, Carnegie Library and two hospitals. The Masons and Elks possess fine buildings and the El Reno theatre has a seating capacity of 1,400. The new office building of the Rock Island system cost $150,000, and the city hall cost $50,000. New Federal building cost $120,000. The El Reno Country Club has a fine clubhouse and maintains one of the finest golf courses in the State. The Grand Lodge Masons maintain the State Masonic Home at this point, owning 640 acres which the United States government sold to that body recently; fine buildings already built and plans for one of the finest homes in the country are being laid. Old Fort Reno, nearby, has been converted into a train station, where horses are gentled and trained for cavalry purposes for use in United States Army. In 1911 El Reno adopted the commission form of government, the executives being commissioner of public affairs — ex-officio mayor; commissioner of finance and commissioner of highways. The city owns its own water plant and extensions, with a capacity of 1,500,000 gallons daily, has 10 miles of paved streets and 15 miles of sewers. The taxable valuation is about $7,000,- 000. The city has four banks, with a capital and surplus of $175,000 and average deposits of $1,500,000. It was first settled in 1890, made a borough the same year and a city of the first class in 1892. The population has increased very fast, being now over 10,000.

EL SABIO, Alfonso X, king of Leon and Castile, last of the dynasty of the houses of León and Castile was the son of Ferdinand III and Beatriz, daughter of Philip of Suabia and sister of Frederick II of Germany. Most carefully educated, he succeeded his father to the throne in 1252, bringing with him to his administrative tasks the reputation of successes gained in several campaigns against the Mohammedans. His reign was cursed with insurrections led by powerful nobles, financial troubles and warlike movements on the part of the Mohammedans. On the death of William of Holland, emperor of Germany, Alfonso hastened to Germany to press his claim to the direct heir. He was opposed in this by most of the nobles of Germany and by the Pope. Nevertheless he maintained the struggle, with superior powers for 15 years. In this struggle, he was often opposed by some of the most powerful ruling dukes of Spain, sometimes standing all his reverses he fought stubbornly on, claiming for himself the ancient title of king of the Romans; and signing his official documents with the great seal belonging to that dignity. He made ready several times to invade Italy and Germany, but trouble at home withheld his arm when he was ready to strike. Finally the united efforts of his powerful enemies and the threat of the Pope to excommunicate him, combined with ever-increasing trouble at home, forced Alfonso to announce his claims upon the ancient throne of the Romans. The opposition of the successive popes to the claims of Alfonso on the crown of Germany was due to the fact that he was the representative of the Suabian princes, long the bitter and uncompromising enemies of the popes. Alfonso was the more inclined to make peace with his enemies abroad in 1275 because of the increased trouble which the Mohammedans were giving him at home. In Granada, Murcia, Andalucía and the populous centres from Murcia to Jerez the Moors rose up against the Christian king in an effort to drive Christianity out of Spain. Alfonso besieged and captured Jerez, Medina-Sidonia, Rota, Santuce, Lebría and Arcos; and the Castile fleet, under the command of Don Juan Garcia de Villamayor, took Cádiz. In 1264 Jaime of Aragón came to the aid of Alfonso. The former captured the province of Murcia while Alfonso carried on the war against Andalucía. These constant wars and the struggle against Italy and Germany forced the king to increase the taxes. This estranged many of the nobles upon whom fell this burden of increased taxation; and Alfonso was forced to make concessions to his underlords which gave them great facilities for the oppression of their tenants. Thus the king ultimately lost the goodwill of nobles and peasants alike. The former, desiring the Castilian king, joined hands with the Moorish sovereigns of Granada, Mahomed I and Mahomed II. The treaty of peace with the Pope and with Germany in 1275, however, strengthened Alfonso and enabled him to make temporary terms with his insurgent nobles. Alfonso departed for Rome (1275) for an interview with the Pope, leaving the cares of his kingdom in charge of his eldest son, Prince Fernando de la Cerda. The latter sent an army under Nuño González de Lara into Córdoba. There the invading forces met with considerable success at first; but in a short while they were surrounded by a greatly superior Moorish force and defeated with heavy loss, among the dead being Nuño and over 400 of his bodyguard. The survivors took refuge in the town of Ecija (May 1275). The regent died in July while on his way to the relief of the besieged Castilian
forces; and Sancho, second son of King Alfonso, a boy of 15, at once took charge of the expeditionary force which he managed with considerable skill. Alfonso, on his return from Italy, made a two years' peace with the Moors, on the conclusion of which the latter again made an attempt to conquer the Christian possessions in Spain. Don Sancho led an army into Granada where he fell into an ambuscade and suffered defeat, losing over 3,000 of his finest knights. Sancho continued with the remainder of his forces at Granada, burning villages and towns and laying waste the country he traversed. But the Castilians were forced to retreat to Córdoba (1281). The following year Alfonso and Sancho quarreled over the succession to the throne and the son declared himself in open insurrection against the father. Sancho stirred up the towns of the country against the king and even sought the aid of the enemies of Christian Spain. But the Pope threw his influence in favor of Alfonso and ordered the bishops of the spiritual head of the Church, returned to their allegiance (1282). Alfonso disinherited his son and carried the war on with the aid of Yacub, ruler of Morocco. The insurrection lost ground rapidly, but just as everything was turning in his favor Alfonso died.

Alfonso the Wise occupies a prominent place in Spanish history as a legislator. He gave uniformity to the laws of his united kingdom, which were, on his coming to the throne, a confused mass of privileges and local observances, often at variance with one another, and frequently subservient of the order of the nation. Out of this confused mass of privileges and local laws he succeeded in creating a certain uniformity of legal observances whose influences were felt in Spain for centuries. He wrote the 'Septenario,' a work wonderful in its day and for the political conditions under which it appeared. This is a sort of political, moral and religious compilation which has served as the basis of numerous legal works which have been at variance with one another, and frequently subservient of the order of the nation. His 'Libro del Espéculo' and 'Espejo de todos los derechos' and 'Capítulos de las Leyes,' and 'Crónica General' are works of legal nature which have been attributed to him, in some cases apparently with considerable reason, among these being 'Estoria de España.'

JOHN HUBERT CORYN, Editorial Staff of The Americas.

EL SOMBRERO DE TRES PICOS (The Cocked Hat). The journalist and novelist Pedro Antonio de Alarcón (1833–91) met with little acclaim for his more ambitious literary performances; in fact, he attained no measure of success in his native land. With his short story 'El sombrero de tres picos,' however, he gained a well-deserved reputation, and with two of them, 'El sombrero de tres picos' and the 'Capitán Veneno,' which are really long enough to be termed novelettes, he won his permanent place in the annals of Spanish prose fiction. The 'Capitán Veneno' is entirely of his own de-
ELEAGNUS—ELAIN.

ELAGANUS. ál-e-ag'núz, a genus of shrubs or small trees of the family Elagaceae. The species, of which there are about 40, are natives of the northern temperate zone, and are characterized by deciduous or persistent entire leaves covered with silvery or brownish scales, solitary or clustered apetalous axillary flowers and one-seeded drupaceous fruits. They are valued in ornamental gardening for their foliage, usually decorative fruits, and mostly fragrant flowers. The deciduous members are hardy in the coldest green ones, which mostly come from Japan and China, only in the south. They are easily propagated by means of seeds, cuttings and layers, and succeed upon almost any well-drained soil in a sunny situation. The best known species probably are: (1) *E. angustifolia*, the oleaster or white olive, which attains a height of about 20 feet. It has been introduced from southeastern Europe or adjacent Asia, and has proved hardy in the bleak and cold prairie States. It is one of the most ornamental of species. (2) *E. argentea*, the silverberry, a native of the colder parts of Canada and the northern border of the United States. It seldom attains a height exceeding 15 feet, and is perhaps the most popular native species. (3) *E. multiflora*, the gumi, a species introduced from northern Asia. It is gaining in favor. It attains a height of about six feet and, like the preceding, bears edible, slightly acid fruit of pleasant flavor. This last species became of horticultural importance during the last 25 years of the 19th century because it produced clusters of fruit in climates too rigorous for most of the other fruit-bearing shrubs and trees.

ELAIS, é-lé'ís, the name given to a genus of palms. The seven species are diocious or monocious, the flowers, especially the males, in dense masses, packed very closely together; the fruit is partly three-sided, but somewhat irregular. *E. guineensis*, the maha or oil-palm of the West African coast, has heads of large fruits. The outer or fleshy part of the fruit is boiled in water, when the oil rises to the surface and may be skimmed off. In its native country it is used for butter. It constitutes one of the chief commercial products of western Africa. *E. melanococca* also furnishes oil. Both species yield by manufacture palm-wine.

ELAOCAVUS, é-lé-o-kar'paas, a genus of plants of the Elacoaceae. The species are shrubs and trees and are found chiefly in New Zealand, Australia and southeastern Asia.

ELAECORUS, é-lé-o-kar'paas, a genus of the staff-tree family (Celastraceae). The plants of the genus are generally trees, natives of southern Asia. They furnish for India, Australia and South America. The drupes of *E. kubu* are eaten at the Cape of Good Hope while the bark of *E. roxburghi*, rubbed with water, is used by the Hindus as an external application to swellings of all kinds. *E. glaucum*, a native of Ceylon, is sometimes called the Ceylon tea-tree. Saffronwood is the product of *E. croceum*, and an oil in common use in Africa is made from *E. argan*.

ELAGABALUS, é-la-ga'ba-lús, or HELI-

ELAGABALUS, he'li-o-ga'ba-lús, Roman emperor: b. Emesa 204 A.D.; d. 222. His real name was Varius Avitus Bassianus, but when a youth he was appointed high priest of the Syro-

ELAINE, é-lé'ín, or ELAIN, the oily principle of fat, obtained by submitting fat to the action of boiling alcohol, allowing the stearin to crystallize and then evaporating the alcoholic solution; or by the simple process of pressing any oily or fatty substance between folds of blotting paper, the oily matter or elaine is absorbed, while the stearin remains. The paper being then soaked in water and pressed, yields up the elaine. It possesses much the appearance and properties of vegetable oil, and olein (q.v.) is liquid at the temperature of 75° F. and has an odor derived from the solid fats from which it has been extracted.
ELAM, the ancient name of a country or region in Asia, east of the Lower Tigris. The cuneiform inscriptions record that a king of Elam conquered Babylonia and Assyria about 2300 B.C. The later ancient writers call this country Susiana, the name being derived from its capital, Susa or Shushan, one of the most ancient cities of the East. It is now known as Khoozistan. Both the country itself, which seems to have been of considerable importance at an early period, and its capital, Shushan, are mentioned in the Bible. Consult Sayce, "Inscriptions of Mal Ami"; Loftus, "Travels and Researches in Chaldæa and Susiana"; Billerbach, "Susa"; Dieu-lafay, "L'Acropole de Susa"; Meyer, Ed., "Geschichte des Altertums" (1913); Scheil, De Morgan, and others in "Monistories de la délégation en Perse" (1900-13).

ELAND, ē-länd, the largest antelope (Oreas canna) found in Africa. It is as big as a fully grown horse, weighs 1,000 pounds or more and stands fully six feet high. The early settlers in South Africa called it "elk." The eland has a short, smooth coat of rich brown color; strong, straight antlers as long as 20 inches, and a broad, fringed dewlap falling about to the knees. The hide makes excellent harness leather and the flesh is decisively palatable. The elands move so slowly and are such gentle creatures as to be easily caught, and hence have been nearly exterminated in their native haunts. At present very few are found. In the equatorial region of western Africa is found the still larger species (Oreas derbianus).

ELAPHURE, ē-lāf'ūr, name for David's deer (Cervus davidianus), whose habitat is Northern China and Manchuria. It is commonly kept in parks by wealthy Chinese and even in Europe. Little is known of its habits in the wild state. It has long shaggy hair and has no brow tine to its antlers.

ELAPINE, ē-lāp'īnē, a subfamily of Colubridae, including venomous snakes having a short, rounded head covered with plates. They are more nearly related to the harmless colubrines than to the vipers, but have a poison-apparatus as in the cobra type. The genus Elaphe is a large one and is found in most parts of the world, but is most numerous in the tropics. Nearly all the snakes of Australia are elapine, the whole race of cobras (q.v.), and others. The genus Elaps is entirely American and is represented by a single species in the United States, the coral or harlequin snake of Florida. See Coral Snake.

ELASMOBRANCHII, ē-lās-mō-brān'g-kī, a sub-class of fishes, containing the sharks and rays. The skull is cartilaginous with only superficial calcifications and no true dermal bones; the gills fixed and shaped like pouches; the upper jaw is the pterygo-palatine bar, and the lower jaw Meckel's cartilage, attached to the skull by a large hyo-mandibular element; the exo-skeleton consists of tooth-like granular tubercles or spines; and the trunk endoskeleton is cartilaginous. The ventral fins are far back and the dorsal fins in the tail; the heart has but one auricle and one ventricle; and the intestine is provided with a spiral valve. The group is nearly coextensive with Cuvier's Chon- dropterygia or cartilaginous fishes and the Placodetidae of Agassiz, and has received various other names such as Selachii and Plagiostomii. Cope distinguishes as orders the Selachii, which includes all living as well as many extinct forms, and the Ichthyomii, which are exclusively carboniferous and have simple clasps and extensive cranial calcifications. See Dog-Fish; Ray; Sawfish; Sharks; Skate, etc.

ELASMOSAURIANS, ě-lās-mō-sā'rē-ənz, gigantic marine fossil reptiles of the order Sauropterygia, found in cretaceous beds. As a living animal it was contemporaneous with Plesiosaurus, of the same order, which abounded in the eastern hemisphere, and as a fossil has been found in Europe and New Zealand. Elasmosaurus had a lizard-like, elongated body, sometimes 45 feet long, flattened limbs which served as oars, and a long, paddle-shaped tail which assisted its motion through the water. The head was proportionately small and with the neck performed twisting motions much like the corresponding parts of the swan. The nostrils were directed forward. The body indicates that this sea-saurian lived on other rapacious fish, which it was able to seize with its crocodile-teeth. The fossil has been raised from cretaceous beds in New Jersey and in Kânsâs.

ELASMOTHERIUM, ě-lās-mō-thē'rē-əm, an extinct rhinoceros which inhabited Siberia, Russia and Germany during the Pleistocene Epoch. It exceeded the Indian rhinoceros in size and bore an enormous horn on the frontal bone of the skull, but no nose-horn. The teeth are very long-crowned, with the enamel ridges strongly crenulated, indicating grazing habits. Some of the native Siberian legends are supposed to refer to this animal; it was a contemporary of early man in that region. See Rhinoceros.

ELASTIC LIMIT. See Strength of Materials.

ELASTIC TISSUE, fibrous tissue in most cases mixed with the fibres of areolar tissue. It occurs in the ligaments of the vertebrae, that of the jaw, etc., also in connection with arteries, veins and lymphatics. It is found in the animal structure whenever an extensible and highly elastic material is required.

ELASTICITY. Every solid, no matter how rigid we may think it to be, will have its dimensions changed upon the application of force. If the resulting distortion does not exceed a certain amount it will disappear when the force is removed. Bodies which recover from the distorting effect of force and resume their original configurations are said to be elastic. The relation between force and the deformation it produces is studied under the title elasticity; the harmful effects of distortion and the proportioning of materials safely to resist given forces belong to the strength of materials (q.v.). The behavior of gases comes under thermodynamics, of liquids under hydrodynamics. In the mechanics of rigid bodies forces are represented by arrows placed at points; actually, they are distributed over surfaces. We are concerned here with the area of action as well as with the magnitude of the
force, and shall therefore use the word stress to denote force per unit area. Stress, contrary to this usage, is generally regarded as synonymous with force, and what we here call stress is commonly called intensity of stress or unit stress. Stress as defined in this article has the dimensions \(\text{PL}^{-1}\) or \(\text{ML}^{-2}\text{T}^{-2}\) and the unit is the pound or ton per square inch and the dyne and kilogram per square centimeter. A force oblique to a surface can be resolved into normal and tangential components. The resulting normal stress is accompanied by change of length. The change of length per unit length is called linear strain; there are likewise areal and volumetric strains. Strain is a pure number without dimensions. Tangential stress or shear stress produces angular distortion due to the sliding of one layer of material with respect to the adjacent layers. For instance, if the two covers of a book are shifted parallel to each other there will be relative sliding of the leaves. Any straight line drawn on the top or bottom end of the book will change its inclination; the change of a right angle is called shear strain. It is the province of the theory of elasticity to investigate mathematically the consequences which result from an experimentally found relation between stress and strain. The first experiments—on the rupture of beams—were made by Galileo, 'Discorsi e Dimostrazioni matematiche' (1638). His results were of no value because he supposed the fibres of a beam to be inextensible, yet his work was the impulse to subsequent inquiries. It was not until 1768 that any relation between stress and strain was published. In that year Hooke in his 'De potentia restitutiva' announced the law known by his name in the form of an anagram ceitinossatius containing the letters of Ut tensio sic vis, i.e., the force varies directly as the extension. He claimed to have discovered it in 1660. Until the end of the 18th century only special problems on beams, columns, and plates were attacked; this period was almost barren of experimental work. The foundation of the mathematical theory was laid by Navier, 'Mémoire sur les lois des corps solides élastiques,' Mémoires de l'Institut, Vol. VII, which was read to the Académie des Sciences in 1821. Progress was rapid after this in the hands of such masters as Cauchy, Clapuyton, Green, Lagrange and Poisson, and culminated in the lifelong labors of Barré de Saint-Venant (1797–1886). For the detailed history of the subject through the time of Saint-Venant consult Todhunter and Pearson, 'History of the Theory of Elasticity and of the Strength of Materials' (Cambridge 1880); subsequent investigations are noted in the introduction to Love, 'The Mathematical Theory of Elasticity' (2d ed., Cambridge 1906).

Strain. Before taking up the relations between stress and strain, we shall study the small displacements suffered by an infinitesimal element \(dx\) \(dy\) \(dz\) within a medium in any state of stress. Fig. 1 shows the projections of two concurrent edges on the \(xy\) plane before and after displacement; the \(yz\) and \(zx\) diagrams are omitted for brevity. Let \((x, y, z)\), the corner nearest the origin, be displaced \(u, v, w\), where \(u, v, w\) are small compared with \(x, y, z\). Then, to terms of the first order, the ends of \(dx\) and \(dy\) receive the axial displacements shown. For if a variable increases infinitesimally, the function will increase differentially; thus if the left end of \(dx\) distant \(x\) from the origin, moves \(u\) parallel to \(x\), a point infinitesimally further from the origin will move infinitesimally more, i.e., \(u + \frac{\partial u}{\partial x} dx\), the derivative being partial to indicate that the increment was due only to a change of \(x\). The \(x\)-projection of the elongated length of \(dx\) is \(dx + \frac{\partial u}{\partial x} dx\), which, since \(x\) is infinitesimal, is itself the new length of \(dx\). Hence the stretch of \(dx\) is \(\frac{\partial u}{\partial x}\) and if the linear strain at \(x, y, z\) is denoted by \(\varepsilon_{xx}\)

\[
\varepsilon_{xx} = \frac{\partial u}{\partial x}, \quad \varepsilon_{xy} = \frac{\partial u}{\partial y}, \quad \varepsilon_{zz} = \frac{\partial w}{\partial z} \tag{1}
\]

the other two components being derived by cyclic permutations of the letters. By definition the shear strains are the decrements of the right angles formed by the concurrent edges at \((x, y, z)\). If they are denoted by \(\gamma_{xy}, \gamma_{yz}, \gamma_{zx}\) in the co-ordinate planes it is evident from Fig. 1 that \(\gamma_{xy} = \alpha_{y} + \alpha_{y}\). Since \(\alpha_{x}\) is infinitesimal by hypothesis, it equals its tangent \(\frac{\partial y}{\partial x}\); likewise \(\alpha_{y} = \frac{\partial u}{\partial y}\).

\[
\varepsilon_{xy} = \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y}, \quad \gamma_{xy} = \frac{\partial u}{\partial x} + \frac{\partial u}{\partial y}, \quad \gamma_{yz} = \frac{\partial v}{\partial z} + \frac{\partial v}{\partial y}, \quad \gamma_{zx} = \frac{\partial w}{\partial z} + \frac{\partial w}{\partial x} \tag{2}
\]

The six quantities \(\varepsilon_{xx}, \varepsilon_{yy}, \varepsilon_{zz}\) are the components or constituents of strain at the point \((x, y, z)\). The shear strain suffered by an element rotates it as a whole, the amount being measured by the rotation of its diagonal. Consider the effect of a partial strain \(\frac{\partial u}{\partial y}\) all other displacements being zero. There will be
no loss in generality if we take a square instead of a rectangle in Fig. 2, because the strain components are independent of the magnitudes of \( dx, dy, dz \). From Fig. 2

\[
dy = (dx + \frac{\partial u}{\partial y} dy) \tan (45 - \delta)
\]

Now \( \frac{\partial u}{\partial y} dy \) is small compared with \( dx \) because \( u \) is by assumption small compared with \( x \); then as \( dy = dx \), the equation reduces to

\[
\delta = \frac{\partial u}{\partial y}.
\]

In the same way \( \frac{\partial u}{\partial x} \) is the counterclockwise rotation of the diagonal due to shearing of the right side of the element. The resultant positive \((X \text{ toward } Y)\) rotation about the \( Z \)-axis is

\[
\omega_x = \frac{1}{2} \left( \frac{\partial v}{\partial y} - \frac{\partial w}{\partial z} \right);
\]

likewise

\[
\omega_y = \frac{1}{2} \left( \frac{\partial w}{\partial z} - \frac{\partial u}{\partial x} \right),
\]

\[
\omega_z = \frac{1}{2} \left( \frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right),
\]

\( \omega_x \) and \( \omega_y \) being obtained by cyclic permutation. These are the component rotations; when they vanish the strain is \textit{irrotational or pure}. There are always at least three orthogonal lines whose directions remain unaltered by strain; they are called the \textit{principal axes} and the planes normal to them the principal planes. If \( u, v, w \) are eliminated from equations (1) and (2) there will be three equations of the form

\[
\frac{\partial \varepsilon_{xx}}{\partial x} + \frac{\partial \varepsilon_{yy}}{\partial y} = \frac{\partial \varepsilon_{xy}}{\partial y} \quad \ldots \ldots \quad (4)
\]

and three of the form

\[
2 \frac{\partial \varepsilon_{xx}}{\partial y} = \frac{\partial}{\partial x} \left( \frac{\partial \varepsilon_{xy}}{\partial y} + \frac{\partial \varepsilon_{yx}}{\partial y} \right), \quad \ldots \ldots \quad (4)
\]

the others being written by permuting \( x, y, z \). These are the equations of compatibility and must be satisfied by every solution of a problem in elasticity. Many of the formulas derived in the strength of materials are not compatible with theory although they may be reasonably in accord with experiment.

\textbf{Stress}.—A stress will be denoted by a capital letter to indicate its direction, with a subscript to show the normal to plane on which it acts. Thus \( X_x \) is parallel to \( X \) on a plane \((YZ)\) normal to \( X \) and is a normal stress; \( Y_y \) is a shear parallel to \( Y \) on the \( XY \) plane. Fig. 3 shows an element under coplanar stress,

\[
X_x + \frac{\partial X_y}{\partial x} dx, \quad Y_y + \frac{\partial Y_y}{\partial y} dy, \quad X_y + \frac{\partial X_y}{\partial y} dy.
\]

all stresses parallel to \( Z \) being zero. It will be seen from the theorem about to be derived that there can be no shear on planes parallel to the paper if there is none normal to the paper. Taking moments of the forces about the upper right-hand corner (edge) we find, after rejecting terms which vanish in the limit, \( X_y = Y_z \);

it is to be observed that the weight and the moment of inertia of the element are vanishingly small. The diagram shows that the shears on two orthogonal faces both point away from, or both toward the edge, hence the

Theorem: Shear stress on any plane is accompanied by equal shear stress on a perpendicular plane, both acting away from or toward the edge of intersection and both being normal to it.

This is due to Cauchy. For the other shears \( Y_z = X_y, \ Z_x = X_z \).

The translations of the element in Fig. 1 are \( u, v, w \), whence the axial accelerations are \( \frac{\partial u}{\partial t}, \ \frac{\partial v}{\partial t}, \ \frac{\partial w}{\partial t} \); the derivatives are partial because they must denote only time-changes and not space-changes. From the general free body of which Fig. 3 is a special case we get by resolving the forces axially

\[
\frac{\partial X_x}{\partial x} + \frac{\partial X_y}{\partial y} + \frac{\partial X_z}{\partial z} + \frac{\partial X}{\partial t} = \frac{\partial P_x}{\partial x} \quad \ldots \ldots \quad (5)
\]

where \( \theta \) is the density and \( X, Y, Z \) are the components of the applied forces (e.g. weight) \textit{per unit mass}. At the surface the internal stresses \( X_x, \ ... \ Y_y \ ... \ must be in equilibrium with the external or applied stresses.

\textbf{Relations between stress and strain}. A material is elastically \textit{isotropic} when it resists stress with equal intensity in all directions. Crystals, fibrous materials, and metals which
ELASTICITY

have been heavily rolled or otherwise worked are unequally strong in different directions; they are elotropic. It has been found by experiment that for many bodies

\[ \text{stress} = C \times \text{strain}; \]

\( C \) is called the modulus of elasticity. It is constant for a given isotropic material but depends upon the kind of stress; an elotropic body has several moduli for each type of stress. The law takes the following special forms.

(1) For normal stress \( p \) and linear strain \( e \) in the direction of \( p 

\[ p = \sigma e; \]

\( E \) is called Young's modulus after Thomas Young who introduced it in 1807. For granular materials like cast iron and stone a more accurate form is \( p = \sigma n \) where \( n \) lies between 1 and 1.1; we shall assume that \( n = 1 \). (See Strength of Materials.)

The longitudinal strain \( e \) is always accompanied by a strain \( e' \) of the transverse dimensions; for a given material

\[ e' = a e; \]

where \( a \) is constant for isotropy. Thus if a rod receives a longitudinal strain \( e \) the strain of any straight line in a cross-section is \( e; e' \) is not an areal strain. In engineering \( 1/n \) is used for \( a \); \( a \) is called Poisson's ratio after Poisson who in 1822 calculated it to be \( 1/3 \) for all materials; experiment has not verified his prediction.

(2) For shear stress \( q \) and strain \( \phi \)

\[ q = \mu \phi; \]

\( \mu \) is the modulus of shear or of rigidity. Young was the first to point out that resistance to "detrition," as he called shear, was different from resistance to stretching. But he did not introduce the shear modulus; this was done by Navier in 1833. The symbol \( \mu \) was first used by Lamé in 1852; in books on the strength of materials \( N \) and \( G \) are used for \( \mu \).

(3) A constant normal stress \( p \) over the entire surface of a body produces a volumetric strain \( \Delta \), called the dilatation, where

\[ \rho = k \Delta; \]

\( k \) being the bulk modulus or modulus of compression.

For isotropic bodies there are thus four constants of elasticity: \( E, \mu, \sigma, k \). It will be shown later that only two of them are independent. Stokes in 1845 ("Mathematical and Physical Papers," Vol. I, p. 75) pointed out that \( \mu \) and \( k \) are of basic importance in theoretical work; in engineering \( E \) and \( \mu \) are more convenient.

For elotropic substances we may still assume the stress to be a linear function of the strain, in which case the generalized forms of Hooke's law are

\[ X_x = C_{xx} e_x + C_{xy} e_y + C_{xz} e_z + C_{xz} e_y + C_{xy} e_x + C_{y} e_y + C_{z} e_z \]

and so on for \( Y_x \), \( Y_y \), \( Z_x \). The 36 coefficients, \( C_{xx} \) to \( C_{zz} \), being the elastic constants. Green in 1837 proved that for conservative systems \( C_{mm} = C_{mm} \) whereby the constants reduce to 21 for elotropic. For isotropy they reduce to 2. To express the stresses in terms of strains for isotropy consider the effect of a single tension \( X_x \). By Hooke's law it produces a strain \( X_x / E \) in its own direction, and

according to Poisson's ratio, a lateral compressive strain \( \sigma X_x / E \). Hence if a parallelepiped is acted on by tensions \( X_x, Y_y, \) and \( Z_z \), the resultant axial strains will be given by

\[ E e_{xx} = X_x - \sigma (Y_y + Z_z) \]

\[ E e_{yx} = Y_y - \sigma (Z_z + X_x) \]

\[ E e_{zx} = Z_z - \sigma (X_x + Y_y) \]

\[ e_{xx}, e_{yy}, e_{zz} \] are called the equivalent simple strains, and when multiplied by \( E \), the equivalent simple stresses. By addition

\[ E (e_{xx} + e_{yy} + e_{zz}) = (X_x + Y_y + Z_z) (1 - 2\sigma) \]

the first parenthesis is the volumetric strain because the change of volume is

\[ (1 + e_{xx}) dx (1 + e_{yy}) dy (1 + e_{zz}) dz = (e_{xx} + e_{yy} + e_{zz}) dx dy dz \]

if the strains are so small that terms above the first order are negligible. The volumetric strain or dilatation \( \Delta \) is then

\[ \Delta = e_{xx} + e_{yy} + e_{zz} \]

Now it is obvious from Fig. 2 that the infinitesimal shear \( \partial u / \partial y \) does not change the area of the face \( dx \ dy \); if one does not, none will, so that shear does not change areas. In the same way it follows that infinitesimal shear will not alter volumes; this is why the dilatation contains only linear strains.

If the stresses in the equation following (6) are all equal to \( X_x \)

\[ 3(1 - 2\sigma) X_x = E \Delta \]

whence, as \( \rho = k \Delta \)

\[ k = \frac{E}{3(1 - 2\sigma)} \]

If \( \sigma = \frac{1}{2}, k \) is negative whence volumes would be increased by compression and decreased by tension; as this does not occur \( \sigma \) cannot exceed \( \frac{1}{2} \). Furthermore a negative \( \sigma \) would mean lateral expansion under tension; this is not true of isotropic materials. Therefore \( \sigma \) is a positive fraction not larger than \( \frac{1}{2} \); experiment verifies this.

If the first equation of (6) is written

\[ X_x = E e_{xx} + \sigma (X_x + Y_y + Z_z) - \sigma X_x \]

and the parenthesis eliminated by means of the equation below (6), there results

\[ X_x = \lambda \Delta + 2\mu e_{xx}; \]

similarly

\[ Y_y = \lambda \Delta + 2\mu e_{yy}; \]

\[ Z_z = \lambda \Delta + 2\mu e_{zz} \]

\[ \lambda = \frac{E}{(1 + \sigma)(1 - 2\sigma)} \]

\[ \mu = \frac{E}{2(1 + \sigma)} \]

It will be proved later that \( \mu \) is the modulus of shear as defined above; hence

\[ Y_y = \mu e_{yy}, \quad Z_z = \mu e_{zz}, \quad X_x = \mu e_{xx} \]

Navier, Poisson, and Cauchy, the founders of the theory of elasticity, derived their equations from a hypothesis of intermolecular actions the consequences of which demanded that \( \lambda = \mu \); then \( \sigma = \frac{1}{2} \), contrary to experiment. They belonged to what Pearson has called the "rari-constant," as opposed to the "multi-constant," school of elasticians. The weight of evidence is in favor of the necessity of two constants for specifying the elastic properties of isotropic materials. To interpret \( \mu \) in the equations just found, consider a cubical element under
tension \( p \) on one pair of faces and compression \( p \) on a perpendicular pair, as on the full-line square in Fig. 4. By taking as a free-body the shaded corner cut off by a 45-degree plane and resolving the forces (stress \times area) parallel and normal to the oblique surface, we find

that a stress \( q = p \) on the oblique face is necessary and sufficient for equilibrium. That is, orthogonal, equal, unlike normal stresses produce pure shear of equal magnitude on any plane at 45 degrees. Take now the dash-line square as a free-body: it is in pure shear of magnitude \( q = p \). Since the change of a right-angle is the shear strain \( \phi \), the change of \( \theta (= 45^\circ) \) is \( \phi/2 \). As the sides of the inner square are not altered in length, \( D \) is constant in

\[ D = l \cos \theta \]  
whence \[ \frac{dl}{l} = \theta \tan \theta \]

But \( \theta = 45^\circ \) and \( \frac{dl}{l} = \frac{\phi}{2} \) \[ \therefore \frac{dl}{l} = \frac{\phi}{2} \]

By eq (6)

\[ \frac{dl}{l} = \frac{p}{E} \]

and as

\[ \frac{\phi}{\mu} = \frac{p}{E} \]

\[ \mu = \frac{E}{2(1 + \nu)} \]

For the purposes of integration it is convenient to eliminate the internal stresses from equations (5). Substituting equations (7) and (8) in (5), replacing the strains by their values in (1) and (2) and using the symbolic abbreviation — the Laplacian operator —

\[ \nabla^2 = \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \]

we find

\[ (\lambda + \mu) \frac{\partial^2}{\partial x^2} + \mu \frac{\partial^2}{\partial y^2} + \rho x = \rho \frac{\partial^2}{\partial t^2} \]

\[ (\lambda + \mu) \frac{\partial^2}{\partial y^2} + \mu \frac{\partial^2}{\partial y^2} + \rho y = \rho \frac{\partial^2}{\partial t^2} \]

\[ (\lambda + \mu) \frac{\partial^2}{\partial z^2} + \mu \frac{\partial^2}{\partial z^2} + \rho z = \rho \frac{\partial^2}{\partial t^2} \]

The internal motions specified by these equations are vibratory since they arise from small elastic displacements within the medium. The fact that they can be verified experimentally furnishes complete evidence of the correctness of Hooke’s law, of our assumption that the displacements are small, and of the validity of the analysis.

Applications.—We shall now solve a few typical problems in order to show the use of the foregoing equations. Most problems unfortunately give rise to extremely difficult partial differential equations; the general methods of integration are fully discussed in the works by Love and Riemann-Weber cited at the end of this article.

(1) A cylinder of density \( p \) and length \( l \) is suspended from one end and hangs vertically.

Take the \( Y \)-axis vertical with the origin below the upper end. Since \( Y \), the tensile stress at any point, is due to the weight of the material below that point, \( Y = gpy \); the five remaining stresses are zero. There are no surface forces except at the upper end where the entire weight of the cylinder is uniformly distributed over the supporting surface; there the internal and external stresses balance. Hence

\[ E_{yy} = gp, \quad e_{xx} = e_{zz} = \sigma_{yy}, \quad e_{xy} = e_{yz} = e_{xz} = 0 \]

Now

\[ \epsilon_{yy} = \frac{\partial \sigma_{yy}}{\partial y} = \frac{gp}{E} \]

\[ \therefore v = \frac{gp}{2E} + v_0 \]

where \( v_0 \) is a function of \( x \) and \( y \) because the derivative is partial. Since there is no shear, \( v \) must satisfy

\[ e_{xy} = \frac{\partial \sigma_{xy}}{\partial y} + \frac{\partial \sigma_{yx}}{\partial y} = 0, \quad e_{yz} = \frac{\partial \sigma_{yx}}{\partial z} + \frac{\partial \sigma_{zy}}{\partial z} = 0 \]

whence

\[ \frac{\partial \sigma_{yx}}{\partial y} = 0, \quad \frac{\partial \sigma_{xy}}{\partial y} = 0 \]

By differentiation,

\[ \frac{\partial \sigma_{yx}}{\partial y} = \frac{\partial \sigma_{yx}}{\partial x} \]

and as

\[ \frac{\partial \sigma_{yx}}{\partial x} = \frac{\partial p}{\partial x} \]

so that

\[ \frac{\partial \sigma_{yx}}{\partial x} = \frac{\partial p}{\partial x} \]

The value

\[ v = \frac{gp}{2E} (x^2 + y^2) + ax + cy + k \]

will satisfy equation (c); substitution in (a) gives

\[ v = \frac{gp}{2E} (x^2 + y^2 + z^2) + ax + cy + k \]

At the upper end

\[ v = 0 \text{ and } k = \frac{gp}{2E} \text{ when } x = 0, \quad y = l, \quad z = 0 \]

The solution must be correct when the rod is rigid; in this case \( E = \infty \) and \( v = 0 \) so that

\[ a = 0, \quad c = 0 \]

Hence

\[ v = \frac{gp}{2E} (x^2 + y^2 + z^2) \]

The formula obtained in books on the strength
ELASTICITY

of materials is \[ v = \frac{\mu}{2\rho} (\nu^2 - \mu) \]

which is therefore correct only along the axis; it is, however, approximately true at any point when the cylinder is very long compared with the radius.

Integrating (b), substituting (d), and supposing as above that \( E = \infty \), we get

\[ \sigma_{xx} = \frac{\partial u}{\partial x}, \quad \sigma_{yy} = \frac{\partial u}{\partial y} \]

if the upper end is free to contract.

(2) A straight uniform rod is twisted by couples applied at the ends.

Saint-Venant was the first to solve the general problem in his great memoir on torsion, 1855, although Coulomb had previously, 1784, succeeded in finding the twisting moment offered by a circular cylinder. The following is a brief sketch of Saint-Venant's method.

Let the cylinder, of any cross-section, have its axis along \( Z \). Since there is no shear on the mantle, \( X^2 = 0 \) and \( \varepsilon_{xy} = 0 \)

\[ \frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad \text{(a)} \]

As there are no external normal forces the normal strains vanish and

\[ \frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} = \frac{\partial w}{\partial z} = 0 \quad \text{(b)} \]

Equations (5) with \( X^2 = Y^2 - Z^2 = X^2 = 0 \) become

\[ \frac{\partial X}{\partial x} - \frac{\partial Y}{\partial z} = 0 \quad \text{(c)} \]

where \( X^2 = \mu \frac{\partial u}{\partial x} + \frac{\partial w}{\partial z} \), \( Y^2 = \mu \frac{\partial w}{\partial z} + \frac{\partial v}{\partial y} \) \( \text{(d)} \)

By equation (b) \( u \) does not contain \( z \) and by (c) and (d) \( u \) and \( v \) are linear functions of \( z \).

All the above equations will be satisfied only by

\[ w = -\gamma z, \quad v = \tau z, \quad u = \rho \phi \quad \text{(e)} \]

where \( \phi \) is a function of \( x, y \). The values of \( u \) and \( v \) show that since \( u^2 + v^2 = \tau^2 (x^2 + y^2) \) and \( u^2 + v^2 = -\gamma z \), the displacement in the plane of the cross-section is (1) normal to the radius vector; (2) proportional to the radius vector; (3) proportional to the distance of the cross-section from the origin. Therefore radial straight lines remain straight and of constant length and the boundary of any section is not distorted in transverse planes. If \( \phi \) is not zero these lines will be warped in the direction of the cylinder axis; \( \phi \) is therefore the warping function. \( \tau \) is the angle of twist.

Equations (e) substituted in (d) give

\[ X^2 = \mu \left( \frac{\partial \phi}{\partial x} - \gamma \right), \quad Y^2 = \mu \left( \frac{\partial \phi}{\partial y} + \tau \right) \quad \text{(f)} \]

As there is no shear on the mantle the resultant of \( X \) and \( Y \) must be normal to the boundary of any section, i.e.,

\[ \frac{\partial \phi}{\partial x} + \gamma \frac{\partial \phi}{\partial y} \]

This is the differential equation of the boundary curve of any section.

The twisting moment equals the sum of the moments of the shear forces on any section, i.e.,

\[ M = \int (xY - yX) \ dx \ dy \]

\[ = \mu \int \left( x^2 + y^2 + \frac{\partial \phi}{\partial y} - y \frac{\partial \phi}{\partial x} \right) \ dx \ dy \quad \text{(h)} \]

The angle of twist, found by differentiating (f) and eliminating \( \frac{\partial \phi}{\partial x} \), is

\[ \tau = \frac{\mu}{2} \left( \frac{\partial Y}{\partial z} - \frac{\partial X}{\partial y} \right) \quad \text{(i)} \]

The differential equation of a circle is \( x \ dx = -y \ dy \); equation (g) reduces to this when \( \phi \) is constant. As there is no lengthening of the cylinder there is no translation of a cross-section and \( \phi = 0 \). Now if \( \phi = a + b \ y \) (g) is the equation of a circle, but as the centre of the circle is at the axis of the cylinder it will be found that \( a \) and \( b \) must vanish. Hence for a circular section \( \phi = 0 \) and cross-sections remain plane. In this case equation (h) gives the well-known engineers' formula.

Equation (g) will represent the ellipse

\[ \frac{x^2}{a^2} + \frac{y^2}{b^2} = 1 \]

provided \( \phi = \frac{a^2 - b^2}{a + b} y \)

Since \( y = \tau \phi \), the contour lines found by giving \( \phi \) a series of constant values are equilateral hyperbolae; in the first and third quadrants of the ellipse the displacements will be negative and in the other quadrants positive. Equation (h) gives

\[ M = \mu \pi \left( a \phi^{\frac{1}{3}} \right) \quad \text{(3)} \]

Vibrations in an infinite elastic medium.

If there are no external forces, \( X = Y = Z = 0 \).

Let all quantities in the \( XY \) plane be constant so that the same state exists throughout that plane; then the \( x \) and \( y \) derivatives in equations (9) are zero, whence

\[ \Delta = \frac{\partial \phi}{\partial z}, \quad \Delta = \frac{\partial \phi}{\partial z} \]

Likewise

\[ \frac{\partial \phi}{\partial z} = \frac{\partial \phi}{\partial x}, \quad \frac{\partial \phi}{\partial y} = \frac{\partial \phi}{\partial y} \]

The equations of motion thus reduce to

\[ \rho \frac{\partial \phi}{\partial t} = \frac{\partial \phi}{\partial t}, \quad \rho \frac{\partial \phi}{\partial t} = \frac{\partial \phi}{\partial t} \]

\[ \rho \frac{\partial \phi}{\partial t} = (\lambda + 2\mu) \frac{\partial \phi}{\partial t} \quad \text{(b)} \]

Equations (a) are satisfied, as substitution will verify, by any function of \( x + \sqrt{\frac{\mu}{\rho}} \ t \). This function must be periodic for otherwise the displacement would become infinite in course of time or would remain as a permanent set. Experiment contradicts both of these suppositions, hence the motion is vibratory. Equation (b) is satisfied by a similar function. If at a point \( x + \epsilon \) at a time \( t + dt \) the displacement is in the same phase and of the same magnitude as it was at \( t \) at a time \( t \)

\[ s + \epsilon s + c (t + dt) = s + ct \]
where $a = \frac{\mu}{\rho}$ for (a) and $a = \frac{\lambda + 2\mu}{\rho}$ for (b);

$$\frac{ds}{dt} = \pm c,$$

which is the velocity of propagation of the disturbance; not the velocity of a material point but of a state of motion. Equation (b) defines the longitudinal, and (a) the transverse waves in an elastic or plastic medium.

**R. F. DeMelo,**

**Assistant Professor of Mechanics, Stevens Institute of Technology.**

**ELASTIN**, an insoluble proteid substance, of which the elastic fibres of connective tissue are composed. It may be conveniently prepared from *ligamentum nuchae*, by boiling with ether and alcohol (to remove the fats) and afterward by prolonged boiling, successively, with water, strong acetic acid and concentrated caustic soda and subsequent successive treatment with weak acetic acid, water, hydrochloric acid and water. When so prepared, elastin is not soluble (without decomposition) in any known solvent. It dissolves with decomposition in concentrated sulphuric acid, however, yielding leucin, but not tyrosin. Elastin is digested both by pepsin and by trypsin and it contains no sulphur. Its percentage composition, according to Muller, is $C = 55.45$; $H = 7.41$; $N = 16.19$; $O = 20.9$.  

**ELATEA. See CITHAREON.**

**ELATER, el’a-ter**, a genus of beetles in the pentameric sub-order, type of the family Elateridae. They are familiarly known as *click-beetles* or *skip-jacks*, from their habit of jerking themselves with a slight noise into the air when they land or are placed on their backs. The body is arched upward and suddenly straightened with a violent muscular exertion, which lifts the animal from the ground. The legs are too short for the ordinary method of righting the body. The larvae are too farinaceous or *wireworms*. Some tropical forms are phosphorescent. See Fireflies.

**ELATERIDE, el’a-ter’si-dé**, a family of *Coleoptera* (click-beetles), tribe *Penitana*, sub-tribe *Sternoxia*. It contains the insects placed by Linneaus in his great genus *Elater*, now broken up into many genera. See Fireflies; Elater.

**ELATERIN, a neutral chemical substance having the formula CaH₄O₂ and obtained by alcoholic extraction of the greenish precipitate thrown down by the juice of the slightly unripe squirting cucumber, Ecballium elaterium. It crystallizes in hexagonal tablets which melt at 400° F. and are insoluble in water, but soluble in chloroform and in hot alcohol. Elaterin has a bitter taste and is a powerful purgative, the dose being from the 40th to the 10th of a grain. A crimson color, changing to a scarlet, is produced when sulphuric acid is added to a solution of elaterin in water and alcohol; this reaction serving as a test for its presence.

**ELATERITE, an elastic, asphalt-like mineral, known as "elastic bitumen." In color it is dark brown, with a specific gravity ranging from 0.9 to 1.2. It occurs abundantly in Derbyshire, England, and a mineral closely allied to it has been found at Woodbury, Conn.

**ELATERIUM, el’a-ter’i-um**, a mixture of principles formed as a precipitate, occurring spontaneously in the juice of the fruit of the wild or squirting cucumber, *Ecballium elaterium*, the active principle of which is elaterin. The squirting cucumber is a small perennial, of the cucumber family, indigenous in Persia, India and in the warmer Oriental countries, and has been extensively cultivated even as far north as England. The fruit itself is 1½ to 3 inches long by 1 to 3½ to 4 inches of an inch, oblong or oval in shape, covered with soft bristles and yellowish green in color. It is firm externally. As the fruit ripens, the rind becomes translucent and the outer skin is thrown into places in the interior with the formation of gas. This accumulates in sufficient quantities to exert considerable pressure, bursting the fruit at its base and squirting the seeds some distance. In this manner the fruit is distributed. Elaterium has been used for centuries as a cathartic, the phenomena of the squirting seeds having suggested its function. Elaterin itself is a neutral principle of the formula CaH₄O₂. It forms in minute white prismatic crystals, without odor and with a slightly bitter taste. Elaterin is one of the most active of all the hydrogogue cathartics. It operates with violence even in minute doses. It is particularly of service in conditions in which there is general dropsy and no inflammatory condition of the intestinal tract. Elaterin is given in doses of from 1 to 10 of a grain.

**ELBA, Italy (Lat. Ilv; Gr. Ἐθάλαια),** small island in the Mediterranean Sea, off the coast of Tuscany, and with several much smaller isles, lying at the mouth of the Gulf of Piombino. The island of Elba is 18 miles from east to west, with a width of 5½ to 12 miles in its widest part. The mountainous districts of the island yield large quantities of superior iron, copper, tin, lead, marble, lode-stones and alum, besides wines and fruits. Tunny and sardine fishing and the extraction of sea salt are other important industries. On the first abdication of Napoleon in 1814, Elba was assigned to him as a residence and empire. Here he accordingly took up his residence, in the month of May; and on 22 Feb., 1815, he secretly left the island, and, landing in France, began that brief and final career, known in history as the "Hundred Days." During his sojourn here Napoleon lived at the Villa San Martino in the town of Porto Ferrajo. It still stands. He caused a road to be constructed between Porto Longone and Porto Ferrajo. Elba has had a chequered history; it belonged successively to Pisa, Genoa, Sora and Piombino. After 1815 it was given back to Tuscany, and in 1860, with the latter it became part of the Kingdom of Italy. "Isola d’Elba" (Florence 1885). Elba was a place of celebrity in the time of the Romans, and famed
then, as now, for its yield of iron. It has a mild and healthful climate and the soil is fertile. Mining, however, occupies the attention of the iron manufacture. Two good ports are Porto Ferrajo and Porto Longone, both well fortified. Pop. 25,480.

ELBASSAN, el-bas'sân, Albania, town on the Scumbi, 35 miles east of its mouth. It stands in the centre of a fertile plain and nearby are a number of hot sulphur springs. There are small manufactures of iron and copper. Pop. about 15,000.

ELBE, el'bê (ancient ALBIS; Bohemian, LAHE, a river of Germany, one of the largest in Europe. It rises on the southwest slopes of the Schneekoppe or Snowcap, one of the Riesengebirge, between Bohemia and Silesia. From this point it flows nearly due south into Bohemia for about 50 miles, when it turns to the west, and after about 40 miles takes a general north-northwest direction till it empties into the North Sea, intersecting Saxony, a considerable part of Prussia, and in later part of its course separating Holstein on its right from Hanover on the left. The length, including windings, is upward of 780 miles. The principal affluents are on the right, the Iser, Schwarz-Eister and Havel; on the left, the Alder, Moldau, Eger, Mulde and Saale. In the lower part of its course the river is divided by five large and seven small islands into several arms, which unite again about five miles below Hamburg. The mean depth is 10 feet, average breadth 900 feet. It is more or less navigable for about 470 miles, but its estuary at Cuxhaven is much encumbered with sandbanks. It is well stocked with fish. On 1 July 1870, the navigation of the Elbe was declared free from Hamburg to Melnik in Bohemia. There is an important system of canal navigation in connection with the Elbe, Hamburg, for instance, being in this way connected with Berlin.

ELBERFELD, el-bër-fél'd, Germany, town in the Prussian Rhine province, 15 miles east of Düsseldorf, in the beautiful valley, and on both Middles at the Wupper, bordered by lofty hills. It has no historical or antiquarian importance. Its prosperity has been acquired mostly within the last century and is due to the cotton manufacture, of which it is the central locality in Rhenish Prussia. The old town was irregularly built with a maze of narrow streets, but the new portion has fine modern streets with buildings of the latest style bordering them; the principal of these are the courthouse and the Rathaus. The city has some fine public monuments. It is an important industrial centre, especially dealing in textiles, their manufacture and dyeing. In addition to cotton, silks, woolens, etc., it manufactures chemicals, leather, furniture and carpets, firearms, rubber goods, paper, machinery and glass. It is also a great commercial centre and has many foreign consulates. It contains a gymnasium, polytechnic school, school of industrial drawing, an institute of music and a school for mechanics. Seven railroads serve the city and in addition there are electric roads to nearby centres. During the period of the great war it was occupied by Elberfeld Castle and became a city in 1610. Silk manufacturing and dye-works were introduced toward the close of the 18th century and there-

after Elberfeld grew rapidly. It was early part of the Duchy of Berg and in 1815 was united to Prussia. It has a unique poor-relief system, which has been adopted in many parts of the world. Pop. 170,195. Consult Schnell, 'Geschichte der Stadt Elberfeld' (Elberfeld 1900); A. Shadwell, 'Industrial Efficiency' (London 1906); Jorde, 'Führer durch Elberfeld und seine Umgebung' (Elberfeld 1902).

ELBERFELD SYSTEM, a system of poor-relief which originated in the appointment of six visitors in 1800, to investigate applications for aid, in the manufacturing town of Elberfeld, Prussia. The city was subsequently divided into districts, the number of visitors was increased and the operations extended, until by 1852 what has become known universally as the Elberfeld System was adopted. Its main features are the division of the city into 26 districts subdivided into 304 precincts, each precinct being administered by an almoner who investigates each application, in case of emergency provides immediate assistance and as long as aid is afforded, visits the applicant twice a month. Money relief is granted fortnightly according to a fixed schedule, any earnings in the meantime being deducted, when needed, working implements are provided. A meeting of almoners under the presidency of an overseer takes place every fortnight to discuss cases and to vote necessary relief, a report of the meeting being laid the next day before the directors who are chosen from four councilmen and four citizens with the mayor as chairman ex officio. The directors superintend and advise on the whole city's work. The positions of almoners, overseers and directors are of a purely honorary character. The advantages of the system in the improvement of the condition of the poor have been strongly apparent, the ratio of persons assisted in 1889 being 7 per 1,000 as against 17 per 1,000 in 1855. See also CHARITIES.

ELBERON, N. J., sea-coast summer resort in Monmouth County, on the Pennsylvania and the Central Railroad of New Jersey. Pop. about 250. Here President James A. Garfield (q.v.) was taken after he was shot by Guiteau, 6 Sept. 1881, and died here 19 Sept.

ELBERTON, Ga., city and county-seat of Elberton County; on the Southern and the Seaboard Air Line railroads; 90 miles northeast of Atlanta. It is in a cotton-growing section and the chief industries are connected with the cultivating, shipping and manufacturing of cotton. It contains manufactories for cottonseed oil, cotton goods, compressing cotton, fertilizers, harness, carriage and wagon shops, ironworks, etc. The quarries nearby give employment to a number. The city contains a public library and owns the waterworks and electric-lighting plant. Pop. 6,483.

ELBEUF, el'bâu, France, town in the department of Seine-Inferieure, 11 miles south-southwest of Rouen, situated in a beautiful valley on the left bank of the Seine. It contains two great churches, Saint Stephen's and Saint John the Baptist's, both of which have fine ornamental glass. In the town and also in the nearby communities there are several cloth manufactories, mostly flannels, double-twilled cloth and waterproofed cloth and light woolens. There are schools for instruction in all the
ELBERING—ELDER

分支 of the local industry. Until the revocation of the Edict of Nantes there were upward of 60 cloth manufactories here, but the dislocation caused at that time was not remedied until 1790, and the industry did not recover fully until about 1840. Pop. 18,290.

ELBERING, Germany, seaport town, in West Prussia, on the Elbering, near its entrance into the Elbe. It is 32 miles east-southeast of Dantzig. It is divided into the old towns, the former of which was once surrounded by turreted walls and gates, but these for the most part have been removed. It has shipbuilding yards, which do a considerable trade in building and repairing vessels. Its manufactures include machinery, chincory, lumber, flax and hemp yarn, woolen and cotton cloth, leather, soap, tobacco and beer as well as trade in agricultural products. There are also oil manufactories, iron foundries, dye and print works and the famous Schichau shipbuilding works for the construction of war vessels. Elbering has excellent railway facilities and is in steamboat communication with Dantzig and Königsberg. By means of a canal it has connection with the Vistula, and the harbor was improved by the opening in 1894 of a mole 3,500 yards long. The town was founded in the early 13th century by colonists who were natives of Bremen and Lubeck. The town grew up around the fortress of the Teutonic Knights. It became a Hanse town but Poland took it in 1454. During the religious wars the place was in turmoil and also suffered much during the wars between Poland, Russia and Sweden. In 1772 it was annexed to Prussia. For many decades it declined but within the present generation has once more become a thriving centre. Pop. 58,636.

ELBOW. See ARM.

ELBOW JOINT. See ARM.

ELBOW PIECES, a medieval armor, the plates used to cover the junction of the pieces which covered the upper and lower half of the arm. These plates were mostly disc-formed, cup-formed, or articulated. Consult Ashdown, "Arms and Armor" (New York 1909).

ELBRUZ, el-broog, or ELBURZ, (1) A mountain range of Persia, running for 450 miles along the southern border of the Caspian Sea. It has a number of subordinate parallel ridges, enclosing extensive and fertile valleys; and unlike most Persian ranges, it has numerous prominent spurs, the highest peak being Mount Demavend (q.v.). The principal traversing river is the Kizil Uzen, which flows into the Caspian Sea. The average altitude is 5,000 feet. (2) Elbruz is also the name of the lovestim summit of the Caucasus.

ELCSAITES, el-seh’ats, or ELKE-SAITES, a sect founded in the 2nd century, during the reign of Trajan. They derived their belief from the teachings of the Book of Elkesai, supposed to have been inspired by an angel. Their system seems to have been a commingling of Oriental philosophy with Judaism and early Christianity, probably put into practice with the idea of restoring the world to the way of those persons seriously troubled by the religious chaos of the day caused by the mighty conflict of greater creeds. The followers of Elkesai or Elkhai are often confounded with Ebianites (q.v.). The best account we have of the Elkesaites is given by Hippolytus in his chief work, "Philosophumena."

ELCHE, el’chah, Spain, town of the province of Alicante, 13 miles southwest of the town of that name, on the railway joining Alicante and Murcia. The surrounding groves of palm trees supplies all Spain with palm leaves for Palm Sunday, and the dates are exported in large quantities. There are also a trade in pome-

brandy, oil, woolens, shoes and sandals of esparto grass, mats of the same material, soap and leather are the principal manufactures. The town has a fine, lofty-domed church, a bishop’s palace and a hospital. Elche is of Roman origin and was early a place of importance. In the middle of August every year Elche is the scene of a medieval religious drama—"La Festa del Misterio de Elche." In some respects it resembles the "Passion Play," at Oberammergau and deals with the Assumption of the Virgin Mary. For the festival consult Paris, Pierre, "Les Fêtes de l’Assomption à Elche," l’Espagne" (in Le Correspondant, Vol. XXVI, p. 156, 1898). Elche has a population of about 30,000.

ELCHEGEN, el'hehng-un, Bavaria, village on the Danube, nine miles northeast of Ulm, which gave the title of Duke of Elchingen to Marshal Ney, who here defeated the Austrians 14 Oct. 1805. In the neighborhood are the ruins of a Benedictine Abbey of the same name, founded in 1128. There are two villages, Ober and Unter Elchingen, the former on the same hill with the abbey, the latter to the northeast of it. The hill on which the abbey stood was occupied by Mack, who had his headquarters in Ulm; when the right bank of the river, repaired the bridge of Elchingen, forced the passage of the river, and took Elchingen by storm.

ELDER, John, Scottish engineer: b. Glasgow 1824; d. 1869. Educated in Glasgow, he was first employed as director of the drawing office of Napier’s establishment, becoming later a member of the great ship-building firm which was known after 1860 as Randolph, Elder & Company, employing more than 4,000 men. His fame rests upon his invention of the compound or running high and low pressure engines, saving nearly 40 per cent of fuel.

ELDER, William Henry, American Roman Catholic prelate: b. Baltimore, Md., 22 March 1819; d. 31 Oct. 1904. When 12 years old he entered Mount Saint Mary’s College, Maryland, and at 18 was graduated and sent to Rome, where he was ordained priest 29 March 1846. Returning to America, he accepted the professorship of theology at Mount Saint Mary’s, became its president, and remained here until consecrated bishop of Natchez, 3 May 1857. On one occasion, when the Federal authorities, who had taken possession of the city, bade Bishop Elder offer certain public prayers and command his clergy to do likewise, he stoutly refused, declaring that in thus ordering them they were usurping the right of religious liberty, and rather than he should be imprisoned; when the case was reported at Washington he was promptly released. In 1878 Natchez was visited by an epidemic of yellow fever and the bishop fell a victim to the plague, which carried him to the point of death.
In 1880 he left Natchez to assume the duties of coadjutor to Archbishop Purcell, of Cincinnati, Ohio, intending to settle the perplexing difficulties that disturbed the diocese. Upon the death of Archbishop Purcell, in 1883, Bishop Elder succeeded to the archiepiscopate of Cincinnati.

**ELDER, *Sambucus*, a genus of shrubs or small trees and a few perennial herbs of the family *Adoxaceae*. There are about 20 widely distributed species characterized by opposite, pinnate leaves, small white flowers usually in compound cymes, and black, red, white or green, juicy fruits (berries or drupes). Many of the species are used in ornamental planting, since they are readily propagated by root and stem cuttings, succeed well upon nearly all soils, are of rapid growth, graceful form, and are attractive both in flower and fruit. The best-known species in America is *S. canadensis*, the common or sweet elder, which is frequently seen in front of town houses, along roadsides, and on the margins of woods throughout southern Canada and the greater part of the United States. It attains a height of 10 feet or more, bears abundant fragrant flowers in midsummer and black berries in early autumn. These fruits are used when they are obtainable plentifully for making pies and elderberry wine. Several horticultural varieties have been introduced for their golden or variegated foliage, and one variety with large fruits was introduced in 1890. The flowers are used for making a wine, a perfume, and a "water" used in confectionery. Economically this species ranks as a minor fruit. Like some other members of its genus, it has also been used in medicine, but is rapidly giving place to other drugs. Probably *S. nigra*, the common European elder, ranks next in importance. It is much larger, often attaining a height of more than 20 feet. The yellow, hard, tough wood is readily polished and is used for making skewsers, fishing-rods, needles for making fish-nets, and as a substitute for boxwood. It is also employed for the same horticultural and economic purposes as the preceding species, and has numerous fancy-leaved varieties. Other well-known species are the scarlet elder (*S. racemosa*), an Old-World species, and the red-berried elder (*S. pulchra*), a native of North America, consistered by some botanists to be identical. There are also several unrelated plants which are popularly known as elder, as box elder (*Nepeta acreoides*), wild elder (*Aralia hispida*), also known as bristly sarsaparilla, and marsh-elder (*Poa frutescens*).

**ELDERS**, in certain churches, a body of men elected by the communicants from among their number to aid the minister in portions of his work. With the minister, they constitute the executive body of the congregation. Among the Jews the elders were the rulers or magistrates. Other names for the institution of mankind considers the old fitter than the young to rule, and at first probably every *elder* was really pretty well advanced in life; but the designation ultimately came to be used more of office than of age. The elders of the congregations are considered as of the same order as the deacons. In the New Testament they are described as having given currency to the tradition of Bishop Elder, taking a chief part in compassing the death of Jesus (Matt. xxvi, 59; xxvii, 20), etc. There were elders, also, of single towns, as of Succoth (Judges viii, 14), and of Jezreel (2 Kings x, 1). The churches of the Reformation found this form of lay assistant well adapted to their systems of church government. Where the Church and State have some interrelation, the election of such officers is regulated by civil law. In the Baptist churches, the pastors were called elders, but the name came to be applied exclusively to the missionaries later on. In the Presbyterian Church, the ruling elders have the function of assisting in the government of the Church, under the supervision of the Presbytery. In the Dutch and German Reformed churches, the elders and deacons assist the clergyman and there is also a ruling elder. The Methodist Episcopal Church has a similar office, but the ruling elder is an ordained clergyman appointed by the bishop. The Shakers have four elders, two male and two female. The elders in the Mormon Church are members of the Melchizedek priesthood. The apostles, the seventy, the patriarchs and the high priest are included in their number, and it is their duty to preach, ordain other priests and deacons, to lead meetings, baptize and bless.

**ELDON, John Scott, 1st Earl of**, English jurist and Lord Chancellor; b. Newcastle, 4 June 1751; d. London, 13 Jan. 1838. He was educated at Oxford, at University College, receiving his M.A. in 1773. In 1771 he won an English prize by his essay on *The Advantages and Disadvantages of Travelling into Foreign Countries*. He had intended taking clerical orders, but gave up the idea in order to marry Elizabeth Surtees, the daughter of a wealthy banker of Newcastle-upon-Tyne (1772). Scott was readmitted to the university and entered the Middle Temple in 1773, where he began his study of law and supported himself by tutoring. His success in the law was rapid. He became a member of the bar in 1776, a bencher in 1783, and in the same year was made one of the king's counsels. His sound knowledge of the law attested by his efforts to improve it, and he entered Parliament in 1778, where he soon made his mark as an independent and serious thinker. He supported the Pitt ministry and in 1788 was knighted. In the same year, he was made solicitor-general. On Thurlow's dismissal from the new Parliament he offered his resignation to Pitt, but was induced to return, and in 1793 succeeded Sir Archibald MacDonald as Attorney-General. His association with the rigorous administration made him exceedingly unpopular. His measures in the state trials, his strict interpretation of the laws and the vigorous laws he assisted in promulgating heightened the effect of his severity. In 1799 he was chosen to succeed Sir James Eyre as lord chief justice of the Common Pleas, and also became sergeant-at-law and a member of the privy council and board of trade. He was also raised to the bench as the 1st Earl of Eldon, in the county of Durham, where he had bought an estate. He became Chief Justice in 1801, and Lord Chancellor of England. Throughout the king's illness he
administered affairs with great surety and force. After the death of Pitt, he was forced to withdraw, but was returned in 1807 in the Portland administration, where he soon became the foremost member of the Cabinet. He bent all his able energies to the subjugation of Napoleonic influence, the king's strongest adherent and served him with all his powers. In 1811, when the king's lunacy became evident, Eldon immediately undertook to gain the confidence of the prince. In spite of attacks by his enemies, he succeeded and by assisting in the formation of the Liverpool cabinet, re-established the Tory policies. He arranged for the marriage of the Princess Charlotte with Prince Leopold of Saxe-Coburg. His resistance to the queen's plans rendered him again unpopular with the mass of people, but gained him the loyalty of the Prince, who just before his coronation as George IV bestowed on him the titles of Viscount Encombe and Earl of Eldon. However, this marked the highest point of his career. After the death of the queen, Camberwell, party, which had come to power and Eldon resigned from the Cabinet. He continued to take an interest in politics and his opinions were highly esteemed by his fellow Tories. He survived to take oaths of fealty to Queen Victoria.

Eldon was an able jurist and administrator, of fascinating personality and an agreeable companion. His faults lay in his adherence to the strict letter of the law, his sophistry and his insistence on hair-splitting definitions and distinctions. His decisions were never hasty nor ill-founded. Consult Townsend, 'Lives of Twelve Eminent Judges' (London 1846); Twiss, 'Life of Lord-Chancellor Eldon' (ib. 1844); Surtees, 'Sketch of the Lives of Lords Stowell and Eldon' (1846); Campbell, 'Lives of the Chancellors' (1874).

ELDORA, Iowa, city, county-seat of Hardin County, near the Iowa River, on the Iowa Central, and the Chicago and Northwestern railroads; 122 miles west of Dubuque. The city is the seat of the State Industrial School for Boys, has a Carnegie library and a public park. Agriculture and manufacturing are its chief interests, but fire and brick clay and coal are found nearby. It has manufactures of brick, tiles, flour, foundry products and lumber. The waterworks are the property of the municipality. Pop. 1,995.

ELDORADO, Ill., city in Saline County, eight miles northeast of Harrisburg, on the Cleveland, Cincinnati, Chicago and Saint Louis, the Illinois Central, and the Louisville and Nashville railroads. It has coal mines, flour mills, bottling works, a machine shop and foundry, lumber yards and factories of medicines, candy, cigars and brick and tile. Pop. 3,366.

ELDORADO (from the Spanish El Dorado, the Gilded Man), the region of undiscovered treasure in South America. In the article Dabana we have traced the famous Eldorado legend to those stories which, at the beginning of the 16th century, were current among the Indians of Darien about a 'temple lined with gold,' and have shown why the Spanish explorers failed to recognize in distant Cuzco, with its temple of the sun-god, the real basis of such accounts. The name Eldorado, however, with which the ever-receding or shifting territory, the subject of all those stories, has been stamped, was at first not the name of a place but of a person; and the name-giving addition to the myth is localized very precisely in the table-land of Bogotá, as follows: Lake Guatavita (north of the present capital of Colombia and nearly two miles above sea level) was regarded by Indian tribes dwelling in that neighborhood in the 15th century as a holy place, and pilgrims who resorted to it often cast their offerings of gold and emeralds into its waters. Wherever a new chief of Guatavita was chosen, nobles and priests of his tribe bore gold and lake, as Mr. Bandelier (in work mentioned below) has written 'upon a barrow hung with discs of gold. His naked body was anointed with resinous gums and covered all over with gold-dust.' The chief plunged into the lake; spectators made the usual offerings of gold and jewels; and, on the conclusion of this ceremony of consecration, the new ruler and his subjects went down to dance and feast in Guatavita village. The Chibchas (q.v.) conquered Guatavita about the end of the 15th century, and under their general government this extraordinary local custom had been discontinued for a number of years before the first Spanish settlements were made on the Caribbean coast — there was no longer an independent Guatavita chief to signify his acceptance of the local religious beliefs in a fashion so dramatic; but native folklore continued for a century, at least, to make much of this glittering symbolic figure and the sacred lake. In 1529, Dahlgren, governor of the German colony in Venezuela, set out from his little capital and probably reached the edge of the high plain of Bogotá by way of the Magdalena River; there the resistance of the Indians obliged him to turn back. Four years later the report of the vast treasure secured by the conquerors of Peru (Atahualpa's 'ransom') alone was officially valued at 3,933,000 ducats of gold and 672,670 ducats of silver) appeared to justify ventures undertaken in reliance upon the wildest Eldorado tales. It is also true that a fresh outbreak of the gold-fever speeded the Spanish colonists everywhere in America, more or less, but especially those in the agricultural settlements; and that leaders of those colonies, in order to retain their men, were obliged to make fresh efforts to find treasure. In Santa Marta, an expedition was organized to ascend the Magdalena River to the highlands; at Coro, Georg von Speyer organized a campaign for the exploration of the Meta plain, far inland. The former expedition under command of Quesada in 1537 reached the old home of the gilded chief; and although Guatavita either hid its gold or was actually poor (40 years having passed since it had ceased to be a place of pilgrimage), the treasure collected in this neighborhood, principally at the villages of Tunja and Traca, was officially valued at 246,676 pesos in gold, or about $1,200,000, besides 1,815 emeralds. Von Speyer's campaign, 1800, captured the royal city of Tunja; the marquis of Castilblanco, governor of the province, with the help of the British, was driven out of Bogotá. On July 10, 1802, the British captured the city, and restored the independence of the colony. El Dorado became a part of the Republican United States of Colombia in 1833.
story of the Gilded Man. Each of these leaders considered himself the discoverer of the country, and they proceeded together to Spain, to substantiate their claims to the Spanish court, leaving their forces to hold the Eldorado which had been despoiled by the Chibchas, ransacked by themselves.

We are, therefore, unable to agree with the distinguished American archaeologist when he says that, after this time, "Transplanted by the over-excited imagination of the white men, the vision of the dorado appeared, like a mirage, enticing, deceiving, and leading men to destruction."

"Am the Inca of the Orioco and the Assi-

zon." His "Gilded Man" had been located, and that part of the myth was buried. Subsequent explorations were planned to discover rich countries which were Eldorados only in the modern sense of the word; and we find that the word was used nearly its present signification at the time when the Amazon River received its name. The legend is especially note-

worthy in connection with the history of the Venezuelan settlement under the direction of the German Welgers. Having received the prov-

ised by the French crown practically as a mortgage security for money loaned, Welser and his associates tried to recover the advances they had made from the revenues of the dis-

trict; and since the coast lands were found to be less profitable than they had expected, they engaged in one Eldorado expedition after another. Dalfinger, Federmann, and Von Speyer have been mentioned; before the utter ruin and failure of the colony at Coro, Von Hutten's expedition penetrated to Omagua, a region near the mouth of the Orinoco. The Spaniards conquerors of Peru and Ecuador were led by the search for further stores of wealth to make the most important geographical discoveries east of the Andes. Gonzalo Pizarro set out from Quito to explore the forests in 1540-42, hoping to find spices there, and also "wealthy regions in which the people went around adorned with gold." His lieutenant, Francisco de Orellana, with 53 men in a bark, becoming separated from the main body of the expedition, went on down the Amazon to its mouth. The missioner Carvajal, Orellana's chronicler, relates that women took part in the fighting against the Spaniards, and that a captive Indian spoke of a tribe of Amazons rich in gold living north of the river. (Compare Prescott's 'Conquest of Peru,' II, 164-65, note.) Wandering Indians brought to Peru about the middle of the 16th century reports of countries rich in gold and silver, which lay far eastward; and the viceroy made use of the Eldorado fever thus excited to rid Peru of a large number of disorderly persons. In 1560 a company of criminals and desperadoes, with women, set out from Santa Cruz de Capa-

coba, proceeding in boats, canoes and even upon rafts, down a tributary of the Amazon, under the leadership of Pedro de Ursua. In January 1561 they were 180 miles from Lima. By the end of two months, they captured the island of Margarita and invaded Venezuela. At least four Eldorado expeditions proceeded from the north coast toward the interior before the end of the century, in addition to that one which Sir Wal-

MARRION WILCOX.

ELDORADO SPRINGS, Mo., city in Cedar County, 100 miles southeast of Kansas City, on the Missouri, Kansas and Texas Railroad. The principal industry is the bottling of water from the mineral springs. Farming and stock raising are carried on also. The waterworks are owned by the municipality. Pop. 2,503.

ELDRIDGE, Shaler W., American abolitionist: b. West Springfield, Mass., 1817; d. Lawrence, Kan., 17 Jan. 1899. He removed to Kansas in 1855, and bought an American House in Kansas City, soon recog-
nized as the headquarters of Freesoilers. In 1856 Eldridge opened the Free-State Hotel in Lawrence, but soon afterward a pro-slavery court issued a writ of indictment, declaring the place a nuisance, and it was destroyed by a mob. On 13 Dec. 1857 he was arrested at Leavenworth on a charge of inciting free-soil sentiments.

Later he became a member of the National Republican Committee and agent to promote immigration into Kansas. Under the last authority he led a large number of settlers to Kansas. During one of these trips, with a party of 350 men, he was taken prisoner by United States troops. Subsequently he recruited a party of Freesoilers, who retook the arms from the United States officers at Lecompton. He was instrumental in giving much aid to the Free-State cause by smuggling large amounts of ammunition and provisions into Kansas Territory. During the Civil War he served in the Union Army.

ELD'S DEER, a deer (Cervus eldi) native to the Malayan region. It is about four feet tall, lives in swampy places and is often found in large herds. Its habits are like those of the Indian swamp-deer. The antelope is a graceful animal that the brow-tine sweeps down over the forehead and that the upright part has numerous points.

ELEANOR OF AQUITANE, queen of France and afterward of England: b. 1127; d. Fontevrault, France, 1 April 1204. She was the eldest daughter and heiress of William IX, Duke of Guienne or Aquitaine, and was married 2 Aug. 1137, to Prince Louis, who in the same year succeeded to the throne of France as Louis VII. She was gay, frivolous, a lover of poetry and art, and could not sympathize with the ascetic spirit of her husband. She accompanied him on the second crusade to the Holy Land in 1147. At that time he complained of her preference for other men, and on their return from Asia they were divorced 18 March 1152. A short time afterward she bestowed her hand upon Henry Plantagenet, the future Henry II of England. This alliance, which made Henry master of Eleanor's vast possessions in France, produced pernicious and protracted wars between France and England.

She bore him many children, but his infidelities and neglect changed her love into hatred. She
incited her sons Geoffrey and Richard Cœur de Lion to rebel against their father, was imprisoned in 1174, and remained in confinement until after Henry's death in 1189, when she was released by his successor, Richard I, who placed her at the head of the government on his departure for the Holy Land. She negotiated his marriage with the daughter of the king of Navarre, and went to Germany with his ransom from captivity. She afterward retired to the abbey of Fontevrault and surviving Richard, lived to see him succeeded by one of her other sons, John Lackland, the signer of Magna Charta. She was a favorite personage with the troubadour poets of the day and appears in a very different light in their works from that in which she is represented by French and Norman chroniclers. Consult Adams, 'History of England, 1066-1216' (London 1906).

ELEANOR CROSSES, memorials of Eleanor of Castile. She was the wife of Edward I of England, and d. Lincolnshire 1290. Her body was taken to London by her sorrowing husband who subsequently erected a monument, terminating in a cross, at every spot where his beloved wife had rested. The places were Lincoln, Grantham, Stamford, Geddington, Northampton, Stony Stratford, Woburn, Dunstable, Saint Albans, Waltham, East Cheap and Charing Cross, but the list varies slightly as given by different authorities. The crosses at Geddington and Waltham remain, although considerably altered by restoration in the latter case. That at Charing Cross, destroyed in 1647, was replaced in 1803 by a new one reproducing the original.

ELAEATICS, ελ-ε-άτ'ικς, a Greek sect, so called because founded at Elea, in Sicily, by Xenophanes of Colophon, about 538 B.C. Zeno, who flourished 464 B.C.; Empedocles, 435 B.C.; and Melissus 428 B.C., were leading philosophers of this school. That which from the commencement distinguished the Eleatic school from the Ionia was its method, which in the one case was dialectic, in the other, empirical. Starting from the observation of external nature, the Ionians endeavored to discover some elementary principle, as water, air, fire, or a combination of elements, by the action of which the phenomena were brought about. Zeno might be accounted for. Eleanos made the abstract idea of Being or God, deduced from the contemplation of the universe as a whole, their starting-point; and their reasons sometimes led them to deny the reality of external phenomena altogether. This was the result of the development which the principles of Xenophanes received from his followers Parmenides and Zeno, the latter of whom denied the existence of variety in any form. See also IONIAN PHILOSOPHY; IONIAN SCHOOL; Xenophanes; Zeno. Consult Windelband, 'History of Philosophy.'

ELECAMpane, 'el-e-kam-pa^n' (Inula heliotroem), a plant of the sunflower family (Compositae). The stem is three or four feet high, thick, pubescent and branching above; the radical leaves are often two feet or more in length; the flowers are large and yellow. The plant is a native of Europe and Asia, naturalized in the United States. It grows abundantly along roads and in waste places. The root is perennial and has a bitter aromatic taste. Elecampane is cultivated occasionally as an ornamental plant and the flowers are sometimes used to adulterate arnica. The root was formerly much employed in medicine, but has fallen into disuse. It contains a number of active principles, the most important being a volatile oil, a camphor, inulin and heliotropin. The receptor of the oil, the action of the drug is somewhat stimulant and stomachic. Elecampane was once very much used in the treatment of bronchitis and amenorrhea. As a hot infusion it subserves practically the same purpose as camomile tea, being a good diuretic.

ELECTION, in law, the voluntary choice between two or more permissible lines of conduct. In equity the choice is between two or more alternative rights or claims which were plainly intended by the person who has granted them to be mutually exclusive. In criminal law it is the choice incumbent on the prosecution to proceed on one of a number of independent felonies of the same degree. In the law of wills the widow's election is her choice whether she will make her claim under her husband's will or under the statute which gives her a right to a specified part of her husband's estate. An election may be explicit and announced, or it may be implicit in the conduct of the person bound or entitled to elect. In neither case is the election binding unless made with a knowledge of all the relevant and material facts; but if these facts are known, the election is final.

ELECTION, in politics, the mode of determining the person who is to fill an office by the votes of the qualified electors. Alternative methods are selection by someone already in authority or by lot. The electors may be the entire body of those of the citizens of the region concerned who fulfill certain very general requirements, as is the case in the various State elections for governor or the election of senators and representatives, or may be a specifically small body of officials, as in the indirect election of senators by the State legislatures, which was alone legal until 1913, when the Seventeenth Amendment to the Constitution was ratified. In the case of the elected kings of Poland and Hungary and the Holy Roman emperor, the election was in the hands of a greater or smaller group. The election of the President of the United States, though nominally entrusted to a representative body of men—the electoral college—is now to all intents and purposes of the direct type, as by custom the electors are mere mouthpieces of the popular vote. The honesty and fairness of elections is secured by stringent laws and by various devices to secure secrecy of the ballot. These are discussed under the head of BALLOT. See also ELECTIONS; CORRUPT PRACTICES ACTS; ELECTORAL FRAUDS AND SAFEGUARDS AGAINST; VOTE, VOTERS, VOTING.

Election is a very old political device. While election by acclamation has always been a recognized means of determining the chief in certain savage communities, it was in the city-states of Greece and in republican Rome that the ballot first became the basis of the government of a highly organized civilized community. This right was limited to some more or less restricted class of free citizens, and was gener-
ELECTION — ELECTIONS

ally exercised in an open assembly not unlike the New England town meeting — the Ecclesia of the Commonwealth. From the period when the empire first made the comitia a mere form and then abolished it altogether to the reappearance of the assembly of the people as a custom of the northern barbarians, elections ceased to play an important part in politics. It survived in a measure in the Church and it reappeared in a very limited form as the method of selecting the Holy Roman emperor. The first relucence of a genuinely popular election after the races of the north had lost almost all memory of their original custom of settling disputes and electing their chiefs in the council of the warriors, was in the form of the election of the officers of the guilds and of the free towns. (See article, Elections and cross-references thereunder). Consult Aristotle, 'Politics'; Freeman, 'Comparative Politics' (London 1873); Jones, 'Readings on Parties and Elections in the United States' (New York 1912); Stanwood 'History of the Presidency' (Boston 1912); Woolsey, 'Politics in the Roman Colonia' (New York 1877).

ELECTION, in theology, the word (singular) is applied to the act of God in selecting some persons from the race of man to be regenerated by his spirit, to be justified, to be sanctified, and to receive other spiritual gifts in this world, with eternal life in the next. The Calvinistic doctrine makes this election take place by God's mere good pleasure, without any foreseen merit in the individuals chosen. The Arminian one considers that God chooses those whom he foresees will accept the offer of the Gospel as true Christians till death. The third chapter of the Westminster Confession, entitled 'Of God's Eternal Decree,' uses more decided language. The strongest adherents of this view are in the Presbyterian churches, though there is a tendency to soften the harsher features of the system. Most Baptists hold the same doctrine, as do the Calvinistic Methodists.

ELECTION DISTRICT. See District.

ELECTIONS. As defined by the courts an election is the act of choosing a person to fill an office by any manifestation of preference but usually by the vote of those entitled to exercise the elective franchise, as distinguished from appointment to office by a single person or officer, as a king, president, governor or mayor. See APPOINTMENTS.

Classification of Elections. If the great body of the voting population decide between candidates, the election is said to be popular or direct. If limited to a small number who themselves have been chosen by the mass of voters, the election is said to be indirect or representative. The choice of United States senators by the State legislatures until the 17th Amendment became law is an example of indirect elections. Theoretically the President is elected by the Presidential electors chosen in the various States but in practice these electors vote for the party candidate. (See ELECTORS, UNITED STATES PRESIDENTIAL). Elections are also classified as national, State and municipal, according to the status of the office to be occupied by the successful candidate.

Early Colonial Elections. — From the earliest colonial days, local officials in New England were chosen in a meeting of the "freemen," much as they are to-day in town meeting. Probably the first elections from which we have any record of the delegates who attended the Virginia legislative assembly in 1619. The earliest date specified that of the election of John Winthrop as governor of Massachusetts "by the general consent of the Court," 18 May 1631. The next in order is the election at Plymouth, 1632-33, although elections were authorized in this colony in 1620 and in the colony of Massachusetts in 1630, and undoubtedly they were held from that time onward. A few years later the records show that elections were conducted proxy, chosen deputies casting the votes of the freemen at the "court of elections." According to some authorities proxies meant usually the carriage of the votes, at first the ballots themselves (slips of paper or grains of corn, etc.), and later the records. The history of the process is hard to interpret. In New Hampshire elections were held from 1633 onward, and in Rhode Island after 1636-38. In Connecticut the earliest election was in 1639; in Maryland 1639. All the New England States, except Georgia elected assemblies almost from the start, and summonses for one session were issued in Georgia. In New Amsterdam (now New York) the right to elect its own magistrates was long withheld by Director General Stuyvesant. "If," he said (1653), "the nomination and election of magistrates were to be left to the populace who were the most interested, then each one would vote for some one of his own stamp, the thief for a thief, the rogue for the tipler, the smuggler, for a brother of iniquity, so that he might enjoy greater latitude in his vices and frauds." In New Jersey elections did not begin till 1668, although authorized in 1665. The first election in Pennsylvania was in 1683. In the Carolinas the first recorded elections were in 1691, but minor elections probably were held as early as 1663. In Georgia all officials were appointed up to 1754.

Authority to Hold Elections. — To be valid an election must have some lawful authority behind it; unless the power is expressly granted by the constitution or by the legislature acting under constitutional authority, the right to hold an election cannot exist or be lawfully exercised. The legislature may prescribe the forms to be observed. Laws enacted to ascertain the will of the people at free popular elections may be mandatory (such as those setting the day of election, requiring the vote to be by ballot, or establishing places within the designated precincts where the election shall be held), or directory (such as provisions prescribing the conduct and return of an election). Minor irregularities in observing the directory laws which do not prevent electors from freely and fairly exercising their right of suffrage or from having their votes properly counted do not vitiate an election, providing such irregularities do not constitute infractions which the law declares shall nullify an election. Statutes providing for the holding of a local election usually require the presentation of a local authority of a petition signed by the prescribed number of qualified persons; when properly presented, the authorities appointed to call the election have no discretion and after the order is issued it is not open to collateral attack.
ELECTIONS

The time and place of holding regular elections are generally appointed in the public laws, and therefore, as electors are supposed to know the law and accordingly would receive notice from the statutes themselves, no proclamation or notice is mandatory, but proclamations for special elections must be issued by the authority named in the statutes and in strict accordance with those statutes. This notice is particularly important in cases of special elections to fill vacancies caused by death, resignation or removal. If the statute requires that the vacancy be filled at the next general election. Usually the statutes require that, for a certain time before election day, notices of a coming election shall be published in one or more newspapers or posted in the form of handbills either at the polling places or at a number of public places. In elections to determine specific questions, the notices must fully inform the voters of the questions to be decided and such notices must not only clearly show the manner of the order but also that they themselves have been signed by the proper officers.

Time and Place of Holding Elections.—

To be legal the time and place of holding an election must be fixed in advance, either by law or by legally authorized officials; and votes cast differently will avail nothing regardless of the eligibility of the candidates voted for. If the time be fixed by general law no other time will be legal, save where the statutes provide for special elections; if the statutes fix the time, no power may annul the election to a subsequent day, unless the constitution or statutes permit such adjournment, though legislatures are within their province in postponing elections in order to do away with frequent and unnecessary elections. A slight change in the voting place should not invalidate otherwise properly conducted elections, provided no voter is misled or deprived of his vote by reason of the change. Under some circumstances the voting place may even be outside the election district, but the electors of the district who vote thereat would not be disfranchised on that account. Congress has power to determine the time of choosing the Presidential electors and on 1 March 1792 enacted that the choice should be made on the Tuesday following the first Monday in December. On 23 Jan. 1845 Congress enacted that Presidential electors be chosen on the Tuesday following the first Monday in November in each quadrennial year, and later (2 Feb. 1892) provided that, beginning with 1876 members of the House should be elected on the same day in biennial years (*even* years), though some exceptions were allowed under the amending act of 3 March 1875, whereby certain States were permitted to continue holding their elections at an earlier date. Amendment XVII to the Constitution (effective 31 May 1913) provides for the election of senators by the direct vote of the people but makes no stipulation as to the time of election, merely providing that when vacancies happen in the representation of any State in the Senate, the executive authority of such State shall issue writs of election to fill such vacancies: *Provided, That the Legislature of any State may empower the executive thereof to make temporary appointments until the people fill the vacancies by election, and the legislature may direct.* Presumably, therefore, elections of senators are held the year preceding the expiration of the incumbent's term of office, the time being designated by the State legislature. Most of the State elections, and in many cases local and municipal elections, are held on the same day as the national election, but in many States minor officials are not elected in the same year as the governor and lieutenant-governor. All the States hold their elections in November with the exception of Louisiana, Maine and Vermont, the election of the first name not occurring in April and of the latter two in September. If a vacancy occur in an elective office, the governor of a State may call a special election or hold the choice over until the next regular election.

Electoral Qualifications, Colonial and Modern.—Details respecting the franchise rights and privileges of the various States will be found in the title for each State in the United States; Electoral Qualifications; Naturalization; United States—Suffrage in the; Votes, Voters, Voting; Woman Suffrage.

Terms of Office, Age Limits and Qualifications for Office; and See Electoral Qualifications, Terms of and Qualifications for Office.

Party Nominations, Primaries, Etc.—The four principal methods of choosing candidates are by the delegate convention system, the direct primary, the non-partisan primary, which is used in many municipalities, and nomination by petition only. The term "primary" is usually applied to the preliminary elections held by the political parties to nominate candidates or to choose delegates whose duty is to nominate candidates to compete in the following regular election. In either case party members only are allowed to vote in the primaries. Originally candidates for local offices announced their own candidacy or perhaps were nominated by an informal caucus; the legislative caucus nominated candidates for State offices; and aspirants for the Presidency were nominated by the Congressional caucus (see Caucus); but the latter two caucuses were soon discarded and by 1832 the convention system was adopted. (See Convention, Political). This system was so indirect and complicated and so flagrantly abused that regulation of nominations became imperative and by 1900 party elections had been placed under the same legal restrictions as the regular elections. Beginning with 1900, however, the convention plan has been rapidly supplanted by the direct primary, under which candidates are selected by the direct vote of the party. Some States also allow each party a direct vote on choice for Presidential nominees. (See Primary, Direct; Primary, Presidential Preference; and in this connection see also Initiative; Referendum; Recall). Under the non-partisan primary (which really is not a primary at all) the whole electorate participates in the selection of candidates later to be voted upon at the regular elections. This system has been developed in connection with the commission form of government (q.v. See also City Manager) as worked out in Des Moines, Iowa, and other places. The two candidates for mayor and the eight candidates for
ELECTIONS

the four commissionerships receiving the highest number of votes may participate in the second and final election. In all elections, party emblems, circles, or other designations are prohibited in connection with candidates' names. In some cities (as Berkeley, Cal.), if any candidate receive a majority of all the votes cast, a second election is unnecessary so far as that particular office is concerned. In some localities preferential voting has been adopted so that national political parties will be eliminated from local elections. If any number of persons not connected with any political parties make nominations in the usual way and to have the names of their candidates placed upon the official ballot, they may present to the proper officials a petition containing the required number of signatures of qualified electors and their nominees may enjoy the same privileges on the official ballot as accorded to those regularly nominated by an existing party. Nominations by petition are used chiefly in local elections, and, unless required by statute, and the Governor otherwise directs, petitions or nominations are used in connection with the names of candidates. Under a law passed in 1907 Wisconsin permits nominations to be made by petition only; but after nominations are filed upon petition of 5 per cent of the number in some cases electors may be called to select the two candidates for each office and those two only are voted upon at the final election. In many States a declaration of party affiliation is necessary under the primary law. Illinois further prohibits the participation in a primary of anyone who has voted in the primary of another party within the preceding two years. Some States (as New York) use a system of party registration similar to that used for general elections. When the voter registers at that time an opportunity is presented to him to declare his party affiliation, if any, and from these declarations a list of party voters is compiled which is used as the registration for the ensuing primary election. The California law of 1909 and the Oregon law of 1901, which allowed electors to vote for either party without divulging party preferences, were declared unconstitutional. Under the Wisconsin law of 1903 the ballot is absolutely secret and the voter may vote for the candidate of his choice. If he so desires, he may vote for one party at any election. The "open primary" eliminates the party test which is applied in the "closed primary." In the non-partisan primary no party test can be applied since the electors vote for any candidate he may choose regardless of party ties.

Campaign Expenses and Contributions.— See Corrupt Practices Acts; Electoral Frauds; Ballot; Bribe; Lobby; Congress, Etc. Voting Districts.— So that participation in elections may be easy, counties, cities and towns are divided into small precincts or election districts, each containing a few hundred voters and operating under the supervision of an election board. Whether composed, as at different places in New York and the Oregon of counties, cities, townships, boroughs, wards of cities, or of precincts, election districts always indicate subdivisions of the State's territory marked out by known boundaries rearranged and declared by public authority. As nearly as possible, city precincts contain an equal number of voters; they must be entire wards or contained wholly within one ward or one town and cannot be composed of parts of adjacent wards or districts. The election district, however, is never used as a unit of representation in local government nor as an administrative division in the conduct of municipal business. See District.

Polling Places.—The law designates the manner of the internal arrangements of polling places so that the voter will have perfect freedom in marking and depositing his ballot. Where the statutes require that polling places contain booths of sufficient size to accommodate one voter and so constructed that the voter will be screened while preparing his ballot. Booths should be shut off by guard rails and no unauthorized person allowed to go within these confines. In most States no official ballot may be taken outside the polling place. Official ballot boxes are required at all elections, and prior to the opening of polls these boxes must be opened for public inspection. During primaries and elections the polls are policed in accordance with the law (though the presence of a police officer at each polling place is not authorized by express statutory provision), and in some cases election officers may exercise the authority of justices of the peace and punish election offenders. Stringent laws have been passed in many States to protect the voter from undue influence while in the act of voting. In most States each polling place is provided within a certain distance from the polling place, in some States polling places must be a certain distance from saloons; and in the advanced States saloons are closed on election days. Oregon requires that no "political badge, button, or other insignia shall be worn at or about the polls on any election day."

Registration of Voters.—All persons possessing the constitutional qualifications of electors may be and in nearly all the States must be officially registered on the voting lists in the districts wherein they reside in advance of each election, the period varying in the several States. If a State constitution or statute make registration a specified time before election day an imperative prerequisite to the right to vote, those not so registered cannot vote, and if their other qualifications comply with constitutional requirements. Nevertheless the courts have held several times that even if a person be not a qualified voter under the constitution on the day the registration books are closed, yet if he acquire the necessary qualifications before election day his vote cannot lawfully be rejected merely because he has not registered. While the constitutional qualifications must be left intact, without excisions or additions, the legislature may prescribe regulations to determine if the prospective voter possess the required qualifications; hence the passage of a registry law requiring registration as a condition precedent to the right to vote is not unconstitutional; where such a law exists an election held without such registration is void, but if the State constitution provide that the legislature shall enact a registration law and the legislature fails to do so, an election without registration is valid. Arkansas and Texas do not require registration; in Oklahoma registration is required in all cities of the first class;
in Kansas and Ohio in cities of the first and second classes; in Kentucky in cities of the first, second, third and fourth classes; in Washington in all cities and towns and in voting precincts with a voting population of 250 or more; in North Dakota in cities and villages of 800 or more inhabitants; in Maine in cities and towns of over 2,000 inhabitants; in Iowa and Nebraska in cities of 3,500 and 7,000 or more inhabitants, respectively; in Missouri in cities of 100,000 inhabitants, and in all cities of Pennsylvania. In all incorporated cities, villages and towns of Illinois which have adopted the election commissioner act of the State, unregistered persons may not vote, but elsewhere they may swear in their votes if they produce a creditable witness to prove their electoral qualifications. In Rhode Island non-taxpayers are required to register each year before 30 June. In the larger cities voters must appear in person before the registering officers, but in rural districts the voter often is registered by official declaration and the registration list is compiled by local authorities, subject to revision on demand of interested parties. In order to prevent false registration of some of the large cities have provided that the voter must tell the local registrar the number of the street and house where he resides, the name and permanent home of the voter and the date of his birth, all of which must be in the poll book. The Ohio law provides that the poll book shall be kept in such a manner that the name of any person appearing thereon may be read and verified without the aid of any book or register. The law further provides that the voter shall be registered in the proper poll book and that his name shall not be entered in any other poll book. In California, the law permits any person to register as an elector who is a citizen of the United States and who has been a resident of the State for 30 days and has resided in the county for 10 days. The law further provides that the voter shall be registered in the proper poll book and that his name shall not be entered in any other poll book. In New York, the law permits any person to register as an elector who is a citizen of the United States and who has been a resident of the State for 30 days and has resided in the county for 10 days. The law further provides that the voter shall be registered in the proper poll book and that his name shall not be entered in any other poll book. In New York, the law permits any person to register as an elector who is a citizen of the United States and who has been a resident of the State for 30 days and has resided in the county for 10 days. The law further provides that the voter shall be registered in the proper poll book and that his name shall not be entered in any other poll book. In New York, the law permits any person to register as an elector who is a citizen of the United States and who has been a resident of the State for 30 days and has resided in the county for 10 days. The law further provides that the voter shall be registered in the proper poll book and that his name shall not be entered in any other poll book. In New York, the law permits any person to register as an elector who is a citizen of the United States and who has been a resident of the State for 30 days and has resided in the county for 10 days. The law further provides that the voter shall be registered in the proper poll book and that his name shall not be entered in any other poll book. In New York, the law permits any person to register as an elector who is a citizen of the United States and who has been a resident of the State for 30 days and has resided in the county for 10 days. The law further provides that the voter shall be registered in the proper poll book and that his name shall not be entered in any other poll book.
tions seem to establish the elector's right to vote and the challenge be withdrawn, the elector, again under oath, must declare that he possesses all the legal requirements. He may then vote but the act of voting, after taking the declaration, precludes further prosecution if his declarations be proven false.

The Ballot.—See BALLOT.

Voting Machines.—See VOTING MACHINES.

Counting the Vote.—Usually the polls are open from early in the morning until a designated hour at night, a list which no more votes may be admitted. Immediately after the last ballot has been deposited the counting begins (sometimes publicly, sometimes in a private room), the details being recorded on the official and standard tally sheets with which each polling place has been furnished. The chairman unlocks the box, extracts the ballots, one by one, opens each and announces the candidate for whom the elector has voted. If mutilated or illegibly marked by the voter the ballot may be rejected; others may not be rejected because of tearing or of slight irregularities in marking unless such mark or mutilation appear to have been made for corrupt purposes; all rejected ballots are set aside and returned with the valid ballots so that, in case of a contest, the proper judicial authorities may examine them. All valid ballots are recorded by the clerks as announced by the chairman and are then filed in the form required by law. The clerks keep two or more independent tally sheets which are tallied at the end of the counting and the results officially announced. The pollbooks and the tally sheets (properly authenticated by the election officials of the district) are then sealed and turned over to some designated official, such as the county clerk or in larger cities to a special board. The ballots are locked and sealed in the ballot boxes which are then delivered to the proper authorities, in some cities, as New York, to the police who preserve them for a stipulated period so that a recount may be made in case of a contested election. After the tally sheets have reached the election board or other designated official, such as the county clerk, they are reviewed to ensure absolute correctness and the results are officially published. In State elections, county or county line may be test at the discretion of the secretary of state who reviews them with the aid of a State board of canvassers. In some States the individual voting districts send their returns direct to the secretary of state; in others these returns are sent to the presiding officers of the two branches of the legislature and are opened and canvassed in their presence. In other States the returning boards consist of certain specially designated officers. It is the duty of the canvassers to issue a certificate of election to the person whom the face of the returns indicates to have been elected. Should a candidate (who may or may not have been present at the count of the ballots) believe he has been defeated by fraud, illegal voting or incorrect counting, he may file a contest notice with the court having jurisdiction, which not only may order a recount but may also enforce its judgment as against the conclusion of the election official. Unless a specific grant of power be made in the State constitution or legislature in conformity with constitutional provisions, the duties of county

and State canvassing boards are wholly ministerial; they are not empowered to go behind the returns, to decide upon the legality of the votes cast nor to throw out the votes of a precinct or district in which fraud is alleged.

Duty to Accept Office.—Every citizen, under the common law every citizen, in peace as well as in war, owes his services to the State when required; hence, after having been regularly elected and duly appointed, persons may be compelled to take the oath and qualify themselves as public officers under pain of indictment or any pecuniary penalty; the only defenses are illegal election or appointment, legal disqualification to hold the office or proof that the office is incompatible.

Contested Elections.—See ELECTIONS, CONTESTED.

Federal Control of Elections.—See ELECTIONS, FEDERAL CONTROL OF.

Electoral Frauds and Safeguards Against.

—See that title.

Majority and Proportional Representation.—See that title.

Majorities and Pluralties.—There is no legal, philological or popular agreement as to the use of the word "majority" in matters of election. In computation it may mean the amount by which the greater number exceeds the lesser, if but two numbers are compared; or the amount by which the greatest number exceeds the total of the lesser numbers; or the amount by which the greatest number exceeds the next to the greatest. For the last case we customarily use the word "plurality," but in England the normal designation is "majority," and candidates have been elected with regard only thereto from time immemorial. The weight of American usage restricts "majority" to excess of the greatest number of votes over the total of the rest, and we say that for a majority a total of one more than half is necessary. This practice dates from colonial times. In Massachusetts, New York, New Jersey, South Carolina and Georgia, a majority seems to have been required; in other States as a rule a simple plurality sufficed. New York put the plurality rule into her constitution of 1777 and most of the other States followed her example, but the belief in the virtues of an absolute majority lingered till the middle of the following century. Propositions to go back to the absolute majority plan are now very rarely heard, and in the matter of popular elections the subject still has importance only because the Constitution of the United States requires an absolute majority of electoral votes for the choice of President. In conventions the majority rule yet prevails, occasionally entailing hundreds of ballots, and in the Democratic national conventions a two-thirds vote is required to nominate. In primaries and caucuses the plurality plan prevails by almost invariable custom, voters everywhere being unwilling to give the time required for repeated ballots.

Under the Constitution a majority vote in the electoral college may elect a President who did not receive either a majority or a plurality of the popular votes cast, though probably the framers of the Constitution intended that no President should be elected without substantial support in a considerable number of States. Often delegations are divided under the system

vol. 10—5
ELECTIONS

of State-wide popular vote. This is possible if a State legislature should decide that the electors of that State be chosen by districts. This system was followed by Maryland up to 1832 and in 1892 the Michigan legislature changed the districts and thus ended the State electoral delegation. But as a rule all electors, save those chosen by legislatures, have been chosen by general ticket since 1836, for which reason the ticket that obtains a plurality of the popular vote elects all the electors of that State. Sometimes, however, when the vote is close, the electors with the highest vote on one ticket may defeat the electors with the lowest vote on another ticket. This happened in California in 1880 when, of the 161,000 votes cast, the difference on the head of the ticket was only 78, with the result that one Republican and five Democratic electors were chosen. In the same State in 1912 two of the Democratic electors overran the lowest two on the Progressive ticket, so that the State sent a divided ticket consisting of 11 Progressives and two Democrats. Often the electors represent a minority of the State's votes, and sometimes the majority of the electoral vote may represent a minority of the popular vote. In 1812 Jackson received 50,556 votes more than Adams, but received 40,300 votes less than his three opponents combined. In 1844 Polk received 38,000 votes more than Clay but the combined vote for Clay and Birney put him in a minority of 24,100. In 1848 Taylor had a plurality of 139,000, but a minority of 151,500. In 1856 Buchanan had a plurality of 497,000 but a minority of 377,000. Lincoln received nearly 500,000 more votes than Douglas but nearly 950,000 votes less than all his opponents combined. In 1876 Hayes, though elected President by an electoral vote of 233 to 219, still had a majority of 80,000 less than his nearest opponent. In 1912 the discrepancy occurred precisely between the electoral and popular votes, Wilson carrying 43 of the 48 States and having a clear majority of 339 in the electoral college, while he had a plurality of 2,150,000 over his nearest opponent, but was in the minority by about 230,000. In 1888 Cleveland received nearly 100,000 more popular votes than Harrison but the latter was elected even though he was in a minority of 500,000. In 1892, however, Cleveland had a plurality of 190,000 over Harrison but was in a minority of 950,000. In 1912 a striking discrepancy occurred between the electoral and popular votes, Wilson carrying 43 of the 48 States and having a clear majority of 339 in the electoral college, while he had a plurality of 2,150,000 over his nearest opponent, but was in the minority by about 2,500,000. Hence, with the exception of Hayes and Harrison, all the Presidents would have been elected by at least a plurality if the election had been directly popular. On the other hand a small popular majority for the electors in one State may swing the election, as was the case in New York in 1864 and 1888; in the former year Cleveland carried the State by 1,047 which gave him the 36 electoral votes of that State and decided the election in his favor; in 1888 these votes were turned over to Harrison by a plurality of about 15,000, thus electing him President. In 1916 was cast the largest vote in the history of American politics. Wilson had a plurality of nearly 370,000 over Hughes but an electoral vote of only 276 against 255 for Hughes, this being the narrowest margin of electoral votes determining an election since 1876. So even was the voting in some of the States that Wilson won New Hampshire by only 36 votes, New Mexico by 184, North Dakota by 2,600, California by 3,700, and Nevada by 5,600, whereas Hughes gained the electoral votes of Minnesota by 392 votes, Delaware by 1,273, West Virginia by 2,721, and South Dakota, Maine and Rhode Island by about 5,000 each. The closeness of the election and the partial delegations of electors were sent to the electoral college. See United States-Dissputed Presidential Elections; Electoral Commission.

ELECTIONS

Irving E. Rines,
Editor of 'History of the United States.'

ELECTIONS. Contested. Under the Constitution, when the electoral college fails to cast a majority vote, the election of President was referred to the House and of Vice-President to the Senate. The former deemed the election of Jefferson in 1801 and of J. Q. Adams in 1829, and the latter elected R. M. Johnson Vice-President in 1837. But in 1876, a dispute arose over the validity of the election of rival groups of electors in four States (see Electoral Commission) and in 1887 Congress enacted a law providing that each State under its own laws should designate a tribunal to determine the legality of its electoral votes; but should no such tribunal have been appointed in case of double returns, the vote of the State is lost unless the electors agree as to which electoral votes from the State are the legal votes. Under Art. I, Sec. 5, § 1 of the Constitution, each branch of Congress is the judge of the election, returns and qualifications of its own members. Although the law may be disregarded, the House usually conducts its investigations of contested elections under sections 105 to 130 of the 'Revised Statutes.' If an election is to be contested, notice must be given within 30 days after the result of the election has been determined; the same period is allowed for an answer; and the testimony must be taken within 90 days. In the House the task of investigating these contests is assigned to three committees, but in the Senate this work is performed by the committee on elections. The investigating committee is always controlled by the party which has a majority in that branch of Congress and its report is seldom rejected. In most of the States each branch of the legislature judges the elections and qualifies some of its own members, and this power is granted also to the councils of many cities. As these bodies are supreme within their respective spheres of action, courts are without jurisdiction to hear and determine contested elections of their members. In half the States, the legislature is empowered to decide gubernatorial contests and contests over one or more of the other State offices, but in California, Delaware and Pennsylvania these contests are tried by a joint committee of both houses. In some States all elections are virtually decided by the legislature sitting as the supreme canvassing board. If a specific mode of contesting elections has been provided by statute, that method alone can be employed. In the absence of any statutory proceeding the only common-law remedy is quo warranto proceedings, under which the court demands proof of the authority by which a person exercises the functions of an office and ousts him if he cannot show proper and legal authority. Strictly speaking a quo warranto proceeding is not a contest between two persons for the same office but merely determines if the person holding the office be or be not a usurper. If the incumbent be proved a usurper, the judgment is that 'Sue et nons' and the proper officials will execute the supposed will of the people by placing the candidate actually elected in possession of the vacated office. W., 'American Law of Elections' (Chicago 1897); Rammelkamp, C. H., 'Contested Congressional Elections' in 'Political Science Quarterly,' Vol. XX, pp. 421-442, Boston 1905); Reinsch, P. S., 'American Legislatures and Legislative Methods' (New York 1907); Rowell, C. H., 'Historical and Legal Digest of Contested Election Cases in the House of Representatives, 1789-1890' (Washington 1901); Taft, G. S., 'Senate Election Cases' (Washington 1903); 'Compilation of Senate Election Cases, 1789-1913' (Senate Document 1036, 62d Congress, 3d session, 1913); and authorities cited in article ELECTIONS.
ELECTIONS, Federal Control of. Under the Constitution the Federal government possesses a large measure of control over elections at which senators and representatives are chosen. Each State legislature possesses the power to prescribe the times, places and manner of holding Congressional elections but Congress is authorized to make entirely new regulations or to add to, modify or alter such regulations, save in cases where the Constitution speaks of senators (Art. I, Sec. IV, § 1). In 1842 Congress provided that members of the House should be chosen by districts and this procedure is still in vogue; an act passed in 1860 prescribed the manner of choosing senators by the State legislatures. On 31 May 1870 Congress enacted a law providing that all persons otherwise qualified should be granted the right to vote at all elections, irrespective of race, color or previous condition of servitude, this act being supplemented by another (28 Feb. 1871) relating particularly to the election of representatives. This act stipulated that voting should be by ballot and also provided for the appointment by circuit judges on application of election inspectors in cities, the main object being to break up the prevailing corrupt practices. Federal courts subsequently declared unconstitutional some parts of this law and in 1894 the sections providing for Federal supervision were repealed. On 2 Feb. 1872 Congress definitely established the Tuesday following the first Monday in November (starting in 1876) as the date for Congressional elections but some exceptions to this rule were allowed under the amending act of 3 March 1875. Since that time (apart from the direct election of senators by constitutional amendment) the Federal government has itself chiefly by legislation pertaining to party activities, and passing acts relating to corporation contributions to campaign funds, publicity of campaign funds, corrupt practices acts, etc. See CORRUPT PRACTICES ACT; ELECTORS; ELECTIONS, CONTESTED.

ELECTIVE AFFINITIES. The Goethe's 'Wandernden Gift' (Electoral Affinities), first issued in 1780, was one of the numerous short stories in the second part of 'Wilhelm Meister,' grew beyond the limits of availability for such use, and was published independently in 1809. Its composition is in the leisurely and somewhat oracular style which makes many of the episodes in 'Wilhelm Meister' seem more like the deliverance of a seer than a mirror of actual life; but here as elsewhere Goethe develops a significant motif in terms of human experience, and the symbolic title befits the manner in which his narrative of what happens to a particular group of persons invites the mind to ponder the inscrutable laws governing human behavior in general. The analogy between chemical reactions and the solution of personal bonds in the moral sphere has for us less of mystical fatality than it had for Goethe's romantic contemporaries; for us, however, as for them the issue raised is momentous, and the treatment—in many respects romantic—leads us to examine the sanctions of the first of all social institutions.

The story deals primarily with a wedded couple into whose domestic circle two other persons are introduced; but of these four, the young girl Ottile is the one upon whom our attention is focused. The others, even the wife, persons of experience in the world, may be left to accommodate themselves to changed conditions; with Ottile we profoundly sympathize; for her devotion, becomes unwittingly involved in the toils of earthly life to which she is a stranger, and must by renunciation and death alone for an involuntary fault. Conceived in dramatic terms, the theme might be said to be the conflict of individual right with social convention. But Goethe's concern is not with any moral question or any dramatic demonstration; it is with the martyrdom of a helpless maiden, considered in its psychological aspect. The work, too restricted in scope to be called a novel, too diffuse to be a Novelle, is a study of singular penetration and completeness in the inner life of a beautiful soul. Translated by J. A. Froude and R. D. Boylan, London 1854. Consult 'The German Classics' (New York 1913, Vol. II).

WILLIAM G. HOWARD.

ELECTIVE AFFINITIES, a term formerly used in chemistry, in connection with the supposed fact that when a given chemical substance is mixed with two or more others with which it is capable of combining, it will exhibit a preferential affinity for one of them, and combine with that to the exclusion of the others. This view of chemical action is now known to be incorrect. See EQUILIBRIUM, CHEMICAL.

ELECTIVE COURSES AND ELECTIVE STUDIES, as applied to colleges and universities in particular, and to all schools in general, may be defined broadly as that principle in education which permits the student to choose his own subjects of study during the time of attendance at school.

The "elective" or "optional" feature of educational systems is not new; it was in existence in many of the leading schools of the Middle Ages, and even earlier. In the United States the principle first appeared in the curriculum of the University of Virginia in 1819. Harvard introduced it in 1820, and from that time on it has gone a-foremost in number and recognition throughout the country. However, so few availed themselves of the privilege of making the elective choice that more and more it came to be required that students should pursue certain studies in order to obtain the degree of bachelor of arts; and such restriction eventually led to the exclusion of all studies that did not contribute to the obtaining of the desired degree. Gradually the secondary schools adopted compulsory courses of study preparatory for colleges, and crowed out many of the studies that might fit the student for business life without going the college road. The special commercial, scientific and art schools came into existence to meet the wants and needs of a large number of students. In the meantime, the addition of many new branches of study so enlarged the educational resources of the larger institutions that a selection of studies became a necessity, and it seemed wise to allow the student to elect a course which should definitely aid him in preparing for a chosen occupation after leaving college. The difficulty experienced in the extension of the elective course has been found in the fact that the choice made by the untutored mind of the average
ELECTIVE MONARCHY—ELECTORAL COMMISSION, 1877

student was likely to be ill-balanced. This de-
fect is overcome where able instructors, those
who understand human nature and its needs,
guide the immature student; or, to use the mod-
ern term, where there are wise *advisers. a
Present practice shows a wide variation from
administrations where the entire course is
rigidly prescribed to those where every study
is elective. In most colleges a part of the
course is prescribed and the remainder elec-
tive. The tendency, however, is toward a
system in which, while there are prescribed
courses, the student is encouraged or perhaps
required to concentrate his energies on some
special line of study, and to round out his
course with studies wholly elective, with the
advice of the professors. In order to ascer-
tain what colleges and universities sanction elec-
tive courses it is necessary to obtain the lat-
est changes direct from the college authorities.
As an illustration of the policy of the edu-
cational institutions in the United States the
following summary gathered from 29 State uni-
versities and 52 private colleges is of interest. Eng-
lish is required in 78 of these institutions; it is elective in 6. One
(at least) foreign language is required in 68;
elective in 14. Mathematics is required in 61;
elective in 23. Natural science is required in
52; elective in 32. History is required in 41;
elective in 43. Physical education is required in
38; elective in 46. Philosophy is required in
32; elective in 52. Psychology is required in
21; elective in 63. Consultations, ‘Evolution of Educational Theory’ (1912); Baker, ‘American Problems’ (1907); Burns, ‘Eлектive System of Studies in Colleges’ (Catholic World, Vol. LXXI, 366); Eliot, ‘Educational Reform’ (1905); and ‘Essays and Addresses’ (1909); Foster, ‘Administr-
ation of the College Curriculum’ (1911); Hanus, ‘Problem of Electives’ (Popular Sci-
ence Monthly, Vol. LVIII, 58); Phillips, ‘Electives in American Education’ (Pedago-
gical Seminary, Vol. VIII, 206); Shaler, Thur-
ber and others, ‘Care of the Child in Black and

ELECTIVE MONARCHY. See MON-
ARCHY.

ELECTORAL COLLEGE. See ELECTORS.

ELECTORAL COMMISSION, 1877. The
electoral vote in the presidential election of 1876
showed 184 undisputed votes for Tilden; 163
for Hayes; four States with 23 votes—South
Carolina, 7; Florida, 4; Louisiana, 8; Oregon,
3—sent in conflicting returns. If the Republic-
ans won all the contests, Hayes was elected by
one vote. Of these States, the first three re-
turned popular majorities for Tilden electors;
but the *carpet-bag* governments in each had
constituted *returning boards,* whose function
was to throw out enough Democratic votes, on
the ground of intimidation of negro voters, to
leave a Republican majority. Neither the re-
ality of intimidation nor the justice of the as-
sumption that but for it the negroes
would all have voted and all voted Republican,
is now disputed by either party. Oregon chose
Hayes electors; but as the returning boards
would give the Republicans the other three
States, and therewith the election if upheld, the
Democrats ousted a Hayes elector on a tech-
nicality and replaced him by a Tilden one, as a
basis of compromise or a menace. Obviously,
the Republicans could not compromise
anything and win; and as they held the admin-
istration and the army, they could defy threats. The
Senate was Republican, the House Democratic;
there was therefore a deadlock on the admis-
sion of returns, as the 22d Joint Rule, throwing
out disputed States, had been repealed by the
Senate 20 January for this very emergency.
Finally, as an alternative to a most dangerous
monarchy, both sides agreed the discretion to pass on all the contests; the Democrats
being confident that it could establish no guid-
ing principle whatever, of going behind the
returns or not, accepting or rejecting State cer-
tificates as conclusive, which would not give
them at least one of the disputed States. They
underestimated the intellectual resources of their
opponents. The act creating the commission
was approved 29 Jan. 1877; its decisions could
only be reversed by concurrent action of both
Houses. The body was to consist of members of each House and five associate jus-
tices of the Supreme Court; the latter as indi-
cated were two Republicans and two Demo-
crats, and were to select a fifth. The Senate
appointed three Republicans,—G. F. Edmunds
of Vermont, O. P. Morton of Indiana and F.
T. Frelinghuyzen of New Jersey; and two Demo-
crats,—T. F. Bayard of Delaware and A.
G. Thurman of Ohio, the latter taken sick and
replaced by Francis Kernan of New York.
The House appointed three Democrats,—H.
Payne of Ohio, Eppa Hunton of Virginia and
J. G. Abbott of Massachusetts; and two Re-
publicans,—J. A. Garfield of Ohio and G. F.
Hoar of Massachusetts. Obviously, therefore,
the odd justice would have the deciding voice.
The Republican judges were William Strong
and Samuel F. Miller; the Democratic, Nathan
Clifford and Stephen J. Field; they chose
Joseph P. Bradley as the fifth. The counsel
were — Democratic: Charles A. Conner of New
York, Jeremiah S. Black and James B. Mc
Kee; Republican: Louis D. Tiffany, At-
man Trumbull of Illinois, R. T. Merrick of
the District of Columbia, Ashbel Green of New
Jersey, Matthew H. Carpenter of Wisconsin,
George Hoadley of Ohio, W. C. Whitney of
New York; Republicans: E. W. Thurlow,
E. W. Stoughton of New York, Stanley Mat-
thews and Samuel Shellabarger of Ohio. Other
lawyers appeared on special points. The States
were taken up in alphabetical order,—Florida,
Louisiana, Oregon, South Carolina,—and the
vote upon each was eight to seven for the Re-
publicans, on every contested point, Mr. Justice
Bradley sustaining all the contentions of that
side and the Republican candidate was de-
clared elected. The broad decision was, that
Congress cannot, as it had done repeatedly be-
fore, go behind the returns and take evidence
as to the manner in which State majorities for
electors have been obtained. On other points
the decisions varied with the cases. In partic-
ular, the Democrats contended that the question
as to the eligibility, etc., of a government official—a combination forbidden
by the Constitution—was decided in two dif-
ferent ways within two days, on the Florida
and Louisiana cases, in both to the profit of
the Republicans; and Judge Bradley published a
defense of his action. The court adjourned
ELECTORAL FRAUDS AND SAFEGUARDS AGAINST

sine die on 2 March. The peaceful acceptance of the decision was much helped by the Democratic speaker, Randall of Pennsylvania, who firmly checked all Democratic attempts to declare the election null and void. The question of the constitution may be found in the 'Congressional Record' (Vol. V, Part IV, 1877). Consult Haworth, 'The Hayes-Tilden Disputed Presidential Election of 1876' (Cleveland 1906).

ELECTORAL FRAUDS AND SAFEGUARDS AGAINST. The most common electoral fraud is bribery (q.v.), consisting of the offer of money or the promise of some reward either to vote "right" or to remain away from the polls. Employers of labor have been accused of attempting to influence the votes of their employees by threats of loss of work, reduced wages, etc.; physical violence has been used many times; and sometimes the threat of loss of social caste has operated to sway the voter. Priests have no right, either in or out of the pulpit, to influence electors to vote a particular way, by threats of excommunication, refusal of the sacrament and the like, and if they do so, it is, according to court decisions, an undue influence which may vitiate the election. The insertion of fictitious names on the roll, the registration of non-residents or non-citizens, etc., is almost impossible under present methods of registration. One source of election evil is found in faulty methods of identifying voters. The fraud that results takes the form of "impersonation" (voting on another man's name), or "repeating" (voting more than once). Sometimes forged naturalization papers are issued to enable the discovery of fraudulent voting. Floaters are employed in many cases, especially in the crowded districts where election officials do not know the individual voters. Where a party has too many votes in one precinct and too few in another, colonization is sometimes practised (see Blocks of Five; and in this connection see also GERRYMANDER); groups of actual voters may be transferred from a "safe" precinct to a "doubtful" one and still fulfil the letter of the law if only a brief residence be required. To lessen the likelihood of such crimes, some states require every voter to establish anew each year his right to vote; others allow a name once on the lists to stay there till death or removal causes it to be dropped. With our dread of red tape and formalities, we hesitate to adopt the ultimate remedy prevailing in France, where every man, as he steps up to the ballot-box, must produce his "electoral card" on which are inscribed his full name, profession and residence. This card is issued by the mayor of the town where the voter lives, after the latter has established his identity and majority by the production of a properly attested "act of birth." Each electoral card is numbered, and when it is presented at the polls, the judge of elections takes it, and calls off the number and name, while two other judges verify the official register list before the ballot is given or taken, and the card is repeated. After the register is closed, the card is retained. These bits of card are strung on a wire and are counted, at the close of the polls, to see if they tally with the number of ballots in the box. Various methods are employed to destroy the efficacy of a ballot after it has been marked by the voter. False counting of ballots has been an easy and common way to vitiate election results. Knives may nullify ballots by adding marks or altering them; ballots may be rejected on trivial grounds; and sometimes ballot boxes may be stuffed before the polls open. Defective ballots may be printed by omitting or shifting the position of candidates' names.

Election frauds developed early, and an especial abuse was the temporary conveying of lands, so as to enable the grantees to vote for a certain candidate. The election laws of Rhode Island, New Jersey and Virginia for the decade 1760-70 declared penalties for these frauds. The illicit use of money in elections began almost at the beginning of political history in America. Rhode Island, for instance, found it necessary to pass a law prohibiting bribery in 1737, and 10 years later replaced it with one even more stringent. Judging by its provisions the evil must have been persistent in that colony. On 14 Oct. 1643 the General Court of Massachusetts, in the words: "that if any freeman shall put in more than one paper or beane for the choyse of any officer, he shall forfeit 10s 1d for every offence; and any man that is not free, putting in any vote, shall forfeit the like somme of 10s 1d." The other New England colonies found no such laws necessary, but all the others had them save New York and Maryland. In England the purchase of votes was for centuries as natural a thing as the sale of boroughs, and no serious attempt to prevent it was made until 1854, when the Corrupt Practices Prevention Act defined bribery, forbade certain petty expenditures and required publicity of election expenses of a certain character. Despite this and other legislation, the evil did not greatly diminish and in 1883 a more drastic measure was adopted, which has served as a model for legislation elsewhere. In England and Scotland if the number of electors does not exceed 2,000, the Parliamentary candidate's maximum allowance for expenses is £100; £100 for every complete 1,000 above 2,000. In Ireland (which contains many small borough electorates), where the number does not exceed 500, £200; exceeds 500 but does not exceed 1,000, £250; exceeds 1,000 but does not exceed 1,500, £275. After this number has been reached, the rate is the same as in England. In the counties where the number of electors does not exceed 2,000 (in England and Scotland) the maximum allowance is £250, with an additional £60 for every complete 1,000 above 2,000. In Ireland, for the same number of electors, the maximum allowance is £500 and £540 respectively, with an additional £40 for every complete 1,000 above 2,000. These items do not include returning officers' fees or the personal expenses of candidates. In the United States all the States have enacted laws penalizing those who commit offenses against the suffrage. Most of the States have provided means to control the use of money in elections, some limiting the amount that may be expended, with the object of compelling a sworn statement of receipts and expenditures; some defining the objects for which money may be spent; some re-
ELECTORAL QUALIFICATIONS

quiring campaign financial committees to render a detailed statement of sources of receipts and objects of expenditures; and many prohibiting absolutely the gift of money or property to any political party, committee or organization by any corporation or joint stock company. The more recent enactment of direct primary, initiative, referendum and recall measures (qq.v.) has also done much to rid politics of corrupt influence. Moreover, if at all possible, the courts prefer to give effect to elections, particularly if they give evidence of being conducted fairly and honestly; and even the most glaring irregularities not actually constituting fraud have been held not to invalidate an election. See CORRUPT PRACTICES ACTS; BALLOT, etc. Consult Brooks, R. C., "Corruption in American Politics and Life" (New York 1910); Ford, H. J., 'Rise and Growth of American Politics' (ib. 1898); Grifith, E. C., 'Rise and Development of the Gerrymander' (Chicago 1907); Lowrie, S. G., 'Corrupt Practices at Elections' (Madison, Wis., 1911); Shaw, re 'National Lesson from Adams County' (in Review of Reviews, Vol. XLIII, pp. 171-180, New York 1911); Schaffner, M. A., 'Corrupt Practices at Elections' (Madison, Wis., 1906); and authorities cited under article CORRUPT PRACTICES AÇETS.

ELECTORAL QUALIFICATIONS: TERMS OF AND QUALIFICATIONS FOR OFFICE.—The theory that suffrage is a natural, inherent right, belonging to every man, is now generally discredited. Political rights are not essential to citizenship, and in a democratic state, as in the case of Amy v. Smith (1 Litt. [K.J.], 326, 333, 342), one judge said:

"A State may deny all her political rights to an individual and yet he may be a citizen. The rights of office and suffrage are political purities, and are denied by some or all of the States to part of their population, who are still citizens. A citizen, then, is one who owes to government allegiance, service, and money by way of taxation, and to whom the government, in turn, grants and guarantees liberty of person and of conscience, the right of acquiring and possessing property, freedom of marriage and social relations of suit and defence, and security in person, estate and reputation. These, with some others, might be enumerated, being unmasked and secured by government, constitute a citizen." Again the Supreme Court has held that—

"The fact that one is a subject or citizen determines nothing as to his qualifications. Such a thing is in different localities and according to circumstances. Citizenship has no necessary connection with the franchise of voting, eligibility to office, or indeed with any other rights, civil or political. Women, minors, and persons non-citizens are citizens and not the less so on account of their disabilities." (United States vs. Rhodes, 1866, 145 U.S. 364; Ex. Part. No. 16,151; see also Minor vs. Happersett, 1874, 21 Wall. 162).

That suffrage cannot be termed a "right" is obvious since no community can ever enfranchise all its citizens, two-fifths of whom are excluded from participation in governmental affairs because legally they are infants and, as such, unfitted to cope with government problems to the benefit of the State. Hence there is no necessary relation between citizenship and the right to vote. Minors and women (the latter by law disfranchised having no legal votes) do not usually possess the right to vote, although they are citizens; and on the other hand, some States and many municipalities permit persons to vote who have no claim to citizenship merely because they are residents and possess the other qualifications. Such a thing as the "popular vote" does not exist since millions of women have not yet been vested with full suffrage; in many States bigamists, bribers, idiots, insane persons, etc., cannot vote; certain classes of foreigners may never exercise the elective franchise; paupers, as dependents, do not participate in shaping the government to which they are a burden and to which they contribute nothing; and the criminal, by his very acts, has exhibited his total incapacity to understand his citizenship privileges. Nevertheless, and in spite of the above restrictions, the suffrage is gradually widening and broadening, partly due to the progress of woman suffrage.

The Right to Vote and the Power to Confer It.—As previously stated, the elective franchise is a privilege rather than a natural right; its extension to any excluded class is a question of political expediency; it may be taken away by the power which conferred it and if this be done no vested right is violated nor bill of attainder passed. Subject to the restrictions of the national Constitution as to race, color and previous condition of servitude, the States possess the supreme and exclusive power to regulate the right of suffrage and to define the qualifications of its voters, however unwise, unjust or even tyrannical its regulations may be or seem to be in this regard. Hence the clauses in some State constitutions requiring of voters the ability to read, understand or interpret reasonably any section of such constitutions are not in contravention of the United States Constitution. Once granted by a State constitution, the right to vote cannot be abridged by the legislature; if they be fixed by the constitution that body cannot add to the qualifications of voters nor create other classes of voters, nor dispense with any of the constitutional qualifications nor enact provisions imposing upon a particular class of citizens conditions and requirements not imposed upon all others. On the other hand, the legislature may enact laws to regulate the exercise of the elective franchise, if those laws do not deny the right of the franchise itself. Under the national Constitution Congress cannot prescribe the qualifications of electors in the States, but Congress may penalize a criminal by forfeiting his United States citizenship, and if under the State constitution only United States citizens are allowed to vote, Congress may deprive a person of the opportunity to enjoy a right which belongs to him as a citizen of the State, even the right of voting, but cannot deprive him of the right itself. The Constitution does not confer the right of suffrage upon anyone individually nor upon any class of persons—the United States has no voters of its own creation in the States. It is true that the Fifteenth Amendment is usually interpreted as giving the negro the right to vote, but it merely exempts from discrimination in the exercise of the elective franchise and no negro possesses the right to vote unless he conform to all the qualifications and restrictions imposed by the State constitutions upon white voters. But Congress may punish the State for the act of who refuses to perform the duties necessary to qualify all colored citizens. Thus the right to vote in the States is conferred by the States but the right of exemption from the prohibited discrimination comes from the national government.

The Constitution says that Congressmen
ELECTORAL QUALIFICATIONS

shall be chosen by the people of the several States and that the electors in each State shall have the qualifications requisite for electors of the most numerous branch of the State legislature (Art. I, § 2, ¶ 1). The States do not define who shall vote for Congressmen but merely prescribe the qualifications of those who vote for the popular branch of their own legislatures and the Constitution says that the same persons vote for Congressmen. Hence Congress cannot exclude from voting in their bodies those who do not vote to the State law in any sense which makes the exercise of the right exclusively dependent on the law of the State. Since the right to vote is not natural, the State, unless expressly prohibited by its constitution, may confer the right upon those who pay taxes in the support of the government; and even though the constitution fix the qualifications of voters at general elections, yet the legislature, in granting municipal charters and providing for special local elections, may make the payment of taxes a condition to the right to vote at such elections. If United States citizenship be a requisite qualification of an elector, a forfeiture of that citizenship will disqualify him, provided a regular legal trial and conviction be shown. Many of the State constitutions provide that persons convicted of infamous crimes or crimes of a high degree lose the privilege of voting and it has been held also that a conviction of crime of a disqualifying nature in a Federal court has the effect to exclude the person convicted from office and to enfranchise the same as if he had been convicted in a State court. A general absolute pardon of the executive restores the convicted person to the full enjoyment of his civil rights, including the right to vote, and a Presidential pardon likewise restores the right to those convicted in Federal courts, but while a Presidential pardon restores the criminal to the rights and privileges of a citizen of the United States, it does not, without the assent of the State, restore him to the exercise of that right if the sovereign power of the State has excluded him from the right of suffrage. Unless pardoned by the executive, ex-convicts continue to be disfranchised. In this connection the existence of a double citizenship in the United States should be mentioned. One authority says:

There is a clear distinction between national citizenship and State citizenship. A person who is a citizen of the United States and a resident of a particular State is necessarily a resident of that State. On the other hand, a person may be a citizen of the United States and not a citizen of any particular State. This is the condition of citizens residing in the District of Columbia, and in the territories of the United States, or who have taken up a residence abroad. So a person may be a citizen of a particular State and not a citizen of the United States, as an alien who has declared his intention to become a citizen and who is by local law entitled to vote in the State of his residence and there to exercise all other local functions of local citizenship, such as holding office, the right to poor relief, etc., but who is not a citizen of the United States. Nothing which a State can do will invest a foreigner with the rights and privileges of a citizen of the United States.” (Corpus Juris, Vol. XI, p. 777).

Colonial Electoral Qualifications.—The principal qualification required of the early colonial electors was that they should be "freemen," a term of various interpretations even in the colonies themselves, but held generally to mean persons of recognized responsibility. In Virginia and North Carolina, Indians and negroes were not allowed to vote. In South Carolina and Georgia the privilege was restricted to white men, but the law was not rigidly enforced, for free negroes were recorded as voting in South Carolina in 1701. In Pennsylvania only natural-born subjects of England could vote; in Massachusetts, after 1664, only Englishmen could vote. In South Carolina, however, the French Huguenots had equal franchise with the English "freemen."

In general, the voter was required to be of good moral character and of the State; immoral behavior might result either in temporary or permanent disfranchisement. In Plymouth voters were to be "orthodox in the fundamentals of religion." Massachusetts in 1631 demanded also, "to the end that the body of the freemen may be preserved of honest and good men," that "henceforth no man shall be admitted to the freedom of the commonwealth but such as are members of some of the churches within the limits of this jurisdiction." This provision, however, lasted only until 1664 and 1665. All persons excluded Quakers, but they were permitted to vote in Rhode Island and Connecticut, which colonies did not specify church membership; while in the other colonies their reluctance to take oaths usually operated to debar them from the franchise. In most of the colonies Roman Catholics were not allowed to vote, New Haven and, for a time, Maryland being notable exceptions. New York excluded Catholics in 1701 and Jews in 1737. Virginia was the only colony specifically debarring women from the franchise, though they were effectively excluded in South Carolina, Georgia and Delaware; but the others incidentally excluded them by according the vote only to "freemen," or by confining the suffrage to males of at least 21 years of age. However, the laws often read "freeholders," rather than "freemen," and it is impossible to tell how far under this the women voted, though at least a few voted in New Jersey. In Virginia a property qualification was required; a voter must have paid into the State funds the sum of $200, either as owner or tenant. Massachusetts, Delaware, Maryland, and New York required an estate of at least $200; and in 1899 New York required that voters for members of the lower branch of the legislature be "freeholders" or pay rates at not less than $40, but in Albany and New York city all "freemen" were allowed to vote. Rhode Island stipulated that voters must possess "competent estates," which, later, were defined as the possession of $500, or a rental list of at least $10 (afterward $50), and still later, $100 per annum. Pennsylvania, New Jersey, Delaware, Maryland, North Carolina, South Carolina and Georgia required the possession of 50 acres of land, of which a certain (varying) portion should be under cultivation. Virginia required the possession of 100 acres of land if untenanted, and 25 acres if a residence not less than 12 feet square were built upon the land and occupied. The same size of house on a small lot in a town fulfilled the colony's qualification in this respect; only those could vote who had occupied brick houses at least 16 feet wide and 20 feet long, and for at least three months preceding the election. The residence qualification in other colonies varied from six months in Georgia to two years in Pennsylvania and Delaware. See also United States—Suffrage in the.
Electoral Qualifications

Broadening of the Suffrage.—When the Constitution was framed in 1787 suffrage qualifications were so divergent in the various States that no attempt was made to impose restrictions and the States were allowed to modify these qualifications as they saw fit. In this wise, the only restriction being that contained in Article I, § 2, ¶ 1 which provides that Congressmen shall be elected by people in the various States who have the qualifications requisite for electors of the most numerous branch of the State legislature. At that time this distinction was of great importance since all the States required the payment of taxes or ownership of real or personal property varying in value from $33 to $200. Moreover, North Carolina distinguished between electors for her legislature; to vote for a member of the lower house the elector need only to have paid taxes, but to vote for a member of the senate he must own a freehold of 50 acres. New York required that all voters for members of the assembly own a freehold valued at $20 or pay rent of 40s. and that taxes must have been paid to the State during the previous year; while the person who voted for senator must be possessed of an unencumbered freehold valued at not less than $100. Gradually these requirements were eliminated, the property test being abolished by Maryland in 1801 and 1809, New York and Massachusetts in 1821, Tennessee in 1834, New Jersey in 1844, Connecticut in 1845, Virginia in 1850, South Carolina in 1865, North Carolina in 1854 and 1867, and the tax-paying test being abolished by New York in 1826, Louisiana in 1845, Ohio in 1851 and Virginia and Mississippi in 1882. Nevertheless, many States continued to insist upon the poll tax and Rhode Island still has a law that prohibits a person who has not paid during the previous year a tax upon his property in the State valued at $134 at least from voting for city councilmen or upon any measure of municipal finance. Some of the other States now have tax or property tests as will appear in the subjoined table. The next great extension of the suffrage was an outcome of the Civil War, when during the Reconstruction period (see United States—Reconstruction in the) the Fourteenth and Fifteenth Amendments to the Constitution were adopted, forbidding the States to discriminate against the negro. Finally women have won voting privileges on an equality with men—in Wyoming (1869), Colorado (1893), Utah (1895), Idaho (1896), Washington (1910), California (1911), Kansas (1912), Arizona (1912), Oregon (1912), Alaska (1913), Montana (1914), Nevada (1914), New York (1917, effective 1918). In other States they possess a restricted suffrage, for details of which see Woman Suffrage. See also Ballot; Vote, Voters, Voting.

Modern Electoral Qualifications.—Most of the States have uniform laws for electors of every officer to be elected in the State, though this statement must be qualified as to those States which permit women to vote in the election of school boards or committees, or which allow women to vote on financial measures. Unlike some European countries, such as Germany, the vote of the lodging-house dweller, the loafer, etc., in the United States carries as much weight in the election as the vote of the wealthiest or most distinguished citizen. Most of the States require that their voters be full-fledged United States citizens. As a rule the State constitutions require that a voter be a male, at least 21 years of age, who is a citizen of the United States, either native or naturalized, and can read or write English or both. The "male" provision, of course, is inoperative in those States wherein women have the vote. Some States, particularly those that are anxious to obtain immigrants as agricultural laborers, extend the privilege of voting to an alien who has declared his intention of becoming a citizen and has resided in the State a certain period of time before election—usually six months to a year. Such a voter is not bound by an oath of allegiance to the United States nor has he forewarned allegiance to his native land; hence a situation might arise under which this voter would help elect the officers of the United States, and in a few days the day the United States might become involved in a dispute with the government of his native country over some question respecting his citizenship. Courts have ruled that if a father become a naturalized citizen of the United States before his son shall have attained his majority, the latter, though alien-born, ipso facto becomes a citizen and need not undergo the formality of naturalization if dwelling within the United States (Revised Statutes, Title XXX, § 2172); but the son above mentioned cannot be vested with citizenship by implication merely because the father declared his intention of becoming a citizen prior to the time the son attained his majority. Basing his statements on court decisions, one authority says:

"While it has been held that citizenship will not be presumed merely from the fact of having owned real estate, having voted, or having held an elective office, it seems that having participated in elections and having held elective offices are facts strongly tending to establish at least a prima facie case of citizenship; and it has been held that, where the State confers the right of State citizenship on aliens who have declared their intentions to become citizens of the United States, the act of voting is conclusive proof of an acceptance of such State citizenship by them." (Corpus Juris, Vol. XI, p. 781).

Some States enfranchise men of Indian descent, native of the United States, while others grant the privilege to Indians who have been declared citizens of the United States by act of Congress and to civilized Indians, not members of any tribe. As a rule, idiots, insane persons and felons are not allowed to vote and sometimes vagrants, paupers, persons convicted of treason, bribe, embezzlers, bigamists, Chinee, etc., are excluded. Some constitutions of State that United States soldiers and seamen gain no voting residence by being stationed in the State, while the residents of the District of Columbia, when it became the seat of the general government, lost the right to vote therein for national officers or on matters of national concern.

Educational and Other Tests.—The educational, property, tax, and good character tests, grandfather clauses, etc., have operated to exclude many thousands of voters—particularly the negro voters of the South. Connecticut in 1854 and Massachusetts in 1856 led the other States in requiring of voters the ability to read the constitution and (in Massachu-
ELECTORAL QUALIFICATIONS

sets) to write their own names. To some extent the national naturalization laws have offset the effects of these tests, since a applicant for citizenship must sign the application in his own handwriting and when taking out his final papers must be able to speak the English language. (See ALIENS; CITIZENSHIP IN THE UNITED STATES; NATURALIZATION).

The execution of the United States was undertaken to assure permanence of white rule, since the negro, during the Reconstruction period, had displayed a total unfitness to govern. Constitutional amendments were adopted to attain this end by law. The constitution of the United States in 1890 required that a prospective voter be registered, a payer of a poll tax, and, after 1 Jan. 1892, able to read any portion of the constitution or to understand it when read to him, or to render a reasonably accurate interpretation of it. The South Carolina constitution of 1895 permitted the registration of an otherwise qualified person, "provided that he can both read and write any part of this constitution submitted to him by the registration officer, or can show that he owns and has paid all taxes collectible during the previous year on property in this State assessed at $300 or more." The Louisiana constitution of 1898 contained similar clauses, but for voters who might be excluded by these tests, the constitution provided that any male "who was on January 1, 1867, or at any date prior thereto, entitled to vote under the constitution or statutes of any State of the United States, wherein he then resided, and any son or grandson of any such person not less than twenty-one years of age at the date of the adoption of this Constitution should be allowed to register and vote at all elections without possessing the educational or property qualifications.

Virginia has imitated this qualification. (See also UNITED STATES SUPREME COURT). The constitutionality of these provisions has not been definitely decided by the Supreme Court, though several cases have been considered. Regarding the Mississippi constitution (Williams vs. Mississippi, 170 U. S. 213), the Court declared that the qualifications did not on their face discriminate between the white and negro races, nor amount to a denial of the equal protection of the law secured by the Fourteenth Amendment to the Constitution; and it has not been shown that their actual administration was evil, but only that evil was possible under them. The Court further stated (Giles vs. Harris, 189 U. S. 474) — "Relief from a great political wrong, if done as alleged, by the people of a State, or by the State itself, must be given by them, or by the legislative and political departments of the government of the United States."

On 21 June 1915 the Supreme Court declared void the "grandfather clauses" of the Maryland and Oklahoma constitutions. In Maryland the clause was inserted in laws governing elections in various cities. In 1908 it was inserted in the law governing municipal elections in the city of Annapolis. It authorized the registration of all adult male voters who were 21 years of age, male children of naturalized citizens 21 years of age, and all citizens who prior to Jan. 1, 1868, were entitled to vote in the State of Maryland or any other State of the then United States, and the lawful male descendants of any person who prior to Jan. 1, 1868, were entitled to vote in the State of Maryland or in any other State of the United States at a State election. The constitution of Oklahoma, upon which that Territory was admitted to the Union as a State, gave something very like manhood suffrage. Prior to the election of 1910, however, an amendment was adopted restricting the franchise. The amendment in part was as follows: "No person shall be registered as an elector of this State or be allowed to vote in any election herein unless he shall be able to read and write any section of the Constitution of the State of Oklahoma; but no person who was on Jan. 1, 1866, or at any time prior thereto, entitled to vote under any form of government, or who at any time resided in some foreign nation and no lineal descendant of such person shall be denied the right to register and vote because of his inability to so read and write sections of such Constitution."

The contentions of the election officers as plaintiffs in error, really setting forth the position of the State, are thus outlined by the chief justice:

"It said the States have the power to fix standards for suffrage and that power was not taken away by the Fifteenth Amendment, but only limited to the extent of the provisions which the amendment established. This being true, as the standard fixed does not in terms make any discrimination on account of race, color or previous condition of servitude, since all negroes and whites, who come within its requirements, enjoy the privilege of voting, there is no ground upon which to rest the contention that the provision violates the Fifteenth Amendment. This, it is insisted, must be the case unless it is intended to expressly deny the State's right to provide a standard for suffrage, or what is equivalent thereto, to assert: (a) That the judgment of the State exercised in the execution of that power is subject to Federal judicial review or to supervision, or (b) that it may be questioned or be brought within the prohibitions of the amendment by attributing to the legislative authority an occult motive to violate the amendment or by assuming that the otherwise lawful power may be invalidated because of conclusions concerning its operation in practical execution and resulting discrimination arising out of it, such discrimination was not expressed in the standard fixed or fairly to be implied, but simply arose from inequalities naturally incident to the standard in order to enjoy the right to vote."

The government insisted, on the other hand, that the "real question involved is the repugnancy of the standard which the amendment makes, based upon the conditions existing on Jan. 1, 1866, because on its face and inherently considering the substance of things, that standard is a mere denial of the restrictions imposed by the prohibitions of the Fifteenth Amendment and by necessary result creates and perpetuates the very conditions which the amendment was intended to banish."

The chief justice summed up the opinion of the court in these words:

"There seems no escape from the conclusion that to hold that there was even possibility for dispute on the subject would be but to declare that the Fifteenth Amendment not only had the self-executing power which it has been recognized to have from the beginning, but which is wholly inapplicable because susceptible of being rendered inapplicable by mere forms of expression embodying no exercise of judgment and resting upon no discrimination other than the purpose to disregard the prohibitions of the amendment by creating a standard of voting which on its face was in substance but a revitalization of the conditions which, when they prevailed in the past, had been destroyed by the self-operative force of the amendment. It
is true it contains no express words of an exclusion, from the stipulated qualification, of any persons on account of race, color, or previous condition of servitude prohibited by the Fifteenth Amendment, but the standard itself inher-
ent brings that result to existence, since it is based purely on a period of time before the enactment of the Fifteenth Amendment and makes that period the controlling and domi-
nant test of the right of suffrage.

"We are unable to discover how, unless the prohibitions of the Fifteenth Amendment were considered, the slightest reason was afforded for basing the classification upon a period of time prior to the Fifteenth Amendment. Cer-
tain it is that the Fifteenth Amendment was in the name of which engaged endowments attributes affecting the qualifications to vote which would not exist at another and different period unless the Fifteenth Amendment was in view."

The Court took the view that under ordi-
nary circumstances the State should decide the question whether the nullification of the excep-
tions of the grandfather clause would at the same time make void the general literacy test to which it was appended. In the absence of a decision by a State court the Chief Justice, however, said that the Federal tribunal would pass upon the question. Ordinarily the provision laid the literacy test, which is legal in itself, would not be destroyed by the wiping out of an illegal accompanying provision. But the plain meaning of the Oklahoma constitution was that the reading test should not be used to disqual-
ify lawful descendants of voters prior to 1866. As this would be accomplished in many cases by continuing the reading test without the of-
fensive exemptions, the whole provision was stricken out. Accordingly in 1916 the Oklahoma legislature passed a proposed constitutional amendment (approved by the voters on 21 Feb. 1916), which prohibited any property qualifi-
cation; it contained the reading and writing clause but this clause was inoperative if, prior to the adoption of the amendment, a prospec-
tive elector had served in the land or naval
forces of the United States or of any State or foreign nation, or in the Revolution, War of 1812, Mexican War, or on either side in the Indian wars or the Civil War; and all lawful descendants of such persons were included. But this amendment was revised by the legislature of August 1916 and now the only restriction on suffrage in Oklahoma is a universal registration act passed by a special session of the legisla-
ture in 1916.

Residence and Absentee Voting.—Gener-
ally speaking, an elector must vote in the pre-
cinct wherein he resides, if he have a fixed place of abode. As employed in the statutes and constitutions in defining political rights, a residence is synonymous with home or domicile, denoting a permanent dwelling place to which the party when absent intends to return. An absence for months or even years, provided the party intended it merely as a temporary ar-
angement, after which he would occupy his former home, would not constitute an abandon-
ment of the party to vote. A person who re-
moves from the jurisdiction, intending to re-
main, thereby loses his residence, even though he may afterward change his intention and return; nor can he vote until he has re-estab-
lished his residence by remaining in the juris-
diction the statutory period. Courts have held, however, that where a person is a bona-fide resident of a county who has moved permanently or domicile in any particular precinct therein, he may vote in any precinct wherein he may happen to be on election day. In 1913 Vermont enacted a law permitting a voter who changed his residence within 15 days prior to election to vote in the town from which he moved previously. Connecticut and California allowed the voter to retain a voting residence in the town from which he moved. Colorado, Iowa, Michigan, Montana, Washington and Wisconsin passed laws permitting voters absent from their home precincts to vote elsewhere in the State. In 1916 Virginia and Oklahoma provided for ab-
sentee voting, the former allowing absent elec-
tors to vote by registered mail and the latter permitting an elector absent from his county to vote in another precinct. Absentee voting occurs sometimes when large bodies of citizens are called into some branch of governmental service, such as the army; this happened in the elections of 1916 and 1917 when the National Guard troops were on the Mexican border, or in France or in cantonments preparing for service abroad, special provisions were made for the ballotting at the camps. In the election of November 1917 Massachusetts adopted an amendment enabling the legislature to establish arrangements for absentee voting.

Voting in Territories and Dependencies.

—As previously stated, residents of the Dis-
trict of Columbia do not vote, the govern-
ing being in the hands of a board of commis-
ioners appointed by the President. From 1802 to 1855 white taxpayers were permitted to vote for local officers; subsequently the taxing qualification was eliminated; in 1867 all adult male citizens white or black were granted the franchise if not disqualified by the Fourteenth Amendment; but in 1874 all suffrage rights were abrogated. Prior to becoming a territory of the United States, Hawaii required residents to register; the electors of members of the senate be possessed of a substantial amount of property, but under the organic act of 1900 all persons may vote who are duly registered citizens of the United States, 21 years of age, resident in the islands one year or more, and who can speak, read and write either the English or Hawaiian language; hence Chinese and Japanese are excluded. In Porto Rico all male citizens, 21 years of age or over, who had resided in the island one year might vote if they passed a property or an edu-
cational test similar to that of South Carolina, but in 1904 a law was passed renewing the property qualification and requiring that after 1906 all registrants should be able to read and write, but permitting those who already were qualified to continue to vote; their ability to speak English or Spanish, that he be an owner of prop-
erty or a taxpayer, and that he take an oath of allegiance. In Alaska both men and women enjoy full suffrage rights.

* Since 1866, no person who on 1 Jan. 1866 was entitled to vote in any State or who then resided in some foreign nation and no lineal descendant of such person shall be denied the right to register and vote because of inability to read and write State constitution. Adopted at election 2 Aug. 1910 but declared unconstitutional by U. S. Sup. Ct. as discriminating against persons of negro descent. In 1916 legislature passed constitutional amendment prohibiting any property qualification and containing the reading and writing clause, but this clause was to be inoperative if, prior to adoption of amendment, prospective elector had served in land or naval forces of U. S. or of any State or foreign nation or in the Revolution, War of 1812, Mexican War, or on either side in the Indian wars or the Civil War, or if elector were a lawful descendant of such person. This amendment was rejected in 1916 at a special election and now the only restrictions on suffrage are a universal registration act passed by a special session of the legislature in 1916.

- Ownership of real estate assessed at $134 above all encumbrances in order to vote in election of city council or upon any proposition to impose a tax. A school tax of $1 is assessed annually on all persons eligible to register.

**Notes:**

- *Sections marked by asterisks indicate tests which are options one for another. Voters are required to qualify under only one test.*
- **Australian ballot or modification of it in force.**
- **No specified time.**
- **Modified woman suffrage, women with same age and residence qualifications as male voters being allowed to vote at certain elections, for certain officers or on special propositions (such as tax assessments; bond issues; school officers; or upon any question relating to education or to schools; or for statutory but not for constitutional officers).**
- **Under the State law of 1913 in Illinois it was construed that women could vote for Presidential electors, members of the State board of equalization, clerk of the appellate court, county collector, county surveyor, members of board of assessors, members of board of review, sanitary district trustees and for all the officers of cities, villages and towns (except police magistrates), municipal judges and upon all questions or propositions submitted for approval at elections. The Supreme Court of Illinois ruled, February 1916, that women cannot vote for national delegates and alternates. The court also held that women cannot vote for State central committeemen and precinct committeemen.**
- **Clergymen are qualified after six months' residence in precinct.**
- **Ministers in charge of an organized church and public school teachers may vote after a residence of six months in the State.**
ELECTORAL QUALIFICATIONS

Federal.—Presidents are elected for four years, senators for six years, and representatives, Article VI, § 3 of the Constitution requires that senators and representatives, members of State legislatures and all executive and judicial officers, State and National, shall be bound by oath or affirmation and the Constitution, but no religious test shall ever be required as a qualification to any office or public trust under the United States. No senator, representative or Federal office holder may be a Presidential elector (Art. II, § 1, ¶ 2). The Constitution states that "no person except a natural born citizen, or a citizen of the United States at the time of the adoption of this Constitution, shall be eligible to the office of President; neither shall any person be eligible to that office who shall not have attained to the age of thirty-five years and been fourteen years a resident within the United States." (Art. II, § 1, ¶ 5). Hence, foreign-born citizens are excluded from this office but children born of parents residing abroad temporarily are not considered foreign-born. No restriction is placed by the Constitution upon the number of terms a President may serve but Washington's precedent of two terms has always been followed. A senator must be at least 30 years old, nine years a citizen of the United States and at the time of election an inhabitant of the State represented. A member of the House must be at least 25 years of age, seven years a citizen of the United States and at the time of election an inhabitant of the State represented (Art. I, § 2, ¶ 2, § 3, ¶ 3). This does not prevent their establishing an office while maintaining their legal residences in the States represented. Article I, § 6, ¶ 2, says: "No Senator or Representative shall, during the time for which he was elected, be appointed to any civil office under the authority of the United States which shall have been created or the emoluments whereof shall have been increased during such time; and no person holding any office under the United States shall be a member of either House during his continuance in office." Accordingly, if a senator or representative accepts another office, his seat in Congress thereby becomes vacant, but if an office-holder be elected to either branch of Congress he may retain his position until his active duties in the legislature begin, whereupon the other office becomes vacant. Regarding the judiciary the Constitution makes no stipulations, the justices being appointed by the President with the advice and consent of the Senate. The same provision holds true of Cabinet officials, save that no one interested in the import trade may become Secretary of the Treasury; though all members of the Cabinet are expected to sever all business or outside connections. (See Cabinet and Cabinet Government; Executive). All other Federal offices are filled by appointment, which is subject only to the restrictions and limitations of custom or Congressional enactment. It is important to note that qualifications to office are limited to citizens. See Appointments to Office; Tenure of Office.

State.—The States quite effectively control their office-holders. The only stipulation in the Constitution as first adopted regarding State office-holders was that they should be bound by oath or affirmation to support the Constitution (Art. VI, ¶ 3). The Fourteenth and Fifteenth Amendments provided that "No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States and that the right of citizens of the United States to vote shall not be denied or abridged by the United States or by any State on account of race, color or previous condition of servitude." Hence any law enacted by a State which expressly deprives a negro citizen of the right to vote or to hold office would be unconstitutional, but the courts have upheld laws which indirectly disqualify certain classes of negroes and therefore they cannot hold office. In the early State constitutions are to be found numerous religious tests for office-holders. The man possessing a moderate means might vote, but legislation was restricted to well-to-do Christians, and in some States none but a rich Christian could aspire to the governorship. In New Hampshire, New Jersey and South Carolina, no Hebrew, atheist or Roman Catholic could become a State officer. In the United States, however, none but a Christian in Massachusetts, Delaware, Pennsylvania, Maryland and South Carolina. Maryland did not open public offices to Jews until 1826. In some New England States church members alone could vote, while the South Carolina constitution extended the privilege to "every free white man, and no other person, who acknowledges the being of a God, and believes in a future state of rewards and punishments." The early constitutions also required that office holders be "Christians" or "of the Protestant religion," or should believe in the Trinity and Inspiration of the Scriptures (Delaware 1776), or should declare themselves to be of the Christian religion (Massachusetts 1780). In New York, Delaware, Maryland and Georgia no priest or minister who held the privilege of holding a civil office, though in Georgia the prohibition is limited to the assembly. (Wiley, Edwin, and Rines, Irving E., The United States, Vol. V, pp. 98-99). Indeed, as McMaster says: "The government set up by many a constitution, despite the principle announced in its preamble, was that of a class. Nowhere, save in Vermont, did manhood suffrage exist. Elsewhere no man voted who did not own a farm or rent a house, or own a specified number of acres of land, or have a specified yearly income. Each one of the State constitutions guaranteed liberty of conscience; but the man who did not exercise that liberty of conscience in such wise as to become a Protestant or a Catholic, a trinitarian or a believer in the divine inspiration of the Old and New Testaments must give up all hope of political preference. Even to such as could subscribe to creeds and doctrines, the way to public office was barred by property qualifications, which increased with the dignity of the office until it became absolutely impossible for a poor man to become a candidate for the State senate or the governorship." ("History of the People of the United States," Vol. V, p. 377).

Most of these requirements have been eliminated, though eight States still retain remnants, among them being South Carolina, whose constitution of 1895 (Art. IV, § 3) provides that no one may be governor who denies the existence of the Supreme Being. Black Diehl qualifications also have been eliminated gradually from the State constitutions. In our early history religious qualifications were not deemed sufficient; heavy property qualifications were added, especially for executive officers, for the governor must not only be pious but rich; the
ELECTORAL QUALIFICATIONS

importance of the office determined the amount of property. According to the South Carolina constitution of 1775 governors' and lieutenant-governors must have in this State a settled plantation or freehold in their and each of their own right, of the value of at least ten thousand pounds currency, clear of debt, while the estate of a senator must be valued at £2,000 currency and of a representative £3,500. The Massachusetts constitution of 1780 provided that senators must possess a freehold of the value of £300 or personal estate of at least £600; representatives must have a freehold of £100 or "any ratable estate" to the value of £200; and a governor "must be seised, in his own right, of a freehold, within the commonwealth, of the value of £1,000." In New Hampshire eligibility to the lower branch of the legislature consisted of being a Protestant and possessing an estate worth £100; a freehold of £100 above all debts in New York; a "personal estate" in New Jersey; a freehold of £500 in Maryland; in North Carolina an assemblyman must be possessed and continue to be possessed in fee simple or for life of a freehold of 100 acres of land; in Georgia he must own 250 acres of land or property worth £250. Usually the qualifications for membership in the upper house were the same as those for the lower house, save that values were twice as great. Some of the recent constitutions of the Southern States contain provisions regarding property or payment of taxes incorporated with the object of excluding negroes from voting and holding office.

</table>

* Not stated in constitution.
† Merely a duly qualified elector. See preceding table.
‡ No specified time required.

Some of the early constitutions required that a governor should be native born, but Connecticut (1818) merely required citizenship, Massachusetts (1817) a citizenship of 20 years and Illinois (1818) a citizenship of 30 years. At the present time citizenship is almost universally required of a State office-holder but the term of residence varies widely—from the bare fact of residence to residence for 10 years next preceding the election. The same variance is seen in the age requirements, ranging
from 21 to 35 for governors, 21 to 30 for sena-
tors and 21 to 25 for representatives while in
recent States the only requirement for the last
two offices is to be a duly qualified elector and
some constitutions contain no limitations what-
soever. The preceding table gives the terms of
office of governors and State senators and rep-
resentatives, together with their age require-
ments States necessary period of residence in
State or district.

Few of the State constitutions place any
limitations on the judiciary, though some con-
tain exceptional provisions. Oregon requires
that her judges be citizens, residents of the
State for three years and residents of the dis-
tricts wherein they discharge their official
duties. California stipulates that members of
the Supreme Court shall be attorneys licensed
to practice before the court, while in Colorado
and New Mexico the attorney-general must be
a lawyer licensed to practise before the Su-
preme Court. In all States, save those having
woman suffrage, the constitutions restrict vot-
ing to male citizens; but many constitutions
are in force requiring officeholders and in some
women have gradually established their right
to hold elective offices. But this privilege has
been denied them in States the constitutions of
which expressly provide that elective office-
holders must possess the qualifications of elec-
tors. Most of the minor office States are not
subjected to constitutional provisions but are
regulated by legislative enactment, many of them
coming under the civil service laws.

Electoral Reform. See Elections.

Electoral System. See the presidential elections or electoral college for President and Vice-President. Prior to 1804 each elector voted for two candidates for President. In the one who received the largest number of votes was declared President; and the one receiving the second largest vote was elected Vice-President. The votes for the first President were: George Washington 69; John Adams (Mass.) 34; John Jay (N. Y.) 9; R. H. Harrison (M.D.) 6; J. C. Randolph (S. C.) 6; John Hancock (Mass.) 4; Henry Knox 3, and scattering 7. In 1812 the electoral votes cast by the electoral college were as follows: For President, Woodrow Wilson 435; Theodore Roosevelt 88; William H. Taft 8; for Vice-President, Thomas R. Marshall 435, Hiram Johnson 88, Nicholas M. Butler 8. Consult McClure, 'Our Presidents' (New York 1905); Stanwood, 'History of the Presidency from 1788 to 1897' (Boston 1898); 'History of the Presidency from 1897 to 1912' (ib. 1912). See Elections; Electoral Commission.

Electors, German Imperial (Ger. Kurfürst), certain princes of the old Holy Roman Empire who had the right of electing the emperors. The number of the electors was early fixed at seven by the Golden Bull of 1356, including the archbishops of Mainz, Cologne and Trier, the king of Poland, the Count Palatine of the Rhine, the Duke of Saxony, and the Margrave of Brandenburg. An election as king of the Romans was held by the German princes to include the imperial title of Holy Roman emperor, but this was contested by the popes, who claimed the exclusive privilege of
granting the title. In 1648, by the Treaty of
Westphalia an electorate was given to Bavaria; but
in 1710 to Hanover. In 1802 the Bavarian
electorship had expired, and the number of
electors was increased to 10 by conferring
the rank on the rulers of Baden, Würtemberg,
Hesse-Cassel and Salzburg. In 1806 the em-
pire was also tied up the imperial diet, the
electors gradually adopted other titles. Consult
Bryce, 'The Holy Roman Empire' (London
1892).

ELECTORS, United States Presidential
(as a body, termed the Electoral College, a
term informally used since about 1821, probably
suggested by the College of Cardinals;
*college of electors* appears in the Act of
1845), the intermediate body for whom, and
not directly for President and Vice-President,
votes are cast every four years. As originally
obtained these were meant to constitute a coun-
cil of the ablest men in the country, exercising
an independent choice of a chief executive. The
theory has never been fact for a moment, and
since the third election not even a pretense;
the institution is retained for very different
reasons, and perhaps primarily for historical
strengths reason. As a fact, the electors are only registers of the already
pronounced party choice in candidates, and ac-
cept the office under a tacit pledge to act only
as such. The electoral colleges are State
bodies, and the integrity as such is scrupu-
ulously guarded. They consist of as many mem-
bers as the State's representation in both
houses of Congress; therefore a State cannot
have less than three, and New York has 45.
The method of appointment is left absolutely
to the State legislatures. Till about, 1820-24 they
were appointed direct by the legislature
in most States; in 1824 popular election had
superseded this method in all but six, and by
1828 in all but one — South Carolina, which
retained it till 1868. The district system, which
derives its electoral vote, has sometimes
been tried as a party compromise; but at
present all parties prefer having all the
State's electors on a general ticket. Each State
appoints the place of meeting of its own elec-
torial college. Congress has fixed the time
of meeting January 8 (except in 1996) and
the Monday in January — to prevent a fail-
ure of any meeting through the refusal of a
minority house of a legislature to join with
the majority house in setting a date. The
State, by act of 3 Feb. 1887, is made absolute
judge of all disputes over appointment or re-
turns; its certificate is decisive between two
sets of returns, and Congress can only inter-
vene if the State itself is unable to decide.
But what is the State? This was precisely
one of the questions before the Electoral Com-
mision (q.v.), and even the new act would
seem to leave room for party decision as
there; and no Electoral Commission would ever
be possible again. In case of vacancy in the
electoral body, by death, resignation, refusal to
serve or for any other cause, the State may pass
laws to fill it; if it has no such law, that vote
is lost, as happened in Nevada in 1864.

At the meeting of the State electoral col-
lege no organization is required; but it is cus-
momary to organize and elect a chairman.
State ballots (which remain the property
of the State) are cast for President and Vice-
President. In the first three elections, each
simply voted (as required by the Constitution)
for two persons, one a resident of a differ-
ent State (the electorship is in them, but not
the one with the highest vote became President, the next highest Vice-President. Obviously,
as soon as parties gained firm organization,
mere party loyalty would invariably produce a
tie; and in 1800 Jefferson and Burr were
also tied up (see, and in the elec-
tors gradually adopted other titles. Consult
Bryce, 'The Holy Roman Empire' (London
1892).

The constitutional provision as amended
in 1804 and in force now is as follows:

The electors shall meet in their respective
States and vote by ballot for President and
Vice President, one of whom at least shall
not be an inhabitant of the same State with
themselves; they shall name in their ballots
the person voted for as President, and in dis-
cinct ballots the person voted for as Vice
President; and they shall make distinct lists of
all persons voted for as President, and of all
persons voted for as Vice President, and of
the number of votes for each, which list shall
sign and certify, and transmit them, in
the seat of the Government of the United
States, directed to the President of the Senate;
the President of the Senate shall, in the pres-
ence of the Senate and House of Representa-
tives, open all the certificates, and the votes
shall then be counted; the person having the
largest number of votes for President shall be
President, if such number be a majority of
the whole number of electors appointed; and if
no person have such majority, then from the
persons having the highest numbers, not exceed-
ing three, on the list on the first place for
President, the House of Representatives shall
choose immediately, by ballot, the President.

*But in choosing the President, the votes
shall be taken by States, the representation
from each State having one vote; a quorum for
this purpose shall consist of a member or members
from two-thirds of the States, and a majority
of all the States shall be necessary to a choice.
And if the House of Representatives shall not
choose a President, whenever the right of
choice shall devolve upon them, on the first
day of March next following, then the Vice
President shall act as President, as in the case
of the death or constitutional disability of the
President. The person having the greatest
number of votes as Vice President shall be the
Vice President, if such number be a majority of
the whole number of electors appointed,
and if no person have a majority, then from the
two highest numbers on the list the Senate
shall choose the Vice President; a quorum for
the purpose shall consist of two-thirds of the
whole number of Senators, and a majority of
the whole number shall be necessary to a
choice. But no person constitutionally ineligible
to the office of President shall be eligible to
that of Vice President of the United States.*

After voting, they make a certificate of
the persons, offices and number of votes, and the
names of the State electors certified by the
"executive authority" of the State; seal them,
and certify each; transmit two to the president
of the Senate, one by messenger and one by
mail, and deposit the third with the Federal
judge of the district. They have then no
further functions.
On the second Wednesday in February, in the Representatives Hall and in presence of both Houses of Congress assembled, the president of the Senate opens and counts the State returns, and announces the result. In case of a tie the House decides by a majority of States, each having one vote; on a tie for Vice-President, the Senate decides in the same way. If no one candidate has a majority, the Houses decide in the same manner, choosing from the three highest candidates on the list. Thus, in 1824, John Quincy Adams was elected President by the House; in 1837 Richard M. Johnson was elected Vice-President by the Senate. But suppose the third and fourth are ties. This quite probable contingency has not been provided for, and may cause trouble. There was formerly a custom, when a State sent in conflicting electoral returns, of announcing the final result in the alternative—so many votes with, so many without, the disputed returns; but the Act of 1879 ended this, and it was always unworkable where the disputed votes were vital to the election. By the 22d Joint Rule of Congress up to 1876, in case of dispute the returns from that State were thrown out, but in anticipation of the struggle over the returning boards, the Republican Senate on 20 Jan. 1876 repealed the rule.

In order to obtain the electoral votes of a State, a party must carry the State. In other words, the electoral vote of a State is determined by the highest popular vote cast in that State. The popular vote for electors is counted, but there is no electoral vote to count unless a State is carried. Consequently, the smaller parties which have not had a large enough popular vote to carry a State have not had the State votes in the electoral college, and must therefore be counted by popular vote only, having no representation in the electoral college at all.

The electoral system, despite its wide divergence from the intent of its originators, and its undeniable undemocratic character, is never seriously menaced, because of its practical utility in settling the presidential question at once on the counting of State votes. With direct popular vote, where parties are closely balanced, the result could not be known perhaps for months.

In accordance with the Reapportionment Act of 1911 the number of electors in the several State colleges is as follows:

- Alabama ........................................ 12  
- Arkansas ........................................ 9  
- California ...................................... 13  
- Colorado ........................................ 6  
- Connecticut .................................... 3  
- Delaware ........................................ 3  
- Florida .......................................... 6  
- Georgia ......................................... 13  
- Idaho ............................................ 4  
- Illinois ......................................... 29  
- Indiana ......................................... 15  
- Iowa ............................................. 13  
- Kansas .......................................... 10  
- Kentucky ....................................... 13  
- Louisiana ....................................... 10  
- Maine ............................................ 6  
- Maryland ........................................ 8  
- Massachusetts ................................ 18  
- Michigan ........................................ 15

- Montana ......................................... 4  
- Nebraska ........................................ 8  
- Nevada .......................................... 3  
- New Hampshire .................................. 4  
- New Jersey ...................................... 10  
- New Mexico ..................................... 3  
- New York ........................................ 45  
- North Carolina ................................ 12  
- North Dakota ................................... 5  
- Ohio .............................................. 21  
- Oklahoma ....................................... 10  
- Oregon .......................................... 10  
- Pennsylvania ................................... 38  
- Rhode Island ................................... 5  
- South Carolina ................................. 10  
- South Dakota ................................... 5  
- Tennessee ....................................... 12  
- Texas ............................................. 20  
- Utah .............................................. 4  
- Vermont ......................................... 18  
- Virginia ....................................... 12  
- Washington ..................................... 7  
- West Virginia ................................... 13  
- Wisconsin ....................................... 3  

The whole number of electors in the United States, until another reapportionment is made, will remain at 531, and the majority necessary to secure an election to the presidency will be 266. See Apportionment.

**ELECTRA**, in Greek legend, the name of several personages. (1) One of the Oanfieides, wife of Atlas, and mother of Dardanus by Zeus. (2) A daughter of Atlas and Pleione, who became one of the Pleiad. (3) A daughter of Agamemnon, king of Argos, who incited her brother Orestes to avenge their father's death by killing their mother, Clytemnestra. Orestes gave her in marriage to his friend, Fylades, and she became the mother of Strophius and Medon. She is the subject of a number of dramas, both ancient and modern.

**ELECTRA**, Benito Pérez Galdós' drama 'Electra,' one of the most conspicuously successful, as well as one of the shortest-lived of modern Spanish plays, was performed for the first time in the face of violent protest at the Teatro Español, Madrid, in 1900. But it is not a dramatization with the author's customary skill, it is written in a spirit of broad tolerance, the didactic touch never being entirely absent from its pages. Yet as a thesis drama the play is unconvincing. In particular, the solution of the conflict between the scientific spirit and the Church, typified in their struggle for the soul of a young woman, is precipitated at the dénouement by means of an apparition which effects a reconciliation between the demands of science and religion through supernatural aid. Undoubtedly this evasion was not without utilitarian justification, and made the performance of the play possible. Galdós had been associated for many years with a program of social, political and literary reform, which had brought to his aid a host of admirers, among whom the great body of the more intelligent of the youth of his country was included. In 'Electra,' he turned to attack directly the forces of conservatism and reaction, and in the sharpness of the issue then joined lies the chief significance of the play. With its production the influence of the author reached its zenith, and his victory assured the succeeding generation that freedom of expression which was essential to the development of modern Spanish letters.

An English translation was published at Chicago, 1911. Authoritative criticism of Galdós may be found in Alas, L., Galdós' (Madrid 1912) also Martinez Ruiz, J. (Azorín), Lecturas españolas' (Madrid 1812).

John Garrett Underhill.

**ELECTRA**. Although Hugo von Hofmannsthal possesses no original genius, he is the most musical of poets who in recent times have contributed to the drama of the German. His power of verbal expression, rather than his dramaturgic skill or his understanding of character, entitles him to praise. A Viennese, he is an aesthetic cosmopolite. In 'Venice Preserved' he has reworked the English tragedy of Othello and in 'Electra' and 'Edipus and the Sphinx' the Greek tragedies of Sophocles, embroidering his models with fresh details and intensifying passion. His rerevision to the Greek was inspired by the presentation at the
ELECTRIC ALTERNATING CURRENT MACHINERY

Burg Theatre in Vienna of Aeschylus, translated into German by Wilamowitz-Mollendorf, and by the suggestion of the critic Paul Schlicht, that modern playwrights should render classic themes in a free fashion. 'Electra' appeared in 1903; and in 1906, in the version of which we are treating, it was played in English with Mrs. Patrick Campbell in the title role. It has also served as the libretto for an opera by Richard Strauss.

The piece is in one act and dispenses with the classic chorus, partly because this would be counter to our stage conventions, and partly because it would detract from the lyrical fervor of the individual characters. The Sophoclean story of Electra's yearning for the return of her brother Orestes to whom she may confide the task of avenging her mother's murder of her father is repeated, with the weakness of her sister Chrysothemis, the appearance of Orestes as a messenger to announce his own death, and his slaying of his mother, Clytemnestra, and her paramour, Agamemnon. Von Hofmannsthal, however, has made no effort to achieve the noble dignity of the Greek. Instead, he has sensibilized Electra, whose lust for vengeance on her guilty mother becomes hysterical and insane. Hatred, she says, has been her bridegroom; curses and despair have been her children. When Orestes finally slays his victims, Electra dances in very ecstasy of joy. As an American critic, Mr. W. P. Eaton, has remarked: 'Pity and fear are not aroused by von Hofmannsthal's play, but curiosity and horror. The emotions are not purged but scraped, irritated, made to shiver and creep.' The best account of von Hofmannsthal is Dr. August Kollmann's monograph in German (1907); he is discussed in English by Elizabeth Walter in 'Poet Lore' (1915), and by Ashley Dukes in 'Modern Dramatists' (1912).

FRANK W. CHANDLER.

ELECTRIC ALTERNATING CURRENT MACHINERY. A loop of wire revolving in a magnetic field is the simplest form of an alternating current generator. The direction of induced electromotive force in the two halves of the loop, which cut the magnetic field, in opposite directions, is such that the combined electromotive force at the terminals is double that of either revolving conductor alone. This induced electromotive force is proportional to the rate of cutting the magnetic lines, and therefore to the sine of the angle by which the plane of the coil differs from the plane midway between the poles and normal to the magnetic flux. At its zero position, or when the planes coincide, the coil is cutting no lines of force and we have sine $= 0$. The electromotive force, however, grows as we depart from this zero position, assuming uniform speed, until, when 90 degrees is reached the rate of cutting of the lines becomes a maximum, sine 90 degrees $= 1$. Passing on, the electromotive force dies away until 180 degrees is reached, when the value again is zero. From 180 to 270 degrees we have an increasing electromotive force, but of opposite polarity and at the end of the revolution, or 360 degrees, again reach zero. Thus we have in one revolution in a two-pole field two waves of pressure of the same form but of opposite sign. One is called the positive wave and one the negative. One such revolution, or one positive wave and one negative wave, constitute what is called a cycle, or period, and in technical literature is designated by the symbol $\omega$. The great majority of systems have a frequency between 60 and 25. Both of these frequencies are standard practice in this country, and the values between are chosen for special cases. Owing to the high frequency of commercial systems, alternators are built with more than one pair of poles, in order to keep the revolving speed within reasonable limits.

Average and Effective Values.—If we plot the values of the instantaneous pressures as ordinates, with time as abscissa, we have a correct representation of the generation of alternating currents, and the shape of the wave. When the total number of lines cut per revolution by a coil revolving at constant speed remains the same, the average induced electromotive force remains constant regardless of the distribution of the magnetic flux. The effective value, however—the value read by the metre and the value which corresponds in its heating effect to the direct current value—is not independent of this distribution.

The Place of Alternating Current Systems.—The direct current for the railway at 550 volts, and for the lighting and power systems of the densely populated centres of our large cities in the Edison three-wire system 110 to 220 volts, seems to have become standard practice. Nevertheless the low radius of distribution without excessive cost of copper, even in the 550-volt railway system with a grounded return, makes necessary a great multiplicity of moderate-sized or small plants, operating at low efficiency. It is here that the alternating current comes to the front. While commutators (q.v.) can be built for collecting direct current for 1,000 volts, alternators can be built for 12,000 volts and step-up transformers of high economy are quite possible at 75,000 to 100,000 volts. Remembering that the copper cost is inversely as the square of the voltage, the great possibilities of the alternating current system are at once seen.

Energy from Waterfalls.—Electric energy from waterfalls that a few years ago were merely points of scenic interest is now supplied to hundreds of cities in North America. There are numerous power plants of from 50,000 to 200,000 horse-power capacity, sending currents with voltage from 25,000 to 150,000 to distances up to 250 miles. See Hydro-Electric Development and Electric Transmission of Energy.

The Alternator.—Small alternators and those of moderate potential usually collect their current from insulated rings mounted on the shaft and connected to the ends of the armature winding. Through brushes, the current is taken to the external circuit. In some machines a rectifier is added for supplying sufficient undimensional current to produce the necessary additional field to overcome the drop due to increase of load. All commercial alternators are supplied with an exciter, or direct-current dynamo, whose function is to supply current to the field windings. The field spools are usually connected in series. The amount of current thus necessary on a full non-inductive load varies from 1 1/2 to 3 per cent of the total output of the alternator. Owing to the difficulty of collecting

large currents by means of brushes and of preserving good insulation between the rings and shaft, the diverging field type of machine is now used in almost all large installations. The field current from the exciter being supplied through cast-iron rings mounted on the shaft, or in the case of the inductor type, consisting of an annular ring surrounding the inductor or revolving element, which consists of laminated iron poles suitably spaced and keyed to the shaft. The windings being stationary, there are no moving connections, either for the field current or the main current of the machine. In either type the alternating current is taken from the terminals of the windings, usually at the bottom of the frame.

Polyphase Machines.—If two armatures, of the same number of turns each, are connected to the shaft at 90 degrees from each other, and revolved in a bi-polar field, and each terminal be joined to a collector ring, we have two separate electromotive forces differing in phase by 90 degrees or a two-phase machine. With 120 degrees phase difference and three sets of armatures we have a three-phase winding. By properly interconnecting the three circuits, we may use the three phases. The transformer is smaller and cheaper. But 25−30 motors are very satisfactory both as to low first cost, range of speed, and good starting torque (q.v.). Frequencies over 60 have been abandoned. The line drop, due to reaction, increases with the frequency: a change of frequency from 25 to 125 would, on the same line, more than double the line drop. While a rule 60 apparatus is cheaper than that for 25 yet the increase in polar speed often becomes difficult without increasing the size and number of poles to an undue power. A certain in 60 apparatus, may be sufficient to make the parallel operation of low speed direct-connected alternators quite difficult.

Self-induction.—When a current is introduced into a circuit a magnetic field is produced, surrounding the conductor, the rise of which causes a counter electromotive force. This electromotive force is called the electromotive force of self-induction. The effect of self-induction upon electric currents is directly comparable to the effect of inertia on a material body. It is that quality that tends to hinder the variation or extinction of the current in a circuit. As this effect is greatest at times of most rapid change of magnetism set up by the current, in alternating current circuits, it becomes a maximum when the inducing current is passing through zero, and, therefore, the counter electromotive force of self-induction lags 90 degrees behind the current in the circuit. It also follows the sine curve provided the current flowing is sinusoidal.

In a circuit containing several impedances in series, the joint impedance is not the sum of the individual impedances, but is obtained by taking the square root of the total added reactances squared plus the total added resistances, squared.

That is, Impedance = \[\sqrt{(R_1 + R_4 + R_3)^2 + (2\pi fL_1 + 2\pi fL_3 + 2\pi fC_1)^2}\]

The joint impedance of several impedances in parallel is found as follows. Construct a parallelogram from the reciprocals of two of the impedances, each expressed in its proper phase relation. The direction of the diagonal will give the phase of the resultant im-
ELECTRIC ALTERNATING CURRENT MACHINERY

pedance and its reciprocal amount will give the reciprocal of its length. For more than two, the method of the polygon of forces is applied. The effect of self-induction varies with the frequency of the current supplied, and as the square of the number of turns in a circuit. The self-induction in the armature of an alternator has two effects. The first is to produce a lagging current and thus lower the terminal voltage, and the second is a demagnetizing effect. The current is thrown into such a phase that it produces lines of force directly opposed to the field and thus lowers the voltage by reducing the total flux. The effect of armature reaction depends upon whether the current is leading or lagging in phase. A lagging current lowers the voltage of an alternator and a leading current raises it.

Capacity.—All insulated conductors have the quality of being able to hold, stored on their surfaces, a certain quantity of statie electricity, and are thus condensers. The charging and discharging of an alternating current circuit causes the current to flow from the generator into the line and then back into the generator again, with the frequency of the alternation in order to keep up the static potential on the line. As this charging current is greatest when the rate of change of electromotive force is greatest, a sinusoidal wave of capacity electromotive force with 90 degrees difference in phase from the machine electromotive force is produced. This leads the electromotive force by 90 degrees and is thus directly opposite to the electromotive force of self-induction. If we have a circuit in which the electromotive force of self-induction is just equal to the capacity electromotive force, and these two parts of the circuit are in series, the effect of both is neutralized and we have, as in direct currents, \( W = E \times C \).

The Transformer.—The one piece of apparatus that more than all else has made possible the electrical transmission of energy over long distances is the transformer. This is the apparatus that receives in one set of coils the dangerous potential of the line and transforms it into whatever potential is desired for lights or motors, which are supplied from an entirely separate generation. The transformer consists of a magnetic circuit of laminated iron or mild steel interlinked with two electric circuits, one, the primary, receiving electrical energy and the other, the secondary, delivering it to the consumer. The effect of the iron is to make as many as possible of the lines of force set up by the primary current cut the secondary winding and there give rise to an electromotive force of the same frequency, but different voltage.

Not only does the transformer make possible the transformation of voltages, but it also permits of changing from one system to another. Thus a single-phase primary may supply a three-wire Edison system, of course, with alternating current. A two-phase system can be changed to a three-phase or vice versa; a four-phase system may be changed to a two-phase, and many other useful combinations may be effected. The Scott connection for changing two-phase to three-phase, or the opposite, uses but two transformers. One has a ratio of, say 10 to 1, with a tap at the middle of its secondary coil. The other must then have a ratio of 10 to 866 = 10 to \( \sqrt{3} \). One terminal of the secondary of this transformer is connected to the middle of the other secondary, and the remaining free ends of both secondaries form the three terminals of a three-phase circuit. The value \( \sqrt{3} \) is the altitude of an equilateral triangle of which the base is unity, and thus we may consider the circuit to be taken from the corners of an equilateral triangle, which represent, in phase and potential difference, a true three-phase system. The current in the transformer of secondary, 866 being the resistant of one of the stator windings of the transformer, is greater than under normal two-phase connections; and, therefore, the windings must have about 15 per cent more copper. If two similar transformers are used the secondary of each has taps giving 50 per cent and 86.7 per cent of full voltage. In many large installations, notably at Niagara Falls, we find two-phase generators feeding three-phase lines through Scott connected step-up transformers. In small systems standard transformers may be used having ratios of 10 to 1 and 9 to 1 respectively, and the results will be quite satisfactory.

The Induction Motor.—Acting upon the well-known fact that a copper disc could be made to revolve by rotating a horseshoe magnet so that the lines of force cut the disc, Ferraris, Tesla, Dobrowolsky and others have developed the present type of induction motor. The credit for the first commercial application of the rotating field caused by currents of displaced phase probably belongs to Tesla. At the present day the value of these discoveries in the transmission and distribution of power can hardly be estimated. The induction motor is somewhat similar to the direct-current shunt motor. Both motors have field and armature windings. In both cases, also, the field is connected directly across the mains. In the shunt motor the armature current is supplied through brushes and a commutator to the windings, while in the induction motor the armature current is an indirect current, the field acting as the primary of a transformer of which the armature is the secondary. In both motors the efficiency is nearly constant in a wide range of armature resistance, as is also the speed regulation of the motors. The less the armature resistance the higher the efficiency and the closer the regulation of speed between no load and full load. In practice, either element may be the one to revolve. The rotation is produced by the reaction of the armature, or indirect current, on the revolving magnetic field, which results in dragging the moving element around in order to keep up with the field flux, as it passes around the face of the primary windings. This field, being the resultant of two alternating fields of different phases, rotates with the polar frequency of the supplied voltage. The secondary winding is made up of copper bars set in slots in a laminated iron core and running across the armature parallel with the axis of rotation. Two copper discs, the top of the copper disc into narrow bars constrains the current to flow into the best direction for producing torque and avoids the waste of the unconstrained Foucault currents in the Arago disc, and thus makes the motor much more
efficient. Sometimes the secondary windings are joined to heavy short-circuiting rings at both ends, resulting in the squirrel-cage type of motor; and in other cases the secondary windings are taken out through collector rings, if the secondary be the rotating element, and starting resistances are inserted in series to lessen the reaction due to excessive starting current and improve the starting torque. When up to speed these resistances are cut out and the terminals short-circuited as in the squirrel-cage type.

The Asynchronous Generator.—If the motor be driven by power from an outside source up to true synchronism, no current will flow in the secondary, and the primary current or field current will be wholly made up of the wattless exciting current, just as in a transformer at no load. The slip, or amount by which the motor operates full load, is synchronous speed, may be as little as 2 to 2 1/2 per cent of the speed of synchronism in large motors, and in small motors may be 5 per cent or more. If the motor above mentioned be forced above synchronism the motor becomes a generator. Provided the connection to the mains is left closed, and when a negative slip of the same amount as full load slip as a motor is reached, the generator will be giving out its full output at the same frequency as the exciting circuit. The possibilities of this system are interesting.

The Synchronous Motor.—The synchronous motor is merely an alternating current generator of special design. Both motors and alternators have a direct current field and an alternating current armature. The operation of a synchronous motor, when once brought up to speed and thrown into circuit, is the same as that of an alternator in parallel with one or more alternators. When the back pressure of the motor is equal and directly opposed to that of the line no current can flow. The friction, however, causes the revolving element to lag slightly behind the line pressure, and a current is driven through the motor by the generator. This current increases directly with the lag behind the central-phase position caused by increased load. A good synchronous motor, while always revolving at the same polar speed as the alternator supplying the line current, will carry a load of five or six times full load before it breaks out of step, and becomes practically a short circuit on the system. The current which passes through such a motor on short circuit, while held down by the inductance of the windings, is yet sufficient to rapidly damage the insulation if not cut off. The great advantage of the synchronous over the induction type of motor is that the power factor can be raised or lowered at will. By raising the field strength of a synchronous motor the current taken by the motor may be made leading and hence help keep up the line voltage on a heavy inductive load. This is of the greatest importance in practice. It is good practice to set the field strength for a good power factor at full load. At light loads the motor is assisting the generator to maintain the required pressure. Another advantage of the synchronous motor is that it can easily be built for very high voltage, especially the revolving field type,—a 12,000 volt motor is not at all unusual practice,—thus the use of transformers may be dispensed with.

The Rotary Converter.—The rotary converter is a specially designed direct-current generator provided, at proper points in the winding, with taps to collector rings, from which, if the machine is run as a motor from the direct-current side, an alternating current may be taken. Usually the alternating current is taken from the secondaries of suitable transformers and supplied to the rings, driving the rotary as a synchronous motor, the direct current being taken from the brushes on the armature. As the reaction of the incoming alternating current about balances that caused by the outgoing direct current, the armature reaction of such a machine is very small and the brushes can be always kept in one fixed position. If the taps from the armature are taken off at points differing 180 degrees from each other, electrically, we have a single-phase rotary. If connections are made 90 degrees apart we have a two-phase rotary, using four collector rings. Taking 120 degrees around the armature for our taps we have a three-phase rotary, using three collector rings. By adding to the number of taps and therefore to the number of rings we may have a six-phase rotary. The output of a rotary is greater than its output as a direct-current generator, chiefly on account of the absence of armature reaction and because at certain positions the current flows straight from collector ring to commutator and thus avoids the loss due to heating. The rotary converter, with its step-down transformer, is the most efficient means we now have of transforming the high tension polyphase currents of our large central stations to direct current for the Edison system, and for railway purposes. This piece of apparatus is wound either shunt or compound, in accordance with the use for which it is intended. As in the case of the synchronous motor, the rotary is a valuable help to the central station by running at a very high power factor. By overexciting the fields the current taken by the rotary becomes leading and helps to build up the current of the central station in case of a heavy load of induction motors by means of the armature reaction of the generators. Owing to very high commutator speeds at the higher frequencies, rotaries are not much used on frequencies above 60 degrees. At this frequency they operate satisfactorily. At lower frequencies, however, rotaries are at their best, and will stand enormous overloads, sudden changes in load and other disturbances, with perfect satisfaction. The voltage of the direct-current end of a rotary is that of the peak of the sine wave of the alternating pressure, and thus a voltmeter across the collector rings would read $E \sqrt{2}$ where $E$ is the direct-current electromotive force in single and two-phase rotaries. In the three-phase system the ratio between the alternating current pressure and the direct current at the commutator brushes is $\frac{\sqrt{3}}{2\sqrt{2}} \approx 0.612$. Thus in the Edison system operating at 250 volts we should have to transform down to $250 \times 0.612 = 153$ volts at the secondary of the transformers. While rotaries can be started up without field, from
the alternating current side, it is not good prac-
tice, excepting in certain special cases. Gen-
erally they are started up exactly like a shunt
motor, synchronized, and then thrown upon the
alternating current line. When a rotary is
started up from the alternating current side,
on closing the field switch it is impossible to
tell what the polarity will be. Rotaries operate
in parallel with perfect satisfaction, as a rule,
on both the alternating current and the direct
sides. The storage battery is always used in a
large rotary installation to ensure against any
possible contingencies. On compound rotaries the
equalizer must be used, just as in the case of
direct-current compound generators. See
ELECTRIC MACHINE.

A. R. CHEYNEY,
Station Superintendent Philadelphia Electrical
Company.

ELECTRIC ANNEALING, a process of
annealing by the heat generated by the passage of
an electric current through the body to be
annealed, or in which heat generated by an
electric current is used in place of ordinary
heat. The heat developed in a conductor by an
electric current is equal to the product of
square of the current by the resistance of the
conductor=C^r. An interesting experiment
showing the fusing power of the electric cur-
rent is made in the following manner: Provide a
glass or porcelain vessel containing a mixture
of sulphuric acid and water. Introduce a lead
plate electrode suitably connected with the
positive pole of a continuous-current generator.
Connect by a flexible wire the negative pole to
a stout pair of metal pliers. When, by means of
the pliers, a metal rod is immersed in the
acid solution, the liquid is seen to boil near the
rod, which is brought to a dazzling whiteness
in a few moments, and presently begins to
melt. The heating is so quickly produced that
the liquid or the body of the rod has not time
to become hot. In a short time a temperature
of 7,000° F., may be developed, and with a very
strong current a temperature of 14,000° F. has
been produced.

ELECTRIC Annunciator, a form of
annunciator used in private houses, offices
and hotels. They are used to call messengers, to
 announce that a telegram is waiting and to indicate the sound
of the alarm in connection with electric burglar-alarm apparatus, and for numerous other
purposes. In some forms of annunciator the source of the call is indicated by the movement
of a needle on the face of the case opposite a
given number; in others a shutter drops, dis-
closing the number or name of the room or
office. See ELECTRIC SIGNALING.

ELECTRIC ARC, the intensely hot bright
flame that forms where an electric current
jumps a gap between two electrodes: called
also voltaic arc. It tends to curve in an arc
following the lines of force, hence the name.
This is a source of light in an arc lamp. (See
ELECTRIC LIGHTING.) The lamp carbons,
which constitute the electrodes, are usually en-
closed to retain the carbon vapors. The car-
bons have to be set at a slight distance apart,
and as the burn between them is so rapid so
as to maintain the correct distance for permit-
ting a good arc. In burning, the carbons create
carbon vapor, which is a conductor, and the
current flows along this vapor conductor in an
arc of visible flame. If the electrodes are in-
pregnated with metallic salts and a powerful
current passed across the gap, the so-called
flaming arc results, of varying color, accord-
ing to the salts employed. Vacuum tube light-
ing is also an almost indistinguishable arc of a somewhat similar
principle. See ELECTRIC LIGHTING and ELECTRIC
FURNACES—ARC Furnace.

ELECTRIC AURA, a current or breeze
of electrified air employed as a mild stimulant
in electrifying delicate parts, as the eye.

ELECTRIC AUTOMATIC FIRE-
ALARM. See ELECTRIC SIGNALING.

ELECTRIC BALANCE, an instrument
for measuring the attractive or repulsive forces
of electrified bodies; a form of electrometer,
consisting of a graduated arc supported by a
projecting plate of brass which is attached to
a perpendicular column. A wheel, the axis of
which is supported on anti-friction rollers,
and is concentric with the central axis of the
graduated arc, carries an index. Over this wheel, in a
groove on its circumference, passes a line, to
one end of which is attached a light ball of gilt
wood, and to the other a float, which consists
of a glass tube about one-fifth of an inch in
diameter, terminating in a small bulb so
weighted that the index may point to the centre
of the graduated arc. The difference between
the weights of the float when in and out of
water is known, and the diameter of the wheel
carrying the index is such that a certain amount
of rise or fall of the float causes the index to
move over a certain number of graduations on
the arc. See ELECTROMETER.

ELECTRIC BATH, a solution in a vat or
tank containing a salt of some metal, as copper,
silver, gold, etc., and connected with the nega-
tive pole of a battery or dynamo. A current
being passed through, the metallic salt is de-
posited on the negative pole, or more strictly
speaking, on the object to be plated, connected
with the pole. The process is called electro-
deposition. (See ELECTROPLATING, ELECTRO-
CHEMISTRY.) The name electric bath is also
sometimes applied to a hot water bath through
which a weak electric current is sent, for the
 treatment of patients. Its therapeutic value
is questioned by many.

ELECTRIC BATTERIES. The electric
battery is a device by which electric energy is
derived directly from chemical action. There
are two types of electric batteries: (1) primary,
and (2) secondary. Secondary batteries are
usually called storage batteries or accumula-
tors, and are discussed in another article.

The battery unit is called a cell. The
simple primary cell, or Voltaic cell, as it is
called, from its inventor, Volta, consists of
two different metals immersed in a weak
water solution of some acid which will act
with unequal intensity upon the two metals.
The greater this inequality of action, the larger
will be the difference of electric potential be-
tween the two metals; and, as the current ex-
cited in the cell depends upon this difference
of potential, the greater will be the strength
of the current that can be secured from the
terminals of the battery cell, and the solution
is the electrolyte.

The chemistry of the primary cell is thus
ELECTRIC BATTERIES

explained: When a piece of metallic zinc is placed in sulphuric acid diluted with water, a chemical union takes place, the acid and the zinc combining to form the new substance, zinc sulphate. In order that this may be brought about a certain amount of oxygen must be obtained to complete the combination, and if the zinc can supply it, it is taken from the water lying next to the zinc, and which is thus decomposed—the hydrogen formerly in combination with the oxygen being set free in little bubbles which cling to the zinc. These bubbles eventually cover the zinc and slow down the formation of zinc sulphate until it nearly ceases. If now a strip of copper be placed in the same vessel, but not in contact with the zinc, the conditions remain as they were; but if the ends of the pieces of zinc and copper above the level of the water are leaned together so as to touch above the water, the chemical action is vigorously renewed, but the hydrogen bubbles now appear on the copper. The action of the acid upon the zinc so reduces its electric potential that when combined with the zinc in the cell the current immediately moves to restore the electric equilibrium. This being restored, the chemical action—the formation of zinc sulphate—is free to go on, and thus the cycle continues until the zinc has been entirely transformed into sulphate. And all the time the action is proceeding the electric current is continually flowing to preserve the equilibrium.

If, instead of the two metals in the cell until they touch, a metallic conductor is placed so low down in the zinc and the other end in the copper, the current will traverse the whole length of the conductor; and this conductor may be cut and a machine inserted, so that the passing current may be made to expend part of its energy in work. The current is observed to flow from the zinc anode to the copper cathode within the battery. Outside of the battery the current flows through the conductor from the copper toward the zinc. From this external movement the copper has received the title of the positive pole and the zinc of the negative pole.

The force or pressure which causes the current to flow is called the electromotive force (commonly abbreviated to E.M.F.). It should be understood that the words "current" and "electricity" are not used in the same sense as with a liquid like water. A better understanding is obtained from the illustration of a steam boiler carrying a high pressure of steam. When a valve into an empty pipe is opened, the pressure of steam in the boiler is transmitted to the further end of the pipe. In this case the steam fills the pipe carrying the pressure with it. In the case of the electric current passing along a conductor only the pressure (E.M.F.) is transmitted, there being no flow of any known material substance.

The electromotive force of a cell is dependent to a large degree upon the kind of acid used to dissolve the zinc. When the two plates are immersed in other acids than sulphuric, a considerable variation is found in the difference of electric potential with which they are able to perform work, and it is to be borne in mind that it is upon this difference that the strength of the current depends. The electric energy produced or released by a cell depends on the number of pounds of zinc and acid consumed in the formation of zinc sulphate. The zinc is the battery fuel and is oxidized just as coal is oxidized in a furnace. The sulphuric acid does not dissolve the zinc itself, but dissolves the oxide as fast as it forms, thus making the action of the cell continuous.

If a simple cell is put in circuit with a galvanometer, it is observed that the current gradually diminishes in strength, due to the film of hydrogen bubbles which adhere to the copper. This condition is called "polarization." If the bubbles are brushed away, the current resumes (nearly) its former strength; but becomes necessary then to establish some mechanical means of removing the hydrogen or to use some chemical substance in the cell which will combine with it and so remove it as fast as it forms. Mercuric chloride is sometimes used for this purpose. In the bichromate cell the oxygen of the bichromate seizes upon the hydrogen and combines with it to form water. In the Leclanché cell the depolarizer is manganese dioxide. Another method of avoiding polarization is a cell construction which admits of using two separate liquids, the metal on which the hydrogen collects being placed in a solution of some chemical which combines with the hydrogen as it forms.

Another phenomenon which affects the strength of current passing through a cell and thence through the conductor which connects the two dry poles of the battery is what is called "resistance." This is of two kinds or divisions: internal and external. The former is that within the cell itself—the metals and the liquids; the latter is the resistance to the current. If this conductor is of some substance which has a low degree of electric conductivity, like lead; or even if of high conductivity, like copper, but is very long, or of very small circumference, or both, the electric current will move along it very sluggishly, as if being held back by some obstacle—a resistance. This has the effect of slowing down the chemical action in the cell, and the result is what is termed a "weak current." With a short and comparatively large conductor of a high degree of conductivity the external resistance is reduced to a minimum. The internal resistance of a cell is increased by polarization, as already mentioned, and this is remedied by using a depolarizer. The internal resistance may also be further reduced by giving the metallic components large areas and placing them quite close together, making the travel of the current through the electrolyte as short as possible.

Primary electric batteries are classified as wet batteries and dry batteries. In the first group liquids are used as electrolytes; in the second, chemicals which retain moisture for a long time take the place of electrolytes.

WET BATTERIES.

Wet batteries are divided into one-liquid batteries and two-liquid batteries. The latter are those which contain one homogeneous electrolyte; the latter have two distinct electrolytes, and the cell is usually divided into two parts by a porous diaphragm which contains one of the metallic electrodes and one of the electrolytes.

One-Liquid Batteries.—Among the principal one-liquid batteries now in use for
economic purposes and in general laboratory work are the following:

**Smece.—** A cell consisting of a platinum plate hung between two zinc plates in an electro-deposited platinum sulphonate solution. The platinum plate is roughened by an electro-deposit of platinum, forming a surface to which hydrogen bubbles will not adhere. The platinum is often substituted by silver, which, however, is roughened by depositing a skin of platinum. A variation of this cell has a grid of carbon rods instead of the platinum plate, the surface of the rods being made hydrogen-proof by carbonizing them a little after the cell is assembled.

**Bichromate,** consisting of a zinc plate suspended between two carbon plates, which are gripped together at the top above the jar. The electrolyte used is a mixture of separately prepared solutions of sulphuric acid and of potassium bichromate. With this cell the zinc plates have to be raised out of the electrolyte when the battery is not in use, to prevent continuous chemical action, and therefore waste of energy.

**Leclanché** has a solution of sal-ammoniac (ammonium chloride) as the electrolyte, and into this dips a zinc bar in one corner of the square glass jar. The other pole is a bar of carbon within a porous jar, the space within being closely packed with a mixture of manganese dioxide and powder coke. The whole is immersed in the electrolyte. The oxygen escaping from the dioxide prevents polarization of the cell, and the porous jar prevents the oxygen from reaching the zinc, while opposition to the passage of the electric current. This cell is useful only for intermittent work, such as ringing bells and buzzers.

**Harrison.—** The negative (internal) pole or cathode is a rod of hard lead around which is compressed a jacket of lead peroxide. The other pole or anode is of zinc, cast in the form of a very thick tumbler which is supported by an amalgamated copper rod running down through it and riveted in the centre of the bottom. Around this rod the tumbler is partly filled by pouring in melted zinc amalgam. The electrolyte is dilute sulphuric acid, or a solution of potassium bisulphate, or of sodium bisulphate. This is a very powerful battery.

**Caustic Alkali or Copper Oxide Cells.—** This type of cell was introduced in 1881 by Lalande and Chaperon, France. Their cell consisted of a glass jar, in the bottom of which the oxide of copper was contained in an iron cup; the zinc plate was supported in the solution of caustic potash by a wire, from the cover of the jar. To prevent the carbonic acid gas of the air from combining with the caustic potash, the solution was covered with a layer of petroleum oil. This cell has undergone many modifications at the hands of Edison, Gordon and others.

**Edison Primary Battery.—** An oxide of copper battery. The elements employed in it are zinc and black oxide of copper. The solution is of high-grade caustic soda, in the proportion of 25 parts of caustic soda to 100 parts of water. The initial electromotive force of these cells is 96 volt; on closed circuit, 0.7 volt. Their internal resistance varies with the size of the plates from .09 ohm to .02 ohm. The capacity of these cells, as commercially constructed, ranges from 50 to 600 ampere-hours. The oxide of copper cell has the advantage that its internal resistance falls with use, inasmuch as the continued reduction of metallic oxide from the oxide of copper increases the conductivity of the plate; in practice, however, a film of metallic copper is deposited in advance on the copper oxide plate to ensure a low resistance at the start.

The containing vessel of the Edison cell is a porcelain jar having a porcelain cover, through which the connecting wires or rods of the plates enter the cell. The copper oxide plate is obtained by roasting copper turnings, which are then ground to a fine powder and mixed with 5 to 10 per cent of magnesium chloride. The oxide is then molded into plates, which are held in a copper frame in the cell, as at CC; Fig. 1; this frame being attached to the cover of the cell and forming one of the terminals, ZZ are the zinc plates, one on each side of the copper oxide plate. Batteries of the oxide of copper type are extensively employed in connection with spark coils for gas-engine work, and for numerous other purposes requiring continuous current, as these are eminently closed circuit batteries. They can also be used as open circuit batteries.

**Gordon.—** A copper oxide cell used extensively for working fire, police and railway signals, and of economical use anywhere. Although designed for closed circuit work it does well also on open circuits. The outer jar is of glass, porcelain or enameled ware, with a cover of the same materials, or of tin, or compressed fibre. A perforated cylinder of tin plate is suspended in the centre of the cell by an iron rod. This cylinder is filled with black oxide of copper. On the outer circumference of the cylinder at equal distances are inserted three L-shaped lugs of porcelain which support a heavy zinc ring, and at the same time insulate it from the tin cylinder. The electrolyte is a solution of caustic soda, and the surface of the cell is covered with a layer of heavy paraffin oil, which prevents the creeping over
of the caustic. As commonly used these cells give six months' service before renewal is necessary.

Two-Liquid Batteries.—Although the one-liquid cells have proved to be adequately non-polarizing, several forms of two-liquid cells retain a hold on the market, and for some of them there is a large demand.

A careful mixture of copper in the bottom of a jar is piled with crystals of copper sulphate, and within it stands a jar of porous earthenware in which is suspended a zinc bar. The electrolyte in the porous jar is dilute sulphuric acid, or, sometimes, zinc sulphate. The electrolyte in the outer jar is a saturated solution of copper sulphate. This is a closed-circuit battery which has been used extensively for telegraph work.

Gravity, a cell with the same components as the Daniell cell, but without the porous jar. The copper element is a spider-like form of sheet copper spreading its legs over the bottom of the jar. This copper form is covered with crystals of copper sulphate, or sometimes there is a perforated copper disc laid upon the top, and the copper sulphate is piled upon the disc. In the upper part of the jar is hung a thick seven-toed crowfoot of zinc—from which this form of cell is often called the crowfoot battery. The electrolyte is of dilute sulphuric acid. A concentrated solution of copper sulphate will soon occupy the lower part of the jar, and above it will float the lighter zinc sulphate solution—with, however, some little diffusion where the two solutions meet.

Minotto, a cell in all respects like the Gravity cell, but with a flat mat of cloth stuffed with sand or sawdust fitted snugly above the copper sulphate to keep the two solutions quite separate. This battery is much used for railway signal work, in spite of the fact that its internal resistance is very high—from four to six times that of the Gravity cell.

Fuller, the approved cell for telephone work consisting of a carbon cathode hung in a depolarizing liquid, a combination of dilute sulphuric acid and a solution of potassium bichromate. A porous inner cup or jar has suspended in it the zinc anode and a little mercury is placed in the bottom. The electrolyte in the porous cup is usually pure water; occasionally a very little sulphuric acid is added.

Grove, a cell consisting of a hollow cylinder of zinc, within which is a porous jar containing a strip of platinum. The electrolyte in the porous cup is strong nitric acid, and in the outer jar is dilute sulphuric acid. This cell is used chiefly in laboratory work.

Bunsen, a cell very similar to the Grove cell except that it has a bar of carbon in the porous jar instead of the strip of platinum.

DRY BATTERIES.

The ordinary commercial dry cell is virtually a Leclanché cell in which the electrolyte is in the form of paste instead of a liquid. It is, therefore, not accurately a dry cell but a moist cell. It is made inside of a cup or cylinder of sheet zinc which forms the anode. This zinc cylinder is lined generally with absorbent paper or layers of blotting paper which are saturated with the electrolyte, a concentrated solution of sal-ammoniac. Through the centre of the cell runs a carbon bar constituting the cathode, and around this is packed the depolarizing paste. The composition of this paste is a trade secret, each manufacturer having his own formula. It is pretty well understood that the absolutely essential ingredients and their usual proportions are as follows: manganese peroxide, 100 parts; powdered coke, 80 parts; vitrified graphite, 20 parts; sal-ammoniac, 20 parts; zinc chloride (30° Baume), 7 parts. Other ingredients which are known sometimes to enter the composition are glucose, dextrose, common salt, lime, arsenic, mercury bichloride, hydrochloric acid and plaster of Paris.

After the paste is firmly packed in nearly to the top, the lining is folded down upon it, a thin layer of sawdust is laid in, a snug collar of corrugated pulpboard is fitted, a layer of sand is spread on; and upon this is nailed in the asphalt cover or seal. Some makers of dry cells place next to the zinc, instead of the pulpboard lining, a prepared paste of flour, dextrose and gum tragacanth, with possibly other ingredients.

A strictly dry cell is made in the same way of dry materials without moisture. This cell is inert until it is wet, and provision is made for the wetting by making the carbon bar hollow and perforating its sides. The end is closed with a rubber cork. When the battery is wanted for use, the cork is removed and water poured in. These absolutely dry batteries are made particularly for shipping long distances across the ocean, as in the Egyptian and African trade.

ELECTRIC BELL, any bell made to ring by the making and breaking of an electric circuit. Common forms are horizontal and vertical. A familiar design has two electro-magnets, parallel and in series, having at their extremity a vibrating armature in close proximity pivoted between them; fixed to this armature is a clap-

Magnet Bell. Door open. Electric Door Bell.
ELECTRIC BLUE-PRINT MAKING—ELECTRIC CONDENSER

Power, and frequently a single coil of wire, wound around an iron core; a vibratory armature, pivoted at one end, is arranged to operate the clapper.

Two coils are used in the electric door-bell shown in the illustration. For a more technical description see Electric Signaling.

ELECTRIC BLUE-PRINT MAKING, a modern process of wholesale photographic printing by the aid of machinery, the electric light and the blue-print (q.v.). One of the best machines is continuous in its operation, and is fed by the operator with great lengths of tracings and blue paper in much the same manner as the washerwoman feeds the wet clothes into a wringing machine. The large wooden drum, around which the tracings and printing paper pass, is moved either by a connection with the shafting or by an electric motor mounted on the apparatus, the speed of the drum being regulated by a device shown on top of the machine. A traveling apron of transparent material takes the place of the glass in the printing frame of the ordinary type, and as it is under tension at all times, it ensures an even and close contact at all points. This apron is a small drum at the top and after passing along the large drum where the contact and exposure take place, it is wound up on the drum below; after the printing operation has been completed it is rewound by hand back on the upper drum. In the rear of the machine are three arc lamps with reflectors, which concentrate the light on the tracings which, with the exposed prints, drop out into the box in front. The blue paper may be kept in a roll ready for use on the upper front part of the machine, or may be fed in small sheets with the tracings where the work being done is of ordinary size.

The machines are made in two widths, 30 and 42 inches; the apron supplied with them is 70 feet long, and prints of this size can be made as regular as smaller ones where it is desired. The ability to make prints of this size greatly enlarges the sphere of usefulness of the blue-print.

ELECTRIC BREEZE, a breeze or stream of particles of air repelled from an electrified point.

ELECTRIC BURGLAR-ALARM. See ELECTRIC SIGNALING.

ELECTRIC CABLE. See ELECTRIC UNDERGROUND CABLES AND CONDUITS.

ELECTRIC CALL-BOX SYSTEM. See ELECTRIC SIGNALING.

ELECTRIC CANDLE, a modification of the arc form of electric light, in which the carbon pencils are parallel and separated by a layer of plaster of Paris. It was invented in 1877 by Jablchowski, a Russian engineer. This invention is noteworthy as having revived interest in electric illumination. See ELECTRIC LIGHTING.

ELECTRIC CLOCKS. See CLOCK.

ELECTRIC CONDENSER, a construction for accumulating electricity, through the effect of mutual induction between conducting plates, as of tinfoil, separated by a dielectric, as of oiled paper; or some similar device as a Leyden jar. When an insulated conductor is charged with electricity by friction, a battery or other source of electromotive force, it will excite or " induce" in any neighboring conductor a charge of electricity. If the electricity in the first body be " positive," that induced in the neighboring body will be " negative." Thus, in Fig. 1, in which A and B are metal plates separated by air, glass, mica, or other insulating material, if A be charged by the positive pole of battery B it will induce a charge of negative electricity on the plate B. Such an arrangement of plates is termed an electric " condenser," and in various forms it is one of the most useful instruments employed in multiplex, printing, automatic, wireless and other systems of telegraphy. It is also indispensable in telephony and has found a field in electric light and power circuits. The electricity held or " stored" in the plates is termed static electricity. The quantity of electricity or " charge" accumulated at the plates is equal to the product of the electromotive force of the charging source by the " capacity" of the condenser. In fact, however, what the condenser holds is electrical energy, which, when discharged, is given up as work and heat. The total amount of energy (expressed in foot pounds) thus stored up by the condenser is

\[
(K \times E^2) + 2.712, \quad \text{where } K \text{ is the capacity of the charged condenser in farads, and } E \text{ is the charged electromotive force in volts. It can be shown that the charge of a condenser rests on opposite sides of the dielectric, and that in charging the condenser as much electricity leaves plate B as enters plate A. The capacity of a condenser varies with the distance between its opposite plates, being greater the nearer they are together, and increases with the surface of the plates. The capacity also varies with the insulating material or dielectric used to separate or insulate the plates. The property of dielectrics to which this so-called inductive effect is due is termed specific inductive capacity. The property which this inductive capacity seemingly imparts to conductors is termed electrostatic capacity, or " capacity." The inductive capacity of air is taken as the standard. Air being unity, the specific inductive capacity of paraffin is about 2; vulcanized India-rubber, 2.94; gutta-percha, 4.5; mica, 5; flint glass, 6.5 to 10. The Leyden jar is a well-known type of condenser. The most common form of condenser is generally constructed of many sheets of tinfoil, separated by thin sheets of insulating material, such as paraffin paper, mica or glass; the alternate sheets of tinfoil are connected together metallically at their ends as indicated in Fig. 2.

In making a condenser for radiography, the glass plate type is recommended as inexpensive and durable, and also much lighter than oil-
immersed types. Photographer's negative glass, tinfoil and shellac are the materials. The foil should be cut to the required size (6 X 8 inches is convenient), and carefully smoothed to take out all wrinkles. The glass should be cleaned with alcohol and coated with shellac, then covered with the foil, and rolled or "squeegeed" so as to be perfectly smooth. In assembling the plates large enough to replace between them. A unit may be made of 10 plates which are bound together with wire or suitable tape, and immersed for one hour in a bath of equal parts of hot melted rosin and beeswax, then allowed to drain and dry. This gives a condenser unit thoroughly moisture proof, with a capacity of .01 microfarad, which is suitable for the ordinary half-kilowatt wireless transformer for the standard 200-metre wave-length.

ELECTRIC CONDUCTIVITY, the property that a substance, as a metal, possesses of conducting an electric current, that is of permitting a current to flow more or less readily: called also conductance. It is the opposite of electric resistance. All the metals possess some degree of conductivity and some degree of resistance, iron being conspicuous in presenting an almost equal degree of these opposite qualities. It will be seen by the following table of comparisons that silver is the best and mercury the poorest conductor.

ELECTRIC DIRECT CURRENT, as distinguished from the alternating current, is so-called because of the fact that it travels in one direction along a conductor. If this current passes through the terminals of a source of energy, as a dynamo, the current is said to flow from the positive pole of the machine along the conductor to the negative pole.

Probably the first man to detect current electricity was Galvani about the year 1786. To Volta (q.v.), however, is certainly due the credit of first developing a practical electrochemical cell. In the year 1800 Volta exhibited a cell known as the "Voltaic Pile," consisting of a series of discs, copper and zinc, alternately separated from each other by a cloth saturated with brine; on joining wires to the end discs, quite a perceptible shock may be felt by touching with the tongue or moistened finger the two terminals simultaneously. This simple device was the starting point of all the electrochemical batteries of to-day. It necessitates a large number of cells, connected in series; that is, the positive terminal of one connected with the negative terminal of the adjoining cell, the electromotive force thus produced being the product of the electromotive force of one cell by the number of cells. By connecting the two negative terminals of two rows of cells, an increased quantity of current can be obtained, at the potential of one row. The first method is called joining battery cells for intensity, and the second for quantity. It is known that the energy generated in a chemical cell is produced by the consumption of zinc. The cost of this energy must necessarily be high, as both the zinc and the chemicals are expensive, so that the use of current electricity was quite limited until the invention of the dynamo and electric machine, which might be called the mechanical method of transforming energy from some source, such as a steam-engine, into current electricity, as contrasted with the chemical method.

In the year 1831 Faraday discovered and announced the principle of electro-magnetic induction. This opened up the field of what might be called the commercial generation of current electricity. The principle discovered by Faraday, which forms the basis of all electro-magnetic machines, is that if a wire is moved in a magnetic field, so as to cut the lines of force, a current will be generated in the wire, and it is upon this principle that all dynamo electric machines depend for their action. The converse of this law he also announced, namely, that when an electric current is applied to the dynamo by some external source such as a battery or another dynamo, the machine will furnish mechanical power. Hence a dynamo electric machine may be considered either as a generator or as a motor.

All dynamos consist of two essential parts, one, the field magnet, which is usually stationary, and the other, the armature on which the copper conductors are mounted and which revolves on a shaft between the poles of the field magnet. This armature is so arranged as to cut the lines of force flowing between the magnetic poles. The lines of force are imaginary lines flowing from the north pole to the south pole of any magnet. They can easily be traced by placing a piece of paper above the magnet and sprinkling on this paper iron filings.
If the paper be covered with mucilage the fillings will maintain a permanent position so that they may be studied at the leisure of the student.

The field magnets may be made of steel, magnetized, or preferably they may be electromagnets made of soft iron over which a coil of wire is wound carrying a current of electricity which induces magnetic lines in the iron. It is to be noted that if the ends of the magnet are bent in the form of a horse-shoe, the lines will be intensified by the reduction of the air space between the poles, and as the amount of current induced in the wire depends on the number of lines of force cut, the current induced will be greater, the greater the strength of the field magnets.

Considering first the ideal simple dynamo:
This would consist of a single loop of wire mounted on centres, and rotating between the poles of a magnet, placed horizontally, each end of the loop being connected to a collector which in direct current machines is called a commutator, and the shaft with the poles outside of the poles, and insulated therefrom. If the loop is placed at right angles to lines of magnet force, in a vertical position and revolved through 180 degrees, each side will pass through the whole number of lines of force flowing between the poles which will induce a current in one direction in the loop. If the rotation is maintained in the same direction during the next 180 degrees, the loop will cut the lines of force in the opposite direction, that is, the lines of force will be passing through it in the opposite direction to that in the first case. This will induce a current which will be in the same direction from the current induced through the first half of the revolution; so that the current will be pulsating first in one direction and then in the other, during each revolution. If the collector or commutator be cut into two halves parallel with the shaft and the ends of the loop be connected one to each half, and if a pair of brushes be supplied to connect the current, one above and one below the commutator, then when the loop is in horizontal position between the poles the brushes will change contact from one end of the loop to the other, and no current is then being generated, the change is made without sparking and current flowing in the same direction continuously can be obtained from the brush terminals. During the moment of changing from one contact to the other, the circuit is momentarily opened or interrupted. This would cause sparking at the brush or collector, were it not that the brushes are placed at a point at which the current is practically zero. This is found in practice to be slightly in advance of the theoretical neutral point on account of lines of force being dragged in the direction of rotation by the conductors.

To advance from the ideal simple dynamo: — the next step is to increase the current in the poles of the field magnet and concentrate the lines of force in the effective space. This is accomplished by placing an iron core on the armature which in the first place reduces the magnetic resistance of the air gap and thus increases the number of lines of force through the armature conductors, and also serves as a support for them. Other machines were built with shuttle wound armatures, the armature consisting of an iron shuttle cut out with grooves longitudinally to take the conductors. These were usually wound with a number of turns of copper wire, the ends being brought out to a two-part commutator. (See ELECTRIC ARMATING MACHINERY.) The next step was to add to the number of coils on the armature so that during each portion of a revolution some part of the armature conductors would be doing maximum work. Should an additional coil be added to the ideal generator, at right angles to the first coil, the capacity of the machine will be doubled. This complicates, to some extent, the collector rings and may necessitate the opening of the circuit when current is flowing so as to cause sparking and burning of the brush. A machine built on these lines would, therefore, be better adapted for generating small currents as the sparking at the brushes would be otherwise very destructive to the commutator. Machines of this type are known as open coil.

The next important step was made by Gramme and Babcock. The magnets were made to close the coils with themselves so as to form a continuous circuit in the armature and connect one collector section to each coil at its junction with the next one, the number of sections being the same as the number of coils. In the four-coil armature, the current generated will either pass to the collecting brush directly, or when it moves out of position so that the contact is broken and made with the next section, the current can flow through the armature coils to the same brush, and when that coil passes from one polar position to another and is giving current of opposite polarity this current can flow directly to the other brush, and so continuous current is generated. There is also no point at which the circuit is open. There may be a slight sparking as the section moves from the brushes, but violent sparking is reduced as there is always another path for the current to flow to either brush.

The drum armature is distinct from the ring armature in that the wires are wound on the outside of the core and do not pass through it. This type is frequently called the Siemens armature on account of the number of successful machines built by Siemens. Of the whole number of lines of force passing between the poles and through the core, there are very few lines passing in the inside, they being diverted by an iron core so that they pass through the wires on the outside of the core; the conductors inside of the core are thus of little use, their only function being to complete the circuit and carry current between the successive turns on the outside of the core; so that by winding the wires on the outside surface only, the amount of idle wire is reduced, the only material that is not active being the cross-connecting pieces at the ends.

The Gramme ring was used very largely on early machines for the reason that it afforded means for easier mechanical construction, and machines of this type were generally successful, on account of their simplicity. Pacinotti designed a core having teeth similar to a gear wheel. In number of lines of force through the armature and pole pieces could be reduced somewhat, resulting in an increased number of lines of force. It also afforded an additional
ELECTRIC DIRECT CURRENT

support to the coils and added to the mechanical strength of the machine.

To be considered next are the field magnets:

There are a number of constructions which may be employed. (1) The so-called permanent steel magnet which consists of a bar or bars of steel bent to the shape desired, tempered and magnetized in a magnetizing coil, which can be varied by means of the magnetic poles of these magnets consisted of placing them in contact with other magnets or with an electro-magnet.

The present method would be to insert the steel bar into a Helix carrying a heavy current and in a short time the bar would be magnetized. The dynamos built with permanent steel magnets of this type are what is known as magneto dynamos. The chief objection to this form of magnet is that a steel magnet cannot be made as powerful as an iron magnet which is energized or, as it is commonly called, excited from a source of electricity. In the first generators permanent magnets were used, but a great step in advance in dynamo design was to arrange the magnet poles so as to be self-excited. A portion of the current generated in the armature was fed back to the electromagnets in series with the field coils, and so excited the magnets so as to excite them. At first, however, magnets were substituted consisting of soft iron upon which was wound a coil of copper wire, the current for energizing these pole pieces being first supplied from a small magneto generator or a storage battery.

Sometimes the machine will not generate starting up not having sufficient current to excite the magnets and it is necessary to excite them from some external source so as to give the initial strength to the magnets and allow them to build up from the current generated in the armature. It is usually found that there is sufficient residual magnetism left in the iron of the field magnets, after the machine has once been in operation, to start the current in the machine and properly build up the fields.

In regard to field windings, two distinct types are used: (1) the series winding, in which all the current generated in the armature passes around the field poles and thence out to the line or open circuit; and (2) the shunt winding in which a portion only of the current is used in the field, the connection being made across the main terminals of the generator. In the first case the wire on the field windings is necessarily large so as to carry all the current for which the machine is designed and in the second case it is a small wire of many turns, the product of amperes and turns being about the same in either case. In another design, both a shunt and a series winding of a few turns is employed, constituting a compound winding.

It will be seen that in the first case, that of the series winding, the field strength will depend upon the resistance of the total circuit, including the resistance of the armature, the field winding and the external circuit. In a machine with a shunt winding in the armature pressure of the armature the current generated will vary in proportion to the demands. This is the standard winding for the series are machines used for city lighting, such as the Brush and Wood types. In the case of the shunt wound machine the current flowing in the field coil depends upon the pressure between the generator terminals, so that with an increased output and consequent loss in the armature the voltage will fall off slightly, thus reducing the field strength. This necessitates some means of varying the field current so as to maintain a uniform pressure at the generator terminals. This is usually accomplished by means of an external resistance in the field circuit composed of German-silver or iron wire, which can be varied by means of a babbitt core and so arranged as to cut out certain portions of this resistance step-by-step and so increase the current through the fields, thus preserving a uniform voltage.

In a combination of series and shunt windings commonly called the compound type, as the output of the generator is increased, there is a greater flow of current through the series windings and consequent increase of magnetic strength of field so that it is possible to compensate for the loss due to the resistance of the armature windings and maintain a uniform voltage at the generator terminals. The voltage as well as the output of the dynamo depends upon the strength of the field magnets, the magnetic permeability of the material and the rate at which the lines of force pass through the armature conductors, so that the higher the speed the greater the voltage output of the dynamo. In the early machines very high speeds were common, armatures of small diameters being employed. These were objectionable for mechanical reasons so that the design was changed in order to increase the number of pole pieces. Instead of the field being composed of two poles, it was arranged so that a greater number of poles could be used, this type of machine being known as the multipolar dynamo. Each conductor would pass between a number of poles during each revolution so that the speed could be proportionally reduced.

The dynamo, as previously stated, is a machine for converting energy in the form of mechanical power into electrical power, or vice versa, so that a motor is a machine for converting energy in the form of electricity into mechanical power. The early types of motors were based on the principle that a magnet would attract the opposite pole of another magnet, and the other stationary, the movable magnets will be drawn around. To make this effective it will be necessary to interrupt the forces at what might be called the dead centres so that the wheel would have continuous motion. This is accomplished by either introducing a screen, or, more satisfactorily, by the use of electro-magnets with a movable contact so that the magnets are energized intermittently, allowing the wheel to revolve in accordance with impulses received from the magnetic poles.

When we consider the dynamo as a motor, the current supplied to the terminals may take two paths, one through the armature and the other through the field coils. The field current energizes the pole pieces, and the current traveling in the armature pressure of the armature the current generated will vary in proportion to the demands. This is the standard winding for the series are machines used for city lighting, such as the Brush and Wood types. In the case of the shunt wound machine the current flowing in the field coil depends upon the pressure between the generator terminals, so that with an increased output and consequent loss in the armature the voltage will fall off slightly, thus reducing the field strength. This necessitates some means of varying the field current so as to maintain a uniform pressure at the generator terminals. This is usually accomplished by means of an external resistance in the field circuit composed of German-silver or iron wire, which can be varied by means of a babbitt core and so arranged as to cut out certain portions of this resistance step-by-step and so increase the current through the fields, thus preserving a uniform voltage.

In a combination of series and shunt windings commonly called the compound type, as the output of the generator is increased, there is a greater flow of current through the series windings and consequent increase of magnetic strength of field so that it is possible to compensate for the loss due to the resistance of the armature windings and maintain a uniform voltage at the generator terminals. The dynamo, as previously stated, is a machine for converting energy in the form of mechanical power into electrical power, or vice versa, so that a motor is a machine for converting energy in the form of electricity into mechanical power. The early types of motors were based on the principle that a magnet would attract the opposite pole of another magnet, and the other stationary, the movable magnets will be drawn around. To make this effective it will be necessary to interrupt the forces at what might be called the dead centres so that the wheel would have continuous motion. This is accomplished by either introducing a screen, or, more satisfactorily, by the use of electro-magnets with a movable contact so that the magnets are energized intermittently, allowing the wheel to revolve in accordance with impulses received from the magnetic poles.
similar to the armature in action as a dynamo, and an electromotive force will be generated in the armature wires, which will be in the opposite direction to the incoming current. This is what is called the counter electromotive force of the motor, and will tend to reduce the amount of current which will flow through the armature conductors. It is, therefore, evident that when a motor is started there will be a rush of current through the armature, as the resistance is very small, and as there is no counter electromotive force while the machine is not in motion to check the flow. For this reason, in the direct current motor it is necessary to introduce an external resistance into the armature circuit to hold back the current which would flow until the machine approaches full speed. The resistance is then gradually reduced until full speed is obtained. The effect of this counter electromotive force when the resistance is cut out entirely is materially to assist the self-regulating qualities of the machine. Any load applied to the motor would tend slightly to reduce the speed, which effect, by also reducing the counter electromotive force and allowing more current to flow through the armature, tends to keep the speed from falling much below its rated speed.

Motors can be built either with a plain shunt field winding or with a series and shunt winding, depending on their requirements. The direction of rotation depends on the direction of the current through the armature. To reverse the rotation, therefore, it is only necessary to reverse the current in the armature, leaving field connections as they are. If the current is changed in both field and armature, the result would naturally be that the machine will continue to revolve in the same direction as before.

To reduce the speed of the direct current motor it is only necessary to add resistance to the armature circuit so as to limit the current flowing therein, and by so doing almost any desired speed may be obtained. If run 1 per cent. of full load, the machine will work up to full rate of speed. There are a number of other methods by which variable speeds can be obtained, one of them being by varying the field strength. Any motor, however, operating at a lower field or armature current than normal conditions would require is naturally operating at reduced power. On account of the valuable features in relation to speed control, reversibility and the automatic speed control inherent in the shunt machine, together with the large torque of the series machine, the direct current motor fulfills more nearly than any other the practical requirements in machine-shops, textile mills and general manufacturing establishments.

For electric railway work, in which the direct current is employed (see TRACTION, ELECTRIC), the compound wound generator and series motor is the usual standard practice. Often this type of generator is over-compounded so as to more than overcome the drop through the armature resistance and allow higher voltage at full load than at no load, so as to come, in a way, the drop of potential on the feeders and preserve the uniform voltage over the system. In lighting and power work the shunt and compound dynamos are both used. (See ELECTRIC LIGHTING). And in the business centres of our large cities where the direct current is generally used, the rotary converter fed from a high tension alternating central station is very often employed, together with storage batteries.

Direct current was more generally used in the earlier installations of electric distribution, in preference to alternating current, for the reason that the direct current motor was developed before the alternating current motor; and the earlier motors possessed any advantages in their ability to be operated at any speed from slow speeds up to the maximum speed for which the motor was designed, and also permitted the use of storage batteries directly connected to the system, thus ensuring continuity and reliability of service.

The shunt and series motor each has its own field of usefulness. When a very powerful starting torque and rapid acceleration are necessary the series motor is used, as in the case of street railway, electric locomotives, electric cranes; and on steamships where the direct current alone is used, as on the Kentucky and Kearsarge, of the United States navy, not only is electricity used for lighting, but also for operating ammunition hoists, hoisting anchors, operating boat cranes, and even the steering gear of the ship itself.

In machine-shops and manufacturing establishments where a more or less constant speed may be required, and in elevator work, the compound and series motors are commonly employed. The shunt motor is very well adapted for operating at any speed desired, and for machine tools it is at present without a peer for an efficient and easily regulated source of power. Unlike the series motor, where the speed varies with the load, the shunt motor is practically a constant speed machine. When thrown on the lines it rapidly comes up to normal speed, and then from no load to full load will not greatly deviate therefrom if purposely thrown to a lower point by the controller. As a series motor would run at 1 per cent. of full load suddenly removed, the shunt motor, or sometimes the compound (which is used in order to preserve an absolutely uniform speed from no load to full load, and is necessary in a few places where absolutely constant speed is required) is the standard motor for driving textile machinery in large mills, factories and other establishments.

Direct current generally meets all of the requirements of the consumers, as it is available for motors of any size; for lighting; for chemical action, such as charging storage batteries or in electro-plating; or for electric heating.

With the large increase in the requirements of individual consumers, the advantages of direct current over alternating current are not as important to-day, for the reason that translating devices have been simplified so that alternating current may be converted, without serious difficulty, into direct current, for any special requirements.

ELECTRIC DISCHARGE, the escape of electricity, whether slowly and silently, or more quickly and violently, from any receptacle or generator.
ELECTRIC DOOR-BELLS — ELECTRIC FARMING

ELECTRIC DOOR-BELLS. See Electric Bells; Electric Signaling.

ELECTRIC DRILL, a drill for metals or rock worked by an electromagnetic motor. For metals a rotary motion, for rocks a reciprocating or percussive action, is imparted.

ELECTRIC EEL (Electrophorus electricus), a great eel inhabiting the marshy waters of the llanos in South America. It belongs to the family Gymnotidae and order Plectosentidae (q.v.), and with a few allied species is distinguished from all other eels by the partial coalescence and modification of the several pairs of longitudinal bodies between the skin and the muscles of the caudal region, divided into about 240 cells and supplied by more than 200 nerves. The eel can discharge sufficient electricity to kill an animal of considerable size, and is said to possess power, when in full vigor, to knock down a man and bend the limb affected, in the most painful manner, for several hours after communicating the shock. By frequent use of this faculty it becomes impaired, and a considerable interval of rest is required to recrust its electrical properties. According to Humboldt the natives of South America make use of horses in taking the electric eel. The animals are driven into a stream or pond where the fishes abound, and the latter, having exhausted their stores of electricity by repeated attacks upon them, are then easily taken. The horses are sometimes so severely stunned by the shocks that they fall and are drowned. Specimens of the Electrophorus electricus are reported to attains for the length of six or seven feet, but ordinarily they are about three and one-half or four feet long. See Electric Fishes.

ELECTRIC EGG, an ellipsoidal glass vessel, with metallic caps at each end, which may be filled with a liquid, by means of which an electric machine acting on it after a vacuum has been made inside the glass.

ELECTRIC ELEVATORS. See Elevators.

ELECTRIC ESCAPEMENT, a device actuated by electric impulse which intermittently arrests the motion of the escape-wheel and restores the train to a pulsative motion — acting, in fact, in the place of a pendulum.

ELECTRIC FARMING. The greatest agent for the advancement of agriculture is electricity. It is the emancipator of the toiler. A motor of even diminutive dimensions accomplishes more work than a man — at less expense — since the power developed by the human machine is the most expensive that man uses. In supplanting manual labor, electricity has a most appreciable effect upon agriculture, due to the fact that agriculture requires great labor with a minimum of skill. In reducing manual labor by the use of electricity the farm operatives, with the exercise of but little mechanical knowledge, may direct the operations of numerous large electrical units and accomplish an aggregate of work that would be absolutely impracticable under ordinary conditions.

In the installation of electricity on the farm, it is necessary, however, that the farmer — user of many and infinitely varied implements and mechanical devices — should avail himself of the co-operation of the engineer; taking advantage of the skill and experience of the latter in adapting the new method to his needs, in order to increase the production of his land. Rural industry in general must look to the engineering profession more and more for the most available utilization of our natural resources through the medium of electrical energy. Industrially considered, the farm is a large user of power, but the sources from which it is derived are at present uneconomic and inadequate in comparison with industrial standards in other lines. Of the 33,000,000 persons engaged in gainful occupations in the United States, not less than 10,000,000 devote their energies to agriculture. In addition, upward of 39 per cent of all the horses and mules in this country are devoted to farm labor. The substitution of electric power, therefore, for even a small proportion of the work now done by farm animals will result in great national economy.

There is no form of service that can supplement manual and animal labor on the farm or country estate as expeditiously from every standpoint, considering expense and convenience, as electricity, and it will be found superior to steam or to any internal combustion engine. In fact, there is no other existing agent that is able to supply the three necessities — light, heat and power — from one and the same source. Due to this fact, hours of labor on the farm or in rural communities may be regulated, as are those of the manufacturing and commercial industries. In consequence, life in rural communities may be made attractive, as much or more so than that of the cities, where the struggle for existence is incessant, and living accommodations — or what corresponds to home life — fall short of the pleasant and healthful surroundings of the countryside.

The giant industries of the country are of recent origin and were started in a humble way, but they now surpass any branch of the agrarian pursuits. This is a condition readily explained, due to the employment of the services of the trained engineer to the advantageous upbuilding of the great manufacturing industries. On the other hand, farming — the oldest of all industries, and the most basic — has been neglected, even to the point of being abandoned in many places.

The machines and implements used on a farm are manifold — ploughs, rollers, reapers, threshers, corn shellers and grinders, shredders, fodder cutters, wood saws, pumps, horse and sheep clippers, and apparatus for unloading and hoisting hay, corn fodder and like products. Another phase of farm life in which a great saving of labor is effected by the use of electricity is in the operation of washing machinery, carpet cleaners, sewing machines, fans, cooking and laundry appliances, none of which could well be served by any other agent than electricity. Besides the preceding partial enumeration of the possible applications of electricity, for power, the electric energy — supplied to its motors either from an outside source or from its own central plant — may be used for light and heat.

Where connection cannot be made with a local electric distributing concern, the farmer should have his own generating station, which
may be operated by water, steam, gas, gasoline, oil or windmill power. Where a stream runs through a farm, or is in the neighborhood, cheap power, both as regards first cost and operating expenses, may be derived from this natural source.

In generating the current by steam power, the cost per kilowatt hour is comparatively high. Somewhat better results may be obtained with a gas-producer plant, which, instead of burning the coal in a steam boiler and using the steam for driving the engine, burns the coal gradually in a producer, generating gas for operating the gas engine.

Gasoline, oil and alcohol engines work on the same principle as the gas engine, as all are of the internal combustion type. Great strides have been made during the past decade in this type of engine, so that it operates with an economy and a precision that requires but little attention.

Another source of energy for the generation of electric current for farm and country residences is the windmill. The early Dutch windmills were built with sweeps of from 50 to 100 feet in diameter, while our modern American windmill has a sweep of only from 12 to 18 feet, but generate more power than the earlier type, with less attention.

All of the above primary powers may be connected to the electric generators by belt, gearing or couplings, and their control may be regulated automatically, so that they require but little attention. There are, of course, certain matters in their operation that experience has shown to be of advantage. For instance, the greatest quantity of energy being required for the daytime, and the load for illumination being small, and wanted principally in the evening, it is therefore not profitable to operate the prime movers other than during the day. The use of the storage battery is therefore of great service in supplying electric energy at periods of small demand, when the generators are shut down. In connection with the storage battery, and with the development of the low-voltage Tungsten lamps, the cost and size, as well as the maintenance expense, may be considerably reduced by the use of storage energy.

The great advantage, in which lies the superiority of a farm operated by electricity, is in the fact that the farmer has at all times under his direct control the entire supply of electric energy available, whether obtained from a public service enterprise or supplied by his individual plant.

Electric farming, while in general use in Germany for the past 20 years, has recently made rapid strides in the United States, particularly in the West and on the Pacific Coast, where central station enterprises encourage the use of electricity for agricultural purposes. There are, however, to be found in the State of New York several notable water-power installations on farms. For instance, there is a 10-foot falls on a stream in Oneida County, N. Y., devoted to hop raising, mixed farming and dairying, on which has been installed a 17-horse-power hydro-electric plant, supplying electricity for lighting the farm buildings and for operating the hop picking motors. The power-dam, of timber-crib construction, is 36 feet long, raising the water four feet, is carried on heavy concrete sills cast in a 2x1.5-foot ditch dug across the stream bed. A row of 12-inch flash-boards held erect by chains positioned by pins removable by a capstan, dropping the boards in case of high water, is above the crest of the dam. There is also provided a supplementary 40-foot spillway, its crest being slightly higher than the main dam, permitting the discharge during heavy floods. A 60-foot canal and forebay lead from the dam downstream to the power-house, where a 17-horse-power turbine wheel has been installed. The latter, by means of belt drive, operates a 12.5 kilowatt generator at 1,100 revolutions per minute. The power-house is 12x16 feet in size.

The drainage area of Otiskany Creek at the point utilized by this plant is 14 square miles, ensuring a supply of water the year round sufficient to drive the plant at full load under the available head of six feet. The distance from the power plant to the farm buildings is 1,700 feet, the current being carried on an aluminum wire stretched on 20-foot poles, 100 feet apart. From the power generated, practically every bit of machinery on the farm is operated, comprising a circular saw, machine lathe and drill press, vacuum cleaning system, adapted likewise for the operation of a dust-extractor, a 10-horse power 25-stall cow house, a cream separator, churn, grindstone, ventilating and cooling fans, electric iron, sewing machine and pump. In addition, besides lighting the premises, five electric heaters are operated, maintaining a constant temperature of 75° throughout the winter. Engineering estimates place the cost of the entire equipment at about $1,800 - dam, power-house, line and equipment - but in its efficiency it is worth many times this sum.

A system that has been adopted much abroad is the installation of a rural central station capable of supplying a number of farms, local industries and country estates with electric current. This may be supplied with power generated by steam, water, gasoline, oil or gas, the co-operative feature resulting in a great saving in the production of electric energy. An example of the service supplied by a single central station in supplying a farming community may be seen in that of Lottin, Germany. Here a central station operates under a 180 horse power of water, however, during certain seasons of the year, when the water is low, a steam generating set of 180 horse power is put into use to keep up the service. It is obvious that this supplemental power may be integrated into use at any time, should the demand for power exceed the capacity of the hydro-electric station.

The distributing system of the Lottin station is 82 miles long. The electric energy is used on 61 farms, including rural industries, and five villages, a total of 24,700 acres. Altogether, 102 consumers are served, these having some 150 motors with a total of 1,500 horse power, the lighting equipment comprising 4,850 incandescent and 20 arc lamps. In one year the consumption amounted to 440,000 kilowatt hours. There are 50 farms with an acreage varying from 60 to 1,800 acres per farm, under cultivation by the plough, with a total of 275 horse power in motors, 1,200 incandescent lamps and 20 arc lamps. Of these farms, 12 contain from 300 to 600 acres, operating 12 motors with a capacity of 122 horse power.

In order to give in concrete form the amount of electric energy necessary on a farm, the fol-
ELECTRIC FARMING

1. Portable Motor Driving Corn Sheller
2. Milking Machines Operated by Motor-driven Vacuum Pump
lowing figures from a 100-acre farm are given. It is assumed that two-thirds of the products are of a stall nature, and that the live stock consists of 3 horses, 10 cows, 15 swine, etc. The figures are an average, taken from the actual experience of a number of farms. It is also assumed that electric energy for power purposes is 5 cents per kilowatt hour, which is a reasonable figure for current used for power purposes only, when purchased from a public service corporation.

The average amount of water consumed on a 100-acre farm is as follows: for the house, for each person per day, 5 to 6 gallons; for cattle, from 12 to 15 gallons per head; for swine and sheep, 1 to 2½ gallons. For pumping 1,000 gallons to a tank elevated 35 feet, the power necessary is about one-eighth kilowatt hour, so that the yearly average energy for 3 horses, 10 head of cattle and 15 swine is about $4.

For a threshing machine of the smaller size, capable in 10 hours of threshing, cleaning and sacking, ready for the market, 80 to 200 bushels, 3 to 5 electric horse power are required. For machines of from 160 to 240 bushels capacity, 5 to 8 horse power are necessary; and from 300 to 800 bushels, from 10 to 20 horse power are required. The energy required for the various products to be threshed and cleaned, per 100 bushels, is, for rye, 25; wheat, 22; oats, 19; and barley, 21 kilowatt hours, or on the average, 22 kilowatt hours, costing $1, which is at the rate of $0.011 per bushel. If hay-baling machines are attached to the threshers, from four to six additional horse power are required.

Fodder cutters, varying from one to two horse power, consume 1.8 kilowatt hours per 100 pounds of fodder, costing 1/16 cent a cut, and as 10 head of cattle consume per year 60,000 pounds of cut beets, etc., the total cost annually for the energy used to operate the fodder machines is 50 cents per head.

One of the by-products of cotton-seed or linseed-oil mills is sold as meal or as cake, and to break it up a special machine is necessary. Such a machine often has a capacity of from 2,000 to 3,000 pounds per hour. The average amount of meal consumed as from one to three pounds per day, which amounts, for 10 head, to about 9,000 pounds per year. The cost of electric energy for operating this machine is 25 cents per year for each animal.

As the cattle are fed from 2 to 3 pounds of crushed grain per day per head, as there are 10 altogether in the 100-acre supposition, a motor-driven grain-crusher is required, capable of crushing some 9,000 pounds per year. This might be prepared at one operation by a large mill, but for the purpose at hand a motor varying from 3 to 5 horse power, according to the size of the mill employed, will do the work conveniently. To grind 100 pounds costs $0.03 for the energy consumed, or for the 9,000 pounds, $2.70 per year.

For running the cream separator, a small motor of about one-fourth horse power can operate 300 quarts of milk per hour, consuming three-tenths of a kilowatt hour, at an expense of $0.01¼. As the average production for 10 cows is 150 to 200 quarts per day, the yearly cost of operating the separator is $1.50.

A churn for 200 quarts of milk, assuming average conditions, requires from one-fourth to one-half horse power, as also does the butter-kneader, and the cost is negligible.

A washing-machine, including wringer, operated by a one-fourth horse power motor, costing complete $165, is used 200 hours per year, or some 3 hours per week. As other work may be done by the woman operating it, her time amounts to but 65 hours during the year. The machine turns out three washes an hour, and the total expense of the whole 780 washes is $35.41. This includes all labor, power and every expense, including overhead charges, and the same applies to the figures for the following machines.

A horse-groomer, costing $75, operated by a one-horse power motor, cleans 4 horses in 36 minutes. It is used 328.5 hours during the year, or 2,190 groomings, and requires the services of but one man. The cost amounts to $72.93, or $0.03¼ per horse per grooming.

A cream-separator having a capacity of 1,350 pounds per hour is operated by a 1/4 horse power motor, and costs complete $350. It is used 183 hours during the year, separating 237,900 pounds of milk at a cost of $88, or $0.037 per 100 pounds.

A butter churn having a volume of 300 gallons and a capacity of 100 gallons per churning, operated by a 2-horse-power motor, costs $118.50. It is operated 88 hours per year, churning 15,000 pounds of butter at a cost of $36.60, or $0.002 per pound. This includes churning, washing and working the butter ready for packing.

A root-cutter with a capacity of 6 tons of turnips an hour costs $26.30, and is operated by a 2-horse-power motor costing $80. It is used 52 hours per year, principally during the winter months, cutting 300 tons of beets and turnips at a cost of $35.94, or $0.119 per ton.

A fodder-cutter, having a capacity of 3 tons per hour of dry fodder, costs $128.10, and is operated by a 10-horse-power motor costing $118.50. The outfit is used 88.70 hours per year, and will cut 180 tons of fodder at a cost of $54.85, with one operative, at a cost of $0.30 per ton.

One of the means by which the farmer may secure his electricity at a low rate is to make his consumption as from hour to hour as possible during the whole 24 hours. The cost of electricity is based on the cost of fuel or water power, attendance and the amount of capital invested in the installation, including generators and transmission system. It will be seen that if all the farmers on a line demand electricity during the same few hours of each day, larger and more expensive machinery must be installed for its generation than would be necessary if the requirements for the same amount of electricity were spread over a greater part of the day.

Consequently, by using power for food-chopping, meat-grinding, dairy purposes, wood-sawing, cooking, washing and general purposes during certain hours of the day, light for morning and evening, and pumping water for irrigation and the household during the night, the farmer may, under the direction of a central station, so consume his electricity that it may be generated at the lowest cost possible.

It is the custom of the central station to concern itself with delivering electricity to the consumer's premises, where usually the user installs his own distributing system through his house, barns, etc.
inasmuch as the majority of farmers can as a rule afford to buy their own machinery, particularly the smaller sizes. In the case of large implements, however, where a very high initial cost may be availed of to secure the benefits of such machinery without its outright purchase, usually through the co-operation with the central station concern. Many such enterprises are only too willing to furnish electric motors, and make wire installation on the farm premises—for both light and power—at a small yearly rental or on low installment payments. In consequence, the farmer may have the cost of his machinery spread out over a number of years, the saving effected in both manual and animal labor being far more than sufficient to pay for the investment. He will eventually become the owner of the equipment, the while making a handsome profit through its use. It has already been demonstrated that farm efficiency can be accomplished in no way more advantageously than through the extension of the use of electricity on the farm.

**ELECTRIC FIELD, any space wherein electric force exists. See Electricity.**

**ELECTRIC FIRE-ALARMS.** See Electric Signalling.

**ELECTRIC FISHES.** Several quite unrelated fishes possess the extraordinary property of communicating an electric shock to animals with which they come in contact. The organs which are the source of this power have been much studied by both anatomists and physiologists. They are in all cases—the possible exception of Malapterurus—formed by the modification of muscular tissue, and consist of a mass of numerous closely packed prisms, each divided into a series of compartments filled with a gelatinous substance. One surface of the fibrous discs thus formed receives a rich nerve supply and is electrically negative, the opposite surface being positive. The entire organ may therefore be likened to a group of voltaic piles. Among the Elasmobranchii (q.v.), many of the skates possess rudimentary electric organs, which reach a high degree of development in the torpedo and an allied genus (Hyphos). In these two genera the organs occupy a large area on each side of the head and the prisms are arranged vertically and are supplied by large nerves, four pairs of which arise from a special electrical lobe of the hinder part of the brain, while a fifth is a branch of the trigeminal. In the electrical catfish (Malapterurus electricus) of the Nile, and some allied species, the entire body is enveloped in an electric layer beneath the skin and the muscles. In the electric eel (q.v.) and all other electrical fishes the organ is placed by the side of the tail and the prisms are disposed longitudinally. Not alone in structure but in the phenomena of rest and activity these organs bear a striking resemblance to muscles, which also normally exhibit weak electrical currents.

**ELECTRIC FLUID THEORY.** To explain electrical phenomena this theory was propounded in 1759 by Du Fay and Symmer. The "theory of electric fluids," as it is called, is as follows: That every body contains an indefinite quantity of an imponderable subtle fluid, that this fluid is composed of two fluids which are self-repulsive but mutually attractive. When a body is in its natural state, the two fluids are in combination, and neutralize each other. The act of electrification consists in the forcible separation of the two fluids, whereby one is diffused over the body rubbed and the other over the rubber, one kind of electricity never appearing without an equal quantity of the other. This premise was regarded as a mere provisional conception, and not a proved scientific truth. See Electricity.

**ELECTRIC FURNACES.** These furnaces are devices for localizing the heat of an electric circuit and utilizing it. In the usual technical use of the term it signifies a device or receptacle in which a comparatively high temperature is developed for the purpose of effecting a chemical reaction or producing a change of state in the substance to be treated, such, for instance, as the reduction of an ore, the formation or disruption of a compound, or the fusion or volatilization of a metal or compound. Electric furnaces comprise means for developing the necessary heat at the point or points desired, and for subjecting the material to be treated, technically known as the "charge," to the influence of this heat. The several types of electric furnace will be briefly described according to the principles employed. The heat development in any given portion of a circuit is proportionate to the resistance offered to the passage of the current; hence those portions of the circuit external to the fuse proper are always composed of metals which conduct the current well, and generally of copper or aluminum, whereas the resistance of those portions of the circuit in which the heat is to be localized is relatively high. These latter portions of the circuit may consist of gases, in which case an arc is formed and the localization of the heat is extreme; of substances of high melting and boiling points, in a state of fusion, when an electrolytic effect, to be hereinafter more fully referred to, usually supervenes; or of solids, such as platinum and other difficultly fusible metals, carbon, graphite and carbonaceous mixtures, or such bodies as the oxides of the alkaline earths which become conductive when heated. These three classes of furnace, wherein the heat is localized in a gas, a liquid and a solid, respectively, may be conveniently designated by the terms arc furnace, electrolytic furnace and incandescent furnace, although as will appear it is not always easy to apply one or another of these names to the actual constructions. Although electrically developed heat is relatively costly, the fact that it can be locally applied, within the interior of the charge if so desired, is an important advantage, and the utilization of the heat is often so complete that its use represents a real economy. The heat lost is that which is carried from the current by the escaping products of the reaction, and that which is conveyed by radiation, convection or conduction, from the walls, the electrodes and other exposed portions of the structure. Inasmuch as the exposed surfaces of a furnace are roughly proportionate to the square of its dimensions, whereas its capacity varies as the cube, it is evident that, other things being equal, the larger the furnace the less will be the percentage of total heat which is lost and the
greater will be the efficiency. This indicates the employment of large units. It is always possible to reduce the expenditure of electrical energy by making use of heat otherwise generated, such as being employed for raising the temperature of the charged materials or in providing an electrical introduction into the electrically heated zone, or for heating the exposed surfaces of the furnace structure in order to check conduction from within. Furnaces in which chemical reactions are conducted, as, for instance, those in which calcium carbide is produced, often yield gaseous products which are not only themselves very highly heated, but are capable, by combustion, of further heat development. It has frequently been proposed to utilize this heat by conducting such gases through or around the incoming charge or by burning them in flues surrounding the furnace, but the greater complexity of the structure and the difficulty of purifying the large volume of dust-laden gas constitute practical difficulties of a serious nature.

The Arc Furnace.—When an electric arc is formed between carbon terminals there is observed to be a definite limit to the length of arc which can be maintained with a given current strength; furthermore this limit, which at first increases almost in proportion to the current strength, decreases very slowly as the current density reaches higher values. The maximum length of the arc is therefore limited.

The temperature of the carbon terminals may attain 3,500° C., at about which point, under atmospheric pressure, carbon volatilizes. The temperature of the current gases of the arc is perhaps a thousand degrees higher. It follows that the arc furnace, in its simplest form, is adapted particularly for subjecting small charges to extremely high temperatures, and its value for experimental work is apparent. For use upon a commercial scale it is generally necessary so to distribute the heat from the arc that a comparatively large body of the charge may be acted upon at a given time. This result may be accomplished by establishing a plurality of arcs in the same position of the charge, by exposing the charge to the heat radiated from one or several arcs not in contact with it, by causing the arc to move relatively to the charge, or by moving the charge through or past the arc. The temperature of that portion of a charge which is in immediate contact with an arc may be a practically that of the arc itself and is uncontrollable; the operations for which this method of procedure is suitable and economical are relatively few. The high temperatures which the electric furnace is capable of producing have opened a new field to chemistry, but in order to insure the formation, in theoretical quantity and in a state of purity, of many compounds, a careful regulation of the temperature is essential; for the highest attainable temperatures are capable not only of giving rise to new combinations but also of breaking them down, resolving them into similar bodies or even into their elements. A single instance of the importance of heat regulation may be offered: If a mixture of sand and coke be cautiously heated in an electric resistance furnace a partial reduction of the sand occurs, and a product containing silica and carbon is formed; at somewhat higher temperature the reduction is complete and there results an amorphous body having the essential composition of carbide of silicon and technically called "white stuff"; at somewhat higher temperature ranges this amorphous body passes into the crystalline carbide of silicon "carborundum," a compound of silicon and carbon differing from the diamond itself; and at still higher temperatures, approximating those of the arc, this carborundum is broken down, its silicon escapes as a vapor, and its carbon remains in the form of graphite. The effect of high temperatures upon reactions is twofold: in the first place the velocity of the reaction is increased, so that chemical changes which at lower temperatures occur slowly or not at all take place rapidly or even with explosive violence; in the second place new conditions of equilibrium are established, and the chemical elements, entering into that combination which, under the circumstances, is the most stable, sometimes give rise to compounds not before known. To produce a given result, however, it is usually necessary to work within definite temperature limits, and since the heat of the arc cannot well be controlled, it is necessary to govern the temperature of the charge by limiting the duration of its exposure to this heat. As above pointed out, this may be accomplished by moving the arc through or past the charge, or by moving the charge through or past the arc, the duration of contact being so adjusted to the quantity of charge and to its specific heat as to bring it to the desired temperature. As a rule, however, the arc as a source of heat is both wasteful and inefficient.

The Electrolytic Furnace.—When a direct current of sufficient volume is caused to pass through a molten salt not only will the salt be maintained in fusion by the heat developed by its own resistance, but it will be "electrolyzed," that is to say, it will be decomposed in such manner that one of its component parts, which may be a metal, will tend to accumulate at one electrode, while another component, which was before in combination with the metal, will appear at the other electrode. The electrode at which the current is entering the molten bath, and at which the negative or nonmetallic portion of the compound appears, is called the "anode," while the other electrode, which receives the positive or metallic element and at which the current is considered to leave the bath, is designated the "cathode." Thus if common salt, sodium chloride, be fused and traversed by a direct current, the negative element chlorine will appear at the anode and the metal sodium at the cathode. If the substance of the anode be such that the element is liberated in contact with it can combine with or dissolve in it, the corresponding compound or solution will be formed: If, for instance, the fused sodium chloride is electrolyzed with an anode of carbon and a cathode of molten lead, chlorine will be evolved at the anode and escape from the bath, while sodium, dissolving in the lead, will yield an alloy from which the metal sodium, or its hydroxide caustic soda, may be obtained. In electrolytic furnaces also it is essential carefully to regulate the temperature, not only because an unnecessary high temperature means a waste of energy, but also because the losses arising through volatilization of the bath and the recombination of the separated prod-
ucts of the electrolysis. So important is this last factor that in certain cases, as, for instance, in the separation of metallic sodium from molten caustic soda, it is absolutely essential to the success of the process that the temperature be maintained within limits of a few degrees only.

The Incandescent Furnace.—This term is commonly applied to those furnaces wherein the heat is developed by the passage of the current through a body which initially at least is non-conducting. Such body may comprise a rod or core of carbon or carbonaceous mixture; a granular bed or core consisting of fragments of coke, retort carbon or graphite; the charge itself, often admixed with a quantity of carbon sufficient for its reduction; the furnace product when this is conductive and possesses a volatilizing point sufficiently high to permit the necessary temperature to be attained; or a pyroelectrolyte, that is to say, an oxide or mixture of oxides which is normally non-conductive or substantially so, but which while remaining unfused becomes capable at temperatures considerably above the normal of carrying the current. Each of these resistance materials possesses its advantages for particular lines of work, but all have in common the advantage of permitting accurate and ready adjustment of the temperature by varying the amount of current passing. These incandescent furnaces have, therefore, the widest applicability, and in case the resistance material used is carbon the maximum temperature attainable is probably not inferior to that of the terminals of the electric arc. The above defined types are not always sharply distinct, but under certain conditions the operation proceeds under two or perhaps all three of the methods. Thus if the resistance consists of fragments of carbon, the current may traverse the interspaces in the form of minute arcs; and if this fragmentary carbon be commingled with a suitable ore or compound there may be present also an electrolytic effect; the primary fusion of an electrolyte is often accomplished by means of a resistance rod connecting the electrodes, or this fusion may be accomplished by the arc. Furthermore a given furnace structure is often capable of either mode of operation through the character of the charge and the adjustment of the electrodes with reference thereto. The most important as well as the most characteristic applications of the electric furnace have relation to certain elements and compounds which cannot be produced directly, if at all, by other means. See ELECTROCHEMISTRY; ELECTROCHEMICAL INDUSTRIES.

Commercial Furnaces.—The carburendum furnace employs a continuous core of coke between the electrodes. This core of broken coke constitutes the resistance, and a high temperature is obtainable. The material for making the carburendum is finely divided coke, sand and sawdust. These being packed around the core, the current is turned on at about 200 volts pressure, and when the furnace heats this may be reduced to less than half the voltage. The core serves as a buffer or buffer, and the mixture of graphite and coke is mixed with carbon rods (two feet long and three inches diameter are grouped in bundles of 60). The resisting core of coke is nine feet long and two thick. About 1,000 horse power are required to run such a furnace, and the product is about one-quarter pound of carburendum per kilowatt hour. There is a considerable loss due to graphite, and the principle of this furnace is made use of in the manufacture of graphite, for which there is an increasing demand.

For the manufacture of calcium carbide, furnaces with carbon electrodes are employed, or sometimes one of the electrodes is of metal. One electrode may be formed of a mixture of broken coke and lime in a crucible, while a carbon or a set of connected carbon rods may constitute the other electrode. Alternating current is usually employed. An arc being formed, the lime begins to give off oxygen, which combines with some of the carbon, forming carbon monoxide, which gasifies and passes away, leaving the pure calcium to unite with the remaining carbon as calcium carbide. A temperature of about 2000° C. is desirable for the process, though calcium carbide can be formed at a considerably lower heat. The King furnace is described under ELECTROCHEMICAL INDUSTRIES.

A similar type of furnace answers for the manufacture of phosphorus; the materials supplied are phosphoric acid and coke. The phosphorus comes out as a vapor and is caught in a rarefied and condensed. Both calcium carbide and phosphorus may be made continuously, by providing means for feeding the furnace with new material and carrying off the product.

In the aluminum furnace a continuous current is employed, the positive electrode being at the top, so that the current may pass downward through the fused mass to the negative electrode, which may be of either iron or carbon. The liquid is thus electrolyzed on the wet principle. The metallic oxide alumina is fed into a fused mass of fluoride of aluminum and sodium (cryolite, Na₃AlF₆), the fluoride being electrolyzed. The oxygen unifying with carbon at the negative electrode the metal collects at the bottom, and may be drawn off through a tap-hole, the process being continuous. Over 150,000,000 pounds of aluminum are annually produced by electrical furnaces in the United States, and large factories have recently been built at Whitney, N. C.

The electric furnace has been tried for smelting a great variety of ores, with many interesting results. Several concerns announce success in smelting zinc ores in the electric furnace, one being at Keokuk, Iowa, where there is cheap hydroelectric power. It is practically certain that within a few years there will be considerable electrolytic smelting in localities where electricity is obtainable in large quantity at low cost.

The smelting of iron ores in an electric furnace was begun in Italy, where Captain Stassano patented a furnace in 1898, and by 1900 ferro-alloys were being produced commercially, and to-day ferro-alloys are generally and preferably made in electric furnaces, of which 114 were known to be in operation and 30 building in different countries just before the European war of 1914. Of these 14 were in the United States, and the majority in Germany, Austria, France and Sweden. These electric furnaces do not pretend to compete with the great blast furnaces in cheap production of iron and steel,
ELECTRIC FURNACES

but their product is superior in the case of alloys of known exact percentage, and the demand for such steels being constant and increasing, the future of the electric furnace is assured. As the cost of electrolytic iron becomes lowered there is a tendency to introduce the furnaces for commercial iron in regions where coal is scarce, as in California. There are large deposits of iron ore in Southern California which are liable to become of commercial importance when electrolytic reduction is better developed, as they have the advantages of cheap coal as a reducing agent.

The first electric iron-making furnace at Shasta, Cal., was completed in 1907, being of the Heroult type, 1,500 kilowatt, three-phase reduction furnace. It had to be rebuilt and rebuilt again, and was not deemed a commercial success until 1911. The furnace proper is a well-burned lime and 12½ pounds of quartz. With coke at $6 a ton and power at $16 a kilowatt year, the cost of these items and for consumed electrodes is $6.87 per ton of pig iron product.

New electric furnaces under construction have an average capacity of 4½ tons. A 25-ton furnace and another of 22 tons were completed at Bruckhausen, Germany, just before the war broke out. In 1911 Germany produced over 60,000 tons of electrolytic iron or almost as much as all other countries combined. The United States production is now (1916) nearly as large. The Heroult furnace, developed in France, is the most popular type and is used in California, South Chicago, Worcester and other places in the United States. The first Swedish furnace was the Kjellin, which was superseded by the Rochling-Rodenhauser, and

**Arrangement of electric-furnace steel plant, Oberhausen, Germany.**

steel shell 27 feet long, 13 wide and 12 high. The bottom slopes toward the tap-hole which is centrally placed in front. There are five 24-inch stacks, extending 15 feet above the roof. Cylindrical graphite electrodes are used one foot in diameter and four feet long. They last about 30 days, but the working is made continuous by fastening a new one to the stump of the one partially consumed. Three service transformers supply three-phase current at 40 to 80 volts to the electrodes. They are each 750 kilowatts, and are water-cooled and oil-immersed. The metal is drawn off three times in every 24 hours. It is not necessary to shut off the current during the charging, so the operation is continuous. The charging is done by cars, running to a platform at the level of the top of the shafts. A normal charge is 500 pounds of magnetite iron ore, 140 pounds of charcoal, 3½ pounds of is especially adapted to refining molten metal. It is built in sizes up to 15 tons capacity, something like a great steel converter, having an enormous steel tank, mounted on rollers and tipped sideways for pouring. One of these has been installed at Landstown, Pa., and uses 300 kilowatts, furnished by a 25-cycle current at 480 volts.

The success of the electric furnace in the iron and steel industry is due to the fact that the product of these furnaces is much purer than the blast furnace, and this notwithstanding the blast furnace product has been vastly improved in purity. Pure iron is essential to making alloy steels with a known percentage of this or that other metal, required for producing certain results. For further details consult 'Electric Furnaces for Making Iron and Steel,' issued by the Bureau of Mines.
ELECTRIC GAS-LIGHTING, a method of igniting illuminating gas by which one or a large number of jets may be lighted simultaneously by an electric spark. In the figure a simple form of electric gas lighter is shown. A metal tongue \( t \), insulated from the burner, is supported near the tip as indicated. A metal rod \( r \) carried on suitable levers brushes across the tongue \( t \) when the knob \( k \) is pulled down, thereby closing and opening, as it does so, an electric circuit which includes the rod \( r \), tongue \( t \), battery \( b \), of two or three dry cells, and a spark coil \( m \), consisting of a bundle of iron wires surrounded by a coil of copper wire. At the reopening of the circuit a spark occurs at tongue \( t \) igniting the gas. For lighting the gas jets in large hails an electric circuit is carried from one jet to the next and two terminals of the circuit are upheld over the gas tip. The spark jumps across from one terminal to the other when the spark coil or static machine is operated, thereby igniting all the jets in the circuit. In this arrangement the terminals of the circuit are arranged in multiple.

ELECTRIC GENERATOR. See ELECTRIC MACHINE; ELECTRIC ALTERNATING CURRENT MACHINERY; ELECTRIC DIRECT CURRENT.

ELECTRIC HEATER. If a wire of more or less resistance is wound on a frame, and a current sent through, the resistance encountered by the current develops heat, and this is the principle of the electric heater. The hot wire or metal is surrounded by some non-inflammable substance that is a good conductor of heat, as porcelain. In a well-known type a metallic paint is fired upon mica strips, which are formed into groups or sets, so that a heater can be built up of any size from these units. For heating an electric car some six sets of conducting wires are coiled around porcelain tubes, the current being supplied with the motor. The cost is stated at about 60 cents a car per day. The method of heating is wasteful where the source of heat is coal, and it cannot be generally substituted for house heating; but it is excellently adapted for small individual heaters, where the cost is less important than the convenience, as for flatirons, kettles, saucepans, dinner plates, soldering tools, toasters, dishwashers and cookers. The industry of manufacturing such small heaters already runs into several million dollars annually in the United States. A recent new use for the electric heater is the stimulation of petroleum wells that are running dry. Heating coils are lowered into the well to melt out the heavy oil accumulation and cause it to flow freely. In the manufacture of armatures, time has been reduced by the use of electrically heated ovens to dry out the moisture. The temperature can be regulated so accurately that there is no danger of melting the metal. In smelting iron the electric heater has also found a field of usefulness, because it maintains a high and uniform heat. The same quality of uniformity has caused the manufacturers of linotype machines to make an electric heater for their melting pots.

ELECTRIC INDUCTION. See Induction.

ELECTRIC LIGHTING. In 1800 Sir Humphry Davy discovered that if two pieces of carbon are joined by conductors to a source of electric current, and such pieces momentarily touched together, so that the circuit is complete and a flow of current established, upon their separation for a short distance, a flame is emitted, and, if the current be sufficiently powerful, this flame will continue, the carbon points will become intensely hot and emit a brilliant light. In separating the carbon points, the extra potential induced by the self-induction of the circuit is sufficient to leap the small air gap and thereby vaporizes a small quantity of carbon. Carbon vapor, being a conductor, allows the current to flow across the gap. The vapor is of high resistance, and therefore it is heated to a high temperature. In 1809, Davy exhibited his arc light before the Royal Institution of London, his carbon points being charcoal from the willow, and his source of current a voltaic pile.

We do not know in which direction an electric current flows through a circuit, and there are many reasons for believing that it flows both ways at the same time. It is usual, however, to assume that it flows in one direction only, namely—from what is called the "positive pole" of the generator, through the external circuit to what is called the "negative pole." According to this view, when a direct, continuous current flows between two slightly separated carbons so as to form an arc, the electricity tears away particles of carbon from the positive electrode, and deposits some of them upon the negative one. Some of the particles become burned in the passage, so that both carbons waste away; but the positive carbon wastes the faster and becomes hollowed out, while the negative one wastes less rapidly and assumes a pointed form. The temperature is high enough to melt the most insufiable substances, such as flint, platinum, and the elements of the group of metal points emit the larger portion of the light, and the positive point more than the negative. The resistance of the arc may vary from 1 to 100 ohms. It requires a current strength of from 3 to 10 amperes, and a minimum electromotive force of 40 to 50 volts, to maintain a satisfactory lighting arc.

Davy used wood charcoal for his electrodes, and while they were of excellent quality, on account of their softness they lasted only a short time. A better heater would burn away, it was necessary continually to adjust them, or the arc would go out. Therefore it was found necessary to have carbons of sufficient density to last a reasonable time, and purity so that the light might be steady. Also to have a mechanism automatically to feed the carbons, and keep them a constant distance apart, as well as automatically bring them together in order to start the arc. Refined petroleum coke, ordinary gas coke, or lamp black is now taken for the base material, mixed with a stiff paste, dried and carbonized out of contact with the air. A very hard and uniform carbon is thus obtained, in any desired size, the usual length being 12 or 14 inches, and diameter
ELECTRIC LIGHTING

7/10, ¼ or ½ inch. Broadly, the lamps may be divided into two classes: series and multiple; each system into two sub-divisions: the open and the enclosed.

The electric energy loss from the point of generation to the lamp may be expressed, W = CR, where W is energy in watts, dissipated as heat, C is the resistance of the conductors, and R is resistance of circuit in ohms.

From the equation it may be noted that the loss is in proportion to the square of the current, so long as R remains constant. Therefore, it was later it was found better to number out arc lamps, it is more economical to keep the current constant, and have the lamps joined in series.

Two types of lamps were evolved to meet these conditions as well as a generator to keep the current at a constant quantity, (1) the differential lamp; (2) the shunt lamp. In the differential lamp, the current must remain at a constant value. The main current is carried to a pair of lifting magnets, over which, but without touching the main coil of high resistance called the shunt magnet, the terminals of which are cut around the arc itself. When current is thrown into the lamps, the main current pulls the carbons apart until sufficient potential is on the electric circuit to form an arc through the shunt magnet, which neutralizes the main magnet, thereby securing a balance, and maintaining the potential at the arc constant. In the shunt type lamp, the shunt magnet circuit is so arranged as to trip the clutch holding the carbons, thereby allowing the carbons to come together, should the potential around the arc exceed the predetermined amount. This lamp will burn upon any current strength, providing it is enough to operate the main magnet.

The conditions common to both types of series lamps are: (1) As the carbons burn away, they must be fed down gradually and not allow the potential around the arc to exceed a certain voltage. (2) Should the carbon rod stick, or anything happen to disarrange the lamp, protective devices called cut-outs will come into operation, so the lamp will not be burned up, or the circuit opened. These open types of lamps are now practically obsolete.

The Enclosed Arc.—The open arc was superseded by the enclosed arc. It was discovered that if the arc be surrounded by a narrow, nearly air-tight globe, it greatly modified the character of the light and the carbon would last much longer. The small globe prevents the air from having access to the carbon, thus diminishing its oxidation. When the lamp is started, it soon exhausts the oxygen contained in the globe, and if the globe is tight, the carbons will last from 80 to 175 hours. This type of lamp held the market for some years and then the flame arc lamp became popular. This was based on the introduction of oxidizing into the carbons, to secure an increased flame arc, somewhat as the Welsbach mantles increase the luminosity of a gas-flame. Calcium chloride, and the oxides of iron, titanium, manganese and other metals, will give good or bad success. In the making of the carbons (which are commonly of petroleum coke ground fine and mixed with tar, forced through dies and dried), the metallic oxides are either mixed with the mass or introduced in a metallic core. An increased voltage is required, as the electrodes are drawn farther apart to get a long flame; in some forms, as the magnetite lamp, the lower positive electrode is simply a permanent knob of copper, while the upper negative electrode carries the mineral salts. Such lamps give a large body of arc or flame and do not burn carbon in the operation, but consume a comparatively flat surface when directly opposed. In one form two carbons are employed, positioned like the sides of a V. The quantity of vapor given off by the flame arc lamps necessitated an open globe at first, but later it was found better to vapor by a draft and largely to enclose them.

Glows and Vapor Lamps.—The Nernst lamp was the next popular favorite. Instead of carbons it employs what is known as a glower, this being a little tube, something over an inch long, and made of the oxides of thorium, zirconium, yttrium, etc., mixed with a binding paste and baked into a condition resembling porcelain. This tube is coated with exides and provided with platinum terminals. On passing a current of high potential through the small or soft part of the glower, called a heater, the current is switched through the shunt magnet, which neutralizes the main magnet, thereby securing a balance, and maintaining the potential at the arc constant. In the shunt type lamp, the shunt magnet circuit is so arranged as to trip the clutch holding the carbons, thereby allowing the carbons to come together, should the potential around the arc exceed the predetermined amount. This lamp will burn upon any current strength, providing it is enough to operate the main magnet.

A distinct advance in durability and long life of the working parts of an electric lamp has been scored by the so-called vacuum tube lamps, in which a long tube is exhausted of air and then supplied with a small quantity of metallic vapor, as of mercury, which lights up when an electric current is passed through, emitting a very soft diffused light, that does not trouble the eyes with its glare, as is the case with most strong lights. The Cooper-Hewitt mercury vapor lamp was first tried out in 1903, at the office of the Evening Post, in New York, and has since been largely introduced for general indoor use. The typical house-lamp employs a tube from three inches long and of perhaps an inch diameter, backed by a metallic reflector. At one end of the tube is an iron mercury cup serving as the positive electrode, while a glass bulb at the other end is the negative terminal. Platinum wires supply the current. The air is exhausted from the tube, which is then sealed. When the current flows, a little mercury is allowed to vaporize in the tube and a soft greenish-white light of great intensity is obtained. Induction coils are placed in the body of the fixture, also an adjuster resistance, shunt resistance and cut-out. Pulling a hand-chain operating a switch starts the light, and if the current fails and it goes out through any accident, an automatic device can be had for relighting it. Lamps are made for both direct and alternating current. One lamp gives normally 3,750 hours' service, or the equivalent of 10 hours a night for one year. These Cooper-Hewitt mercury vapor lamps are also manufactured with tubes of a great variety of lengths and doublings, for use in factories, mills, machine shops, stores, photograph and moving-pic-
tured studios, etc. They bring illumination wherever it is wanted commercially, closely reproducing daylight conditions and obviating strain on the eyes from glaring lamps. For outdoor use the Cooper-Hewitt quartz lamp is supplied, which employs a short tube of fused silica (or quartz glass), permitting a high temperature and stronger current for brighter illumination, as in railway yards, parks, etc. Such lamps have lasted for months without attention.

The Moore vapor tube glow lamp is manufactured in various forms, and is much valued for coloring matches, owing to its close approximation to daylight conditions. By the employment of different vapors it can be made to yield blue, white, yellow or rose light. It requires renewal of carbon dioxide after 1,000 hours' use, but the tubes will last four or five thousand hours. It is run on 110-volt circuits at 23 amperes.

The Incandescent Lamp.—The great objection to the use of the arc system of lighting was that the light was too intense for most purposes required inside. It could not be readily subdivided. From the earliest days of electric lighting, various inventors endeavored to subdivide the light. The idea of using continuous conductors, instead of the discontinuous as in arc lighting, was tried almost every conceivable form. These conductors were to be heated to a white heat and rendered incandescent by the passage through them of an electric current. The great difficulty arose from the fact that to give useful results, the working temperature of the material was so near its melting point, that any slight increase in the current would destroy the conductor. In 1878 a great improvement was effected in the platinum filament incandescent lamp, which was obtained in a condition safely to withstand a much greater current strength. The filament was placed in a vacuum, and slowly heated therein. The occluded gases were slowly liberated, and it was discovered that if a high vacuum were maintained and the wire raised to a point just below its melting point, the point of fusion was raised, and the physical character of the metal was considerably changed. This lamp, however, was never a commercial success.

Later inventors experimented with the platinum lamp, enclosed in vacuo, but the greatest improvement was made by the substitution of carbon filaments for platinum. This was done by an American, J. W. Starr, who employed plates inside a glass vessel containing a Torricellian vacuum. Many patents were taken out in all countries for lamps of various types, but none were commercially successful; many, perhaps, for the want of a cheap method of generating the electrical energy, as well as the failure of the lamp itself.

The advent of the first successful incandescent lamp dates from about 1879, when Edison gave us the carbon incandescent lamp, and from that time the growth of the incandescent electric lighting industry has been extremely rapid. It was discovered that if a high vacuum of a carbon filament attached to two platinum wires, a glass bulb in which a vacuum is formed, and finally a threaded base attached to the bulb, and designed to hold the lamp in its socket.

The following is in a general way the method by which the lamps are made. The bulbs are blown at the glass factory whence the manufacturers obtain them directly. The first manipulation consists of preparing them for the filament. The nature of the filament varies with different systems. There are three kinds employed. Some (Swan) employ cotton threads; others gelatine or vitriol coated (Khotinsky Lave-Fox); and others use vegetable fibres (Edison-Siemens). Finally, some employ a natural fibre submitted to a chemical process (Langhans Cruto Seel). Form is given to the filament according to its nature, either by means of a die, or between cylinders, or by cutting it out while in a plastic mass. The fibre thus obtained is transformed into compact carbon by prolonged baking at a high temperature in a crucible or by heating with the electric current itself. To give the filament homogeneity and the desired resistance a layer of carbon should be deposited on its surface. This deposit is affected in many ways. A very simple method termed "flashing" consists in immersing the filament in petroleum spirit immersed in that liquid. The filament being cut to the desired length, Edison clamps the carbon with platinum wires and covers the points of attachment with a layer of electrolytic copper; Lave, Fox and Swan deposit a large quantity of carbon there, while other manufacturers employ a special cement or solder. The filaments may be fixed in the bulb in two ways: either the two wires are fused into a piece of glass called the budge, which is next fused into the neck of the bulb; or else the wires are fixed separately on the edges of a glass socket, which is then fused into the bulb. A small tube is also fused to the top of the bulb in order to provide for the production of a vacuum. The exhaustion of the lamps takes place by means of mercury pumps. The vacuum obtained, the lamp is tested. Then the luminous intensity and the resistance when cold are measured. The dimensions of the filaments vary with the luminous intensity of the lamp; they should be proportionately greater as the normal intensity of the lamp is higher. These dimensions depend also upon the specific resistance of the carbonized substance. As to the form of the section of the filament, the circular one is preferable because it presents the minimum resistance for a given illumination.

The reason for withdrawing the air from the bulb is that if the filament were heated in the air the oxygen of the air would combine with the carbon, causing combustion and consequent destruction. But if enclosed as it is in a vacuum, the filament is slowly destroyed by the intense heat at which it is operated. Aside from the advantage named is the fact that there is no heat-conducting medium between the filament and the globe, practically all the heat that is emitted is retained by the filament itself. The filament (a small amount is lost by conduction through the leading-in wires). If there were any gas or vapor within the bulb it would conduct additional heat to the glass walls, and also dissipate heat by convection, so that with a given current in a given filament the temperature of the filament would be reduced, and, therefore, less light would be obtained. The destruction of the filament referred to is not due to combustion because as just explained there is no oxygen left in the bulb. There is a combination of the filament by some process that has
never been positively identified or explained, the results being that impalpable particles of carbon are deposited on the inside surface of the bulb, causing a gradual darkening of the glass that is the only direct loss.

The leading-in wires are made of platinum because that metal has the same coefficient of expansion by heat as that of glass. Were the coefficient different, small cracks would form in the bulb and the vacuum would be spoiled. Carbon may be made of twice that material, or more, and the general rule is that almost all conductors increase in resistance when the temperature is raised. Its resistance decreases rapidly with an increase in temperature up to the red point. Thereafter, up to the white, the resistance decreases more slowly. The ordinary carbon filament, when at its working point, has about one-half the resistance as when cold. The standard filament gives out a mean illumination of 16-candle power at right angles with the axis of the lamp from base to top, which may fluctuate.

The power required for the usual 16-candle power standard lamp varies from 50 to 64 watts, depending upon the temperature at which the filament is operated. The higher the temperature of the filament the higher the efficiency is, watts per candle power, and also the shorter will be the life. The life of the filament in this way limits the efficiency of the lamp. The candle power of the incandescent lamp may be greatly increased by simply increasing its filament temperature by the simple expedient of increasing the current, but thereby its life is shortened. The increase in candle power is not directly in proportion to the increase in current but in a considerably higher ratio.

It is important to maintain the potential on the terminals of an incandescent lamp at the normal working point. Any slight excess materially shortens its life. The resistance of an incandescent lamp filament is much lower when hot than cold, approximately in the ratio of two to one; that is, the resistance is twice as high cold as when hot when at normal burning temperature. The illumination is rated in candle power and power consumed in watts per candle measured when the lamp is giving its rated candle power, but this condition is not obtained throughout the life of the lamp, and is a large portion of its active life. When a new lamp is placed in circuit it will usually give the full candle power or a trifle more at the start, and the candle power will rise to a value from 5 per cent to 11 per cent higher than the rating. It soon, however, begins to fall off with a constant diminution up to the breaking point.

The rise and fall of candle power are due to changes in the structure of the filament. The resistance at first decreases, allowing more current to flow and consequently higher temperature and more light. This is indicated by the rise of the curve from 16.2 candle power to 17.3 candle power during the first 50 hours. Then the diminution of resistance ceases and is followed by the gradual wasting away of the filament. The gradual increase in resistance, by reducing its cross section. The current thus gradually falling off, taken together with the decreased surface of the filament and the deposit of carbon upon the globe, causes the fall in candle power indicated. The decrease in candle power is not directly proportional to the decrease in current, thus the energy per candle power increases rapidly after the first few hundred hours.

The Tungsten Lamp.—The tungsten filament has revolutionized the incandescent lighting industry and is reducing the use of arc lamps. The carbon filament is rapidly going out, and the old-fashioned arc lamps are being replaced either by groups of tungsten lamps or Nernst or vapor lamps. The tungsten filament has a life of 1,000 hours, and some have been run for 6,000 hours. A tungsten filament 200 hours is long for other filaments and arc lamps. The tungsten also has the advantage of diffusing the light more, there being more turns in the filament, and it is closer to daylight in its coloration. The tungsten is a truly automatic light, requiring no attention beyond an occasional dusting. Tungsten is not so rare a metal as once supposed, and its great resistance to heat—it melts at 3200° C.—renders it a most fit metal for filaments. At first it was found exceedingly difficult to form it into the minute diameter wire form needed. It is exceedingly brittle and fragile, and early attempts to draw it through fine dies, such as are used for making the most delicate strands of copper and steel wire, were failures. Kuzel solved the problem by making the solution of the evaporation of the surplus moisture and squiring the residue through a die, getting a thread which would bear handling. Such a filament is “flashed” in a mixture of steam and hydrogen, and as the steam decomposes the oxygen unites with the carbon of the filament. Later a method of drawing the metal was worked out successfully and is preferred to the squirted film. The character of tungsten is such that a very long and frequently lapped filament is required to give the necessary light. This is an advantage, reducing the glare.

In recent tungsten lamp practice nitrogen gas is introduced in the bulb after extracting the air as fully as practicable. It has been demonstrated that the pressure of the gas in this manner would not allow the tungsten to become red hot, thus setting the heat lost by its introduction to the bulb. As tungsten lamps can be made of 1,000 to 2,000 candle power, and show a life of 1,000 to 2,000 hours, they have naturally become very popular.

Wiring and Fixtures.—The building regulations of all large cities contain more or less stringent regulations as to the wiring of buildings, the result of somewhat numerous fires caused by careless wiring in the early stages of introducing electric lighting. Cables carrying street wires are now abundantly insulated, and the individual wires entering buildings are carefully insulated and protected from accidental abrasion. At the point of entering a building, a switch-box is usually placed, with accommodated for one or more fuse-wires. These are short connections made of easily fusible wire, as a mixture of lead and zinc, so that when by accident a strong current reaches the switch, the fuse is instantly burned out, and the current can go no further, having no wire conductor. Wires for incandescent lighting are usually covered and boxed in, under certain regulations of safety, and led to the various points of use—to ceiling fixtures, pendants, electroliers, brackets, portable lamps, etc. The pendant, with flexible cord, that can be swung to any convenient point within its radius, is easily the
most popular lamp. The modern idea of interior lighting of dwellings involves the use of a semi-transparent inverted half globe, as of thin porcelain, with which the light is hidden, covered with a glass bead on a white ceiling, from which a soft radiance is reflected downward over the surroundings. This plan diffuses the light in a most acceptable manner.

The low value of the common radiants is due to the fact that they are based upon the intense light of carbide of coal.

If the conversion of coal into light is through the medium of the incandescent lamp, we throw away 95 per cent of theoretical energy, and secure as light only 95/100 or practically 1 per cent of the energy of the coal. However, the incandescent light is almost a perfect light. Since it gives off no waste products of any kind, it has no deleterious effects upon the atmosphere of the rooms or buildings in which it may be utilized. Its light is white, soft and yet not dazzling. The lamp itself is rather ornamental than otherwise, and lends itself readily to external ornamentation without danger of fire, since of course it gives off no flame. Nevertheless, by way of caution it may be noted that, comparatively insignificant as is the heat from the incandescent lamp given out through the glass bulb, it cannot be allowed to rest for an undue time in touching proximity to inflammable materials, since experiments have shown that when such a lamp is encased in two thicknesses of muslin for about six minutes and fresh air is admitted to the interior, the muslin has burst into flame. Again, an article of celluloid pressed against the lamp for three minutes has ignited; and a newspaper, under similar conditions, ignited in three-quarters of an hour.

**ELECTRIC LOCOMOTIVES.** See Traction, Electric.

**ELECTRIC MACHINE,** or Dynamo Static Machine (now extensively employed in therapeutics), for exciting electricity by friction or by static electric induction, as distinguished from dynamo electric machines in which electricity is excited by cutting magnetic lines of force. The excitation of electricity by friction was observed by the ancients, and the word electricity is derived from the Greek word electrum, signifying amber, in which the attracting power of electricity after friction was first noticed. See **Electricity, Frictional.**

It was subsequently found that a glass rod or a rod of sealing wax also possessed this electrical property when rubbed. Later on, other methods of exciting static electricity, such as by the electrophorus, were discovered. Such methods were, however, slow and laborious, and better devices were sought for, resulting in the development of two general types of dynamo static machines, namely, frictional machines and induction machines, the first representing the rubbed glass rod or wax type; the second, the electrophorus type. These machines provided means whereby the rubbing and the induction might be performed continuously and mechanically.

**Frictional Electric Machine.**—The first continuous frictional machine, due to Nairne, consisted of a glass bottle or hollow cylinder mounted on a horizontal axis, well insulated, and turned by a winch or handle on suitable supports. (See Fig. 1.) On one side of the cylinder and pressing firmly against it, is placed the "rubber," a cushion of leather, c, stuffed with horse-hair, and sometimes faced with amalgam. From the upper edge of the cushion a flap, s, passes over the cylinder, reaching half way round. A brass cylinder, or a wooden cylinder plated with metal, p, termed the prime conductor, supported by a glass or ebonite rod, a, is placed as shown. A metallic comb is attached to the left end of the prime conductor, as indicated in figure.

Before the machine is set in operation an amalgam of zinc and tin or other suitable metals, is sprinkled or pasted on the surface of the rubber. When the cylinder is turned electric sparks are seen and heard to play on the cylinder from the edge of the flap, negative electricity being accumulated on the amalgam surface and positive electricity on the surface of the cylinder, due to the friction between the glass and the amalgam coated surface of the rubber. As the cylinder is a non-conductor of electricity this positive charge is held on its surface until the cylinder in revolving brings it beneath the comb, where it acts inductively on the prime conductor, p, attracting negative electricity to its near end and repelling positive electricity to its far end; the negative electricity escaping across the points of the comb as an electrical breeze, or brush discharge, uniting with and neutralizing the positive electricity on the glass cylinder opposite the comb, which portion of the cylinder is then ready to receive a positive charge as before when it again reaches the rubber. When the prime conductor by these successive charges of positive electricity has attained a high potential, sparks several inches in length will jump from its far end to the hand or any other ground connection. To obtain a continuous supply of electricity from the prime conductor, p, it is necessary to connect the rubber, c, to the ground, which is usually done by allowing a metal chain attached to a steel plate on the back of the cushion to lie on the floor or table, this permitting the negative electricity excited in the rubber to escape to earth. In this way also a negative stream of electricity may be drawn from the machine. The use of the amalgam on the rubber has the effect of largely increasing the conductivity of the rubber, and the material from which amalgam coated pale green bottles are made, being most suitable for this purpose.

![Fig. 1 — Cylinder Frictional Machine.](image-url)
Plate Electric Machine.—This is another form of the frictional machine. The principle of its operation is the same as that of the cylinder machine just described. It consists of a circular plate of glass, or ebonite, E, Fig. 2, in place of the cylinder. Two sets of rubbers, S, S, S, P, are placed on opposite sides of the plate, and as the plate is rotated positive electricity is developed on the glass, and is collected by the prime conductor, S, virtually as in the case of the cylinder machine.

Static Electric Induction Machine.—These machines depend for their action upon static induction as exemplified in the case, for instance, of the electrophorus which may be briefly described here.

Electrophorus.—A simple electrophorus consists of a cake of resin or vulcanite 12 or 15 inches in diameter and one inch thick, resting on a tin or iron plate. A disc of metal, termed the cover or carrier, somewhat smaller than the cake of resin, is provided with an insulating handle. When the cake is rubbed with dry flannel it becomes negatively electrified. If now the cover be placed on the cake, its positive electricity is attracted to the side of the cover next the cake. The electric charge on the resin is not discharged into the cover, however, because, on account of the slight accidental irregularities of the two surfaces, the cover will be in actual physical contact with the resin at only a few points,—perhaps at not more than three. The electricity residing in the resin at the points of true contact will be discharged, but not that at other points, because the resin is a non-conductor, and so its electricity cannot pass directly to the covering plate by conduction. Now if the cover be touched by the finger, its negative electricity will escape to earth. If now the cover be lifted from the cake it will contain free positive electricity which may be used for charging a condenser or Leyden jar. The cover may again be placed on the cake and the foregoing process may be repeated a number of times before the charge in the resin will be entirely exhausted. The cake when electrified, with the disc in its place, and undisturbed, will retain its charge for weeks.

A number of induction machines based on the foregoing principle have been devised, among the best known being the Holtz and the Wimshurst, which are sometimes termed continuous electrophori.

Holtz's Electric Induction Machine.—This consists of two glass plates or discs about two feet in diameter, placed side by side and separated by a very small air space. One plate is fixed; the other is rotated, the fixed plate being slightly larger. The moving plate is mounted on a well-insulated axle. On diametrically opposite points of the fixed plate there are two sector-shaped holes or windows. On the back of the fixed plate, at the windows, are glued paper inductors or armatures, blunt tongues from which they are caused to pass through the windows until they nearly touch the moving plate, which must be rotated in the direction opposite to that in which the tongues point. Opposite the inductors there are placed metal combs attached to brass rods or electrodes, which carry brass balls that at their terminals are movable to and from one another. In starting the machine the two balls are brought together and a negative charge from a rubbed ebonite rod is given to one of the inductors; then when the plate is rotated and the balls are separated, sparks jump across the space. The action of the machine is very complicated and need not be gone into here further than to say that in effect it is virtually similar to that of the electrophorus; the initial charge imparted to the armature inducing opposite electricity in the rotating disc, which in turn delivers a charge to the metal comb, which charge by successive additions as the disc rotates is augmented until it attains a potential of 50,000 volts and more. These discs are rotated at a speed varying from 120 to 450 revolutions per minute. See Electritherapeutics.

Wimshurst's Influence Machine.—This machine, due to Mr. James Wimshurst, is one of the most efficient and reliable of the induction electric machines. It consists of two glass discs, which in practice have varied in size from 14½ inches to 7 feet in diameter. These discs suitably mounted on insulated axles are placed side by side and both are rotated, but in opposite directions. On the outer surface of each disc thin metal strips, or sectors, M, are glued, as indicated in Fig. 3. Two adjustable
metal "neutralizing" rods, r, terminating in small brushes that slide over the metal strips, are supported as shown, at oblique angles to one another; one opposite each disc. U-shaped collectors are carried on the shafts, diametrically opposite to one another, and are electrically connected to the electrodes or prime conductors, c c. These collectors are supported on metal rods that rest in what are practically Leyden jars or condensers, J J. The best position of the brushes on rods, r r, relatively to each other and to the condenser, is found by actual test to be virtually as shown in the figure.

The object in employing condensers, J J, is to add capacity to the prime conductors, thereby increasing the amount of electricity that can be accumulated, and hence increasing the energy of the discharge, and this use of condensers is common to all static electric machines. The action of this machine in operation is also complicated. The Wimshurst machine is self-exciting, that is, it starts without any externally applied electric charge, as is requisite with the Holtz machine. It has been thought that the initial charge is due to the friction of the air in the space between the two oppositely revolving plates, this space not exceeding one-eighth of an inch. Apparently the metal sectors are the equivalent of the inductors in the Holtz machine; the neutralizing rods serving to allow the repelled electricity in one sector to escape to a diametrically opposite sector on the same plate, where it in turn acts inductively on the opposite sector on the opposite plate, the final electricity which it reaches the collectors being carried off as a discharge by the prime conductors. Frequently a small Wimshurst machine is used to excite a larger Holtz machine.

All static electric machines, owing to the high potentials which they develop, require extra precautions as regards insulation, even the damp atmosphere of a room preventing their successful operation. Some other insulating materials, such as ebonite and gutta-percha, are less hygroscopic than glass, but these materials are not so durable as glass; hence the latter is given preference for the plates of these machines. But to add to their insulating qualities they are always covered with a shellac varnish, and are encased in a glass chamber or box from which moisture is extracted by sulphuric acid or other desiccators, contained in suitable vessels within the chamber. These machines are now usually operated by electric motors. Although the electro-motive force developed by these machines is very high, the current, owing to the high resistance of the machines, is comparatively low. Thus tests have shown the output of a Holtz machine to be, with a six-inch spark, 71,000 volts and 00048 amperes, equal to 34 watts, and with a spark of 18 inches, 180,000 volts and 0002 amperes, equal to 36 watts (Seldon.) The efficiency of the machine is, in the first instance, 27 per cent, and in the second 19.5 per cent. The output is approximately directly proportional to the rotation of the plates. The Holtz machine and others of its type are continuous current machines, and at a given speed their current output and electro-motive force are constant. By efficiency is meant the energy given out by the machine as compared with that expended in driving it. (The efficiency of a dynamo electric machine is often over 90 per cent.) The electric power expended in driving these machines, under test, was, in the first case, 126 watts, and in the second case, 18 watts. Hence machines of the Holtz and other static machines show an efficiency of 40 to 46 per cent, with an output of 10 to 12 watts.

To increase the volume of current from static electric machines, the number of plates is increased. Hence machines of the Holtz and other more or less similar types thus constructed with from 6 revolving and 6 stationary plates to 16 revolving and 16 stationary plates, or more as may be desired. In many cases the stationary plates are square or oblong sheets of glass. For therapeutic purposes, machines, giving at least a 12-inch spark, are considered advisable. Plates made of micanite have been tried for static machines, but with some doubt as to their durability. See ELECTROTHERAPEUTICS.

William Maves, Jr. Consulting Electrical Engineer.

ELECTRIC MICROPHONE. The principle of this instrument was discovered by Prof. David E. Hughes, an American resident in London, who announced the discovery in a paper delivered before the Royal Society, London, in 1878. The microphone, as the name implies, largely amplifies sounds. It consists of a vertical carbon pencil pivoted loosely at both ends in solid carbon receptacles which are fastened to a thin sounding board, which board is suitably upheld by one edge on a solid block or base. When the carbon pencil is made part of an electric circuit in which are also a small battery and a telephone receiver, sounds are many times amplified; even a small cotton ball dropped on the block is heard in the telephone like a bullet falling on the floor. A number of theories have been advanced to explain the action of the microphone; one, adopted by the courts in this country in a case in which the validity of the Berliner telephone transmitter was an issue, being that the action is due to the remarkable effect of sonorous vibrations in varying the electrical resistance at the point of contact between solid electrodes. The most common form of carbon telephone transmitters in use to-day are varieties of the microphone. It may be added that Professor Hughes gave this instrument to the world gratis. The principle of the microphone has also been utilized in a stethoscope and in a telephonic relay.

ELECTRIC MOTOR. The electric motor is simply a dynamo reversed, a machine for transforming electrical energy into mechanical power. It takes its power from off a wire, as sent by a dynamo from the source. To understand the technique of its construction and operation, consult the articles on ELECTRIC DIRECT CURRENT; ELECTRICITY and ELECTRICAL ALTERNATING CURRENT MACHINERY. The small electric motor has displaced the steam engine in a great number of uses, and continues to supply an immense variety of purposes by having some waterfall to rotate dynamos, and sending out current, much of which is used for
small electric motors, driving individual machines. Users of machinery in almost all lines now accept it as the best practice to equip all large machines with individual motors, and in this way not only make their operation independent of other machines, but also save the expense of surplus power and of running shifting and belts when the machines are idle. While electric motors have cost more in some cases than steam or gas engines, and while the charge for electric power in many localities is higher than for direct steam power, yet the convenience and the doing away with cumbersome overhead shafts and belts has more than offset these. The individual motor permits machines to be located without reference to shafting lines, and makes for greater efficiency and output. With each added machine a new motor comes, and there is no throwing out of central engine plants to make way for larger. The small electric motor may be built in as a part of the machine, or it may be bolted to the floor or ceiling. It may be direct-connected if the speed of the machine is appropriate, or it may be connected by reducing gears, rendered nearly noiseless by introducing rawhide. Rawhide connection is often used direct or through cone pulleys, and where the power transmitted is light, a friction connection is made satisfactory by covering the smaller of the opposed pulleys with a leather face. Where machines are small it is common to group them for motor-driving; four or six machines will all be fed to one motor, conveniently located in the centre of the group.

Manufacturers wind motors in an almost infinite number of ways to suit an endless variety of conditions. By placing resistances in the circuit, a considerable variety of speed is permitted. For printing presses a motor is made with a continuous current transformer of variable ratio. This permits a slow speed without loss, as a small current at full pressure is instantly convertible to a large current at low pressure. Continuous current series motors are preferred where the work is very heavy as in starting under heavy load, as with a crane hoist, or when encountering extra load from friction or dampness, as with cotton spinning machines on a day of high humidity. Single-phase alternating current motors have special uses, but are not well adapted to sudden changes of load. Motors that are both shunts and series wound are in large demand. This type is used on passenger elevators. The driving drum that carries the wire rope that hoists and lowers the elevator is commonly driven by this type of motor. To secure the needed gear reduction without grinding noise, a steel worm and gunmetal spur gear are run in oil. When the operator pulls the rope or lever in the elevator he turns the starting switch or controller on or off. An arm of the motor shaft acts against the brake of the motor, so the brake is turned on to prevent the motor from starting to race, and is normally held out of operation magnetically. Thus if the current fails the brake slows up the elevator. An automatic switch is placed to shut off the current at the top and bottom of the elevator's travel.

**ELECTRIC NAVIGATION.** Vessels of small draft are now propelled by electricity. The power drives a motor, which actuates a screw propeller. The current is generally supplied by a storage battery. From their noiselessness electric boats are peculiarly available for noontime torpedo operations, and the universal equipment of modern warships with electric lighting and power plants makes their use possible at all points. This type is often termed an electric launch, and most of all electric boats fall under this category.

**ELECTRIC PEN,** a pen invented by Thomas A. Edison, bearing on its head a small magnet, arranged to rapidly reciprocate a needle so that it protrudes and withdraws from the point. When connected with a battery this pen may be used to write or make drawings which appear on the paper as a series of perforations. The paper so perforated can be used for stencil printing, and several hundred copies struck off.

**ELECTRIC PENDULUM,** a form of electroscope consisting of a pith ball suspended by a non-conducting thread.

**ELECTRIC PHONOGRAPH.** See Phonograph.

**ELECTRIC POLICE SIGNALS.** See Electric Signaling.

**ELECTRIC POWER.** See Electric Machine; Power.

**ELECTRIC RAILROAD.** See Traction, Electric.

**ELECTRIC RAILROAD BLOCK SIGNALS.** See Electric Signaling; Block Signal System.

**ELECTRIC REPULSION,** the mutual tendency of similarly electrified bodies, or similar electric charges, to repel one another.

**ELECTRIC RESISTANCE,** that non-conducting property of a substance that resists or limits the passage of an electric current; the characteristic that goes to make a good non-conductor or insulator; sometimes called reluctance. It is defined mathematically as equal to the electro-motive force divided by the current-strength. All metals present some resistance to an electric current, mercury being the most resistant. For the relative resistance of metals see table under Electric Conductivity.

The resistance of a conductor varies directly as its length and inversely as its cross section. A box containing coils that are designed to resist or impede a current is called a resistance-box or rheostat. The starting-box of an electric car and the controller of a machine run by motor are based on this principle. The unit of electrical resistance is the ohm. See Electrical Units.

**ELECTRIC SIGNALLING.** While it is true in a broad sense that any method of communicating intelligence to a distance is embraced in the term telegraphy, in the present instance the term electric signalling will be employed to cover the signaling systems and methods described in this article. This term is perhaps the more appropriate inasmuch as certain of the systems to be outlined in reality partake more of the nature of mere signals than of a means of transmitting intelligence as that term is generally understood. Almost without exception electro-magnetism is employed in the operation of electric signals. See Electro-Magnetism.

The Electric Door-Bell.—This is perhaps
the best known and one of the simplest methods of electric signaling. In its operation it employs a primary battery, a push button at the door, a vibrating bell within the house, and a wire connecting the push button and the bell. The bell and its armature, the connecting wire, the push button and the battery, comprise the electric circuit. The push button is merely a key consisting of two strips of metal which when pressed together allowed the current to flow. The electric bell consists of a coil of wire wound around a soft iron core. Its armature carries at its free end a small hammer which, when the armature is attracted, strikes against a small gong, ringing it. The vibration of the hammer is brought about by a very simple device. Normally the armature rests against a contact point which is a part of the circuit; the armature itself also being a part of the circuit. The circuit is normally open at the push button. When this button is pressed the circuit is closed and the armature of the bell is forthwith attracted, its hammer striking the gong. At that instant inward, however, the armature leaves the contact point against which it had been resting, with the result that the circuit is opened at that point. This has the effect of permitting the magnet of the bell to lose its magnetism, whereupon the armature attracts a spring which holds the armature in position for the next cycle. When the circuit is again closed the circuit with the result that the armature is again attracted, which action is continuously repeated so long as the push button is pressed in. A small spiral or tension spring serves to keep the push button normally open. See Electric Bell.

Annunciator Signals.—The *annunciator* or call-bell systems so generally used in hotels and offices utilize the principle of the door bell. Annunciator systems in fact might be termed multiple electric door-bell systems. Usually a wire runs from each room to a central point or office where the annunciator is placed. This annunciator contains within its case a small electro-magnet for each room. One battery is caused to supply the current for all the circuits by connecting the battery terminals to the terminals of the battery. In a similar way one bell at the annunciator is caused to respond to all the calls that come. The armature of each electro-magnet within the case carries a small shutter, on which is placed the number or letter of the room which it is connected. This shutter is held out of sight by means of a small catch hook attached to the armature of the magnet until the push button in a given room is pressed, whereupon the armature is attracted, releasing the shutter, which instantly drops, showing the number. At the same time the annunciator bell rings, directing the attention of the clerk to the call. In other forms of annunciators the falling of the armature is caused to deflect a small flag on the face of which is marked the number, name or letter of the room. There may be almost any number of rooms for 1 up to 100 or more connected with one annunciator. In practice a single wire, called the armature, is run from each room to the battery and annunciator to all rooms. From each room a separate, individual wire is then run, from the “common return” in the room, through the push button and then down to the electro-magnet in the annunciator, there-by supplying a separate circuit for each room. In order to restore the shutters to their normal position after the call has been received, a rod is provided with a knob at its lower end which projects below the under side of the case containing the annunciator magnets. By pushing up the rod a cross-bar within the case is raised and this cross-bar in turn lifts up and resets the shutter and armature for the next call. In the later form of annunciators which are now frequently operated by alternating current of low voltage, the shutters of the annunciator are electrically reset by merely pushing a button, thereby closing the circuit of an electro-magnet.

Burglar Alarm Signals.—For simple domestic purposes the arrangement employed for burglar alarm signals is also closely akin to the systems just described, the main difference being that the finger push button is displaced by a circuit closing contact in the frame of a window or the jamb of a door. To bring about the result desired the circuit closer is placed on the window frame in such a way that the movable portion of the circuit closer projects beyond the surface of the window frame. The contacts of the circuit closer are held apart normally by a simple spring. In order that when the window is closed this projection may not be depressed, a piece is cut out of the window sash at a point directly opposite the projecting circuit closer. In an analogous manner the circuit closer is attached to a door jamb. The wires leading to the circuit closer are concealed behind the woodwork. When a window is raised or a door is opened by an intruder the contact points of the circuit closer are brought together, whereupon the annunciator bell is rung, giving the alarm, and at the same time the alarm is indicated by the dropping of the corresponding shutter in the annunciator. The annunciator is located in any desired part of the house, usually in a bedroom. The method described is termed an open circuit method. In such systems where from each room is run to the terminals of the battery, batteries, such as the ordinary dry batteries, may be used. In some cases, to guard against a momentary opening of a door or window, such as would only occasion a short ring of the alarm bell, not sufficient perhaps to arouse a sleeper, an auxiliary arrangement is provided at the annunciator consisting of a drop arranged to close the bell circuit continuously until the drop is reset. A small switch is provided near the annunciator by means of which the alarm circuit may be opened during the daytime so that needless alarm may not be given by the ordinary opening of windows. Other switches are also used for the purpose of testing the various circuits to see that they are in proper working condition. See Electric Annunciator.

Central Office Burglar Alarm System:—This system, as the name implies, relates to one in which the ringing of an electro-magnetic alarm in a central office will announce the presence of intruders in the building or buildings in which the wires are installed. The central office may be any convenient distance from the protected buildings. These systems are frequently termed electric protective systems. The plan usually adopted is to run a net-work of wires through parti-
ions, across floors, skylights, etc. These wires are part of a circuit extending to the central office, and the said wires are so connected with the circuit that any interference with them, after they have been set, will cut out a high resistance, consisting of a coil of wire, suitably placed in the circuit of the protected building. The purpose of this resistance is to increase the strength of the current in the circuit to operate the instrument in the central office. On the other hand, if a resistance is not cut out, but instead the wires of the circuit be cut or broken, the circuit will be cut or broken, and the consequent absence of current, or even a slight decrease of current, will likewise cause an alarm in the central station. The doubled-balanced instrument at the central office is usually a relay, the armature of which carries a needle that normally stands at a zero point, from which point it may be deflected in either direction. An increase of current on the circuit deflects it in one direction—a decrease of current allows a spring or weight to deflect it in the other direction. The alarm is given when the needle moves and an attendant is despatched to the premises from which the alarm has emanated. Each relay is of course suitably numbered or otherwise designated in the central office so that the building with which it is connected is known.

Telegram Message Service or Emergency Signals.—This service relates to the supplying or calling of messengers, policemen, firemen, etc., at the call of or by a subscriber, in whose house or office a "call box" has been placed. The subscriber electronically communicates by means of a wire with a central office at which the messengers are located, and from which office communication with police and fire headquarters can quickly be made. Each call box is numbered and is supplied with what are termed "hooks" and "break" attachments which are in operation by the turning of a crank on the cover of the box. These attachments, when thus operated, transmit automatically to the central office the number of the box, which at once indicates at the nearest point of the signaling box. The construction and operation of the call box are as follows: A crank is mounted rigidly with a recoil spring on a shaft. On this shaft is mounted, but loosely, a cog-wheel. A "break-wheel," having a number of slots in its periphery, is geared with the cog-wheel in such a manner that it receives a tendency to turn in a given direction, but it is normally prevented from turning by the engagement of a pin on its side with a curved cam which is attached to a prolongation of the crank arm. When, however, the crank lever is turned to, say, the right, preparatory to sending in a call, the cam is automatically moved out of the path of the said pin and the break-wheel is then free to move. By a suitable pawl and ratchet, the cog-wheel is prevented from movement in the direction opposite to that of the break-wheel, so that the effect of turning the crank is to wind the recoil spring. When the crank is let go the spring unwind and turns with the break-wheel which completes a revolution; at the end of which it is again held by the pawl as before. The break-wheel is made part of the circuit leading from the box to the central office. A flat metal spring which is also part of the said circuit rests on the periphery of the break-wheel in such a manner that when the wheel is making its revolution the spring falls into the slots on the said periphery and opens the circuit as many times as there are slots provided. If, for instance, the number of a given box is 24, there will be cut on the periphery two slots. In succession, then an interval of unbroken metal surface followed by four slots in succession. The circuit in such a case, as the wheel rotates, will be opened twice in succession, closed for an interval, and then opened four times in succession, with the result that a bell at the central office will give out, first two strokes, and then four strokes, on its gong. A large number of such boxes can be placed on one circuit without causing confusion. The call box just described suffices to send in a swift call for a messenger. When it is desired to make it possible to electrically communicate with a policeman, doctor or fireman by the same type of box, it is provided with a "stop" that projects through the cover in such a way that the crank cannot be moved beyond a certain point. The ordinary position of the stop should be at the messenger call, in which case the number of the box only would be sent in when the crank is turned. If, however, a doctor should be desired, the stop is moved to a point marked "doctor," on the cover of the box, and in turning the crank it is moved up to that point. This further movement of the crank has the effect of bringing into operation one or more additional slots on the periphery of the break-wheel in consequence of which the box number is preceded by one or more single strokes on the bell, which indicates that a bell at the central office attendant that a doctor, fireman or policeman, as the case may be, is desired.

Fire Alarm Telegraph Signals.—The importance of electricity as a time saver in announcing the existence of a fire can scarcely be overestimated. A special feature of the electric fire-alarm system is that it not only gives the alarm, but also indicates to the firemen the location of the fire, or within a very short distance thereof. It may be noted that a simple fire-alarm system is that in which an operator at the central station can send signals over the wires of the systems just described, in that it consists of a central office or station in which alarm apparatus and battery are located, and of signal boxes in the streets and elsewhere by which to transmit alarms to the central office. A wire connects the central station with the various signal-boxes in the streets and fire-engine stations. In each signal box is placed a break-wheel, practically similar to that used in the call-boxes of the district messenger or emergency service; the main difference being that owing to the more exposed position of the fire-alarm boxes and their greater relative importance, more substantial boxes are employed. In general these signal boxes are supplied with an inner and outer door to protect the apparatus from the elements. The signal boxes are provided with a crank or a hook which on being operated causes an alarm to be sent to the central station giving the number of the box from which the call has emanated. The signal box is also provided with a small electric gong, which rings each time the circuit is opened. This intimates to the one sending in the alarm, that the alarm is being properly transmitted. It also
serves the purpose of intimidating anyone who might open an adjacent box to send in an alarm therefrom, that the alarm is already being sent, thus preventing interference. At the central station and the various fire stations a gong is struck a number of times corresponding with the number of the box from which the alarm emanates. In the same circuit also an ink-registered register in the central office marks on a paper strip the number of the signaling box, thus giving a permanent record of such alarm. Inasmuch as it is not good practice to put more than 25 or 30 signal boxes on one circuit, but yet is very important that all the fire stations in a given district should receive the alarm, a repeating device is utilized at the central station which receives the alarm from any one of the circuits and thereupon repeats it automatically or manually to all the other circuits. It frequently happens that two or more street boxes on the same circuit are pulled simultaneously by different people. To prevent the confusion of signals that this would ordinarily entail special arrangements have been devised, termed the non-interfering succession signaling. These boxes not only prevent interference with the signals already in process of transmission by any given box, but also permit every box that may have been pulled simultaneously to send in its signal in rotation automatically.

**Automatic Fire-Alarm Signals.**—In many of the large cities of the United States an auxiliary to the regular fire-alarm system, consisting of some form of thermostat included in a circuit in the building to be protected, is employed. This system again is somewhat analogous to the messenger telegraph system described, the chief difference being that in the one case the signal box is manually operated, while in the other case an increase of temperature, due to fire, affecting the thermostat causes the alarm to be transmitted. Thermostats are of different types. One type consists of a crescent-shaped spring, made up of two strips of metal, steel and copper, one over the other. One end of the spring or strips is fastened to a support, the other end being inserted in a contact point of an electric circuit. As the metals named do not expand equally under increased temperature the spring as a whole bends or buckles when the temperature increases, and the movable end makes connection with the contact, thereby closing the alarm circuit with the result desired. Other types of thermostats are made of easily fusible alloys. Still another form of thermostat consists of a drum-shaped box, holding substances which have a high expansion under increased temperature. The expansion causes the ends of the box to bulge, thereby closing an alarm circuit.

**Police Electric Signals.**—These may be considered as more or less amplified fire-alarm systems, consisting as they do of signal boxes placed on poles and in booths along the routes of the policeman; from which boxes signals of all kinds may be transmitted to and from police headquarters. The signal boxes are connected by a suitable wire with headquarters; and each box has a break-wheel, carrying the number of the box from which the alarm is also hereby sent in the box by means of which the policeman may converse with the main station. In fact the telephone is used nearly exclusively, the policeman as he arrives at a signal box sending in a signal which intimates to the attendant at headquarters the number of the box at which he has arrived in the course of his beat, whereupon the attendant communicates with the policeman and takes his number, thus getting a record of his whereabouts. If the officer desires to send in a special signal regarded as for an ambulance or wagon, or for assistance, he can do so by a special arrangement within the box. In some cities certain citizens are supplied with keys of the signal boxes. Such citizens are authorized to send in signals for police assistance in cases of emergency, and thus the police force is practically augmented by a volunteer service. In many cities also the police signal apparatus is kept in a kiosk or sentry-box on the sidewalk curb. On the top of these boxes an electric colored lamp is placed and so connected that it may be lighted from police headquarters to call a policeman to the post for instructions.

**Railway Electric Block Signals.**—A block system in brief consists of a means of showing manually or automatically certain signals which indicate to the train boxes not only certain portion or section of the track before him is "clear" or occupied. The road is divided into sections or blocks which are of various lengths depending in a great measure on the topography of the route and the amount of traffic. The length of a block varies from 500 feet to several miles. The signals employed in a block are either safety, caution or danger, represented by a white light or sign, a green light or sign and a red light or sign, respectively. The sign usually consists of the well-known semaphore arm or blade. In automatic electric systems the circuits and apparatus are generally so arranged that the entrance of a train into a block sets the danger signal and that signal is displayed until the train passes out of that block into the next, when the danger signal is lowered and the caution signal is shown. When the train passes into a second block ahead the caution signal is lowered and safety is shown. The part assigned to electricity in the operation of these signals is relatively small. Electric signals which are placed in circuits capable of being opened, closed or short-circuited by the car wheels of a train, which electro-magnets are caused directly or indirectly to operate the signals. In what is known as the Hall Block Signal system the blades are operated against gravity by an electric motor placed in a case at the top or foot of the pole supporting the signals; suitable battery being provided for the operation of the motor. Thus when a train enters a given block a circuit is closed which starts the motor which in turning, by a system of cog-wheel gearing, raises the blade to a prearranged point, at which time the motor circuit is automatically opened and the signal is held in position by an electro-magnet until the train moves out of the block, when the blade is released and falls by gravity, means being provided to graduate and safeguard the fall of the blade by means of friction, due to the action of a centrifugal governor. Another electric block system uses a disc enclosed in a drum-shaped box, on the top of which a disc is operated by an electro-magnet, the latter being attracted by an electric current which is under
control of the engine, the latter operating, as it passes, a heavy circuit breaker by the side of the track. There is one of these circuit breakers at the beginning and end of a block. The engine thus sets the signal to danger as it comes into a block and sets it at clear as it leaves the block. A device named the Miller Cab signal is different from the foregoing systems. It consists of suitable apparatus and battery for operating certain electric lights in the engine cab. Normally a white light is burning, but when there is another train on the track in which the train enters, the circuits are so operated that the white light is cut out of the circuit and a red light is lit up in its place. This notifies the engineer of the near proximity of another train. See Block Signal System.

For a more detailed and illustrated account of the foregoing systems, the reader may be referred to the author's "American Telegraphy and Encyclopedia of the Telegraph."

Author of "American Telegraphy."

ELECTRIC SMELTING. See Electric Furnaces; Metallurgy.

ELECTRIC STORAGE BATTERY.

Electrical energy is developed in commercial quantity at the present day almost exclusively by means of a dynamo-electric machine, driven in turn by a steam engine, gas engine, water wheel or other prime mover. A plant of either of these kinds is somewhat complicated, so as to require skilled care in its operation; the electrical energy is available only while the machinery is in actual motion, and at such points as are connected with the generating plant by suitable electrical distributing circuits.

A device to supply electrical energy, under isolated conditions, and in such form as to be instantly available over long periods of time is therefore an almost imperative necessity and the device which science has developed for this purpose is known as the electric storage battery. The storage battery does not, as its name might imply, store energy in the electrical form, but rather in the chemical, and hence it belongs to the general family of electro-chemical apparatus.

Electro-Chemistry of Storage Battery.—The essential "working parts" of a battery, broadly speaking, are three in number, namely, active material of the positive and negative plates, respectively, and the electrolyte solution, surrounding and electrically connecting the first two.

For the purpose of causing these working parts to function as a battery, there are required a number of subsidiaries, equally necessary, whose duties are mainly mechanical and electrical in their nature. The active material consists of a more or less cemented mass of powder, possessed in itself of very little mechanical strength. To retain this material in its condition there are required the "grids," which, as the name implies, are in most cases flat metallic plates of very open grid-like structure, with projections or "luggs" at one corner, to serve for making the electrical connections.

Since the plates of opposite polarity would quickly discharge themselves if allowed to touch, they must be kept apart, and this is invariably accomplished by the insertion of "separators" between them.

As the electrolyte is almost invariably a liquid, rarely a jelly-like substance, there is required a retaining vessel, glass or hard rubber jar, lead lined tank or steel jar, according as the case may be.

Reference to Figs. 24 and 25 will make clear the general construction; the plates, alternately positive and negative side by side, with separators between, and resting or hanging in a jar which holds the electrolyte. A very necessary detail of design is that there shall be left sufficient clear space beneath the plates so that the sediment which gradually collects may settle there without contacting with the plates and causing a short circuit.

While attempts have been made to utilize all sorts of materials as "working parts," the successful combinations have narrowed down, until to-day there are practically only two in commercial operation.

The older and far the most generally used is known as the lead-sulphuric acid type; the newer as the alkaline, or, more generally, the Edison type. A description of each type separately will follow by a brief analysis of its characteristics.

Equations of the Alkaline Battery.—The Edison battery is chosen as the representative of the alkaline type because, although other varieties have been developed, and have met with limited success in Europe, yet Mr. Edison has carried the development of the type so much beyond any of the others that to-day his is the only alkaline battery of commercial importance.

The positive active material consists of nickel peroxide; the negative of spongy, metallic iron; the electrolyte of caustic potash or caustic soda solution. The chemical affinity of the sponge iron for oxygen constitutes the chief working force of the cell, diagrammatically represented in Fig. 1, in which A and B are the positive and negative plates and C the active material, immersed in the electrolyte within the retaining vessel.

The reaction of discharge may be explained thus: KOH readily splits up into the two "ions" OH and K; the former tending to travel to the negative plate, and there combine to form FeO₁₂ and H₂O; while the K ion tends to travel to the positive plate, and there combine with part of the oxygen of the NiO₂, and with water from the electrolyte, thus forming again KOH, exactly equal to the initial quantity.

The reaction may be represented as follows:

\[3\text{Fe} + 8\text{KOH} + 6\text{NiO}_₂ \rightarrow \text{Fe}_₃\text{O}_₄ + 8\text{KOH} + 2\text{NiO}_₂\]

It will be seen that the net result is a transfer of oxygen from the positive to the negative, accompanied by a concentration of caustic potash at the positive and a dilution at the negative; the total amount of caustic in solution remaining constant throughout. The reaction of recharge is held in check, and the electricity is furnished to the electrodes much as in the lead cell, described more fully on a subsequent page. During the process of charge the reactions are exactly reversed, with metallic
iron as the result at the negative plate and nickel peroxide at the positive.

The reaction on charging, however, does not take place directly in proportion to the amount of current, with the result that the charge must always considerably exceed the discharge in order to restore the cell to its initial condition. Moreover, the active materials in discharge are never completely converted according to the reactions shown; there always remain large proportions of metallic iron and nickel peroxide, even in a discharged cell.

Description of Edison Cell.—Caustic potash solution has but slight effect upon steel and none upon metallic nickel; hence nickel plated sheet steel constitutes an ideal material for almost all the structural parts of an alkaline cell, and is used for positive and negative plates, as well as for retainer.

The positive plate, Fig. 2, consists of a number of thin-walled steel tubes placed side by side and united by a surrounding frame,

![Diagram of Edison Cell](image1)

**Fig. 1.**
Diagram of Edison Cell.

likewise of sheet steel, nickel plated. Each tube is made up of a spirally wound, and double sealed, strip of thin sheet steel very finely perforated and filled with the active material, nickel peroxide. This material, however, happens to be an extremely poor electrical conductor, and in order to give it the necessary conductivity the material within the tube is interspersed with extremely thin transverse discs of metallic nickel, about 80 of them per inch length of tube. The nickel is prepared in the shape of extremely thin flakes, and a measured quantity of these is fed into the tube, alternately with a measured quantity of nickel hydroxide (which is later converted into nickel peroxide). After each double charge of flake and hydroxide a ramrod enters the tube and compresses the contents which are thus gradually built up till the tube becomes full, when it is pinched off and later assembled with others

![Edison Positive Plate — Vehicle and General Service — 1/3 size.](image2)

**Fig. 2.**

![Edison Negative Plate — Vehicle and General Service — 1/3 size.](image3)

**Fig. 3.**

into a complete plate. The usual diameter of the tubes is about one-fourth inch, though latterly a smaller size is also used to some extent. In assembling the plates right and left wound tubes are used alternately to eliminate twisting tendencies, and each tube is strengthened by a number of tight-fitting steel rings at frequent intervals.
The detail with which the manufacture of this plate has been worked out is extremely interesting, but limitations of space preclude a full description.

The negative plate (Fig. 3) is somewhat similar in design, with the difference that the active material, in this case metallic sponge iron, initially introduced as oxide of iron, is contained within small rectangular pockets or boxes of perforated sheet steel. The surface of the boxes is corrugated to give strength, but as the iron inside is a good conductor there is not required the mechanical pressure which necessitates the cylindrical form of the positive tubes. The pockets are about one-eighth inch in thickness and are locked by pressure into a surrounding frame of sheet steel very similar to that of the positive.

Positive and negative plates are assembled alternately, with small hard rubber insulating strips between; and the plates of each kind are united by a bolt extending across the whole group, through the holes at the top corner, as shown in Fig. 4. Hard rubber frames around the edges and bottom of the group insulate it effectively from the steel case which holds the electrolyte and retains the whole cell as a working unit.

The steel case is closed by a cover of the same material, which is welded all around so as to be perfectly air tight. This feature is necessary in order to exclude the carbonic acid of the atmosphere, which is readily absorbed by caustic solution, and which if allowed thus to enter into an alkaline cell exercises a very detrimental effect upon its operation. A check valve in the cover permits the egress of oxygen and hydrogen liberated during charge, while it excludes all atmospheric air with its contamination of carbonic acid.

The Edison cell of to-day is a very highly developed piece of electro-chemical apparatus, bearing ample witness to the genius of its inventor. The fact of its being built of nickel plated steel throughout gives it a ruggedness and a finished appearance which can hardly be matched by other types. If operated under favorable conditions it will last for a long time, often upwards of 1,000 cycles of charge and discharge.

It possesses on the other hand certain apparently inherent properties which very much limit its application, and which absolutely exclude it from many of the fields to which storage batteries are applied; under the heading of characteristics these points will be more fully brought out.

**Electro-Chemical Equations of the Lead-Sulphuric Acid Battery.**—The oldest and most generally used type of storage battery employs as its active materials peroxide of lead for the positive plate, spongy metallic lead for the negative, and for the electrolyte an aqueous solution of sulphuric acid, of about 25 to 40 per cent strength.

A cell of this kind is diagrammatically shown in Fig. 5, in which A and B are the positive and negative plates, respectively, each with a coating or râke, C, of active material, held in contact with it, while both plates are immersed
in the sulphuric acid electrolyte, held in a suitable containing jar.

Between sulphuric acid and metallic sponge lead there exists a strong chemical affinity, which constitutes the basic operating force of the lead cell.

So soon as the internal reactions are permitted to take place, by the closing of the external circuit, the sulphuric acid, $H_2SO_4$, begins to split up, $SO_\text{aq}$ going to the negative plate, there combining with the sponge lead to form lead sulphate, $PbSO_4$, and in so doing liberating a small amount of electricity. A small part of the electrical energy that had been applied to it. Repetition of the experiment showed that the cell slowly but steadily gained in capacity for storing energy, while occasional reversals greatly accelerated the gain.

The explanation of the phenomenon as we now understand it is this: Metallic lead, when placed in sulphuric acid, is immediately attacked, with the formation of a thin skin of lead sulphate, which, being insoluble, protects the metal from further action. Electrolysis, however, removes the sulphate upon the positive to peroxide of lead and peroxide the sulphuric acid to work a little further into the metal beneath; and it is thus that the action is cumulative and the amount of lead in a porous or "active" state continues to increase. Electrolysis affects the negative, however, merely in reducing the lead sulphate to metallic lead, so there is here but little cumulative action, and hence occasional reversal is necessary to build up the thin skin of "active material" on both plates together.

Months of charge, discharge and reversal were required to build up a layer sufficiently thick to make a battery of useful capacity. Hence other inventors set about to shorten this arduous process, known as "formation," and finally Faure, in France, and Brush, in America, about simultaneously discovered that they could apply to the plates a thick coating of lead oxide, made into a sort of putty-like paste with sulphuric acid, which, by means of a single slow charge was converted into thoroughly porous active material.

Subsequent improvements on Plante's process have shortened it until now it is about as quick and as cheap as Faure's process, so that at the present time both are successfully employed, the Faure very much the more extensively.

### Plante and Pasted Types Compared.

The Plante and "pasted"* types as now used differ very distinctively in their design, though electrically the difference is much less than would be expected. The Plante plate consists of pure lead, upon the surface of which there is "formed" a thin layer of "active material" having a thickness of the order of a few hundredths of an inch. The layer is necessarily thin in order to prevent its peeling off readily; hence a very large surface is required, and this is usually obtained by making the lead plates in the form of a number of parallel transverse leaves, as shown in Figs. 13 and 14. The surface area is increased by this construction anywhere up to 8 or 10 times that of a plain sheet of equal superficial area.

The "pasted" (Faure) type, on the other hand, is characterized by a relatively thick mass of porous active material, retained by an open-
work grid or lattice of lead-antimony alloy, as shown in Figs. 6, 7 and 8.

Both types of plate can be used as either positive or negative, but certain characteristics make the one or the other better suited to particular classes of service, as will appear hereafter.

**Negative Plates.** — *Exide Negative.* — The negative plate of a lead storage battery, at least theoretically, is quite a simple matter; the sponge lead which constitutes the active material has considerable mechanical tenacity and is therefore relatively easy to hold in place upon the skeleton frames or "grids" to which it is applied. There is no destructive action upon the lead-antimony alloy which these grids are made, and they may therefore be as light as methods of manufacture will permit. Fig. 6 shows a negative grid of the type which is now standard in the United States, and which is still best known under its original name of the "Exide." Fig. 7 shows a cross-section of the same grid, and shows how the active material occupying the interior spaces is locked in place so as to be both retained and protected, while Fig. 8 shows the finished plate, the active material filling all the interior spaces. This type of plate is used in sizes from about three square inches surface up to 700, in thickness from three-thirty-seconds to one-fourth inch, and for every variety of purpose for which lead batteries are employed.

**Box Negative.** — For some purposes, however, it is desirable to have a plate which will give the maximum possible life, consequent increased weight being a secondary consideration. To meet this requirement the "box" negative shown in Fig. 9 is used. This plate may be considered as a development of the exide type, inasmuch as the active material is held within two protecting surfaces, which, in the case of the box plate, consist of finely perforated lead sheets, while in the exide type they consist of parallel bars with relatively large openings between. The box plates are used almost entirely where long life is the main consideration, but the greater weight of grid, with consequent greater cost, has caused them for most purposes to be superseded by the Exide type.

The grids of the Exide type are castings of antimony-lead alloy, made as light as possible consistent with necessary mechanical and electrical conductivity. The box grids are composite, consisting of perforated lead sheets, upon which are cast intersecting ribs, or bars, of antimony-lead alloy, which gave the necessary strength; and each plate consists of two parts riveted together, with the active material enclosed between them.

While any oxide of lead may be used for the active material of negative plates, a long process of elimination has finally resulted in
the universal adoption of litharge PbO, for this purpose, applied as a putty-like mass, made by mixing the litharge with dilute sulphuric acid. An initial charge, or "formation," converts the litharge into metallic sponge lead, giving the plate a characteristic light slate color.

**Plante Negative.**—There are still a few Plante negatives used, in this country only, such a one being shown in Fig. 10, but their weight and cost are against them, and they are to-day almost a thing of the past.

**Positive Plates.**—The positive plate offers a more complicated problem, chiefly because lead peroxide, under the conditions which exist in a storage battery, does not possess much sustained mechanical strength, but gradually becomes soft, and in time is loosened from the plate, falls to the bottom of the cell and thenceforward plays no useful part in the life of the battery.

To maintain the capacity over an extended period of charges and discharges three distinct methods are employed.

![Fig. 10. Plante Negative Plate for Train Lighting — 1/6 size.](image)

**Pasted Positive.**—In the pasted type of plate, when new, only a part of the lead peroxide is available for entering into the chemical reactions of the cell, as the acid penetrates only partially into the interior of the mass. As the surface wears away the action penetrates farther in, and thus the inner part of the mass acts as a reserve and maintains the capacity for a number of cycles, roughly stated at 300 to 500. By making the plate very thin, say of the order of one-eighth inch, the reserve of active material is cut down to a minimum, hence giving a plate of maximum capacity per unit of weight, but of relatively shorter life.

Positive plates of the pasted type are universally employed where lightness, or maximum capacity for given weight, is the primary consideration, and the correct balance between thick, heavy plates of long life and thin, light ones of shorter life, to meet special conditions, is a continual problem to the designer. The general trend of modern practice, however, is toward much thinner plates than were thought practicable a few years ago, a thickness of three-thirty seconds inch being quite common.

The Exide type of pasted plate, Fig. 11, which has become standard in the United States, and largely so in Europe, is very similar to the negative plate, except as to its active material. The grid, Fig. 12, is, however, more substantial in its design than the negative, in order to withstand the greater corrosion and mechanical stresses to which it is subject. While various oxides, or mixtures of such, are used by different manufacturers as positive active material, the usual material is red lead, PbO₂, mixed to a putty-like mass with weak sulphuric acid, or ammonium sulphate solution. The initial charge, or formation, converts this into lead peroxide, a material which when dry has about the consistency of plaster of Paris and a very characteristic dark chocolate brown color.

**Plante Positive.**—The Plante plate is also subject to the continual, slow washing away of its lead peroxide, but the original layer is more durable than the peroxide made from red lead, so it lasts a considerable time in spite of its thinness. Moreover, all the while that the original layer is disintegrating and falling away, the electrolytic action is penetrating farther into the metallic lead of the plate and forming

![Fig. 11. Exide Positive Plate — Vehicle and General Service. Approx. 1/5 size.](image)

![Fig. 12. Exide Positive Grid. About 1/5 size.](image)
fresh active material, in the manner of the Plante formation, and thus there is a balance between loss and gain, and the capacity of the plate is maintained for a long period, say about two or three times as long as in the case of the pasted plates. For effecting this extended life, however, there is required a large reserve of pure lead; so that in actual practice the Plante plates weigh from two to three times as much as pasted plates of equal capacity.

Figs. 13 and 14 show a Plante type of plate known in this country as the "Tudor," used largely in Europe, and consisting of an integral one-piece casting; while Fig. 10, though actually a negative, may be used as illustrating the Gould type, made from rolled sheet lead, by a spinning process.

In this country and in England a modified Plante plate, known as the "Manchester," has largely superseded all of the above, chiefly on account of its superior mechanical construction. The Plante plate is made of pure lead, because this metal is attacked by the electrolytic action at about the right rate to replace the loss of lead peroxide; but pure lead is very soft, hence these plates are much subject to buckling and breaking. The Manchester plate (Fig. 15) differs in that a rigid grid, or frame, of antimony-lead alloy furnishes mechanical strength, while small, pure lead, spirally wound "buttons" (Fig. 16) inserted in holes of the grid (Fig. 17) furnish the active material which performs the electro-chemical function of the plate.

The combined mechanical and electrical endurance of this type of plate has given it a very broad field of application; its weight, roughly triple the pasted type, and its consequent cost constitute its chief limitations.

Ironclad Type.—During the past five years a third type of positive plate has come into prominence in this country, founded on the principle first successfully developed by Philip, in France, about the year 1898. This plate, known as the "Ironclad," is shown in Fig. 18, and differs from those heretofore discussed in that a porous exterior envelope retains the active material in place, so that the large reserve necessary with other types is here unnecessary.

The plate consists of a number of cylindrical pencils, one of which is shown in section in Fig. 19; a central-lead antimony core furnishes support and conductivity for the surrounding mass of active material, itself again enveloped by the perforated hard rubber tubes (Fig. 18). The perforations in the tube consist
of minute saw cuts of the order of one hundredth inch wide; and so effective are these tubes as "retainers" that the plates which employ them have a life approximating 1,000 cycles of charge and discharge, being two to three times that of the flat plates, Fig. 11, in which the active material is left exposed.

The life of the Ironclad plate is thus about the same as that of a Tudor or Manchester plate, while its capacity-weight ratio is about on a par with the pasted types.

With the Ironclad plate loosening and washing out of the active material is reduced to a minimum, and, contrary to what might be expected, the protective rubber tube offers but very slightly increased resistance to the passage of the electric current.

This type of plate, in conjunction with an exide negative of suitable thickness, is fast becoming standard in this country in all portable service where durability is a prime factor.

Separators.—Thus far we have limited ourselves to the question of the plates of the lead battery; but though they undoubtedly constitute the greater problem of storage battery design, yet the manner in which they are assembled is almost as important as the design of the plates themselves; and next in order of importance come the "separators." Considerations of space, weight and electrical resistance all demand that adjacent positive and negative plates be maintained as close together as possible, yet without touching anywhere. To fulfill these requirements spacers or separators of some sort are inserted between them. Here again countless schemes have been tested out, but to-day practically only two types have survived, and these often used in conjunction.

The older of the two is the perforated rubber separator, shown in Fig. 20, as a flat sheet of perforated hard rubber, and often, when used alone, provided with a series of parallel ridges on one side, to afford sufficient acid space between plates. When so used, however, even though the holes be small, "trees" of lead are very apt to develop on the negative plates, which in time find their way through to the positives and cause short-circuits.

The perforated rubber separator used by itself is therefore not satisfactory and has been almost entirely replaced by the wood separator, examples of which are shown in Figs. 21 and 22.
thicker piece, grooved, and in either instance treated by a special chemical process. The distinctive feature of the wood separator is that it is not perforated, with the result that short-circuits are practically eliminated, while its electrical resistance is nevertheless almost negligible.

**Fig. 22.**
Flat Wood Separator General Stationary Service. 1/10 size.

In many cases the grooved separator and plain perforated rubber are used together, the flat of the wood against the negative plate, this making an excellent combination, used in most of the vehicle propulsion and many other portable batteries.

The flat veneer with split dowels is used chiefly in large stationary batteries, where the grooving would constitute too great a wastage of wood.

**Containers.**—The vessels which contain the complete element—plates, separators and acid—are of three different kinds: hard-rubber jars, where lightness and ruggedness are required, that is, for all kinds of portable service; glass jars for stationary service in the smaller sizes; lead-lined wooden tanks for the larger stationary installations.

**Electrolyte.**—The electrolyte in lead batteries is dilute sulphuric acid of the highest available purity and of strength varying according to conditions. Where space and weight are of utmost importance, stronger acid, about 1.280 specific gravity, is employed, but where these items are non-essential a greater bulk of weaker acid, say 1.200 specific gravity, answers better, in that it causes less loss from local action, especially on the negative plates.

**General Assembly.**—So much variety exists in the details of assembly employed by different manufacturers and for different purposes that it will be possible to mention only a few of the controlling factors and to give a few illustrations of complete cells (Figs. 24, 25 and 28).

In all present-day designs, positive and negative plates are placed alternately side by side, all of like polarity being firmly united into "groups" by means of "lugs" which project from the upper corners. Fig. 23 shows a positive and a negative group as used in the small auto starting battery of Fig. 26; and these illustrations also show the general manner in which...
the plates are united, by a lead-welding process, to the connecting straps which form the terminals of the cell.

The corrosive action of the acid electrolyte makes this lead welding necessary, and in most instances it is applied, not only in fastening the plates to the cell terminals, but also in fastening adjacent cell terminals together, so that there is a solid metallic contact from cell to cell throughout the whole battery.

Between the plates, and thus keeping them apart, lie the separators; the whole element so proportioned as to fill the container, tightly in portable batteries, somewhat loosely in stationary ones.

The plates are usually either supported upon ridges projecting upward from the bottom of the jar (Fig. 24) or are suspended from the top of the jar (Fig. 25) or from the lid or in some equivalent manner.

Tight covers for the containers have to be provided only for portable service; stationary cells are generally left open for ready inspection and access.

**General Principles of Complete Battery Assembly.**—Till now we have dealt with only the single cell, which forms the electrical unit of which a battery is built up. This unit has a current output dependent upon the number and size of plates which it contains, while its electro-motive force has a fixed value, roughly two volts, virtually independent of its size. Hence the current requirements of a given battery determine the size of cells to be employed, and the voltage requirements the number of cells to be used in series. As the field of the storage battery is very broad, so the design varies greatly, including almost every conceivable combination from the small three-cell battery for auto starting (Fig. 26) to the large central station battery of 150 cells, as shown in Fig. 30.

**Inter-Cell Connectors.**—For connecting the individual cells together electrically, various forms of "connectors" and "bus bars" are in use, usually made of lead or lead-antimony alloy, occasionally of copper, protected by a coating of electro-deposited lead. In Fig. 27 is shown a connector as used, not only for auto starting batteries, but for most other portable and semi-portable types. Composed of lead, or alloy, it is made to fit over the tapered terminal posts (Fig. 23), to which it is permanently secured by means of a hydrogen flame, or its equivalent, which melts the lead of both post and connector till they flow together and become united.

In Fig. 25 there are no connectors proper, the pure lead straps to which the plates are attached having prolongations adapted to be bolted together from cell to cell.
having a projecting "lug" which reaches part way over the edge of the cell where all are united to a substantial lead bus bar, as in Fig. 30 and at "D" in Fig. 28. The bus bar "C" in this figure is one of the battery terminals, and the lead is reinforced by a large tapered plate of copper, to which is bolted the copper bar that connects the battery to the switchboard.

In Fig. 30 are shown a number of these terminals with the large copper leads off. In this instance the battery is so arranged that the number of cells in circuit may be varied by means of a motor operated "end cell switch," so as to vary the voltage at will, or more usually to maintain the voltage constant by throwing in additional cells as the E.M.F. of each falls off during the progress of discharge.

Insulation.— In the small portable batteries, such as the auto starting type, insulation of the individual cells is easily accomplished by the rubber jars themselves, which accordingly are placed side by side in a box of suitable size. When, however, a number of such cells, say 40 or more, are connected in series, as in Fig. 30, it is found necessary to divide the series amongst a number of boxes, or "trays," each one preferably containing not more than 8 or 10 cells.

In small stationary batteries a flat glass tray under each cell is often used, as shown in Fig. 25, a little sand being placed in the bottom to give an even seat for the glass jar. Larger stationary cells are usually provided with double insulation of some kind; thus in Fig. 28 the tank rests upon a glass-oil insulator, "B," which in turn is supported by a large inverted stoneware cup, "A."

Characteristics of the Storage Battery.—
The primary useful quantities furnished by a storage battery are electromotive force, or P.D. (measured in volts), and current (measured in amperes); since the time during which a given current may be maintained is frequently of controlling importance there arises a third quantity called the capacity, the product of the current and the time which the battery can furnish it. Frequently the relation of these three primary attributes to the weight of the battery is a vital factor; while the effects of internal resistance and temperature are scarcely less important. The characteristics of a battery therefore consist of the relations of these quantities one with another. In the following discussion the unit considered is in every case a single cell.

In speaking of the discharge of a battery, the term discharge rate is very frequently used, commonly expressed in terms of the time during which the discharge can be maintained; the four-hour rate for instance being that rate which the battery can hold for four hours. The so-called "normal rate," originally that for which the battery was intended, is actually of but little significance, since the modern battery may be discharged at almost any rate without injury.

The capacity is limited by the fall of voltage to a point where usefulness ceases, this point being again arbitrary, but through large experience fairly well defined as about 1.00-1.80 for the lead cell, about 0.6-1.0 for the Edison type.

Many variations exist in the design of modern storage batteries, and each design possesses its own characteristics; the curves which follow are chosen as fairly representative, but of course cannot pretend to fit all cases.

Characteristics of the Edison Cell.—Capacity—Temperature.— The capacity of a given Edison cell is very nearly a constant quantity independent of the rate of discharge, amounting under ordinary conditions to about 11.5 ampere hours per pound. The capacity, however, very markedly dependent upon temperature, to an extent which varies with the discharge rate. This variation with temperature is so great that there results a critical point, below which the Edison cell becomes practically inoperative; and since this point is from 30-50° F., depending on conditions, it constitutes one of the chief limitations to the usefulness of this form of battery. If given a chance to discharge rapidly, when slightly below the critical temperature, the battery will gradually warm itself; but for immediate action at low temperatures it is unworkable.

Voltage — "P.D."—Fig. 31 shows a typical voltage curve of an Edison cell during its "normal" or five-hour rate of discharge, and during the corresponding charging rates of discharge the voltage is higher, while at higher rates it becomes lower. Fig. 32 summarizes a number of discharge curves by giving the initial, the mean and the final voltage at rates up to six times the normal. It is noticeable that the voltage falls off very rapidly with increasing discharge rates and that the maximum current obtainable is only about 14 times the normal, while the maximum watt output is reached at about seven times the normal rate.

It is of interest to notice that the mean voltage of the Edison cell is about 60 per cent that of the lead type and that the percentage drop during discharge is about triple with the Edison. It is thus necessary to employ at least 65 per cent more cells of Edison type for a given discharge voltage; and still more than this if the discharge rate be high.

Efficiency.—Comparing the mean values of the two curves of Fig. 31 we arrive at the value — 72 per cent — as the mean "unit efficiency; the corresponding amper hour efficiency is approximately 88 per cent, while the watt hour, or energy efficiency, the product of these two, is 65 per cent.
In actual practice, the charging is frequently done from a fixed source of voltage equal to or slightly exceeding the maximum, 1.75 in the present case; hence under these conditions, the commercial voltage efficiency is but 68 per cent.

Also, in practice the charge required is greater than that shown in Fig. 30, so that show that at ordinary temperatures and moderate discharge rates the Edison battery may give excellent service. At high rates, or low temperatures, however, its performance is so limited that it is now seldom used where such conditions prevail. It is these conditions which have excluded it entirely from the field of auto self-starting; while on the other hand, in other

![Typical Charge & Discharge Curves of Edison Cell - Normal Rate](https://example.com/fig31)

actually the ampere efficiency is about 80 per cent. The commercial watt hour efficiency of the Edison battery, where worked to its full capacity and charged from a source of constant voltage, is thus found in actual practice to average hardly above 55 per cent. Where charged from a source of variable voltage, and where worked to partial capacity only, the efficiency may be much higher, depending on actual conditions.

*Capacity and Weight.*—The energy capacity of the Edison cell at normal rate and temperature is about 14 watt hours per pound. With higher rates, or lower temperatures, this value falls very markedly.

*Summary.*—The characteristics noted above service, as for instance, train lighting and mine lamps, it has proved very satisfactory.

**Characteristics of the Lead Cell.**

*Capacity.*—The capacity of a given lead cell is mainly dependent upon two variable factors: (1) the rate at which it is discharged, and (2) its temperature.

1. The effect of varied discharge rates is shown by the curved line in Fig. 33, from which it will be seen that the capacity varies inversely with the rate, though not in direct ratio. While the abscissae of this figure show the discharge rate in terms of the normal, vertical lines at intervals give the rate in terms of the duration of discharge.

The shape of this curve is very characteris-
tic of all lead batteries, though differences in design modify it appreciably. Thinner plates tend to give a flatter curve, thicker ones a more sloping one.

A very important corollary of the variation of capacity with rate exists in the fact that a lead cell which has been completely discharged at a high rate, if allowed to stand for some hours, will largely recover, so as to give a considerable further discharge. In the case of a continuous discharge of diminishing rate, the ultimate capacity approaches that which would have obtained had the final rate been maintained throughout. In the operation of an electric vehicle the rates on starting, up grades, etc., exceed the normal rate by five to one or more; yet owing to the periods of rest, or low rate, the capacity attainable is practically identical with that of a continuous normal rate discharge. The normal rate for batteries of this kind is usually that corresponding to a continuous discharge of four or five hours.

2. Temperature at time of discharge exercises a direct influence upon capacity to the extent of about 6½ per cent per 10 degrees F. It thus comes about that at 0° the lead battery has about 54 per cent normal capacity, and that it is perfectly workable at temperatures much lower even than this, especially where the discharge rate is lower than normal.

Discharge Phenomena.—1. Voltage (or \( VD \)).—Of equal importance with the capacity of a battery is its voltage characteristic, a typical curve of which is shown in Fig. 34. Starting off at approximately two volts, there is a gradual falling off, till the end approaches, when the voltage rapidly drops below a useful value. The curve shown is for the normal rate, but is fairly indicative of the general behavior of a lead cell on discharge. With higher rates, however, the curve is lower throughout its length, and more nearly approximates a slanting straight line. Referring again to Fig. 33, the three upper lines, with the scale of ordinates at the right hand side, summarize the effect upon voltage of various discharge rates up to 10 times the normal. It is of interest to note that at 10 times normal the mean voltage has lost but 20 per cent; that the maximum watt output occurs at about 25 times normal; and that short circuit gives about 50 times normal discharge current. Comparison between these curves and the corresponding ones for the Edison battery, Fig. 32, is very significant. The Edison battery is inferior (a) in that it has a much greater percentage drop in voltage during discharge at any given rate, and (b) in that the lead battery can discharge at about three times as high a rate as the Edison.

2. Acid Change ("Gravity").—It has been pointed out in discussing electric-chemical equations, that the amount of free sulphuric acid varies as discharge proceeds, and the third curve of Fig. 34 shows for a particular case what this change amounts to. Barring the fact of a lag at the start, the change of acid, measured by hydrometer, varies directly with the ampere hours drawn from the cell; but the amount of change depends so entirely upon the relative volume of acid contained in a given cell, that the numerical values of this curve in Fig. 34 have no general significance.

3. Temperature Change.—The lead cell to a slight extent is a thermo-electric accumulator, inasmuch as a slight disappearance of heat accompanies the discharge. This phenomenon is graphically shown in the lower curve of Fig. 34, where it is seen that the temperature dropped 9° F. during discharge. At higher rates, the heat generated by internal electric friction overbalances that absorbed, and at the one hour rate the temperature rises about to the same amount as it dropped at normal rate. The absorption of heat on dis-
charge, while of much theoretic interest, is of little practical value.

Internal Resistance.—One of the most valuable attributes of the lead battery is its high conductivity, which enables it to yield up its stored energy at extremely high rates. It is impossible to state the resistance definitely owing to variation of design; but by way of illustration it may be said that a cell of the type from which Fig. 34 was taken, having a normal rate of 35 amperes, has an internal resistance of about .0014 ohms at beginning, and .0028 ohms at end of discharge. Since it is mainly through its influence upon voltage that internal resistance is of interest, the data furnished by the curves of Fig. 33 give the practical information required better than an attempted formula for calculating resistance.

Efficiency.—During charge, the P.D. of a lead cell starting at about two volts rises gradually and finally becomes constant at a rather indefinite value, from 2.5 to 2.6 volts, following the general trend of the upper curve of Fig. 34. The mean height of this curve is 2.3 volts; that of the discharge curve 1.95 volts. Hence the volt efficiency is 85 per cent.

In commercial operation, it is found necessary that the charge exceed the discharge by about 15 per cent, so that the ampere hour efficiency is about 87 per cent, the watt hour efficiency about 75 per cent. When worked to less than 100 per cent capacity, both voltage and current efficiency are higher; so that in such cases it may reach or even exceed 90 per cent, as in regulating service, where charge and discharge succeed each other rapidly and for a few minutes duration only.

Where a battery is charged from a fixed voltage, on the other hand, this voltage must at least equal that at the end of the charge; hence where worked to full capacity under these conditions, the volt efficiency is about 75 per cent, the watt hour efficiency about 65 per cent. These conditions are the most prevalent, except when a battery is charged directly from a generator, whose voltage is made to vary according to the charging curve.

Capacity Weight Ratios.—The capacity per unit weight of lead storage batteries varies all the way between 1.4 amper hour per pound of cell in the heavier stationary types, such as Fig. 25, to about 5.5 in the lightest thin plate types for portable service, Fig. 26. These figures, as a basis of comparison, refer in all cases to a discharge rate approximating the five-hour. To find the corresponding values for other rates, reference should be had to the capacity curve of Fig. 33, bearing in mind that 100 per cent in this figure corresponds to an actual capacity of 4.6 ampere hours per pound.

Since the mean discharge voltage under
ELECTRIC STORAGE BATTERY

varied field to which batteries are applied, would be beyond the scope of this article; but a few fundamental principles with wide applicability to all cases may be briefly stated.

1. Care of Electrolyte.—Evaporation of the water of the electrolyte is constantly taking place, especially while the cell is gassing freely at the end of charge; this must be made up by periodic additions of water. Since the amount of water thus added during the life of a battery is many times the original amount contained, any impurities in the water accumulate quite rapidly. Hence it is very important to use only pure water for this purpose, and among the impurities commonly present chlorine and iron in any form are especially to be avoided. Addition of acid should be avoided.

2. Regulation of Charge.—If a battery be habitually charged too little, the active material becomes gradually more and more converted into lead sulphate, until in time it ceases to function. Very long continued charge is then necessary to restore it to a working condition. If on the other hand it be charged too much, the gas bubbles liberate from the plates given rise to a softening and engraving action upon the positive material, which detaches it from the plates, and in time leaves the grids bare, and no longer workable. Experience has demonstrated that best results are obtained when each charge exceeds in ampere hours the previous discharge by about 15 per cent.

Several methods are in use for determining the correct amount of charge, as follows: (a) The "ampere hour" metre shows directly, both the current withdrawn on discharge and that put in on charge, from which the latter may be regulated; a very generally effective method when the discharge current is not too low, say 10 per cent of the normal. (b) The battery may be charged till the voltage ceases to rise; one of the older and less reliable methods. (c) The best indication of the state of charge is that based upon specific gravity of the electrolyte. If the specific gravity be read at regular intervals during charge, it will be found to rise steadily for a time, and then become constant. When three successive readings covering a period of about an hour show no change in gravity, it means that chemical action between plates and electrolyte has ceased, and hence that the charge is complete, and should be stopped. This method of determining charge is far the most reliable, and should be used wherever possible; and in any case should be used from time to time, to check up and make certain that charging is being done correctly. A single cell is usually selected as a "pilot" for taking readings with this method.

While the life of a battery may be much increased by careful regulation of the charge, according to the above principles, yet many hundreds of thousands of batteries are in successful operation, where the only care observed in charging is to arrange that it is ample, regardless of other considerations.

The strength of electrolyte used in storage batteries is not standardized, but varies with different design of battery, with the individual cells of a given battery. In general where weight is a prime factor, higher gravity, usually about 1.280 specific gravity, is used; where weight and bulk are not important lower gravity, 1.200 or even 1.150, are preferably employed. In the former case the volume of acid is small, and the drop of acid during discharge is correspondingly large, so that in discharged condition it may be 1,150; in the case of a stationary cell, where there is no close limit to bulk, the acid which reads perhaps 1,200 on charge will drop during discharge to about the same point as the other, namely, 1,150-1,170. It is thus impossible to give any generally applicable values for the specific gravity of the electrolyte, but the theory of charging till a maximum is reached holds universally true.

The specific gravity of sulphuric acid of the concentration used in batteries varies with temperature, a rise of 10° F. causing a drop of .003 specific gravity; and as a matter of reference it is usual to correct all readings to 70° F.

Applications of the Storage Battery.—The field of the storage battery to-day is so broad that a few of the most important applications only may be enumerated, as follows:

- Propulsion of Automobiles and Commercial Trucks.—Usually 40 or 42 cells, capacity of 100-250 ampere hours, type of cell as per Fig. 24.

- Propulsion of Mine Locomotives.—40-88 cells, 200-300 ampere hours capacity. Fig. 36.

- Propulsion of Small Industrial Trucks.—Usually 12-16 cells, 100-200 ampere hours capacity, type of cell as per Fig. 24.

- Propulsion of Submarine Torpedo Boats, while running submerged.—Usually 120 cells, 4,000-14,000 ampere hours capacity.

- Electric Lighting of Railway Trains.—Each car equipped with a battery, usually 16 cells, 150-350 ampere hours capacity. Fig. 35.

![Fig. 35. Two Cell Unit of Train Lighting Battery, which consists of 16 Cells in all. Approx. 1/10 size.]

Starting and Lighting of Automobile.—Usually 3 cells, designed to give 150-250 amperes for short intervals of a few minutes duration. Fig. 26.

Airplane Motor Ignition.—Usually 4 small cells, to insure motor reliability.

Mine Lamps.—One or two cells, 8-12 ampere hours capacity.

Railway Signal Service, for operating the signals which control the movements of trains. Wireless Telegraphy as the source of power, both ashore and afloat, in army and navy, as well as commercial service.

Telephone Stations furnishing power for the telephone systems. Practically every central is provided with a battery, charged from a small dynamo, and for the purpose of assuring con-
of man can collect without any apparent effect on this vast storehouse of nature. But the sun is also a natural dynamo, of vast potential activity and subject to electric stresses of a violence far transcending anything we have or can experience on this earth. One of the apparently effects of the electric and chemical activities of the sun is displayed in the sun-spots, which occur there with irregular frequency, appearing to come and go in undetermined cycles. The cause of these sun-spots is largely conjectural, but the view is generally accepted that they represent openings or vortices in the outer gaseous envelope of the sun. However this may be, it is apparent that they are in some way connected with the electric storms or violent changes of magnetism that occur on the earth. These electric stresses occur at intervals that cannot be predicted, but are comparatively frequent, and perhaps once or twice a year the violence of the magnetic changes is sufficiently abnormal to be characterized as a great storm, which for a short time paralyses the action of more or less electric machinery, much as a great storm of wind and rain paralyses the traffic of a large city.

For the past 25 years or longer many scientists and a number of observatories have been more or less engaged in studying the phenomena of these storms and have striven to formulate a correct theory of their origin and progress. The difficulty is not that reasons cannot be found for such irregularities of the earth’s potential, but rather that there are so many plausible explanations which cannot all be true, that the investigators are puzzled which clues to follow. Early observations disclosed a periodicity in the electrical storms, that clearly tended to follow the displays of sun-spot activity. If these spots were the direct cause it would be reasonable to expect the following electrical storm on the earth to come at a definite interval; but the fact is that an electric storm always lags behind the sun-spot activity, and lags all the way from a few hours to a few days. While the average lag is about 38.4 hours, the lag in great storms is only about 20 hours, indicating that the more violent the influence the swifter the travel.

Another sort of evident periodicity in electrical storms is their recurrence in periods of about a month. Some observers have figured numerous intervals corresponding with the lunar month, while others have noted a close correspondence with the synodic months of 29 and a fraction days, this synodic month representing the dates on which the earth, sun and moon come almost or quite into a direct line. This suggests that the storms are influenced by the sun and moon jointly, or that in some way the moon directs these extraordinary electric activities of the sun toward this planet.

Certain other well-established phenomena have been established with reference to these storms. Not only are they coincident with sun-spots to a marked degree, but also with displays of the aurora borealis or “northern lights.” Evidence of the latter is a palpable and evident evidence of magnetic disturbance. Another pertinent fact discovered is that the magnetic storm is about twice as apt to occur in the nighttime as in daylight, which is accounted for on the supposition that the rays strike the earth’s atmosphere at a great height and are deflected.
by the earth's magnetic currents, being mainly manifest on the hemisphere opposite the sun. They appear not as magnetic needles confined to the dark hemisphere; in fact they frequently strike the earth and circle it several times before their force is spent. Prof. L. A. Bauer, of the Carnegie Institute at Washington, discovered that in two great electrical storms (in 1902 and 1903) the magnetism circled the earth at a speed of about 7,000 miles a second, requiring 3/4 to 4 seconds only to complete the circumference. It had previously been supposed that all magnetic needles felt the storm at the same instant. He not only demonstrated this travel, but showed that some storms traveled from west to east, others from east to west. Other things we know about electric storms are that the smaller storms are comparatively local, being termed equatorial storms and polar storms according to the portion of the earth's surface affected. There are also types recognized as positive and negative storms.

Within recent years a new theory has developed, which may be summed up with the idea that pencil-shaped emanations or shafts of Roentgen or cathode rays, or perhaps of negatively charged particles, are shot out by the sun during periods of sun-spots, and that when the earth runs into one of these the effect here is an electric storm. This hypothesis assumes that the same electric activities that produce sun-spots also produce these pencil-shaped shafts of rays and not that the sun-spots are responsible for them. Professor Bauer points out that the fact that electric storms may travel in either direction and that the earth is against this pencil-like shaft theory, as these should intercept the earth always in the same way. The professor has also noted that these storms seem to break at a height of about 75 miles in the earth's atmosphere and that as they come closer to the surface their effects are felt more severely. He contends that the energy of electric storms is supplied by the earth itself and not by the sun or sun-spots; that the same activities in the sun that cause sun-spots, set in motion the electric storms and move them as a throng sets in motion the activities of the powder in a gun.

Prof. Kr. Birkeland, of Christiania, has made exhaustive experiments with vacuum tube apparatus of his own designing, in the effort to prove the theory of cathode ray origin or something similar. He has succeeded in duplicating much of the phenomena of the electric storm and made many valuable records, but his theories have not been generally accepted.

**ELECTRIC STRESS,** the force that causes the deformation of the surface of a substance within an electric field.

**ELECTRIC SUNSTROKE,** a stroke that prostrates a person in a manner resembling sunstroke, brought on by prolonged exposure to a strong electric light.

**ELECTRIC TELEGRAPH.** See Telegraphy.

**ELECTRIC TELEGRAPH CABLE.** See Cable; Telegraphy.

**ELECTRIC TELEPHONE.** See Telephone.

**ELECTRIC TENSION.** See Electric Batteries; Electricity; Electro-motive Force.

---

**ELECTRIC TORPEDO,** a torpedo operated by electricity. There are various kinds of electric torpedoes. The Siemens-Edison torpedo is driven by an electric motor and its motions are controlled from the shore by electricity. The torpedo proper is carried some distance below the surface of the water by a vessel immediately above it, from which it is released by rigid bars. In the torpedo is a cable reel on which the conducting cable is disposed. An electric motor and controlling gear are also contained within the torpedo. In its front the explosive is placed. It is driven by a screw propeller actuated by the electric motor. As it moves it pays out cable so that it has no cable to draw after it through the water, the cable lying stationary in the water behind it. This avoids frictional resistance to its motion. The maintenance of the torpedo at a proper depth is one of the advantages of the system over other methods.

**ELECTRIC TRANSMISSION OF ENERGY, Long Distance.** An electric transmission of energy obviously occurs when the relay of a Morse telegraph circuit, or the sensitive mirror used in submarine sounders, for example, responds to the feeble current impulse originated at the transmitting end of the wire. It is also obvious that we have the electric transmission of power in the ordinary use of electric light or electric motors. When the generator is stationed in the building in which that light or power is used. But generally speaking the term electric transmission of energy denotes the transmission of energy on a large scale by means of overhead or underground conductors or cables and its transformation into heat, chemical energy or mechanical power at the remote end of the conductors. When the distance to which this electric power is transmitted exceeds say 15 or 20 miles it is usually spoken of as the long distance transmission of electric energy or power.

In cities like New York where electric energy for lighting, power and railway traction is transmitted distances ranging from less than a mile to 15 or 18 miles a very powerful power house the conductors are usually placed in cables in underground conduits and the maximum electromotive force transmitted is about 11,000 volts. This pressure is directly generated by a steam-driven alternating current generator and is transmitted over the conductors to sub-stations, where by means of step-down transformers the pressure is dropped to say 600 volts alternating current which when direct current is desired by rotary converters is converted into direct current for the street mains, the feeders of the railway system and for charging storage batteries which in turn give out direct current at times of heavy demand or when otherwise required; or when alternating current is required for service mains the 11,000 volts is transformed to say 240 volts. When water power is available, as at Niagara Falls and innumerable other places in this and other countries, the electric transmission of power on a large scale to distances of 25, 50, 100 and 200 miles from its source is not uncommon.

In order that electric power may be transmitted economically to long distances the use of high electric pressure or tension is essential, since otherwise the cost of copper in the conductors would be excessive. For example: It
has been calculated, on the basis of 5,000 volts, that to transmit 2,356 kilowatts a distance of 100 miles would require about 22,862,737 pounds of copper in the conductors, assuming a line drop of 750 volts, or 15 per cent of the total electro-motive force, whereas 40,000 volts the total amount of copper required would be about 357,230 pounds. Even doubling the pressure would quarter the amount of metal required for a given distance and given line drop. In the electric transmission of power to long distances the use of alternating current is generally utilized, and transformers are utilized to increase the electro-motive force on the transmission line and for reducing it at the points of distribution. Where the electro-motive force on the line does not exceed 10,000 volts generators developing that electro-motive force may be employed. When that line voltage is exceeded the station voltage adopted is about 2,300 volts; this being stepped up by transformers to the electro-motive force desired on the line. This moderate voltage admits of the use of lighter copper wires or conductors in the station apparatus than higher voltages would require. In present day practice, however, the use of 150,000 volts is not uncommon and line insulators and transformers to withstand this pressure are now employed. Indeed, manufacturers are prepared to supply transformers capable of operating at 200,000 volts. In North Carolina and South Carolina over 1,000 miles of 100,000-volt transmission circuits are in operation on the system of the Southern Power Company, which derives its power mainly from hydro-electric developments. In California there is a 150,000-volt circuit from Big Creek to Los Angeles, a distance of 240 miles, on the system of the Pacific Light and Power Corporation. The conductors of this circuit are supported on steel towers. In addition this company has in operation 105 miles of 60,000-volt circuits, 240 miles of 50,000-volt circuit, and 83 miles of 15,000-volt circuits. These last circuits are supplied with current from the 150,000-volt circuits at various distribution points by means of step-down transformers in sub-stations.

Modern usage in the matter of type of alternating current employed leans largely toward three-phase. (See Electric Alternating Current Machinery). For each circuit this requires three conductors which are arranged on the poles and cross-arms usually in an equilateral triangle, the wires being separated from one another by a distance of six or eight feet. The wires are in some cases transposed on the poles, to form in effect a long horizontal spiral. This is generally done to prevent inductive effects on the telephone wires used for signaling on the same or adjacent poles, although some engineers also think that spiraling the conductors diminishes the impedance of the circuit. So far as the telephone line belonging to the transmission company is concerned the simplest way to avoid inductive effects is to spiral the telephone circuit. While, as just intimated, the long-distance transmission of energy is carried on chiefly by means of the alternating current, transformers, etc., high potential transmission in at least one instance in Europe has been effected with continuous current. In this instance the line pressure is 60,000 volts, which is generated directly on the line by six dynamo

machines in series, each generating 10,000 volts. At the point of distribution six motors are connected in series and each motor is caused to drive a generator which in turn develops electrical energy of a desired potential and current output.

For the supports of the transmission line the choice is practically between the use of wood poles or steel towers. The kind of wood employed for the poles varies somewhat with the locality, cedar being used in the northern States and redwood in the Pacific Coast States. These poles must be of sufficient height to afford ample clearance from ground and sufficiently strong to withstand wind strains, etc. Poles fitted to meet these requirements and to carry two three-wire circuits should be about 35 to 40 feet in height, set 5 to 6 feet in the earth and be 12 to 14 inches in diameter at the butt and at least 8 inches at top. The use of steel towers permits longer spans and consequently diminishes the total number of insulators necessary. With wooden poles the maximum length of span is 180 feet; minimum 80 feet. With steel towers using 12 to the mile the span between towers is 440 feet. On one long-distance transmission the towers are made up of four galvanized iron posts 40 feet in length, 3 inches by 6 inches with three-sixteenths inch angles, the posts being stayed with suitable angles and cross rods.

For the very high potentials used on long-distance transmission lines extra precautions as to insulation are requisite, both where the wires leave the power-houses and on the poles or towers. For insulating the conductors from the poles or towers large porcelain discs are now commonly used, in a series of four or more (arranged somewhat like Japanese dinner gongs), termed suspension insulators, the upper disc of which is attached to the pole or tower. The conductor is attached to the lowest disc. Much care is required in the manufacture of these insulators. This series arrangement of insulators has largely increased the amount of electro-motive force that can be successfully employed in electrical transmission of power as the electric potential is divided between the individual discs. Other types of insulators for high tension service consist of large petticoat insulators about 12 inches in diameter across the top, 12 inches in height and weigh 18 to

![Power House Terminal of Transmission Line](image-url)
20 pounds. They are supported on the cross-arms or on the pole itself, by wooden or iron pins, rakes, or by metal rods. These wooden pins are found fairly satisfactory, but above that pressure they are found to vary by a peculiar action of the current, and it is advisable on this account, as well as for mechanical reasons, to employ cast iron or metal composition pins. These pins are from 15 to 17 inches in height and they maintain the insulator about 12 inches from the pole or cross-arm. (See illustration, which shows an iron tower, a three-wire circuit, with cross-arms, pins and porcelain insulators; also the openings in the gable of the power-house by which the high tension conductors pass out.)

The choice of metal for the conductors in this service is virtually confined to copper and aluminum. It is known that there is a tendency to a brush discharge, termed corona, in the air between conductors conveying currents at high pressures that leads to a waste of electric energy when with wires of given diameter a critical electromotive force is reached. The critical electromotive force also varies with the distance between the wires. It was at one time thought that this effect would constitute the limiting factor in the long-distance transmission of electric power, but in Prof. Harris J. Ryan's paper, 'Conductivity of the Atmosphere at High Voltages' (consult 'Proceedings American Institute Electrical Engineers, Vol. XXI, No. 3), he shows that, regardless of the metal employed, by increasing the diameter of the conductors, whereby the electric gradient is kept below the breaking down point, the corona effect is reduced to a minimum. At the point of the wire in the vicinity of the wire, this effect is avoided. For example, to avoid atmospheric losses between conductors separated by an air space of four feet, with barometric pressure of 29.5 inches of mercury, temperature 70° F., the conductors must have, for an operating electromotive force of 50,000 volts, a diameter of at least .058 inch; for 100,000 volts, .192 inch; for 150,000 volts, .430 inch; for 250,000 volts, .990 inch. On this account it has been deemed advisable in numerous cases to employ aluminum conductors, since weight for weight its diameter is much greater than that of copper.

For instance, on a 150-mile line in California transmitting 745 kilowatts (10,000 horse power) at 40,000 volts, aluminum conductors seven-eighths inch in diameter are used. In a 100-mile, 60,000-volt transmission line in Mexico a copper wire three-eighths inch in diameter is used. The transmission line from Shawanigan Falls to Montreal, Canada, employs aluminum conductors carrying 12,000 horsepower at 50,000 volts. Steel-cored aluminum conductors are also used for this purpose and in some of the latest high tension transmission lines steel-cored copper conductors are utilized.

To provide a system that will be as nearly absolutely reliable as practicable duplicate circuits are in the majority of cases constructed, in order that if one circuit becomes inoperative the other may immediately be brought into service. In some cases these circuits are erected on one set of poles. In others two separate pole lines are built.

Wherever possible private rights of way are obtained for the transmission line and it is of advantage to have this way so wide that danger from falling trees shall be avoided. Rights of way along steam railway tracks are not considered desirable for the reason that the smoke from the engines so impairs the insulating quality of the insulators that frequent cleaning and washing of the insulators is rendered necessary. Even on private routes the cleaning of the insulators is at times essential to maintain the insulation.

The distance to which electric energy can be profitably transmitted from a source of electric power is not yet definitely determined. Much depends on the cost of fuel at the distributing points and the amount of energy to be delivered. In California, where coal is dear, electric energy is now being commercially transmitted from a number of water-power plants in that State to an amount exceeding 100,000 horse power at a pressure of 40,000 to 60,000 volts and to distances ranging from 50 to 250 miles. In Switzerland electric energy from water power is transmitted to the point of consumption and sold at $20 per horse-power hour per annum. There the price of coal is $6 to $8 per ton, but labor is cheap. Electric energy generated by the force of falling water is transmitted 85 miles by wire is sold in Montreal, Canada, at $15 per horse power per annum at a profit. But while as stated the distance to which electric energy may be commercially transmitted is yet undetermined, calculations have been made by reputable electrical engineers which indicate that under proper conditions electric power may ultimately be profitably transmitted in large quantities, say 200,000 kilowatts, and at a pressure of 170,000 volts, to a distance of 500 miles. This transmission would entail the employment of copper wires of a diameter so large that the dissipation of energy by brush discharges between the conductors would be avoided. Should this conception be realized it would obviously bring New York, Chicago and other large cities within reach of the electrical energy developed at Niagara Falls. Indeed the calculation just referred to was based upon the amount of mechanical power utilized in New York. Consult 'Proceedings American Institute of Electrical Engineers, December 1904.' See Power, Transmission of.

WILLIAM MAVER, JR., Consulting Electrical Engineer.

ELECTRIC UNDERGROUND CABLES AND CONDUITS. In the first attempts to operate the electric telegraph, over 60 years ago, both in this country and in Europe, the wires were placed in cables underground; but owing to imperfection in the methods of insulating the wires, as well as in the type of conduit or pipe employed, and of the manner in which the conduits were laid in the earth, the cables and conduits failed after comparatively short service and the use of overhead wires supported on poles was resorted to and became the universal practice, which continued almost without interruption for a quarter of a century.

Beginning about 1890, however, there has been a movement in all the principle cities of America and Europe to place all electric wires underground in order that the streets may be freed from the encumbering poles and overhead wires. In New York city, especially, the movement to this end was carried on vigorously and persistently, with the result that for many years
there has not been a pole supporting telephone, telephone, electric light or trolley wire in any part of Manhattan borough, such wires all being placed in cables in conduits under the surface of the streets.

**Electric Underground Cables.**—The type of underground cable used for telephony, telegraphy and electric light and power purposes varies greatly. For example, the conductors used in telephony have a diameter of .040 inch; those for telegraph purposes about .080 inch; those for electric light and power range from one-quarter of an inch to one inch and over in diameter. The smaller electric power wires are employed in high potential and comparatively light current work; the larger wires in low tension and heavy current work. It is thus feasible to place about 400 telephone conductors, or 100 telegraph conductors, in one cable in a three-inch underground duct or pipe, while it is only practicable to place two, three, or, at most, five electric light or power conductors in a similar duct. The insulating material used for telephone conductors is usually a wrapping of paper saturated with oil on a circular cardboard sheath. The wrapping is 12 inches the thickness of the wall of which is about .038 inch. The insulating material of electric light and power cables is usually a rubber compound, oil paper or varnished cambric, which is from one-eighth of an inch to nearly half an inch thick, depending on the electric pressure to be withstood, which, in the case of low potential circuits, is about 220 to 600 volts, and in the case of high potential circuits may range from 1,000 to 30,000 volts. Gutta-percha, which has been employed for the insulation of long submarine cables, is not used for underground cables, owing chiefly to its low softening point under heat, 120° F., which temperature is not infrequently encountered in subways in cities.

Cables designed for underground work are encased in a lead envelope to protect the insulating material from water, moisture and the effects of gases, acids, etc., in the underground conduits. For crossing rivers such cables are also armored with iron wires in addition to the lead covering, as a mechanical protection.

Aluminum is not used because of its bulk for a given conductivity, which bulk is about 1.5 greater than copper. The increased amount of insulating material and lead covering, as well as space in the conduits, that would be required in the case of aluminum for a given conductivity would be virtually prohibitive of its use for underground cables.

The copper wire used in cables is drawn to the required size in the wire factory. If the wire is to be insulated with a rubber compound it is next drawn through a paper tube to prevent sticking. An eraser is inserted between the sulphur used in the rubber compound and the copper. When the covering is paper, linen or fibre the wire is not tinned. The tinning process consists in passing the wire through a vat of molten tin. For electric light and power cables, when the conductors do not exceed .204 inch diameter, they are usually solid, or of one wire; above that size they are generally stranded to obtain flexibility. The wires are stranded in a stranding machine in one process, the wires being wound on reels, which are held on suitable spindles on the frame of the machine. A single wire is held in the center of the frame and is slowly drawn through a guide. The wires for the first layer are wound spirally around the central wire; the wires for the second layer are held on another frame and are laid over the first layer in an opposite direction, and so on for the additional layers required. The strand is wound upon a drum and is then ready for the insulating process.

**Rubber Insulation.**—The rubber used in the insulating material for cables is pure Pará rubber. After the rubber has undergone treatment by washing and kneading to remove the impurities which it always contains in its crude state, it is then mixed, by suitable machinery, with the ingredients that go to make up the compound, such as litharge, whiting, blue lead and sulphur. Then strips of the compound are placed over the wire. There are two general methods by which this is done, termed, respectively, the seam and seamless methods. In the seam process the rubber compound is calendared into a sheet of any required thickness, which is then cut into long strips. These strips are then passed between two grooved rollers having sharp cutting edges. The wire to be covered also passes in the centre of the grooves of these rollers, and as it does so the rubber strips are pressed closely against it, the knife edges of the rollers cutting off the surplus rubber strip. The wire thus insulated is fre-

![Fig. 1.—Rubber Covering Machine.](image-url)
the wire in reverse spirals. The wire thus taped passes to the "take up" drum \( T \), thence to the reel \( R \). In the case of rubber-covered wires the next proceeding is to immerse them in a water tank for 12 or 24 hours, after which they are electrically tested for defects in the insulation that may be due to air-holes, foreign substances in the insulation or any other cause.

The vulcanizing process consists in placing the insulated wire in an oven, where it is kept at a temperature of 250° to 300° F. until the rubber compound is brought to a desired degree of hardness and tenacity, the proper time for effecting which is a matter of experiment and varies with different compounds. Sulphur is the chief ingredient in the compound that brings about these results. The compound usually enters the oven a yellowish compound and comes out a dark-blue color. This color may be varied by using different ingredients in the compound, and in some cables certain of the conductors are colored by this means to act as "markers," or distinguishing wires for testing purposes.

Paper Insulation.—The conductors intended for telephone work are covered very loosely with two layers of dry, soft paper, laid on spirally, in practically the manner in which tape is placed over the rubber insulated wire. This type of insulation is found to be the most satisfactory yet devised for telephone cables, its capacity being quite low, about .080 microfarad per mile of conductor. The insulation resistance of each conductor is about 500,000,000 ohms per mile. The wires thus insulated are twisted in pairs with a lay of about three inches, the pairs being laid up in reversed layers and built up into cables of 50, 100 and 200 pairs, after which they are lead covered as a protection against moisture. Paper cables for electric light
and power and telegraph service are made up of reversed layers of strips of manila paper to a desired thickness by means of a paper-covering machine such as is indicated in Fig. 3. In this figure w is the wire moving in the direction of the arrow. By suitable motive power the reels it carrying the paper strips are revolved in opposite directions around the wire.

When thus covered the conductor is wound on a reel and placed in an oven until all moisture is driven out of the paper. The reel, with the insulated conductor, is then immersed in a vat of boiling oil for several hours until the paper is thoroughly impregnated with the oil.

Varnished cambric insulation consists of strips of varnished and oiled linen cambric, which are placed over the conductor in as many layers as may be desired, varnish being applied between the layers.

When insulated the conductors are ready for their lead covering, if to be used as single conductors; or if to be employed in cables, they are now ready for cabling. In the latter case the number of conductors in a cable will vary with the purpose for which the cable is designed. Telephone cables for underground use may consist of as many as 400 conductors, which are first twisted in pairs and are then cable by a cabling machine virtually similar to a standing machine. For telegraph uses single conductors, to the number desired, are laid up spirally in the usual way. The copper ribbon over each insulated conductor is grounded by connecting it with the lead covering of the completed cable. The static lines of force set up by the telegraph currents in the conductor expend their energy in setting up induced currents in the copper ribbon and thus the conductors proper are protected or screened from the effects of parallel static induction.

For electric light and power purposes, especially for high potential circuits, three conductors in one cover are now generally used. These conductors are laid up spirally and taped, the spaces between the conductors being filled with jute rope, in the act of cabling. In other instances the three conductors are bunched and a "jacket" of paper is laid over them. This is termed a jacketed cable or "split" insulation. The cable thus laid up is then taped after which it is ready for the lead covering.

The process of lead-covering cables is as follows: The cable is drawn through a die in a die-block, and, as it passes through this die, hot lead in a semi-plastic state is pressed in a uniform thickness around the insulating material by pressure from a hydraulic ram, the pressure exerted on the end of this ram sometimes amounts to 500 tons.

Illustrations of various types of underground cables are given in the accompanying figures. Fig. 4 represents a telephone cable; Fig. 5 a telegraph cable; Figs. 6 and 7 a one-conductor and two-conductor cable for high tension electric light and power circuits, respectively; Fig. 8 a low tension, heavy current cable for electric light and power; Fig. 9 a three-conductor electric power cable for 10,000-volt circuits. In this cable each conductor c is made up of a strand of 37 copper wires, each .082 inch in diameter. π is the oil-saturated paper or varnished cambric around the conductor, .17 inch thick. x is the jute filling. j is the paper jacket, also .17 inch thick. l is the lead covering, .13 inch thick. The lead is usually alloyed with 2 or 3 per cent of tin. The outside diameter of this cable is 2.56 inches. The weight of each conductor is 4.00 pounds per mile; the weight of the lead covering is about 13 tons per mile.

Rubber and paper cables are now made to withstand pressures of 25,000 volts, and some miles of cable carrying current at this pressure are to-day in operation in underground conduits, but the ordinary operating pressure to-day is from say 2,000 to 11,000 volts for underground cables.

Electric Underground Conduits.—The most obvious method of placing wires underground would be to provide a tunnel under the streets, in which not only the electric conductors but also the gas and water pipes of a city might be placed. This method is, however, so expensive that it has only been adopted in two or three places in the world, and then for only comparatively short distances in very crowded thoroughfares. For instance, there are several such tunnels in London, England, namely, the Holborn Street tunnel, about seven feet in height by 12 wide, and the London Street subway and the Victoria Embankment tunnel, seven feet by nine feet. The total length of these London tunnels is about six miles and they cost approximately $140,000 per mile, including ventilators, side passages and entrances.
In some of these tunnels, water and gas pipes, pneumatic tubes and telephone, telegraph and electric-light wires have been placed. In Paris at one time some of the sewers were utilized for the same purpose, but this plan was not greatly favored and has not been followed elsewhere. Tunnels for electrical conductors were also built in Detroit, Mich., the longest of which is about 232 feet in length. It is six feet six inches by three feet six inches in the cross-section.

Solid Conduits.—Another plan which has been utilized for this purpose is one in which the conductors are well insulated and laid directly in the earth; or in which the conductors are laid in notches in a tube or duct, by which means they are kept apart. The tube is then filled with an insulating compound, which, when it hardens, holds the conductors securely in position. This is termed a "solid" conduit. One of the earliest forms of solid conduit was that used by Morse, between Washington and Baltimore. This consisted of five wires insulated with cotton and placed within a lead tube which was laid directly in the earth. In different parts of Europe, in the middle of the last century and afterward, wires were laid directly in the earth without other covering than the insulating material around them, which was usually a bitumen compound or gutta-percha. Insulation laid in this way is not long lived. One of the first solid conduits used in this country for electric lighting was one in which a lead-covered cable is laid directly in a wooden trough, the cable being uncoiled directly from a cart reel, the box being then filled with an insulating compound. To protect the cable from injury, a thick plank was placed over the box.

In many European cities solid conduits are placed under the sidewalks. The cables are laid on a bed of sand, s, as indicated in Fig. 10. A galvanized iron wire netting, κ, is placed over the sand, separating it from a bed of concrete, n, upon which the asphalt, λ, of the sidewalk is laid. The object in using the wire netting is to warn workmen of the presence of the cables.

Edison Solid or Iron Tube Conduit.—This is the conduit adopted by Edison for the distribution of electric current by the three-wire system, for light and power in cities. It consists of an iron tube about 20 feet in length, into which the three conductors, usually copper rods, separated from one another by hemp or jute cords, are inserted. An insulating compound is then forced, under heavy pressure, into the tube at a temperature of about 300°F. The copper rods project about two inches at each end out of the tube. The tubes are laid end to end in the earth, when the conductors in one tube are connected to those in the next by a flexible copper strand. A split iron box is then jointed and clamped over the ends of the tube and the box is then filled with an insulating compound through an opening, which is then closed by a screw plug. In this system no manholes are employed, but instead, at suitable distances, water-tight junction boxes are used, into which the conductors are led, as outlined in Fig. 11. This is really a switch-box, by means of which the current from the "feeder" conductors is distributed to the "mains" or "service" conductors. These boxes are also utilized to break up the mains into shorter sections, to open the circuits for testing and other purposes.

The disadvantage of "solid" conduits is that in case of defects in the cables there is no means of repairing them short of tearing up the streets. Neither is it convenient to add to or take from or to increase or diminish the size of conductors used in the "solid" system. These disadvantages do not exist in the case of what is termed the "drawing-in" conduit system, to be described presently.

Bare-wire Conduits.—Still another plan utilized in some parts of Europe, and known as the "bare wire" conduit, consists of uninsulated, or bare, strips or rods of copper placed in tubes underground and held in position by insulators, or else the conduit itself is composed of an insulating material and is protected from moisture. This plan is not in extensive use.

Drawing-in Conduit.—The method which is now most generally employed in this country is that known as the "drawing-in" conduit. In
ELECTRIC UNDERGROUND CABLES AND CONDUITS

drawn into the ducts. In a "drawing-in" conduit system, the ducts containing the "feeder" cables or cables for arc circuits are termed "trunk" ducts and are usually the lower tier or layer of ducts. The ducts carrying the distributing cables are termed "distributing ducts" and are placed at the top. So-called "hand-holes" are laid flush with the surface of the street every 40 or 50 feet to give access to the distributing ducts and cables for electric light and power service. One type of manhole is shown in Fig. 12. This is a brick manhole; others are made of concrete. The hand pump shown is used to provide fresh air where gas is prevalent in the streets. The size of the manholes and number of ducts varies with the requirements of a given locality. Some manholes are from 4 to 5 feet square; others are 12 to 15 feet deep and 6 to 8 feet wide. The number of ducts in a conduit may range from 2 to 3 ducts to 200 or 300 ducts; the larger number usually being near the power-house or the telephone or telegraph headquarters. The manholes and hand-holes are provided with double iron covers. Some of the covers are designed to make the manholes air- and water-tight; other covers are perforated to ventilate the conduits, to prevent the accumulation of gas from adjacent gas mains, which occasionally causes explosions in the subways. The respective conductors in the

cables are joined together by twisting or by copper sleeves, in the manholes; the conductors being separated from one another by insulating material. A lead sleeve is then placed over the joints and soldered to the main cable. A hot insulating substance, as wax or paraffin, is poured into the sleeve through a small hole in the sleeve, the holes being soldered thereafter. For telegraph and telephone distribution, pipes are run from the manholes into the vaults of an adjacent building, from which point the wires are led to the subscribers' offices in the block.

The cables are drawn into the ducts by means of a rope and windlass; they are usually too heavy to be drawn by hand. Electric motors carried on wagons are also used to draw in the cables, the current for the motor being supplied by a storage battery, an adjacent power wire or a portable gas engine. In order to get the rope through the duct, a wire is sometimes placed in the duct as it is laid. More frequently, however, the ducts are rodded by means of a stiff steel wire, or by means of screw and socket rods, similar to those used by chimney sweeps, one rod being screwed into the manhole, which is then pushed along the duct until the distant manhole is reached, when a rope is attached to one end of the rods and drawn through the duct.

For the ducts used in the drawing-in system different material and varying lengths of pipe or tube are employed. At one time, wrought-iron pipe, 3 inches in diameter and 20 feet in length, joined together by thread couplings and laid in hydraulic cement, was extensively used in this country. About 5,000,000 feet of such pipe were laid and are still in service, but in recent years earthenware, terra-cotta or vitrified brick, stone and cement-lined pipe are mostly employed. The iron pipe and cement-lined ducts are round, about three inches in diameter. Many of the holes in the vitrified brick ducts are square, with an opening of about three inches. Fig. 13 illustrates a section of cement-lined pipe under construction. These tubes are of riveted sheet wrought iron and lined with five-eighths of an inch of pure cement. The tubes are six to seven feet long and two to three inches in diameter, as required. A large quantity of these tubes are in use in this country and Great Britain.

In Fig. 14 is shown a 12-duct vitrified clay conduit entering a manhole. Conduits of this type are made in blocks of two, three, four and six ducts. The four- and six-duct blocks are six feet long; the two- and three-duct blocks
are three feet in length. These blocks are laid in cement, end to end, and are held in position relative to one another by dowel pins. The walls of these blocks are five-eighths of an inch thick. A wrapping of wet muslin is laid around each joint and over the muslin cement mortar is placed. Earthenware conduits are also made in single ducts, 18 inches in length.

Wood pipe conduits consisting of wooden tubes which have been especially prepared to withstand decay are used quite largely. The single tubes are about eight feet in length and have socket joints. The tubes are laid in the trench in tiers, the lower tier resting on planking. In the various types of underground conduits mentioned and others the ducts are broken to add strength to the structure. Care is taken in laying these ducts to exclude cement, stones or any other obstacle that would obstruct or injure the cables in the drawing in process.

Fig. 14.—Vitrified Clay Conduit.

In the case of conduits for electric traction, the ducts are laid at the side of the tracks, underground, and wide manholes are provided at street intersections. For the feeders and other cables of the New York subways, conduits are laid in the wall of the structure and access is given by openings in the wall at suitable intervals.

It is well known that frequent interruptions to overhead telegraph and telephone lines are occasioned by severe wind, snow and sleet storms in this country and Europe, and in consequence the question of placing all such wires in underground conduits has frequently been raised. The great cost of such an undertaking, however, together with the fact that the speed of telephoning and telegraphing would be greatly diminished, owing to the increased electrostatic capacity of the cables as compared with overhead lines, combined with other electrical obstacles, has been prohibitory of the attempt to carry out such a plan in this country on a large scale. In Great Britain an emergency underground cable system has been laid between Birmingham, London and Edinburgh. For this purpose an iron pipe containing a 76-conductor telegraph cable, with openings at certain intervals to give access to the cable, is employed. In the United States long stretches of underground telephone cables have been constructed, notably between New York, Philadelphia and Washington. E. C. The successful operation of underground telephone (metallic) circuits at such distances has been made possible by the use of the Pupin inductance coils placed at certain intervals along the circuit and by the use of the audion telephone repeater.

ELECTRIC VEGETABLE GARDENING. Experiments carried on at the government agricultural station at Amherst, Mass., since 1900, show that the use of electricity by the farmer is a distinct and valuable stimulus to nature and exerts a marked influence upon the germination of seeds and the growth of farm products. Scientists argue that roaming about loose in the atmosphere there is a vast fund of electrical force, which, by means of specially devised apparatus, can be attracted to the earth and distributed through the ground where the gardener has sown his seeds. The apparatus by means of which the electricity is caught and harnessed has been tested at Amherst and has proved to be a complete success. Briefly described it consists of a number of copper spikes which are elevated at the top of a 50-foot metallic pole. These spikes gather the electric fluid from the atmosphere and convey it to the foot of the pole, where it is caught by wires buried a few feet beneath the ground and distributed over as large a section as the gardener desires. Each of the poles will gather and distribute enough electricity to cover several acres of ground. With this apparatus experiments have been made which may be summarized as follows: After seeds have been subjected to the electric treatment for a period of 24 hours, it was found that over 70 per cent of the seeds were germinated by the aid of electricity than in a like quantity of seeds sown in ground that lacked the electrical stimulant. As the scientists in charge of the experiments wished to make a very complete test, the electric current was applied to seeds that were allowed to stay in the ground for 48 hours. In this case it was found that 20 per cent more seeds had germinated in the electrified ground than in the soil where the seeds had been left to sprout under normal conditions, and in 72 hours this percentage had dropped to 6, thus showing that the use of the current for the purpose of stimulating germination under all the tests was a decided success.

In the various tests seeds subjected to only a temporary current of electricity have been found to show the effect for a few hours and then resume their normal growth. In one instance, to produce a constantly beneficial effect it was necessary to apply the electricity every hour to germinate growing plants or seeds.

Another interesting experiment, made in 1902, was planting in two sections of ground, the soil in both of which had been carefully selected to ensure it being exactly alike, seeds of the following vegetables: parsnip, lettuce, carrot, turnip, radish and onion. To one of the sections of ground a mild current of electricity was applied. The following day the plants in the electrified plot began to appear, the turnips sprouting first. The rapidity of growth of those plants in the electrically treated ground was far in advance of those treated in the ordinary ground. The second day plants broke through the surface in both plots, those in the electric garden showing considerably the more rapid growth; the foliage was rank and when har-
VESTED was nearly twice as high as that of the non-electric plot. The roots also were larger and showed a marked difference in favor of electricity. One peculiarity was that in the electric plot for every pound of roots very nearly a pound of tops was produced, while in the other case for every pound of tops there grew 1.43 pounds of root, but the difference in the total was all the favorable to the electric. With reference to the other vegetables, the lettuce proved a failure in both plots. The carrots showed a marked superiority in the electric bed over those in the non-electric. The onion plants came up in both beds and grew finely for a time, then blasted and not one developed, neither electric nor non-electric.

Besides the electric treatment of the soil, experiments have been made with the electric light for stimulating the growth of plants and the general effect has been to hasten the maturity of lettuce, spinach and similar products. It has been found that the electric light has the stimulating effect of daylight upon the plants and crops thus encouraged by light from arc lamps have shown 30 to 60 per cent increase. In short, it has been clearly demonstrated that by means of electricity nature can be forced to do double duty without lessening the worth of her products. See ELECTROCHEMICAL PLANTS.

ELECTRIC VEHICLES. The first vehicles operated by electric power from a storage battery appeared in 1892, but they failed to attract the attention of the general public until 1900, when the very superior performance of the electric carriage in a winter parade in the city of Cleveland, Ohio, gave them immediate prominence. The chain-drive models appeared in 1914, and continued to be the prevailing type until 1919, when the shaft-drive for the smaller vehicles was adopted. Up to that time electric vehicles were equipped with pneumatic tires. By 1912, however, solid rubber tires had been generally substituted and the battery had been enlarged to 40 cells. These two changes were the cause of a great improvement in the quality of the metal used in constructing the electric car, in order that the jars of the road might be completely absorbed and the additional weight safely carried. The result has been that the electric is the highest class of all self-propelled cars.

For city use and for the short haul, the electric possesses many advantages over steam and gasoline vehicles, the most considerable being its simplicity of construction. There are only three parts to the mechanism: the battery, the motor and the controller—no gears, no clutch and no engine as in the gasoline and steam driven cars. The motor is an engine of the rotary type, delivering a continuous torque at any desired speed up to 25 miles per hour, without the crude and bulky mechanism which controls the two or three speeds between which choice must be made with the gasoline car. Moreover the operation is noiseless. There are no nauseous odors of gasoline and burnt oil, and there is no danger from fire. The car can be driven by merely opening a switch and the battery being charged as often as exhausted. No chauffeur is needed, the car practically taking care of itself and seldom needing any repairs or expert attention. The great drawbacks are two—the weight of the storage battery which supplies the current and the limited radius of operation at a single charging of the battery, about 30 to 35 miles. In some Electric vehicles the radius of travel is as high as 60 miles, the weight of the battery being doubled. The usual type of battery constitutes about one-third of the weight of the car and costs about $500. The Edison battery is good for 10,000 miles and then has to be replaced with a new one. The Edison battery costs a good deal more, but is guaranteed for four years, during which a car may easily make 60,000 miles, so that while the Edison battery costs more to install it is very much more economical in the long run. The average consumption of energy is about 100 watt-hours per ton mile.

But it is not as the passenger or pleasure car that the electric vehicle demonstrates its greatest utility. This lies rather in the commercial world, where the small truck or moderate speed capacity is widely in use, in as many as 124 lines of trade. As taxicabs in cities where the speed limit is 15 miles per hour, the electric excels, showing almost no delays for repairs, changes of machinery, or tire trouble, great elasticity in movement, no thoroughfares, no repair account and the cheapest motive power. The last-named feature has become still more marked as the cost of gasoline goes up and the cost of electric current is continually diminishing. An electric taxicab on trial in Detroit made the remarkable record of 12,000 miles in one year without any repair whatever. Another field in which the electric has made good is as the light delivery wagon, especially for the large department stores. For this use the slow-speed type of motor is in favor, running about 800 to 900 revolutions per minute, at 80 volts and 28 amperes, 4 pole series type, unsaturated. The winding is arranged for either 60 or 80 volts on larger trucks, to be used with a 60-cell Edison or 42-cell lead-acid battery. In some cases, where motors run without attention except an occasional renewing of the brushes and lubrication, from eight months to a year. The control most generally in use is the horizontal lever, and there is a motor brake besides an efficient foot brake. The standard battery equipment is 42 cells of 15 plates each for the lead type, or 60 Edison cells of the G-7 type. For the establishment which runs its own electric plant the matter of charging the batteries becomes merely a matter of adjustment to the other work of the plant. In several cities the battery rental plan has proved popular with owners of electric vehicles. The cars can be bought without the battery and this be supplied at a stated rate per month, the battery being charged as often as exhausted. The cost of such service is not excessive, being about half the initial cost of a new battery, and there are no delays while the battery is being charged—the exhausted battery being lifted out and the fresh one put in its place.

The electric type, however, is not limited to the light service, as trolley trucks are operated successfully in the transportation of coal, ice, flour, sugar, lumber, beer, etc. Fire engines to run at a speed of 25 miles per hour are in use in some cities, a particularly effective ladder truck being able to divert its motive power to...
ELECTRIC WAVES—ELECTRIC WELDING

raising a 90-foot ladder, which is accomplished in 10 seconds. In several of the larger cities the Post-Office Department uses two-ton electric trucks to move mail in bulk, there being 20 of these in New York alone. For motive power for baggage and freight trucks in railroad terminals and on docks, electricity has been proved highly efficient. These little vehicles have a speed of seven to eight miles per hour when empty, and five to six miles per hour when loaded and cost to run about one cent per mile. Other adaptations of the electric vehicle are the truck crane for loading and unloading and moving materials in foundries and other manufactories of heavy products and in workshops and their yards, as road machines and road tractors, as warehouse trucks for moving goods and delivering them to gangways, as mine locomotives and in place of hand trucks in loading and unloading vessels.

One of the incidental advantages of the electric vehicle is the considerable saving in insurance costs, both for the vehicle itself and for the premises in which it is stored. In 1916 there were 40 concerns engaged in building electric vehicles and the number in use in the United States was estimated at above 60,000.

ELECTRIC WAVES, a motion or disturbance of the ether or medium in which electricity manifests itself, appears to move, of a character similar to light waves, of varying length, according to the nature of the discharge but with a velocity similar to that of light. The wave theory was early held by Clerk Maxwell, Lord Kelvin and others, but was first demonstrated by Heinrich Rudolph Hertz (q.v.), who began experimenting about 1887. He discovered that electric waves would produce a slight sparking between metals when very nearly in contact. About 1887 he exhibited a special form of condenser, which he termed a radiator, but which would now be called an oscillator, as it discharges across a spark gap with oscillations. In connection with this he employed what he termed a resonator, but which would now be styled a wave-detector. By radiating electricity at different oscillations and detecting their harmonic distances, while demonstrating their non-appearance at intermediate points, Hertz proved the theory of wave action and that electricity travels in the same way as light, and paved the way for the later invention of wireless transmission. Hertz also reflected and refracted the waves, thoroughly demonstrating their action under the same laws as light waves. For a time the waves were referred to as Hertzian waves in honor of his contribution to science. The study of the waves was at once taken up by numerous students of electrical phenomena, and Lodge, Kelvin, Polnareff and others made investigations which increased knowledge of the subject. Bose designed an instrument for producing very short electrical waves so they should be more easily studied than Edison's. The first of an improved and proved form of detector, and E. Rutherford brought out a magnetic detector. These were outclassed later by William Marconi's coherer, and that has yielded place to still more accurate detectors now used in radiography. See TELEGRAPHY, WIRELESS.

ELECTRIC WELDING. The heat of an electric arc may be employed in fusing or welding metals, or the heat given out in the body of metal acting as a resistance to the passage of a heavy current, without any arc or spark, may effect that result. The arc method appears to have been first employed by De Meritens in 1881. In this instance leaden pieces designed to be united in the form of storage battery plates were arranged together as an extended positive electrode, and an arc was drawn between them and a negative rod manipulated by means of an operating handle. Part of the heat energy of the arc served to melt the lead and cause union of the adjacent pieces, but much the larger proportion of the energy escaped by radiation and convection. The electric arc was thus akin to a gas blowpipe as commonly used in lead-burning in the construction of tanks for the chemical industries. Following De Meritens, heating by electric arcs has been applied to the fusing and welding of metal parts in plants by Bernardos and Olszewski, Coffin and others. When, as in the Bernardos and Olszewski method, the carbon electrode is made positive to the work, carbon is transported through the arc and is likely to enter the metal undergoing the process, which constitutes the negative pole. This addition of carbon may render iron or steel hard and unworkable, and cause cracks to be formed during the cooling of the fused mass at the joint or filing. By the employment, instead of carbon, of an electrode of the same metal as that of the work, Slavienoff overcame this difficulty. The gradual melting of the metal electrode furnishes metal for forming joints, or for repairing or supplementing castings which are defective; such as those which are incomplete or contain blowholes. More recently the work is made the positive pole and this results in a greater proportion of the energy than formerly being expended in heating the metal undergoing the operation. Inasmuch as the conditions of energy supply for sustaining the arc are but little different from those often found in the commercial operation of arc lamps from constant potential mains, arc welding may often be practised by connections made to such mains. When the welding resistance is put in series with the fusing arc in a branch from direct current lines at a potential difference of 200 volts or thereabout. With work such as that to which the Bernardos and Olszewski method has been found to be applicable, the current in the arc may vary from 150 amperes up to 500 or more. The potential across the arc itself will generally be from 100 to 150 volts. With the metal electrode used by Slavienoff the current needed will be greater and the arc potential less than the above amounts. It appears that in certain cases the current may even surpass 4,000 amperes.

While a moderate application of these arc processes for fusing and welding iron and steel has been made, the range of operations to which they are suited is somewhat limited and their success depends largely upon the skill of the workman. He must protect not only his eyesight from the glare of the large arc, but also the surface of his body, and must avoid the irritating vapors which arise from the flame. At the same time vigorous ventilation cannot
be employed, for motion of the air tends to dis-
urb the arc and render the work more difficult.
A large proportion of the energy is radiated or
carried off in the hot gases from the arc. To
to these energy losses must be added that due to
the use of the steadying resistance for obtaining
stability in the current of the arc. On the other
hand the appliances needed for arc fusing or
welding are simple and the source of current
energy often conveniently found in existing elec-
cric circuits. One of its most recent uses has
been in adding metal to rail surfaces where
worn at the joints, particularly street railway
rails in situ. A considerable extension of the
use of arc welding has recently taken place,
owing to improvements in materials and meth-
ods and to increasing demand for its use in
original construction and repair work.
Wedermann, in 1874, proposed to deflect an
electric arc formed between the usual carbons by
a jet of air, forming thereby an electric blow-
pipe. More recently Zerener has in a similar
way employed an arc deflected by a magnet as a
sort of blowpipe for welding iron. In addition,
the curious electric heating action first published
by Hoho and Lagrange has been proposed for
welding metals. If a negative electrode of a
different material than the work becomes immersed in a liquid bath, such as a solution of
potassium or sodium carbonate, the surface of
such a negative electrode, where immersing glow
with light, gas bubbles arise from it, and the
electrode itself heats rapidly in spite of its im-
merison in cold liquid. A bar of iron used as
the negative electrode may thus be brought to
incandescence and removed for welding, or it
may even be melted under the liquid of the bath.
The loss of heat in such a liquid heating process
is necessarily somewhat great.
The Thomson process of electric welding,
which differs radically from the arc heating
operations above described, was first announced
in 1884. It has since gone into extensive com-
cmercial use. No electric arc is employed, but
the heat which effects the welding is solely due
to the resistance of those parts of the metal
pieces at the contact where they are to be
welded. This resistance is, of course, extremely
low, and the delivery of sufficient energy for
heating and welding is the result of the
passage of relatively enormous currents.
Their potential is only two or three volts, more
or less. The metal pieces to be welded together
are held respectively in massive clamps or vases
of highly conducting metal such as copper, with
a slight portion only of each piece projecting to
form the joint. These projections of the pieces
are brought together in firm contact, for which
purpose at least one of the clamps is made mov-
able toward and from the other, both of them
being mounted on a firm support. The pieces
having been adjusted to meet in correct relation
for the subsequent formation of the weld uniting
them, an electric current sufficient in amount to
heat the contact portions of the pieces to the
temperature at which they soften and unite, is
passed from clamp to clamp, thus traversing
the joint and the short projecting portions of
the pieces between the clamps. So heavy is the
current at commutation that a break spanning the space between the clamps could be heated and melted. The completion of
the weld after heating is effected by pressure
exerted to force one clamp toward the other,
which results in a slight upsetting or protrusion
of metal at the weld called a burr. For copper
a pressure of about 500 pounds per square inch
of section is usual, while with iron it is 1,250
psi, with tool steel 1,800 pounds or more. Nearly
all of the metals, even those like antimony and
bismuth which are brittle and crystalline, may be
united by this process, and many different metals
and clamps are joined one to another. In some cases
as with high carbon steels, a flux such as glass
of borax, is employed to facilitate union at tem-
peratures not high enough to burn or destroy the
texture of the metal. Mild steel and iron wads
are usually made, as in ordinary forges, at weld-
ing heat, or that which melts or fluxes the ordi-
nary black oxide scale upon the metal. The
heavy welding currents cannot be conveyed
without great loss to distances of even a few
feet unless conductors of prohibitive section and
cost be used. The welding clamps are in
practice carried directly upon the secondary
terminals of a special welding transformer. The
Thomson welding transformer is a construc-
tion like a lighting transformer in which the
usual secondary circuit of numerous turns is
replaced by a single winding, the conductor constituting
ordinarily only a single turn around the iron
magnetic core. The primary or inducing cir-
cuit is similar to that of the ordinary trans-
former for alternating current and it is sup-
plied from alternating current dynamos or lines
as usual in such work. It will be seen that the
secondary conductor is unique in character, be-
ing often a bar or casting of many square inches
of section of copper of short length. The circuit
of this single turn secondary is completed only
by the meeting ends of the work pieces in the
clamps. It will thus be evident that the chief
resistance or opposition to the flow of the low
voltage current in the single secondary turn
will be at the proposed joint or weld between the
clamps. Here it is then that the trans-
formed energy is for the most part given out
as heat, the section of metal which can be
welded depending upon the scale of the apparatu-
sus used and the energy of the primary source
which is available. The welding transformer has
found convenient application in welding
of metal pieces for forging, bending, shaping,
brazing or the like, in addition to welding. It
has also in the Lemp process been divested of
its welding clamps and applied to the local
annealing of the hardened face of arms, plates,
so as to facilitate drilling and tapping, or cut-
ting into desired shapes. The welds made by
the Thomson process are usually butt welds,
though lap welds are also made with almost
equal facility. In butt welding there is of course
an upset burr, or protrusion of metal at the
joint. In many cases this is not removed, and
it renders the joint stronger than other adjacent
sections. Oftentimes the joint is pressed or
forged while still hot so as to remove the burr
at the joint. In other cases the joint is fin-
ished by filing or grinding. The welding clamps
are modified in form and disposition to suit
the shape and size of the pieces to be held, and
the pressure used to effect the weld is either
manually applied by levers or is obtained from
a strain rod, spindles, or hydraulic means under control by suitable
valves. The heating effects of the electric cur-
rent are so perfectly adjusted by regulating appliances that most of the metals formerly regarded as unweldable, yield good results with the process. Even slender pieces, such as sections of leads, may be joined together with great ease. The operation of the electric welder is characterized by uniformity, rapidity, flexibility, cleanliness, neatness, accuracy and economy. It has found extensive application to repetition work; single machines making sometimes as many as 2,000 welds per day of 10 hours. It is used widely in the wagon and carriage industry for tines, axles, bands, fifth wheels, etc., and for wire bands for affixing rubber tires to wheels. Many parts of bicycles and automobiles are built up, by electric welding. In the construction of tools and parts of machinery and particularly in the wire industry it plays an important part. Another important field is in the welding of wire or strip into hoops or bands for barrels, tubes, pins, etc. Machines are in operation producing electrically welded wire fencing, in which the wire which in the fence are horizontal are welded to verticals at intervals, the action somewhat resembling that of a loom. In joining pipe into continuous lengths or girds, and also in welding in situ street railway rails into a continuous track the electric weld possesses a special adaptability. An interesting application of the electric welder is found in the production of steel tubing by the progressive welding of a longitudinal seam. A long strip of flat sheet or strip is rolled up so as to cause the lateral edges to meet. It then passes between welding rolls whereby the heating current locally traverses the meeting edges and welds them. The operation is progressive from one end of the pipe to the other as it is fed through the machine. The result is a pipe of uniform diameter with walls of even thickness, having a delicate bead along one side where the weld has been made. This bead is removed if the pipe be subsequently mandrel drawn with a reduction of its diameter. In the earlier electric welders the operations of clamping the pieces in place, applying and cutting off the electric current and exerting mechanical pressure, were usually manually controlled. Machines more or less automatic are now frequently employed. In recent types adapted for rapid repetition of work upon identical pieces, the action is entirely automatic; the machine runs continuously and its sequence and actions is definitely determined by its construction. These machines are power driven, movements being imparted for clamping the pieces as they are fed to the machine, for closing the current switch, for exerting pressure to complete the weld, for cutting off the current and for releasing the pieces from the clamps after the operation. In wire fence and chain machines the stock is itself fed automatically and the welding continued until the machine is stopped or the material exhausted. The energy required to effect electric welds naturally varies with the size of the pieces and with the material. It also depends upon the time consumed in the work, which time may be made shorter or longer even with exactly similar pieces. The following table gives the results of some tests made upon different sections of iron, mild steel, brass and copper in the form of bars. The figures are only approximate and would vary considerably if the welds had been made in times different from those given. In general, working at a greater rapidity would lessen the total power used but require larger apparatus for the increased output required during the welding:

One of the recent and most important developments of electric welding by the Thomson process is known as "Spot" welding, and is particularly applicable to the union of sheet metal overlapped. The process is known as the Harmatta method, and is an effective substitute for riveting with the advantage of leaving the metal sheets united in spots but without rivet heads or other deformation projecting. The surfaces of the sheets may, in fact, be left smooth or with only slight indentations. To accomplish this result the two sheets to be spot-welded are placed one against the other and, as it were, pinched together between two heavy points or electrodes from a welding transformer secondary circuit. These electrodes being placed opposite each other press the sheets together at any desired spot, the current is then sent through them, when the sheets, where they are in contact, instantly attain the welding heat and the joint is effected in a spot with unwelded metal around it, as in riveting. The electrodes used usually have at their ends the form of truncated cones; that is, they narrow toward the work, in this way concentrating the current flow at the limited spot to be welded. On cutting off the current after a weld is made and releasing the pressure of the electrodes on the sheets, they may be moved to a new position, another spot weld effected, and so on until as many are made as desired.

Projection welding is a modification of spot welding in which the sheet metal pieces are first given small projections by stamping or otherwise. In other cases small pieces of metal are placed between the sheets at spots where the weld is to occur. Then the whole is pressed between the current carrying electrodes which may now be of such spread as to cover a num-
ber of such projections or spots at once, all being welded simultaneously. Spot welding in its various forms finds a large and rapidly extending application, particularly to sheet steel structures, such as steel car bodies, automobile bodies, metal containers, etc. It has become the general method of uniting stamped metal pieces which subsequently are to be enamelled. For example, hardcover sauce pans before enameling and the rivets were plainly to be seen under the enamel. By spot electric welding the union is effected without visible change in the metal surfaces and the covering of enamel is in consequence uninterrupted and without projections.

The process is capable of further great extensions in its application to the union of overlapped sheets or plates. Riveted joints, always more or less unsightly and often disadvantageous to construction by taking up room and giving an irregular surface can often be abolished and the spot weld substituted therefor with benefit. Besides its advantage of leaving a smooth surface, it effects a great saving of time and economizes material. As in the case of electric welding generally, the spot weld gives rise to new modes of construction of metal objects and greatly assists the substitution of pressed steel for castings or forgings.

ELIHU THOMSON.

ELECTRIC WIRELESS TELEGRAPH. See DEFOREST WIRELESS TELEGRAPH SYSTEM; MARCONI; TELEGRAPHY; TELEGRAPHY, WIRELESS.

ELECTRICAL ALARM, or THERMOSTAT, an instrument arranged to give an alarm or announcement when the temperature in its vicinity reaches a pre-determined degree. (See ELECTRIC SIGNALING, Automatic Fire Alarm Signals). Thermostats are also employed to automatically maintain a given temperature by opening and closing drafts, through the medium of electro-magnetically operated devices. Thermostats are operated on open or closed circuits, as desired. There are electro-pneumatic and mercurial thermostats which operate by expansion of a gas or mercury, respectively.

ELECTRICAL DIAPASON, a tuning fork the vibration of which is maintained by means of electro-magnetism virtually on the principle of the electric door-bell. (See ELECTRIC SIGNALING). This instrument, provided with a resonator, was employed by Helmholtz in his notable experiments on the composition of sounds.

ELECTRICAL ENDOSMOSIS. See OSMOSIS.

ELECTRICAL ENGINEERING. Electrical engineering is probably the youngest of all the professions, for it has hardly been recognized as a regular profession for more than 15 years past. As a result, the men who have reached prominence in it to-day have attained their positions from widely different courses of preliminary training; many of them are men who started life in other lines of work and afterward turned to electrical pursuits on account of the sudden growth and importance of the business. In consequence of this, all methods of preliminary education are represented and their relative values can be estimated. The argument runs largely between two classes of men—one the practical man and the other by the theoretical electrician; the graduate of the machine shop and the graduate of the university. Both of these types have attained success, but the correct answer to the argument will probably be found in a ware riveted together. In the past some of the most successful electrical engineers have belonged distinctly to the class of practical men with little theoretical training, but the conditions have changed. In the early days of the profession, there was little theory; the predetermination of results and work was carried on largely by guesswork or by cut and dry approximations. At the present time, however, such a state of development has been reached that exactness of result is essential to success and work based upon either becomes impossible to a satisfactory condition of an art a man with practical experience only may become very familiar with all the existing types of apparatus and, knowing their various applications, may qualify, to an extent, as an engineer. But the work of the electrical places electrical engineering apart from all the other engineering branches, for new discoveries and theories make radical changes from year to year in the construction and operation of electrical machinery. The engineer whose education is based only upon practical experience cannot keep up with the progress and change resulting from it, and falls behind; whereas, the man with knowledge of the theory, and a mind trained by the theoretical studies and scientific reasoning, easily grasps the theory of the change and re-adjusts his mind to the new without difficulty or delay. Many instances can be cited of men who have been prominent as electrical engineers, who have been dropped out of place in the course of the rapid progress while they have been made, on account of a lack of theoretical foundation in their knowledge. Those who have retained their positions throughout the growth of the art have done so by persistent study along theoretical lines.

In its present state electrical engineering is the most scientific of all engineering professions. A man must be to a great extent a physicist, a chemist and a mathematician, as well as be familiar with machinery and its design, in order to be a worker in the broadest field. Many of the problems connected with other branches of engineering can be solved by common sense and by one's sense of proportion as guided by experience and by the eye. But most of the problems in electricity are invisible, so to speak, and can be understood only through their expression in the form of symbols. Probably no one will dispute to-day that the preliminary education of an electrical engineer demands a special training in those theoretical branches, mathematics, physics, chemistry and mechanics, sufficient to train his mind into accurate methods of thought and reasoning and to supply the precise training he will need in the practice of his profession. But theory alone is not all. The human mind is such that it works with difficulty in pure theory without a series of mental pictures to fix and co-ordinate the ideas, and
the study of theory is likely to make little lasting impression unless the physical meaning of the theory is brought out by constant association with practical work. The constant study is necessary, even to keep up with the progress of the times. But an electrical engineer should be willing to do more than this. He should study to keep ahead of progress and do his share toward the instruction of others.

H. W. Buck,
Consulting Electrical Engineer, New York.

ELECTRICAL MANUFACTURING INDUSTRY. The electricity as to the electrical manufacturing industries in the United States are fairly well revealed in the statistics of the Bureau of the United States Census for 1914, giving the latest authentic figures available, although these can be supplemented by later data in various ways that bring the information up to 1917 and that illustrate the swift and enormous expansion of the various electrical arts and applications. Electrical applications divide themselves into two large groups. One of these comprises the production of apparatus; and the other, times larger, embraces the utilization of the apparatus chiefly through the agency of what are known as "public utilities," such as telegraphy, telephony, electric lighting and power supply and electric traction. One group of industries manufactures operating materials; the other group manufactures "service." In the United States, as sharply contrasted with Europe, these agencies are in the hands of private capital to an overwhelming degree, and the comparative figures of efficiency, economy and earning power are equally on the side of individual initiative and enterprise.

As to the production of electrical machinery, apparatus and supplies, the data are given here-with for 1914, when the total output for 1121 establishments was placed at a value of $359,412,676, against which may be placed the fact that in 1916, three concerns billed a total sales of not less than $305,000,000. The very lowest estimate for 1917 is $600,000,000 and in view of the enhanced cost of raw material it would not be surprising if it ran ten times that amount. These figures are revelatory of many new conditions governing the electrical arts, such as the change from steam engines to steam turbines in the generation of electrical energy, the increased use of water power, the invasion of electricity into many new fields of supply, industrial, commercial and domestic; the greater use of the electric motor; the advance of electric heating; the supersession of the arc light by the larger incandescent; the complete conquest of the incandescent lighting field by the tungsten filament lamp; the irresistible intrusion of the electric locomotive, not only into steam railway terminals but into the operation of long stretches of main line, where cheap water power is available for the generation of current.

It will be noted that dynamos have greatly increased in size, and have fallen off in value, owing to this fact. In the early days of the electric-light and power industry it was customary to employ high speed, single valve automatic steam engines for driving belt generators, as the best regulation of speed could be obtained.
ELECTRICAL MANUFACTURING INDUSTRY

with engines of that type, for incandescent lighting. The steam economy of those engines was so low as a consumption of 40 pounds of steam per one horse power per hour. The mechanical efficiency was rarely as great as 85 per cent and the electrical efficiency of the generators was rarely 75 per cent. Corliss type engines were used for arc light circuits where the load was uniform and close regulation was not so essential. Their economy rarely exceeded 30 pounds of water per one horse power. For incandescent lighting there was an average consumption of at least 10½ pounds of coal per kilowatt hour and for arc lighting 8 pounds of coal per kilowatt hour. This compares with the present Interborough Rapid Transit 50,000 kilowatt steam turbo generators requiring as little as one and one-half pounds of coal per kilowatt hour; while it is understood that the Cornell Creek station of the Detroit Edison Company has an economy even superior to that.

There is a 60,000 k. v. a. triple steam turbine under construction for the Interborough system, which will have an actual capacity of 70,000 k. v. a. and is expected to have an economy of 11 pounds of steam per kilowatt hour. The increase in the size and economy of hydro-electric generating units is equally notable. The largest water turbines for electrical service are the three single runner units installed in the plant of the Tallassee Power Company on the Yadkin River, North Carolina, with a guaranteed rating of 31,000 horse power under an effective head of 180 feet, and 27,000 horse power under 165 feet at 154 r. p. m. The turbine runner weighs 20,000 pounds, is a single piece of solid bronze and is probably the largest casting of its kind ever made.

It is to be understood, however, that the manufacture and production of electrical apparatus and material is but a small part of the electrical industry as a whole. The total capitalization is placed as high as $12,000,000,000, the gross sales and earnings are rated at above $2,500,000,000, and the number of persons employed at more than 1,000,000. The accompanying figures were published during 1916 which while based on earlier data can be shown to be in many respects far short of the actuality. A conservative estimate for the total service and output value of electricity in 1917 made and published by the writer is as follows:

In general, most of the estimates are based upon returns of the United States Bureau of the Census. A comparison of the estimates in different sections of the industry on isolated electric stations made it apparently reasonable to assume that the totals for this branch are one-half of those for central stations. Statistics for the electrified mileage of steam railroads are based upon the latest available figures of miles of track to which were applied the approximate averages of electrice and steam railroad statistics. The very costly terminals were not taken into account.

1 Includes for 1914, number and output of 91 establishments engaged primarily in other lines of industry, but which manufactured electrical machinery, apparatus and supplies valued at $24,261,961; and for 1909, number and output of 142 similar establishments which made electrical machinery, apparatus and supplies to the value of $18,728,916.

2 A minus sign (—) denotes decrease.

3 Excludes and resistances only.

4 Figures not available.

5 Includes a considerable number of starting motors for gasoline automobiles, not separately reported as such.

6 Not including fixtures made by establishments engaged primarily in the manufacture of gas and electric fixtures.

7 Including insulated wire made in wire-drawing mills.
ELECTRICAL MANUFACTURING - INDUSTRY

Electric Light and Power Statistics.—It is unfortunate that the authoritative statistics as to the four great groups of electrical public utilities which manufacture "service" as compiled by the government—telegraphy, telephony, electric light and power—and electric street railways do not go back to a later period than 1912. Their figures under an act of Congress are taken by the United States Bureau of the Census every five years, the last being compiled in 1912 and the next not being due until 1917, and not becoming available before the middle of the year. The data for 1912 are therefore presented herewith subject to the expansion up to date to date under the average rates of increases that are apparently revealed.

1 The term "station" as here used may represent a single electric station or a number of stations operated under the same ownership.
2 Exclusive of $36,500,030 in 1912, $20,093,302 in 1907 and $7,703,574 in 1902, reported by street and electric railway companies as income from sale of electric current for light or power or from sale of current to other public service corporations.
3 In addition to salaries and wages, includes the cost of supplies and materials used for ordinary repairs and replacement, advertising, fuel, mechanical power, electrical energy purchased, taxes, and all other expenses incident to operation and maintenance, and for 1912 charges for depreciation and charges for sinking fund.
4 Includes auxiliary engines.

Various items in connection with the central station electric light and power industry may here be noted. Statistics as to its income are regularly compiled by the Electrical World on a basis in excess of 60 per cent of the totals reported from month to month; and these show for 1916 an income of not less than $425,000,000 from electric service. If the return from other service such as sale of electrical supplies, steam heating, refrigeration and return on investments be considered, the total 1915-16 income of the industry cannot possibly be put lower than $450,000,000, and it is probably far in excess of that. The number of electric meters on all central station consumption circuits in 1912 was 3,617,189, coinciding very closely with the number of customers, and it is estimated on this basis and others that there were not less than though in projection and searchlight use it has made such strides that an arc search light operating in New York has made its beam visible in Philadelphia, 90 miles away. There is also a large use of arc lights in motion picture work. Owing to the advancing perfection of the incandescent lamp through the stages of carbon, metallized carbon, tantalum and tungsten filaments, the number of spherical candle power hours delivered for one cent has risen from 13.9 in 1885 to 71 in 1916, an increase of nearly 500 per cent in about 30 years, during which time the price of the lamp and the price of electrical energy have both decreased enormously. The rate here given is figured on operation at 1,000 hours of energy at 10 cents per kilowatt hour for current. Among the chief advances of the period in
electrical development outside of railway work have been those in electro-chemical and electro-metallurgical development, both stimulated undoubtedly by the great war and both dependent upon the supply of cheap current. Thus one plant building in 1916 in California was to use 2,500 horse power of electrical energy generated by a hydro-electric company, with an output of 5,000 tons of caustic soda and 10,000 tons of "bleach." The electrolytic production of hydrogen and oxygen has increased enormously, so that over 300,000,000 cubic feet of hydrogen per year are thus manufactured in the United States. It is interesting to note, however, that while the electrical fixation of atmospheric nitrogen has increased enormously abroad, representing about 300,000 tons at the beginning of 1916, or a gain of over 250 per cent in three years, requiring 1,000,000 horse power, little corresponding activity has been shown in the United States up to this time of writing; although several processes of proved value are of American origin. On the contrary, the development of the electric iron furnace has been remarkable. Electrical castings command a premium where unusual durability and resistance to stress are needed. On 1 Jan., 1916, about 73 electric steel furnaces were in operation in the United States with an output of about 100,000 tons per year, but a terrific jump was made during 1916, so that the number of American furnaces was at least doubled, while their output has been estimated at 1,000,000 tons by a conservative authority. Probably the United States has now more electric furnaces than any other country.

The business of the central station has a constantly growing diversity factor. The revenue of one leading system in 1916 was derived as follows: Commercial lighting, 37 per cent; power for industrial and general purposes 22 per cent; residence lighting, 18 per cent; power for electric railway use 23 per cent. The item of residence lighting reveals one of the large opportunities before the central station, and includes an endless variety of apparatus and appliances, ranging from the curling iron to the electric range for cooking. In other cities than the one quoted the proportion of commercial and domestic service would average higher, although taking the country as a whole perhaps only one house or family in every five has electric service. However, very few new houses, even in remote rural districts, are built now without electrical wiring.

Electric Railway Statistics.-Hence forth are given the latest available official statistics for the electric street railways of the United States, in this case, as in those of electric lighting, being the Census Office figures for 1912, the next compilation not being made by the government until 1917 and not available before 1918-19. The present figures serve, however, as a safe basis from which to estimate the advance in the succeeding five years in almost every respect at an average rate of increase not in excess of 8 per cent. It is a well-known fact that, as to surface traffic, street railways have been subjected to a serious competition from the automobile " jitney," but this element of loss has been largely reduced; while on the other hand it has stimulated the street railways to develop many types of new and better service, adding to the return on the investment and to the satisfaction of the public. While the surface traction lines—trolley or slot-conduit—have been working out their own salvation through this strenuous period, elevated, subway and steam railroad electrification have undergone a marvelous expansion as indicated by other statistics. The gross income of operating street railways—virtually all electric—is given for 1912 as $520,000,000. The income of all electric service, urban, interurban and main line, is estimated for 1917 at not less than $500,000,000.

### Condensed income accounts:

- **Revenues**
  - **Net earnings**
    - **Operating expenses**
      - **Merchandise gains and losses**
        - **Depreciation**
          - **Operating income**

### Notes:

1. A minus sign (−) denotes decrease.
2. Includes track lying outside the United States, namely—1912, 31.91 miles; 1907, 27.52 miles; and 1902, 4.20 miles.
3. Exclusive of track not operated.
4. For 399 companies in 1907 and for 797 companies in 1902.
5. Figures not available.
6. Represents 899 companies in 1912, 734 companies in 1907 and 390 companies in 1902.
7. Exclusive of companies doing freight traffic only and in 1902 of four companies not reporting revenue passengers.
8. Exclusive of six companies in 1907 and of 18 companies in 1902, which failed to furnish this information.
9. Exclusive of 12 companies in 1902, which failed to furnish this information.

### Telephony and Telegraphy

The general statistics of the telegraph and telephone industries of the country are shown both comprehensively and comparatively in the following table. These two branches of the great modern art of the communication of intelligence are separate and distinct, yet are very closely interwoven in their physical relationships; and at various times and in various ways have been largely conducted financially as one business. The economic reasons for such a combination are not far to seek and are recognized in the existence in most countries of a united telegraph and telephone governmental administration; whereas in the United States such a policy, under the prevailing private ownership, has been declared illegal. American telephone and telegraph systems as to apparatus used and results obtained are in general infinitely superior to anything prevailing elsewhere. A point to be noted in
ELECTRICAL MANUFACTURING INDUSTRY

The accompanying table is the relatively disproportionate magnitude of the younger art, telephony, in all respects, particularly investment and earnings.

1 Includes farmers or rural lines, and in 1907 and 1912 systems reporting annual incomes of less than $5,000; therefore, except for number of systems or lines and miles of wire, figures do not agree with those shown in other tables.

2 Exclusive of 114,339 miles of wire owned and operated by railway companies.

3 Not reported.

The extent to which the condition of the times affect electrical utilities is strikingly shown in the fact that while for the period of eight months in 1917 the American (Bell) Telephone and Telegraph Company's earnings rose from $171,608,490 to not less than $194,337,712, the operating net income was but $47,439,392 as compared with $47,586,666. The whole gain of nearly $23,000,000 was thus negated with $150,000 more thrown in; but the gain was there all the same, and in due time the larger interest charges due to rapid increases of capital will work out to advantage. On the basis of total operating revenues of the Bell system of $270,000,000 the year 1917 will show at 10 per cent increase an amount well in excess of $200,000,000. For telephony as a whole, including the independent systems, a total of, say, $425,000,000 might be set down. The physical statistics of the Bell telephone system and its growth are strikingly shown in the accompanying table.

Telegraphy.— As an industry the telegraph showed a remarkable recovery following the outbreak of the European War, and at the end of 1917 there were no fewer than 60,000 telegraph operators engaged at telegraph centers in local offices, brokers' offices, etc. The number of distinctively telegraph offices, including railroad depots, being placed at 30,000. The annual report of the Western Union Telegraph Company for 1917 is a sufficient indication of revived prosperity now and in recent years. The report showed that the company in 1917 experienced the most prosperous year in its history. The earnings available for common dividends were equal to $12.79 per share as against $12.42 in the previous year. This amount was earned on almost $100,000,000 stock. During 1917 the company paid 94½ per cent dividends, compared with 5½ per cent in 1916. The statement for 1917, with comparison, follows:

<table>

These significant figures are matched by those with regard to wireless telegraphy. Thus, gross earnings of the Marconi Wireless Telegraph of America have nearly doubled during the period of the war, while expenses, including taxes, were less during 1917 than in 1914. The company's net income for 1917 was $609,430, and undivided profits and reserves on 31 Dec. 1917 amounted to $2,150,000. The capital stock is $10,000,000.

Electrical Export Trade.—The effect of
batteries from $967,146 to $3,286,674; electric motors from $2,818,743 to $5,895,696; transformers from $624,483 to $1,265,459; telegraph instruments from $76,271 to $539,389; incandescent lamps from $575,072 to $2,301,407; electric meters from $2,818,743 to $5,895,696.

**Electrical Ships.**—A decided novelty in the field of electrical manufacture is the equipment of electrically propelled ships. The world is familiar with the use of launches driven by storage batteries and with submarine boats in which the same motive power is employed; but in the modern electrical ship propulsion is secured by means of electrical energy fed from steam turbine generators to electric motors mounted on the propeller shafts. The success of this method in the United States collier Jupiter would seem to be very emphatically evidenced in the provision in the Navy Bill of 1916 for four giant battleships or cruisers each requiring 180,000 horse power delivered to four screw shafts turning at full speed at about 250 revolutions per minute, which yield a rate of travel through the water of 35 knots per hour. Each of the ships is to have installed four high speed turbine-driven generating units, similar to those responding to the present direct steam-driven Arizona, is under construction. No other nation has yet ventured on such an experiment.

**Thomas C. Martin,**
Secretary National Electric Light Association.

**Electrical Measuring Instruments.** The four fundamental electrical quantities which are being constantly measured in electric circuits are ohms, amperes, volts and watts. Another quantity of much commercial importance is watt hours.

The usual method of measuring ohms, that is, the electrical resistance of a circuit, is to use a Wheatstone Bridge, which is described elsewhere. The electrical resistance of a circuit may also be measured by what is called "fall of potential method," which consists in sending a measured current through the circuit and measuring the difference of potential between the terminals of the circuit, as illustrated in Fig. 1. When the current is measured in amperes and the difference of potential is measured in volts, the resistance is obtained by taking the ratio of the volts to the amperes.

The instruments used in this measurement are
ammeters and voltmeters, which are described below.

In measuring amperes, advantage may be taken of any one of three different physical effects of the electric current: (1) The electro-chemical effect, (2) the magnetic effect, and (3) the heating effect. Instruments which are used for measuring currents by taking advantage of the first of these phenomena are called voltmeters. When an electric current is passed through a dilute solution of sulphuric acid and water, the water is electrolyzed and the component gases, oxygen and hydrogen, are given off respectively at the two metallic terminals by means of which the current enters and leaves the water. These two terminals may be placed in the two limbs of a vertical U tube, such as the arrangement illustrated in Fig. 2, where A and B are the two ends of the U tube and EE are the two metallic electrodes. The arrow shows the direction of the flow of the electric current from the battery. A riser C is provided to maintain the supply of acidulated water as the gases collect in the upper limbs of the tube.

![Diagram of Voultmeter and Ammeter](image)

**Fig. 1.** Arrangement for measuring resistance by "fall of potential."

![Diagram of Water Voltmeter](image)

**Fig. 2.** Water Voltmeter.

A water voltmeter such as is here illustrated has not been found convenient or satisfactory for measuring currents, and voltmeters in which the electrolytes are the solutions of salts of metals are preferred for actual measurements. Copper plates in a solution of copper sulphate may be used or silver terminals in a solution of nitrate of silver. Voltmeters are not now used in practice, as they are not sufficiently convenient for general use; but the silver voltmeter at one time proved to be so satisfactory for use as a standard that the International unit of current (the ampere) is defined as the current which flowing for one second through a suitable voltmeter will deposit .001118 grams of silver on the cathode.

Most of our common instruments for measuring currents depend upon the magnetic effect of the current for their indications, and each is really a modified galvanometer provided with a pointer to indicate the deflections of the needle or movable coil. Such instruments arranged for convenient, everyday measurements of electric currents are generally called ammeters or ammeters, and they are made in numerous forms, some of them intended to be mounted upon switchboards in dynamo rooms, and others made up in more or less portable form so that they may be carried around to be used at any convenient time. The switchboard instruments—namely, those intended to be mounted on switchboards—are used in large numbers in electric lighting plants or works, where they may be seen mounted upon marble or slate boards along with switches for controlling the current. The dynamo attendant sees to it that the dynamo is not overworked.

Portable forms of these instruments are ordinarily used in laboratories for experimental work.

According to the mechanical details entering into their construction electromagnetic ammeters may be roughly divided into three classes: (1) Those having soft iron parts which are moved by the magnetic attraction set up by the current in the coils of the instrument; (2) those having permanently magnetized parts which are acted upon by the magnetic force set up by a current in the coils of the instrument, either the coil or the magnet moving under the influence of the magnetic force; (3) those having no iron in their construction, but having two coils, one of which is moved by the magnetic force exerted between them when a current flows in both.

The moving parts of these instruments are usually mounted on pivots which are carefully finished to reduce the friction to a small value, and the instruments may be considered equivalent to galvanometers arranged with the moving parts mounted on pivots, instead of being mounted upon a delicate suspension, and each provided with a pointer arranged to play over a scale graduated to read in amperes.

If the magnetic force caused by the current in the coils of an ammeter had nothing except the friction to overcome, every current capable of moving the pointer would pull it entirely across the scale. As the instrument should be constructed so that the range of movement of the pointer is proportional to the current in the windings, a proper force must be arranged to hold the pointer back, and this may be done by properly counter-weighting the parts or using a suitable spring to oppose the magnetic force set up by the current.

Instruments of the first class may be cheaply
constructed, and formerly were commonly made
by dynamo builders for use in electric light
plants, but it is difficult to make them extremely
accurate because the coercive force of the iron
prevents it from responding equally to equal
magnetic changes. For this reason instruments
of the first class cannot, as a rule, be used
where great accuracy is essential, but only where
an accuracy within from 2 per cent to 5 per
cent is sufficient. For measurements that re-
quire greater accuracy, instruments belonging
to the second or third class are usually used,
and these can be made so that their readings
do not vary more than one-half of 1 per cent
from true values when the instruments are used
with proper care.

The best form of such instruments consists of
a modified D'Arsonval galvanometer with
a movable coil mounted upon pivots and ar-
ranged with a pointer to play over a scale,
which was first successfully produced by Dr. Ed-
ward Weston. The Weston ammeters and volta-
meters made of this construction may be prop-
erly said to have revolutionized the everyday
measurements of amperes and volts.

Fig. 3 shows a plan of a Weston ammeter
for measuring direct currents. A A represent
the binding posts of the ammeter through which
the current may be led to and from the instru-
ment. W W are wires within the instrument,
and E consists of a series of conducting shunts
between the conductors W W. The movable
coil C is connected by the wires w w with the
binding posts, and through this movable coil
there flows a fixed proportion of the current,
which bears a ratio to the total current depend-
ing upon the electrical resistance of the shunt
E and of the movable coil. The movable coil
is mounted on pivots within the magnetic field
of the permanent magnet M, and any motion
which is caused by the magnetic effect of a
current flowing through the coil is opposed by
the spiral spring D. The spring and the pole pieces
of the magnet M are carefully designed so that
the movement of the coil shall be directly pro-
portional to the current flowing through the coil,
and the deflection is indicated on the scale
S by the pointer B that is attached to the coil.

Fig. 4 shows a sectional end view of the
working parts of one of these instruments. A
stationary soft iron cylinder is mounted within
the movable coil C for the purpose of produc-
ing radial direction and uniform density of
the magnetic flux in the space between it and
the pole pieces of the magnet, within which
space the conductors of the movable coil move.
Weston or similar instruments are used a
great deal where accurate portable current meas-
uring instruments are required, and instruments
following this type are now manufactured in
large numbers in this and foreign countries.

Magnetic instruments belonging to the third
class are frequently called electrodynamometers
because their indications are caused by the
magnetic effect of the current in the fixed coils
acting on the current in the movable coils.

Fig. 5 shows an early form of electrodyna-
nometer which is arranged for use as an am-
peremeter. This is often called the Siemens
Electrodynamometer. The coil marked F is
fastened to the frame of the instrument, and
the coil marked M, which stands at right angles
to the first, is suspended by a heavy silk fibre
or a wire so that it is free to rotate. The ends
of the conductor composing the movable coil
dip into little cups C C containing mercury,
and these are connected with a circuit arranged
so that a current can enter and leave the mov-
able coil. The spring G is attached at one end
of the movable coil, and at the other end it

is connected to a thumbscrew T called a torsion
head, by means of which this spring may be
twisted. When a current flows in the coils, the
magnetic force tends to turn the movable coil
so as to place it parallel with the fixed coil.
This force is balanced by twisting the spring by means of the thumbscrew. The amount of twist is shown by the pointer B, and it is proportional to the force exerted by the coils on each other, which in turn is proportional to the square of the current flowing in the circuit. The pointer S indicates when the movable coil is at its zero position.

Very accurate and permanent standard instruments have been designed for measuring currents by this direct magnetic action, but they have not been made sufficiently portable to bring them into much use. The most important of these are the current balances of Lord Kelvin, one of which is illustrated in Fig. 6. The fixed and movable coils in these Kelvin balances are parallel to each other and horizontal. The force with which the coils tend to move with respect to each other when a current flows in them is directly balanced and weighed by means of a slider moving on a scale beam. In order to avoid any disturbing effect from the earth's magnetism, coils are placed at both ends of the balance arm.

Instruments utilizing the heating effect of the current are usually called "hot-wire" instruments. If the heated wire is carefully enclosed so that its temperature is not affected by air currents, it will rise a definite number of degrees in temperature for each current that is passed through it and this rise is approximately proportional to the square of the current. This heating of the wire is indicated by its expansion in length; and the wire, if properly selected and protected, will take up a corresponding length with each current which may flow through it, so that measuring its length is equivalent to measuring the square of the current. A simple model of an ammeter depending upon this action is illustrated in Fig. 7. The long, thin wire is clamped at one end in a stationary binding post and the other end is wrapped around and fastened to a small wheel of metal. This wheel is supported on steel pivots, one of which is connected to another binding post. The wire is kept under a constant strain by means of a spring which is fastened to the periphery of the wheel. When the wire is heated and thereby lengthened, the wheel is turned by the contraction of the spring and a pointer which moves over a graduated scale indicates the amount of expansion of the wire. When the wire cools again and contracts, the wheel is pulled back into its old position by the shortening of the wire.

A refined instrument of this type suitable for reasonably accurate measurements, is illustrated in Fig. 8. The extension of the measuring wire A B is indicated by a pointer moved by mechanism attached to the pulley D. The case protects the wire from air currents and the use of two stretched wires, A B and B C, through only one of which the current to be measured flows, neutralizes the effect of the general temperature of the surrounding air.

Instruments of this type are particularly useful in measuring the high frequency currents of radio telegraphy.

Instruments for measuring electrical pressures, in volts, may be made of the same forms as the ammeters utilizing the magnetic effects and the heating effects of electric currents. Such instruments are ordinarily called voltmeters and when they are constructed to utilize the aforementioned effects of the electric current they are really ammeters wound with coils of high resistance so that very little current will be wasted in the process of making the measurements of the voltage. Such an instrument really measures the very small current that is caused to flow through the resistance of its winding by the voltage to be measured. The resistance of the instrument is of constant value and the voltage is therefore directly proportional to the flow of current through the instrument. It is consequently possible to graduate the scale so that the position of the pointer indicates volts.

In most ammeters and voltmeters the scales are so divided and marked that the divisions read directly in amperes and volts. These instruments are generally called "direct reading" instruments.

Currents which rapidly alternate in direction cannot be measured by magnetic instruments like the Weston instruments having permanent magnets; but they can be measured by instruments having soft iron parts which are moved by the magnetic attraction set up by the current in the coils of the instrument, or by
instruments of the electrodynamometer class or by hot wire instruments. In the first class of instruments, the soft iron core is always attracted by the coil in which current flows, without regard to the direction of the current and the attraction in an electrodynamometer is also independent of the direction of the current because the current reverses at the same time in both coils. Any iron cores which are used in volt-amperes, however, differs from the watts in an alternating current circuit when the power factor is less than unity and a summation of instantaneous values of the product must be secured. Instruments made which in themselves perform this double measurement and multiplication so that their indications are directly proportional to power and these instruments are called wattmeters. The simplest form is an electrodynamometer in which one coil is wound with many turns of fine wire exactly as though it were to be used as a voltmeter coil and the other coil is wound with a few turns of coarse wire as though it were to be used in an ammeter.

The action of such a wattmeter is best explained by an illustration. Suppose it is desired to measure the power used by an electric motor—the fine wire coil of the wattmeter is connected across the terminals of the motor and the coarse wire coil of the wattmeter is connected in series with the motor. The magnetic effect of the fine wire coil is then proportional to the voltage at the motor terminals and the magnetic effect of the coarse wire coil is proportional to the current flowing through the motor. The force, at any instant, to move the movable coil, is proportional to the product at that instant of the two magnetic effects and the pointer moves over the scale so as to indicate the average force, thereby indicating the watts which are transmitted through the circuit.

The connection of a wattmeter in a circuit is diagrammatically illustrated in Fig. 10, where W is the wattmeter, V V' are the terminals of the fine wire coil and C C' are the terminals of the coarse wire coil. This figure is intended to show a dynamo furnishing current to a set of incandescent lamps L L L L, and the wattmeter is introduced in circuit for the purpose of measuring the power delivered to the lamps.

The number of alterations made in each second by the alternating currents that are ordinarily used in practice is so great that the movable coil of an electrodynamometer acts exactly as though it were pulled around by a continuous force proportional to the average of the variable force which results from the magnetic action of the alternating current. This is true whether the instrument is arranged to be used as an alternating-current ammeter, in which instance the two coils are placed in series with each other and both are of low resistance; or the instrument is arranged to be used as a voltmeter, in which instance the two

---

**Fig. 9.—Thomson Alternating Current Amperemeter or Voltmeter, in which magnetic effect of coil acts on bit of soft iron.**

**Fig. 10.—Illustration of the manner in which the coils of a Wattmeter are connected with the main circuit.**
resistance re-enforced by a supplementary non-inductive resistance coil and is a voltage coil to be connected across the terminals of the circuit.

The wattmeter already described is called an indicating wattmeter, but it is often desirable to make a registry of the integrated consumption of energy by a customer during a given period, such as a month, and such an instrument is illustrated in Fig. 11, which is called the Thomson watt-hour meter. This is built like a little electric motor without any iron in its working parts. It is arranged with its revolving part or armature A to be connected to the circuit like the fine wire coils of a wattmeter and its field magnetizing windings W W to be connected in circuit like the coarse wire coils of a wattmeter. The magnetic pull which tends at each instant to make the armature rotate is proportional to the product of the two magnetizing effects, so that the rotative effect, or torque, is proportional to the watts in the circuit. If the speed of such an armature is made proportional to the magnetic pull, it is easily seen that every revolution of the armature means a certain number of watts used for a fixed length of time. Such instruments usually have attached to the spindle of the armature a set of dials D like those of a gas meter, which record the revolutions and are so marked that the consumption of electric energy may be recorded in what are known as "watt hours." A more convenient unit for commercial instruments is the kilowatt hour, each kilowatt hour being 1,000 watt hours, and the dials of such instruments usually read in kilowatt hours.

If no external retarding force were applied to the armature of such an instrument, it would tend to run at an excessive speed for any current flowing through the apparatus and to make the instrument give an accurate record of power, a retarding force which is proportional to the speed of the armature must be applied to the spindle. This is admirably arranged by placing at the bottom of the spindle S a flat disk of aluminum C, on either side of which are placed the poles of permanent magnets M. The rotation of the disc between the magnet poles generates electric currents in it which are attracted by the magnets and retard the motion of the disc.

When the power in alternating current circuits is to be measured, it is necessary to make the self-induction of the fine wire coil of such a wattmeter practically negligible in comparison with the resistance of the coil, to prevent the readings of the instrument being affected by the frequency of the alterations of the current. This is brought about by introducing a coil of high resistance and of practically no self-induction in series with the fine wire moving coil of the instrument.

Another form, called an induction watt-hour meter is usually used for recording the watt-hours in alternating current circuits. This instrument in its simplest form illustrated in Fig. 12, consists of coarse wire coils F F and a fine wire coil C connected to the circuit as in a wattmeter. The iron core of the fine wire coils is adjusted so that the magnetic flux lags in phase, 90 degrees behind the phase of the voltage, thus producing a magnetic field out of phase with the magnetic field produced by the coarse wire coil. These two magnetic fields act on an aluminum disc armature D and cause it to rotate like the armature of an induction motor. Permanent magnets are associated with the disc so as to cause the retardation of the rotation as in the Thomson watt-hour meter.

Sometimes a continuous record of amperes, volts or watts is desired and in that case the
ELECTRICAL RESISTANCE — ELECTRICAL TERMS

pointer of an indicating instrument is tipped with a pen which plays over a moving dial or strip of paper, thus leaving a record of changes in the circuit. Instruments thus equipped are called cued-up-drawing instruments. Fig. 13 shows part of a record taken from a curve drawing wattmeter.

Various other instruments are used in electric circuits, such as those indicating the power factor of alternating current circuits, called power factor meters; those indicating the frequency of alternating currents, called frequency meters; and those indicating the phase and frequency relations between the currents in two alternating current circuits, called phase meters or synchroscopes. Descriptions of all such special instruments may be found in standard works on electrical engineering.

DUGALD C. JACKSON, Professor of Electrical Engineering, Massachusetts Institute of Technology.

ELECTRICAL RESISTANCE. See RESISTANCE, ELECTRICAL.

ELECTRICAL TERMS. The development of electrical industries and applications during the last 20 years has been so rapid and considerable as to constitute one of the salient characteristics of this era. Prior to that time a knowledge of electrical phenomena, terms and phrases was limited to a few philosophically minded persons. During that time, however, this knowledge has not only spread to a large professional and artisan class enlisting to-day more than a million persons in the United States alone, but has also extended in a considerable measure to the public at large. We can even read through the pages of the columns of a newspaper without encountering electro-technical words or phrases. The telegraph delivers its messages at every door. The telephone whispers into thousands of households in every large city. The electric light shares with the primate flame the brightening of the evening fireside. These things speak in a language of their own and force their own terms upon our speech. The following is a list of about 100 of the electrical terms in very general use:

AIR DYE. — A transformer which is cooled when operating, by a blast of air delivered through its framework.

ALTERNATING CURRENT. — A current which periodically alternates, or reverses in direction. — A to-and-fro electric current as distinguished from direct current. See ELECTRIC ALTERNATING CURRENT MACHINERY.

AMMETER. — An abbreviation of amperemeter. An instrument for measuring the electric current flowing through it.

AMPERE. — A unit of electric flow or current, theoretically defined, by electromagnetic principles, from the centimeter-gramme-second system of units. Practically it is about 1.118 milliamperes of silver per second in a standard type of electromagnetic bath.

AMPEREALT. — The electrode from which a current enters an electrolyte or conductor. A positive electrode.

ARC. — The luminous element of a column of intensely heated vapor maintained between two closely opposed, or slightly separated, conducting pencils which are usually of carbon. Much used for the illumination of streets, factories, and grounds. See ELECTRIC LIGHTING.

ARMATURE. — In an electromagnet, the movable element of iron or steel which is attracted or repelled by the poles. In a dynamo, the element which is connected with the line, and which is subject to rapid cyclical changes in magnetic flux during operation. See ELECTRIC ALTERNATING CURRENT MACHINERY.

ASYNCHRONOUS MOTOR. — An alternating-current motor in which the rotation is not synchronous with the rotating element of the generator supplying the driving current. See ELECTRIC ALTERNATING CURRENT MACHINERY.

BRANCH-PURF. — A fuse inserted in a branch of a circuit.

BRUSHES OF A DYNAMO-ELECTRIC MACHINE. — The conductors which convey current from one element to another, when there is relative motion between them. Stationary conductors resting upon a rotating commutator and carrying current either to or from the same. See GENERATOR.

BUS-BARS. — An abbreviation of "Omnibus-bars." The main conductors in a central station, to which generators or feed-wires may be connected.

CANOPY. — In electric wiring of buildings, a metallic plate or disc attached to a wall or ceiling at an outlet to conceal the hole made where the wires protrude.

CIRCUIT. — The electrode by which a current leaves an electrolyte or conductor. A negative electrode.

CHILING-RSETT. — An insulating block fastened to a ceiling, in which electric supply wires terminate, and from which a pendant flexible cord, or other pair of conductors, descend to a lamp or fixture. Usually circular in form and fairly ornate in appearance.

CIRCUIT-BREAKER, ELECTRIC. — (1) A device for opening and restoring a circuit either by hand, at will, or automatically, in the case of an overload. (2) A switch that automatically opens at overload, usually by electromagnetic mechanism.

COHERER. — In radio telegraphy, a receiving device consisting of an imperfect contact, the resistance of which is broken down on the passage of an electric wave, thereby enabling an electromagnetic mechanism to respond.

COMMITTUR. — A device for controlling or changing the direction or path of a current. In a dynamo, the element which enables the alternating current to be delivered to the armature as a unidirectional current to the external circuit.

COMPASS MOTOR OR GENERATOR. — A motor or generator having both a shunt winding and a series winding on its field magnets.

CONTINUOUS CURRENT. — A current uniform both in strength and in direction. A steady direct current.

CONTROLLER. — A device for controlling an electric machine or circuit. A controlling switch.

CONVERTER OR ROTARY CONVERTER. — A machine which operates by means of a rotating commutator to convert alternating currents into direct currents for distribution.

CURRENT, ELECTRIC. — A flow or passage of electricity along an electric circuit, usually measured in amperes.

CUT-OUT, ELECTRIC. — (1) A device for automatically interrupting an electric circuit in the event of current flows, by the melting of a fuse-wire or strip carrying the current and having a definite melting point. (2) A device for supporting or holding an electric fuse.

DIAPHRAGM. — An insulating material capable of being subjected to electric stress.

DIRECT CURRENT. — A current which, however greatly it may vary in strength, always flows in one and the same direction. A unidirectional current. See ELECTRIC.

DIRECT CURRENT. — The method of sending messages in both directions simultaneously over one and the same telegraph wire. See TELEGRAPH.

EFFICIENCY OF A DYNAMO, MACHINE, APPARATUS OR TRANSLATING DEVICE. — The ratio of the power given out of the power taken in, usually measured in per cent. The ratio of output to input. A measure of the effectiveness of transformation or utilisation of power by a device. Example, a motor which delivered 9 horse power, mechanically, while receiving 10 horse power, electrically, would have an efficiency of 90 per cent.

ELECTRODE. — The conducting terminal by which the electricity finds either ingress to, or egress from, an electrolyte, a conducting mass or a dielectric body. Usually, a metal plate immersed in an electrolytic solution.

ELECTROLYSIS. — The chemical change accompanying the flow of electricity through electrolytes, to which nearly all conducting liquids belong. See ELECTROLYSIS.

ELECTROMAGNET. — A magnet excited by an electric current and whose magnetism may be destroyed by removing the exciting current.

ELECTROMOTIVE FORCE (abbreviated E.M.F.). — The force in an electric circuit which produces therein, or tends to produce, an electric discharge or current. Electrical pressure. Voltage. Usually measured in volts.

ENCLOSED ARC LAMP. — An arc lamp enclosed almost air-tight within a narrow glass globe, and carrying in the contained air soon becomes consumed during operation, thus leaving the carbons burning in inert gas
and greatly prolonging the duration of their serviceable lives.

FUSE.—In an electric distributing system, a supply con- 3ductor carrying current from a power-house to main consumers, and not liable to be overloaded, the fuses or 3rals are used for protecting the system against fires or 3rals.

FIRE SIGNAL.—Originally, an electric lamp held fixed to a wall or ceiling. Now, any electric signal system for delivering messages or other information to a set of receivers.

FIRE ALARM.—The number of complete cycles, or to-and-fro motions, effected by the 9current in one second of time.

GALVA.NOMETER.—An instrument for measuring the strength of an electric current. Usually a sensitive instrument which measures the strength of a very feeble current, as distinguished from an ammeter.

GALVANOSCOPE.—An instrument for detecting the passage of a very feeble current.

GENERATOR, ELECTRIC.—A machine which is capable of generating an electric current. Usually a dynamo-electric machine, but not necessarily so.

GROUND.—(1) The earth, considered as an electric con- 2ductor. (2) A return circuit provided through the ground.

(3) A fault or leak of electricity to the earth through a 3defect in the insulation of a conductor. See ELECTRIC CURRENT.

HIGH-POTENTIAL SYSTEM.—In electric distribution, a system of conductors, generators, transformers and substations in which the pressure or voltages is relatively high. Specifically, an electric distributing system, which, according to the law of insulation, lies within the system over 500 volts and less than 3,500 volts.

INFLAMMABLE.—An electric lamp consisting essentially of a glowing filamentary conductor maintained at an incandescent temperature by a traversing electric current.

INDUCTION MOTOR.—An alternating current or discharge, gradually or rapidly decreasing to zero voltage. Overload.—An excessive load upon a machine or device. An abnormal or an extra load.

JOULE, INTERNATIONAL.—A unit of work theoretically defined for the International Electrotechnical Committee. It is the work done by one ampere under a pressure of 1,000 volts in one hour.

Kilowatt Hour.—A unit of work generally used in the 3sale of electric energy. One thousand watt hours, 3,000,000 joules, approximately 2,700,000 foot-pounds or 1,200 long-foot tons, or 1.34 horse-power hours.

LIGHTNING ARRESTER.—A device connected to an electric circuit to prevent the passage of the protective current from damage by atmospheric electricity. Commonly a device connected to an inclined wire, when the voltage is greater than the pressure of the wire, and a conductor is broken down, the lightning dis- 4charge may be deflected. See GENERATORS; LIGHTNING ARRESTER.

LOAD.—The output of, or demand upon a machine, usually measured either in terms of current delivered or of power delivered. A load may be light, heavy, normal, full, half, excessive, etc., according to the output of the machine at the time considered.

LOW POTENTIAL SYSTEM.—In electric distribution, a system of conductors, generators and translating devices in which the pressure or voltage is relatively low. Specifically, an electric distributing system, which, according to the law of insulation, lies within the system over 50 volts and more than 10 volts.

MAGNETIC FIELD.—Any region in space permeated by magnetism. A magnetised space. Commonly a magnetized air-space.

MASS.—The magnetism or magnetic influence which permeates a magnetic field. This influence passes at any point both intensity and direction to these properties, the magnetic lines of influence may be concurred of as stream lines or lines of magnetic flow or flux, and may be expressed in terms of a unit named the Maxwell.

MAINS.—In an electric distributing system, the street-supply conductors to which the main consumers are connected. The main conductors intended for connecting to lamps, motors, or other devices. In house wiring, the principal supply wires, as distinguished from submains, taps or branchers.

MICROWAVE.—A million ohms; and the prefix "mea" signifying by convention one million, and literally, in ancient or modern Greek, "great."

MICROPHONE.—An apparatus capable of having its resis- tance affected by very feeble currents of electricity, enabling such sounds to be heard with the aid of a telephone in the circuit. In telegraphy, the carbon trans- mission of the order of 200,000 miles per second, against which the speaker's voice is directed.

MORE GROSS CODE.—The code of dots and dashes forming the alphabet of the Morse system of telegraphy. Morse SYSTEM OF TELEGRAPHY.—The system of telegraphy originally devised by Samuel Morse. The use of an electromagnet placed in the telegraph line circuit responds to impulses of the sender's key, and actsuate an armature in such a manner as to give either audible or legible signals to the receiving operator. See TELEGRAPHY.

MOTOR, ELECTRIC.—A machine designed to convert electrical power into utilizable mechanical power. Motors almost invariably operate on electromagnetic principles.

MOTOR-STARTER.—An automatically operated device for starting motors with proper control and speed by the simple act of closing a switch.

MULTIPOLAR Dynamic.—A dynamo having more than one pair of magnetic poles in its field frame.

OHM, INTERNATIONAL.—A unit of electric resistance, theoretically defined by electromagnetic principles, from the centimeter-gramme-second system of units. Practically defined as the resistance offered by a uniform column of pure mercury 106.3 centimeters long and weighing 14.4521 grammes, at the temperature of melting ice.

OIL-COOLED GENERATOR.—One which is cooled, when operating, by a flow of oil through its frame.

Oscillating CURRENT.—An alternating current or dis- charge, gradually or rapidly decreasing to zero voltage.

OVERLOAD.—An excessive load upon a machine or device. An abnormal or an extra load.

PHASE.—The fractional development of an alternating electric wave with reference to a cyclic condition such as the zero point in the positive direction. Usually measured in degrees of 360 to the complete cycle.

POLYPHASE SYSTEM.—An alternating current distributing system employing a plurality of alternating currents definitely defined as to the relative phases of the currents, such as the zero point in the positive direction. Usually measured in degrees of 360 to the complete cycle.

QUADRUPLE TELEGRAPHY.—The method of sending four messages simultaneously one above the other in the same telegraph wire, two in one direction and two in the opposite direction. See TELEGRAPHY.

RAIL-BONDS.—The conducting straps or bridges applied between contiguous ends of rails in an electric railway in order to improve their electric conducting power.

RELAY.—A device in which control is by circuit opening or closing the same, with electromagnetic elements, inserted in a circuit line, which, by the movement of its armature, operates a sounder, or other translating device, in a local circuit, with a signal or other effect which could not directly exert. See GENERATORS; TELEGRAPHY.

RESONANCE, ELECTRIC.—The property of conducting substances by virtue of which they obstruct or oppose the passage of an electric current. Usually measured in ohms. The opposite or inverse of conductance.

RESONATOR.—An adjustable electric resistance.

ROTOR.—The rotating element of a machine as distinguished from the stationary element.

SERIES MOTOR or GENERATOR.—A motor or generator whose field-magnet winding is connected in series with, or in succession to, its armature. See GENERATOR.

SERIES-PARALLEL CONTROLLER.—A device on the platform of an electric street car, operated by a handle, through the aid of which the motorman can with his left hand connect the motors under the car on the next route in parallel, so as to vary the speed of the car.

SIDE.—In electricity, the side of a conductor, the terminal or cover, usually of glass, secured over a lamp in order to scatter or reflect the light and produce either a better distribution of light or a high intensity of light upon the eye of the observer.

SHUNT.—An electrical device by which a conductor which is applied to the service wire an apparatus or branch in order to divert a part of the current from that branch. Shunt may be placed, at any point along a conductor, whose field-magnet winding is connected in shunt to, or in parallel with, its armature. See GENERATOR.

SHORT-Circuited.—Connected by a wire between the terminals of a device by which an excessively strong current is produced. Usually a metallic bridging between two or more supply
VOLT, INTERNATIONAL.—A unit of electric pressure or current-driving electric force, theoretically derived, by electromagnetic principles, from the centimeter-gramme-second system of units. Volt is a certain fraction of the electromotive force of a standard type of voltaic cell at a standard temperature.

WATT.—A unit of power, activity, or rate of working, equal to 1,746th of a horsepower, or to 44.4 foot-pounds per minute. The power expended by an E.M.F. of one volt through a resistance of one ohm. The power expended by one ampere through a resistance of one ohm. Theoretically derived from the centimeter-gramme-second electromagnetic system of units.

WATT HOUR.—A unit of work, much used in electrical measurements, equal to the work done in one hour at an activity of one watt; approximately 2,700 foot-pounds; exactly 3,600 joules. The work done by one ampere under one volt pressure, in an hour.

WATTMETER.—An instrument connected to an electric circuit and measuring the power delivered to the circuit in watts.

WHEATSTONE BRIDGE.—An instrument devised by Sir Charles Wheatstone for measuring electric resistance, by effecting a balance between the resistance to be measured and an adjustable known resistance. The balance employs a bridge or bridging conductor, usually containing a galvanoscope.

WIRELESS TELEGRAPHY.—Generally, any method of signalling which does not employ wires. More specifically, the method of signalling which employs invisible electromagnetic waves radiated from sending stations and intercepted at the receiving station. See TELEGRAPH, WIRELESS.

For definitions of mechanical terms see the articles in this encyclopedia on MECHANICAL TERMS; BOILER SHOP TERMS; FORGE SHOP TERMS; ENGINE; ENGINEERING AND STRUCTURAL TERMS; TOOLS; VALVE AND VALVE TERMS; WORKSHOP TERMS; and LOCOMOTIVE, PRINCIPAL PARTS OF.

A. E. KENNELLY,
Professor of Electrical Engineering, Harvard University.

ELECTRICAL UNITS. Two systems of electrical units are in use by electricians, known respectively as the Practical system and the C. G. S. (centimeter-gramme-second) system. The former is used in electrical engineering, the latter in the notation of electrical science. The Practical system is sometimes called the Q. E. S. (quadrant-eleventh-second) system. It is based on the earth quadrant, or 10 1/2 centimeters as the unit of length; 10 1/2 gramme as the unit of mass; and the second as the unit of time. The foundational mechanical units from which the Practical system of electrical units is developed are the dyne and the erg. The dyne is a unit of force, assumed to be that force which gives a weight of one gramme a velocity of one centimeter per second during that second. The erg is a unit of work, being the energy exercised when a weight of one gramme is moved a distance of one centimeter with the force of one dyne.

Arranged alphabetically, the principal units of the Practical system with their definitions and their ratios to the units of the same class in the C. G. S. system are as follows:

**Ampere** (the unit of current)—the rate, or volume-per-second, of current flowing through a conductor in which the resistance is one ohm, when the pressure is one volt. It is one-tenth of the C. G. S. unit of current, designated as 10— that is, 10 to the —1 power.

**Coulomb** (the unit of quantity)—the quantity of electricity passing through a conductor in one second when the rate is one ampere. This unit is not often employed.
ELECTRICITY

Quantity is generally designated in amperes, an amper hour being 3,600 coulombs. The coulomb is $10^4$ C. G. S. units of quantity.

Farad (the unit of capacity) — the capacity of a condenser which would require a charge of one coulomb to establish a difference of potential amounting to one volt between the conductors forming the condenser. The farad being expressed by figures inconveniently large, the micro-farad, the one-millionth part of a farad, is commonly used. A farad is equal to $10^6$ C. G. S. units of capacity.

Henry (the unit of inductance) — the inductance produced in a circuit when the current is changing at the rate of one amper per second and is producing in the circuit a difference of pressure amounting to one volt. A henry is equal to $10^8$ C. G. S. units of inductance.

Ohm (the unit of resistance) — the resistance of a column of mercury weighing 14.4521 grammes, of such constant cross-section as to be 106.3 centimeters in length. In designating very high resistances the unit used is the megohm, equivalent to 1,000,000 ohms. The ohm is $10^6$ C. G. S. units of resistance.

Volt (the unit of pressure) — the electro motive force (E. M. F.) required to force a steady current of one ampere against a resistance of one ohm. The volt is equal to $10^8$ C. G. S. units of pressure.

Watt (the unit of power) — a current of one ampere flowing under a pressure of one volt — equivalent to one joule per second. The usual commercial unit is the kilowatt, or 1,000 watts. The commercial consumption of electric current is commonly designated as kilowatt hours. The physical unit of power called one horse power is equivalent to 746 watts. The watt is equal to $10^8$ C. G. S. units of power — that is, $10^8$ ergs per second.

ELECTRICITY is a form of energy (q.v.), like mechanical energy or energy of motion, heat, radiant energy (as light), chemical energy, etc. Electric energy is the form of energy most recently introduced into everyday life and is, therefore, not yet quite familiar, so that we still ask, "What is electricity?" while ages ago mankind ceased to ask, "What is gravity?" or "What is light?" although the manifestations of electric energy are no more wonderful and inexplicable than those of gravity. That is, the cause why a stone falls to the ground and water flows down hill is just as mysterious as the manifestations of electricity. In nature electric energy manifests itself during atmospheric disturbances as lightning (q.v.), but the energy of lightning is too erratic for use. For the production of electric energy on a larger scale recourse must be had to the stores of energy afforded by nature. In large amounts energy is found in nature, first, as mechanical energy in the waterfalls and to a lesser extent the wind, and second, as chemical energy in coal, wood, oil, natural gas, etc.

Generation.— In the transformation of the mechanical energy of waterfalls into electric energy, the water power is first converted into rotary motion by the turbine or water-wheel, the latter then converted into electric energy by the electric generator or dynamo. Chemical energy can be converted directly into electric energy only to a limited extent, as chemical energy of metals. This is done in the electric battery. (See Electric Battery). But due to the high cost of the chemical energy of metals, the production of electric energy by means of the battery is commercially feasible only where small quantities are required and the cost of the energy therefore secondary to the convenience of generation, as for signaling purposes, bells, annunciators, etc. The chemical energy of coal and other combustibles cannot be directly converted into electric energy, but is converted into heat energy by combustion, the heat energy transferred from the gases of combustion to the water in the steam boiler, converted into mechanical energy in the steam engine or steam turbine and the mechanical converted into electric energy in the electric generator. In a gas engine the heat energy of combustion is directly converted into mechanical energy. In any transformation of energy from one form to another a certain loss occurs by conversion into heat. This loss is moderate in the transformation of water power into mechanical energy, very small in the transformation of mechanical energy into electric energy, but enormous in the transformation of heat into any other form of energy. Our modern theories consider all forms of energy as different modes of motion; of the masses in mechanical energy, of the molecules and atoms of matter or of the electrons with electric, chemical, etc., energy. Heat is the simplest form of energy, irregular motion of the molecules or motion without definite speed and direction. It is, therefore, intelligible that in any conversion of energy, that is, of a regular motion into another regular motion, some of the energy is lost by losing its regularity of motion, that is, converted into heat, the more the greater the difference between the two forms of motion, and that when converting irregular into regular motion, that is, heat into other forms of energy, this loss is specially great. The cost of electric power derived from water power does not differ much from that derived from coal by the steam engine, the cost of coal in the latter case offsetting the interest on the greater investment required in developing the water power and transmitting the electric power to the place of consumption. Hence where coal is cheap the steam power may be more economical, and where water power is found which can cheaply be developed, or where coal is expensive, water power is more economical.

Use.— Electric energy is hardly ever used as such, but only after transformation into other forms of energy, mainly mechanical energy, heat, chemical energy and light. Since electric energy is generated from other forms of energy, it follows that it is used essentially as an intermediary form of energy. For this it is better suited than any other form of energy, its high efficiency and simplicity of generation and reconversion and especially the almost unlimited flexibility which permits transmission over long distance, distribution with the simplest means and unlimited subdivision and ease of control.
Mechanical Power.—The electric motor is a secondary and not a primary source of power, that is, it does not convert the stored-up energy of the coal into electrical energy as the steam engine, but mechanical power has to be exerted somewhere to produce the electric power which is reconverted into mechanical power in the electric motor. The advantage of the electric motor is that the mechanical power can be utilized at a distance from the source of power; the factories and mills may be located far distant from the water power and the railroad train or street car receive the power from the distant station. The power generated at one place can be distributed efficiently to a large number of places, or all motors of the city may receive their power from one central generating station. Instead of an extended and inefficient system of belting, individual motors may drive the machines of the factory or mill. All the cars or trains of a railway system may receive their power from one generating system, perhaps a water-power as Niagara. The electric motor is under more perfect control than almost any other motor, and when not used continuously, the production of sodalum can be stopped in starting and operation. Mechanical power in small quantities can be produced almost as efficiently as in large units and a great subdivision of power becomes thereby feasible. In the field of mechanical power generated by electricity, also belong telegraphy and telephony, or the transmission of signals and speech over long distances.

Light.—For lighting, electric energy usually is first converted into heat and the light given by the incandescence of very refractory solid substances, carbon or tungsten (wolfram), the tungsten wire or carbon filament of the incandescent lamp, or the glowing tip or crater of the arc lamp carbons. (See Electric Lighting.) Here again, especially with incandescent lamps, the main advantage lies in the absolute steadiness, control and flexibility of the light, the simplicity of turning it on or off, and its relatively high efficiency, which gives a light with less heat than the gas flame or kerosene lamp. It is generally preferred for the intermediate form of energy only a very few per cent of the electric energy are converted into light, most being dissipated as heat, with the gas or kerosene flame the percentage of energy converted into light is still much less. Recently considerable work is being done and with great promise of converting electric energy more directly into light by electro-luminescence in luminous arcs, which promise an efficiency of light production very much greater than the incandescent or carbon arc lamp, and there is a possibility of still very much higher efficiencies of light production by electro-fluorescence.

Heat.—The conversion of electric energy into heat means a degradation of energy from regular to irregular motion and in the heat process commercially practicable only.

1. For the production of temperatures beyond those which can be reached by combustion. At very high temperatures chemical affinity and therefore combustion ceases and temperatures beyond this cannot be reached by combustion but are reached by conversion of electric energy into heat in the electric furnace. By this means chemical compounds have been produced for industrial purposes which were either entirely unknown or mere curiosities before, as the carbides, calcium carbide, boronide, boron, silicon metal, etc.

2. Electric energy is used for heating where the temperature has to be perfectly controlled.

3. For intermittent use, such as flat-irons, etc., where heat production by combustion is inefficient.

4. Due to its convenience and cleanliness for domestic uses to a limited extent, electric heating and cooking are coming into use.

Chemical Energy.—Electric energy is converted into chemical energy either directly in the electrolytic cell or indirectly with heat as intermediary in the electric furnace as discussed above. Electrolysis (q.v.), that is, the chemical action of electric energy, is used exclusively for the production of aluminum, magnesium, calcium, etc., metal, is used for copper refining, certain special chemicals, for bleaching powder, and many other compounds.

Storage.—Electric energy cannot be stored as such conveniently, but the ease and efficiency of conversion of electric energy into the chemical energy of metals and metallic oxides, and conversely, permits the storage of electric energy as chemical energy in the storage battery. (See ELECTRIC STORAGE BATTERY.) Charging the storage battery means converting in it electric energy into chemical energy, discharging, the reconversion of the chemical energy into electric energy.

Forms of Electric Energy.—Electric energy is used as direct current, as alternating current and as high frequency current. In the direct current circuit, the electric current continuously flows in the same direction, and the electric pressure or voltage therefore also is constantly in the same direction. Direct current is required for electrolytive work, therefore also for the charging of storage batteries. It is commonly preferred for electric lighting, especially where the demand is very concentrated, as in the centres of large cities. All electric batteries give direct current. Electric generators or motors may be built for direct current as well as for alternating current. In the alternating current circuit, the electric current and thus the electric pressure reverses periodically, usually 120 or 50 times per second, and the number of double reversals or cycles per second is called the frequency of the alternating current. Sixty and 25 cycles per second are the standard frequencies. Usually several alternating currents are used in the same system, which reverse successively, and the system then is called a three-phase system, if three, a quarter-phase system, if two. Successively reversing few per cent of the heat energy expended under the boilers of the steam engine driving the electric generator is recovered, so that electric heating is usually more expensive than direct generation of heat by combustion and therefore commercially practicable only.
required, it is produced from the alternating current supply by rotary transforming devices, so-called "converters," or stationary devices, so-called "rectifiers."

High frequency currents are alternating currents reversing very rapidly, often a hundred thousand or million times per second. Often they are not constant in value, but die out and then start over again, so-called "oscillating currents." They are mainly used for wireless telegraphy and telephony.

**Measurements.**—Since all forms of energy are convertible into each other, they can be measured by the same measure. Heat being the simplest form of energy, the measure of heat has been the usual measure of energy. It is the calorie, or the amount of heat required to raise one litre of water from 0° to 1°C, or the British Thermal Unit (B.T.U.), that is the amount of heat required to raise one pound of water by 1° F. However, due to the far greater convenience and exactness of electrical measurements, the electrical unit of energy, the joule or watt second (one watt current for one second time) in electronic ware is rapidly replacing the thermal unit or calorie, even in chemistry. Generally, the kilo-joule, or thousand joules, is used. Other forms of energy usually have some measure, convertible into calories or into joules. So, mechanical energy is measured in foot-pounds, or kilogram-metres, and the flow of mechanical energy, or mechanical power, in foot-pounds per second or horse power, 1 horse power = 550 foot-pounds per second, = 76 kilogram-metres per second, = 178 calorie seconds. The value of electric energy or electric power is measured either in the mechanical measure, horse power, or electric measure, watts, 746 watts = 1 horse power. Usually the kilowatt or 1,000 watts = 1.34 horse power, is used. 1 kilowatt = 238 calorie second. 1 kilowatt second = 1 kilojoule (KJ). Most forms of energy are resolved into the product of two components; a quantity and a pressure component, as the power of a waterfall is the product of the quantity of water flowing and its head or pressure. So, electric pressure is a quantity component called "current" and measured in amperes, and a pressure component called "electromotive force" or "potential difference" or "voltage," and measured in volts, and the electric power then is the product of volts and amperes, 1 watt = 1 volt x 1 ampere and one joule = 1 watt x 1 second is the electric energy. Just as a small quantity of water under a high head may give the same power as a large quantity under low head, so a small current at high voltage may represent the same electric power as a large current under low voltage. The smaller the quantity and the higher the voltage the less the loss in transmitting the power. Therefore, for long distance transmissions high voltages are used, the higher the greater the decrease in voltage or voltage loss. Voltages are employed for general use, due to the difficulty and danger of handling high voltages. The instrument measuring electric power is called the wattmeter, that measuring electric current or flow of quantity is the ammeter, that measuring electric pressure or voltage is the voltmeter.

**Conductors and Insulators.**—Some substances, as metals, carbon, salt solutions, etc., are conductors of electricity, others as air, glass, rubber, paper, oils, etc., are insulators. There is, however, no perfect conductor nor perfect insulator, but even the best conductors, silver, copper, aluminum, offer still some resistance to the flow of electric power and thereby cause a loss of energy which is proportional to the square of the current flowing and appears as heat in the conductor. For transmission of electric power conductors are therefore used to direct the flow of power, copper or aluminum, surrounded by insulators, as rubber, paper. It is not sufficient, however, merely to surround the conductor by insulating material, but the insulating material must have sufficient thickness to withstand the electric pressure or voltage, otherwise it is disrupted, that is, the electric power penetrates it as spark discharge. The ability to withstand electric pressures is called the dielectric or disruptive strength and is of foremost importance in insulating electric circuits of high voltage. Very good insulators are not necessarily of very high dielectric strength, for instance air, which is perhaps the best insulator, has rather low disruptive strength, that is, is easily penetrated by an electric spark. However, though not as good insulators as air, have very much greater dielectric strength.

**Physiological Effects.**—Electric energy is perceived by the senses either indirectly by transformation into other forms of energy, as light and sound in the spark discharge or lightning, or directly if the electric current passes through the body. A large current of very short duration, or electric discharge, causes a shock which when very powerful, as in lightning, may be fatal. A current flowing continuously through the body causes a specific sensation which with increasing voltage and therefore increasing current becomes unbearable, the muscles contract and become uncontrollable, so that in case of accidental contact with electric circuits the victim is unable to let go, and ultimately at high voltages death may result. With alternating currents, the specific sensation decreases with increasing frequency, so that at very high frequencies even large currents are little felt is resolved. (See also ELECTRICITY, CAUSE OF DEATH BY)

The amount of current flowing through the body depends upon the electric pressure or voltage and the resistance of the body. This resistance is mainly produced of the skin, and of the contact resistance, therefore depends upon the nature of the contact between body and electric circuit. When loosely touched with dry hands a 100-volt circuit may hardly give any sensation, while grasped with wet hands a 50-volt circuit may be unbearable. Only at very high voltages the nature of the contact becomes of less importance and the electric current penetrates as arc. Electric pressures below 500 to 600 volts are considered as still safe, since only in cases of exceptionally good contact with such voltages serious results may occur. Much higher isages are usually employed for general use, are on record of contact with 10,000 to 20,000 volts without fatal results, in cases where the duration of the contact has been very brief.

The causes of death by electricity are:

1. The direct effect of large power exerted upon the body, causing destruction by heat, etc., as in electrocution where several horse power are used.

2. Mechanical destruction of vital organs by very heavy discharges, as lightning.
3. Paralysis of the nervous system, stoppage of the heart and respiratory organs. In these cases resuscitation by artificial respiration, etc., when immediately resorted to, is very promising, especially if only respiration has stopped, but the heart is still beating.

Therapeutically electricity is used as stimulant on the nervous system and for carrying substances through the skin into the body electro-chemically. It is very useful in the hands of expert physicians but like any powerful agent, in the hands of a layman, is harmful and dangerous. The electric healing devices advertised, broadcast, as electric belts, etc., are mere swindles and without any value. See Electrotherapeutics.

Prospect.—Only the very beginning has been made in the use of electricity as secondary form of power for transmitting energy from its natural source, waterfall or coal mine, to the place of consumption, factory, city, railway. Here very great strides are still to be looked forward to, resulting in a much more efficient use of the stores of energy afforded by nature. The transportation of energy is the independence of man of his immediate surroundings, in the necessities of civilized life. These necessities are materials and energy. The transportation, distribution and supply of materials has been organized in the last century by its system of railway, steamship and other transportation agencies, and the generation, transmission, distribution and supply of energy is now being organized by electric power, in the system or network of transmission and distribution which includes the whole country and interconnect the electric power generating stations — steam and hydraulic — with the places of energy demand. Only electricity can fulfill this requirement of energy supply of our civilization, due to the high efficiency of its transmission, the practically unlimited possibility of subdivision in distribution, and the efficiency and simplicity of conversion of electric energy into any other form of energy, from the small lamp of a few watts power consumption, to the huge motor of thousands of horse power. In the production of light from electric energy at present the efficiency is low, due to the use of heat as intermediary form of energy. A direct conversion of electric energy into light giving an efficiency of 50 per cent or more would make electric lighting many times cheaper than any other form of illumination and so displace all other illuminants. In this direction fair promise of a gradual advance exists. The direct conversion of the stored energy of coal into electric energy and thereby the elimination of the enormous loss of energy between the chemical energy of the coal and the electric energy is still entirely hopeless and no clue to its solution visible. In electro-chemistry (q.v.), that is, the transformation of electric into chemical energy, lies an enormous field for artificial respiration by powerful industries, as the aluminum and carbide production, and therefore holds out the hope of most wonderful advances in the future. See Electrochemical Industries; Metallurgy; and various other articles in this volume on electrical subjects.

CHARLES P. STEINMETZ, General Electric Company, Schenectady, N. Y.

ELECTRICITY, Its History and Progress. There is perhaps no better illustration of the slow growth of knowledge than the noting physical things than the fact that the identity of lightning and electricity in some of its other modes of manifestation should have escaped detection for so many centuries of the world's history. Lightning, of course, and certain other manifestations of electricity, were known to the philosophers of ancient times, but to them no thought was more remote than that these manifestations had a common origin. Pliny (61–115 A.D.) in his book writes: "The ancient Tuscan's by their learning hold that there are nine gods that send forth lightning and those of eleven sorts." This was in general the early pagan idea of lightning. The property of amber when rubbed of attracting light bodies, such as particles of feathers, a property now known to be electrical in its nature, must have been familiar to philosophers many hundred years before the Christian era, although Thales of Miletus (640–548 B.C.), one of the seven sages of Greece, is mentioned as having been the first to observe this phenomenon. Pliny has several references to this peculiar property of amber. Pliny's 'Natural History,' (trans. Philemon Holland, London 1634, pp. 606, 608, 609).

The peculiarity of the magnet or loadstone in attracting iron was likewise known to the enlightened men of that early period, but neither in the case of electricity nor of magnetism had these philosophers any conception of the real nature of the phenomena involved, attributing the peculiar properties of the substances named to some occult vitality possessed by them. It is not, however, much to be wondered at that the philosophers of long past ages should have failed to observe any relationship between the electricity of lightning, amber and the torpedo, when as we shall see, many who may be termed modern philosophers — those of the 17th and 18th centuries — failed for years to discover this identity, even when in possession of electric machines capable of in many cases the effects of lightning, and for long after the knowledge of the electrical properties of amber had been extended to wax, glass and other substances. Even the correlation of electricity and magnetism escaped particular notice for some years after the affinity of these phenomena had been demonstrated. Possibly the earliest and nearest approach to the discovery of the identity of lightning and electricity from any other source, is to be attributed to the Arabs, who before the 15th century had applied the Arabic word for lightning (raad) to the torpedo. The Greek word for amber, however, is elektron, and it is due to the fact that this substance was the first known to possess the property mentioned that the word electricity is derived.

Centuries passed after the discovery of frictional and animal electricity before any advance appears to have been made in the production of electricity artificially or before any important developments of value were made in the art.
Toward the latter part of the 16th century a physician of Queen Elizabeth's time, Dr. William Gilbert (1540-1603), undertook a number of careful electrical experiments, in the course of which he discovered that many substances other than amber, such as sulphur, wax, glass, etc., (consult Bassetley's 'History of Electricity,' London, 1757), were capable of manifesting electrical properties. Gilbert also discovered that a heated body lost its electricity and that moisture prevented the electrification of all bodies, due to the now well-known fact that moisture neutralized the action of such bodies. He also noticed that electrified substances attracted all other substances indiscriminately, whereas a magnet only attracted iron. The many discoveries of this nature earned for Gilbert the title of founder of the electrical science. Since Gilbert's time scarcely a year has passed in which some new discovery relating to the science and art of electricity and magnetism has not been made. This is especially true during the years since 1872.

The immediate following Gilbert one of the most notable was Dr. Wall of England (1650). During one of his experiments on approaching his fingers to an electrified rod, Dr. Wall saw a spark, accompanied by a noise which he likened to lightning and thunder. Wall's contemporaries and some comparatively recent writers have thought that this was the first time an artificially produced electric spark had been observed. This, however, is doubtless an erroneous view. Archbishop Eustathius, of Thessalonica, a Greek scholar and writer of the 12th century, for instance records that Woliver, king of the Goths, was able to draw sparks from his body. The same writer states that a certain philosopher was able while dressing to draw sparks from his clothes, a result seemingly akin to that obtained by Symmer in his silk-stocking experiments, a careful account of which may be found in the 'Philosophical Transactions,' 1735.

It would indeed have been surprising if the electric spark had not been observed prior to Dr. Wall's time (although its origin may not have been recognized) when it is considered that any one shuffling across a carpet in dry, crisp weather, or if whipped with a piece of fur while his body is insulated, will accumulate a charge of electricity upon his person that will discharge with a spark into any other person or piece of metal that he may touch. The present writer has even noticed electric sparks passing from his clothes to the metal fixtures of a hand bag that he was carrying while walking on a stoned pavement in cold, dry weather.

Robert Boyle was another of the experimenters in electricity of this period (1650). One of his important discoveries was that electricity in a vacuum would attract light substances, this indicating that the electrical effect did not depend upon the air as a medium. He also added resin to the then known list of electrics. (Consult Boyle's 'Experiments on the Origin of Electricity,' and Priestley's 'History of Electricity.') Up to about the year 1682 the only known way in which electricity could be developed was virtually that known to the ancients, namely, by rubbing rods of amber, glass, wax, resin or similar substances. The amount of electricity producible in this way was very small. At this time Otto von Guericke of Magdeburg (also the inventor of the air-pump) invented an electric machine consisting of a sulphur globe or ball, suitably mounted on a shaft and rotated by a handle. Using his hand as a "rubber" (see ELECTRIC MACHINE), von Guericke obtained electricity in fairly large quantities, the production of which was accompanied by light and sound.

The electric machine was subsequently improved by Hawkesbee or Hauksbee, Litzendorf, and by Prof. George Mathias Boze, about 1750. Litzendorf substituted a glass ball for a sulphur ball of Guericke. Boze was the first to employ the "prime conductor" in such machines, this consisting of an iron rod held in the hand of a person whose body was insulated by standing on a cake of resin. Dr. Ingenhousz, in 1746, invented electric machines made of plate glass. Consult Dr. Carpe's 'Introduction to Electricity and Galvanism,' London 1803.

Experiments with the electric machine were largely aided by the discovery of the property of a glass plate, glass paper, or what is known as tinfoil, of accumulating a charge of electricity when connected with a source of electromotive force. This property, now and for many years availed of in the electric condenser, was, according to Priestley ('History of Electricity,' 3d ed., Vol. I, p. 102), first observed by Von Kleist of Leyden in 1754. Von Kleist happened to hold, near his electric machine, a small bottle, in the neck of which there was an iron nail. Touching the iron nail accidentally with his other hand he received a severe electric shock. In much the same way Prof. Pieter van Musschenbroek assisted by Cunaens received a more severe shock from a somewhat similar glass bottle. Sir William Watson of England greatly improved this device, by covering the bottle, or jar, outside and in with tinfoil. This piece of electrical apparatus will be easily recognized as the well-known Leyden jar, so called by the Abbot Nollet of Paris, after the place of its discovery. The electric machine was soon further improved by Prof. Andrew Gordon, a Scotchman, of Erfurt, who substituted a glass cylinder in place of a glass globe; and by Giessing of Leipzig who added a "rubber" consisting of a cushion of woolen material. The "collector," consisting of a series of metal points, was added to it by Benjamin Wilson about 1746, and Mr. John Canton of England (also the originator of the first pith ball electrometer) in 1762 made a notable improvement in the efficiency of electric machines by sprinkling an amalgam of tin over the surface of the rubber.

In the second quarter of the 18th century (1729) Stephen Gray in a series of interesting experiments for the first time demonstrated the difference between conductors and non-conductors (insulators), showing amongst other things that a metal wire and even pack thread conducted electricity, whereas silk did not. In one of his experiments he sent an electric current through 700 feet of hempen thread which was suspended at about "Hiram's height," up to about the year 1682 the only known way in which electricity could be developed was virtually that known to the ancients, namely, by rubbing rods of amber, glass, wax, resin or similar substances. The amount of electricity producible in this way was very small. At this time Otto von Guericke of Magdeburg (also the inventor of the air-pump) invented an electric machine consisting of a sulphur globe or ball, suitably mounted on a shaft and rotated by a handle. Using his hand as a "rubber" (see ELECTRIC MACHINE), von Guericke obtained electricity in fairly large quantities, the production of which was accompanied by light and sound.
posed to measure the strength of electrification by its power to raise a weight in one scale of a balance while the other was held over the electrified body and pulled to it by its attractive power. (Carrus.)

The Sir William Watson already mentioned conducted numerous experiments, about 1749, to ascertain the velocity of electricity in a wire, which experiments, although perhaps not so intended, also demonstrated the possibility of transmitting signals to a distance by electricity. In these experiments an insulated wire 12,276 feet in length was employed and the transmission of a signal from one end of the wire to the other appeared to the observers to be instantaneous. Monnier in France had previously made somewhat similar experiments, sending shocks through an iron wire 1,319 feet long.

About 1737 Hawkesbee and Du Fay independently discovered that there were apparently two kinds of frictions, electricity, namely, that which is developed by rubbing glass and resin, respectively. The former electricity Du Fay termed "vitreous," the latter "resinous" electricity. Later, these electricity were termed "positive" and "negative" electricity, respectively, by Franklin, Dr. Watson, Lichtenberg and others.

Theories regarding the nature of electricity were quite vague at this period, and those prevalent were more or less conflicting. Franklin considered that electricity was an imponderable fluid pervading everything, and which, in its normal condition, was uniformly distributed in all substances. He assumed that the electrical manifestations obtained by rubbing glass were due to the production of an excess of the electric fluid in that substance and that the manifestations produced by rubbing wax were due to a deficit of the fluid. This theory was opposed by the "two-fluid" theory due to Robert Symmer, 1759. By Symmer's theory the vitreous and resinous electrieties were regarded as impure fluids, each fluid being composed of mutually repellant particles while the particles of the opposite electrieties are mutually attractive. When the two fluids unite by reason of their attraction for one another, their effect is neutralized. The act of rubbing a body decomposes the fluids one of which remains in excess on the body and manifests itself as vitreous or resinous electricity.

About 1750 various tests were made by different experimenters to ascertain the physiological and therapeutical effects of electricity. Mainbray (or Mowbray) in Edinburgh examined the effects of electricity upon plants and concluded that the growth of two myrtle trees was quickened by electrification. These myrtles were electrified during the whole month of October, 1746, and they put forth branches and blossoms sooner than other shrubs of the same kind not electrified. (Priestley's 'History of Electricity,' p. 138). The Abbé Menon tried the effects of a continued application of electricity upon men and birds and found that they were not affected on losing weight, thus apparently showing that electricity quickened the excretions. The efficacy of electric shocks in cases of paralysis was tested in the county hospital at Shrewsbury, England, with rather poor success. (Philosophical Transactions, p. 786, 1754). In one case reported a palsied arm was somewhat improved, but the dread of the shocks became so great that the patient preferred to forego a possible cure rather than undergo further treatment. In another case of partial paralysis the electric treatment was followed by temporary total paralysis. A second application of this treatment was again followed by total paralysis, whereupon the further use of electricity in this case was stopped.

For further accounts of the early use of electricity as a remedial agent the reader may consult De la Rive's 'Electricity.' See also article Electrotherapeutics.

Up to the time of Franklin's historic kite experiment (see Electricity, Atmospheric) the identity of the electricity developed by rubbing and by electric machines (frictional electricity), with lightning had not been generally established. Dr. Wall, 1807, Abbot Nollet, Hawkesbee, Gray and Winckler had indeed suggested the resemblance of the different phenomena of electricity and lightning, but they were not impressed by Franklin's argument. In another of his experiments, wrote Dr. Wall, great and light phenomena of the electric matter with that of lightning may be demonstrated. (Franklin, 'Experiments and Observations on Electricity'). Dalibard, at Marly, near Paris, on 10 May 1742, by means of a vertical iron rod 40 feet long, obtained results corresponding to those recorded by Franklin and somewhat prior to the date of Franklin's experiment.

Franklin's important demonstration of the sameness of frictional electricity and lightning was performed in 1751, doubtless added zest to the efforts of the many experimenters in this field in the last half of the 18th century, to advance the progress of the science. Amongst those workers may be mentioned Watson, Boze, Smeaton, Le Monnier, De Romas, Jallabert, Becquerel, Cavendish, John Canton, Franklin, Symmer, Nollet, Winckler, Riehman, Dr. Wilson, Kinnersley, Priestley, Aepinus, Delaval, Cavendish, Coulomb, Volta and Galvani. A description of many of the experiments and discoveries of these early workers in the fields of electrical science and art will be found in the scientific publications of the time; notably the Philosophical Transactions, Philosophical Magazine, Cambridge Mathematical Journal, Young's 'Natural Philosophy,' Priestley's 'History of Electricity,' Franklin's 'Experiments and Observations on Electricity,' Cavalli's 'Treatise on Electricity,' De la Rive's 'Treatise on Electricity.' Among the more important of the electrical experiments and researches at this period were those of Francis Aepinus, a noted German scholar (1724–1802) who demonstrated the effect of positively charged objects on the earth in England. To Aepinus is accorded the credit of having been the first to conceive the view of the reciprocal relationship of electricity and magnetism. In his work 'Tentamen Theoria Electricitatis et Magnetismi,' published in Saint Petersburg, 1759, he gives the following amplification of Franklin's theory, which in some of
its features is measurably in accord with present day views: "The particles of the electric fluid repel each other and attract and are attracted by the particles of water with a force that decreases in proportion as the distance increases; the electric fluid exists in the pores of bodies; it moves unobstructedly through non-electric (conductors), but moves with difficulty in insulators; the manifestations of its existence are unequal distribution of the fluid in a body, or to the approach of bodies unequally charged with the fluid." Aepinus formulated a corresponding theory of magnetism excepting that in the case of magnetic phenomena the fluids only acted on the particles of iron. He also made numerous electrical experiments, amongst others that apparently showing that in order to manifest electrical effects tourmalin requires to be heated to a temperature between 37.5° C and 100° C. In fact, tourmalin remained electrified when its temperature is uniform, but manifests electrical properties when its temperature is rising or falling. Crystals which manifest electrical properties in this way are termed pyro-electrics, amongst which, besides tourmalin, are sulphate and carbonate of lead.

Cavendish independently conceived a theory of electricity nearly akin to that of Aepinus ("Philosophical Transactions," 1771). He also (1784) was perhaps the first to utilize the electric spark to produce the explosion of hydrogen and oxygen in the proper proportions to produce pure water. The same philosopher also discovered the inductive capacity of dielectrics (insulators) and as early as 1775 measured the specific inductive capacity for beeswax and other substances by comparison with an air condenser.

About 1784 C. A. Coulomb, after whom is named the electrical unit of quantity, devised the torsion balance, by means of which he discovered what is known as Coulomb's law: "The force exerted by one electrified body varies inversely as the square of the distance; not as Aepinus in his theory of electricity had assumed, merely inversely as the distance. According to the theory advanced by Cavendish the particles attract and are attracted inversely as some less power of the distance than the cube." With the discovery, by the experiments of Watson and others, that electricity could be transmitted to a distance, the idea of making practical use of this phenomenon began, about 1753, to engross the minds of "inquisitive" persons, and to this end suggestions looking to the employment of electricity in the transmission of intelligence were made. The first of the methods devised for this purpose was probably that, due to Lesage (1774). This method consisted in the employment of 24 wires, insulated from one another and each of which had a pith ball connected to its distant end. Each wire represented a letter of the alphabet. To send a message, a desired wire was charged momentarily with electricity from an electric machine, when the pith ball connected to that wire would fly out; and in this way messages were transmitted. Other methods of telegraphing in which frictional electricity was employed were also tried, some of which are described in the article on the telegraph (q.v.).

Hitherto the only electricity known was that developed by friction or rubbing, which was therefore termed frictional electricity. We now come to the concept of galvanic or voltaic electricity. The first mention of voltaic electricity, although not recognized as such at the time, was probably made by Sulzer in 1769, who on placing a small disc of zinc under his tongue and a small disc of copper over it, observed a peculiar taste at the place of contact, and a white deposit at their edges. Sulzer assumed that when the metals came together they were set into vibration, this acting upon the nerves of the tongue, producing the effects noticed.

In 1790 Prof. Luigi Galvani of Bologna on one occasion, while conducting experiments on "animal electricity," as he termed it, to which his attention had been turned by the twitching of a frog's legs in the presence of an electric machine, observed that the muscles of a frog which was suspended on an iron balance, and at once electrified by a copper hook that passed through its dorsal column underwent lively convulsions without any extraneous cause; the electric machine being at this time absent. To account for this phenomenon Galvani assumed that electricity of opposite kinds existed in the muscles and nerves constituting the charged coatings of a Leyden jar.

Galvani published the results of his discoveries, together with his hypothesis, which at once engrossed the attention of the physicists of that time; the most prominent of whom, Alexander Volta, professor of physics at Pavia, contended that the results observed by Galvani were due to the two metals, copper and iron, acting as "electromotors," and that the muscles of the frog played the part of a conductor, completing the circuit.

This precipitated a long discussion between the adherents of the conflicting views; one set of adherents holding with Volta that the electric current was suspended on an electromotive force of contact at the two metals; the other set adopting a modification of Galvani's view and asserting that the current was due to a chemical affinity between the metals and the acids in the pile. Michael Faraday wrote in the preface to "Experiments and Observations in Electricity," relative to the question whether metallic contact is or is not productive of a part of the electricity of the voltaic pile: "I see no reason as yet to alter the opinion I have given; but the point itself is of such great importance that I intend at the first opportunity renewing the inquiry, and, if I can, rendering the proofs either on the one side or the other, undeniable to all." Even Faraday himself, however, did not settle the controversy, and while the views of the advocates on both sides of the question have undergone modifications, as subsequent investigations and discoveries demanded, up to the present day diversity of opinion on these points continues to crop out.

Volta made numerous experiments in support of his theory and ultimately developed the pile or battery (see VoltaiC Pile), which was the precursor of all subsequent chemical batteries, and possessed the distinguishing merit of being the first means by which a prolonged continuous current of electricity was obtainable.
Volta communicated a description of his pile to the Royal Society of London and shortly thereafter Nicholson and Cavendish (1780) produced the decomposition of water by means of the electric current, using Volta's pile as the source of the electricity. In 1800, Faraday, employing a voltaic pile of approximately 250 cells, or couples, decomposed potash and soda, showing that these substances were respectively the oxides of potassium and sodium, which metals previously had been unknown. These experiments in electricity (q.v.), the investigation of which Faraday took up, and concerning which in 1833 he announced his important law of electrochemical equivalents, viz.: *The same quantity of electricity—that is, the same electric current—decomposes chemically equivalent quantities of all the bodies which it traverses; hence the weights of elements separated in these electrolyses are to each other as their chemical equivalents.* Employing a battery of 256 cells, Faraday in 1830 showed that if the current was increased so that it could be seen, Davy in 1809 gave the first public demonstration of the electric arc light (q. v.), using for the purpose charcoal enclosed in a vacuum.

Somewhat singular to note, it was not until many years after the discovery of the voltaic pile that the sameness of annual and frictional electricity with voltaic electricity was clearly recognized and demonstrated. Thus as late as January 1833 we find Faraday writing (*Philosophical Transactions,* 1833) in a paper on the electricity of the torpedo: *"After an examination of the experiments of Walsh, Ingenhousz, Cavendish, Sir H. Davy, and Dr. Davy, no doubt remains on my mind as to the identity of the electricity of the torpedo with common (frictional) and voltaic electricity; and I presume that so little will remain on the mind of others as to justify my refraining from entering at length into the philosophical proof of that identity. The doubts raised by Sir H. Davy have been removed by his brother, Dr. Davy; the results of the latter being the reverse of those of the former."

The general conclusion which must, I think, be drawn from this collection of facts (a table showing the similarity of properties of the diversely named electricities) is, that electricity, whatever may be its source, is identical, as it were, in its effects.

It is proper to state, however, that prior to Faraday's time the similarity of electricity derived from different sources was more than suspected. Thus, William Hyde Wollaston, b. 1766; d. 1828 (another noted and careful experimenter in electricity and the discoverer of palladium and rhodium), wrote in 1801 (*Philosophical Magazine,* Vol. III, p. 211): *This similarity in the means by which both electricity and galvanism (voltaic electricity) appear to be excited in addition to the resemblance that has been traced between their effects shows that they are both essentially the same and confirm an opinion that has already been advanced by others, that all the differences discoverable in the electric machines are merely accidental; that the one is less intense, but produced in much larger quantity.* In the same paper Wollaston describes certain experiments in which he uses very fine wire in a solution of sulphate of copper through which he passed electric currents from an electric machine, which is interesting in connection with the later day use of almost similarly arranged fine wires in electrolytic receivers in wireless, or radio-telegraphy.

In the first half of the 19th century many very important additions were made to the world's knowledge concerning electricity and magnetism. For example, in 1819 Hans Christian Oersted of Copenhagen discovered the deflecting effect of an electric current traversing a wire upon a suspended magnetic needle. This discovery gave a clue to the subsequently proved intimate relationship between electricity and magnetism which wasstrom's law. Ampère who shortly thereafter (1821) announced his celebrated theory of electro-dynamics, relating to the force that one current exerts upon another, by its electro-magnetic effects, namely: (1) *Two parallel portions of a circuit attract one another if the currents in them are flowing in the same direction, and repel one another if the currents flow in the opposite direction. (2) Two portions of circuits crossing one another obliquely attract one another if both the currents flow from the point of crossing, and repel one another if one flows to and the other from that point. (3) When an element of a circuit exerts a force on another element of a circuit, that force always tends to lie in a direction at right angles to its own direction.*

Professor Seebeck, of Berlin, in 1821 discovered that when heat is applied to the junction of two metals that had been soldered together an electric current is set up. This is termed Thermo-Electricity. (See THERMO-ELECTRICITY.) Seebeck's device consists of a strip of copper bent at each end and soldered to a plate of bismuth. A magnetic needle is placed parallel with the copper strip. When the heat of a lamp is applied to the junction of the copper and bismuth an electric current is set up which deflects the needle.

Peltier in 1834 discovered an effect opposite to the foregoing, namely, that when a current is passed through a couple of dissimilar metals the temperature is lowered or raised at the junction of the metals, depending on the direction of the current. This is termed the Peltier "effect." The variations of temperature are found to be proportional to the strength of the current and not to the square of the strength of the current as in the case of heat due to the Joule resistance of a conductor. This latter is the **C R** law, discovered experimentally in 1841 by the English physicist, Joule. In other words, this important law is that the heat generated in any part of an electric circuit is directly proportional to the product of the resistance of this part of the circuit and to the square of the strength of current flowing in the circuit.

In 1822 Schweigger devised the first galvanometer (q.w.). This instrument was subsequently much improved by Wilhelm Weber (1833). In 1825 William Sturgeon of Woolwich, England, invented the horseshoe and straight bar electromagnet, receiving therefor the silver medal of the Society of Arts ("Trans. Society of Arts," 1825). In 1837 Henry and John Faraday (both noted workers of this period) jointly invented a reflecting galvanometer for telegraph purposes. This was the forerunner of the Thomson reflecting and other exceedingly sensitive galvanometers once used in submarine signaling and still widely employed in electrical measurements. Arago in 1824 made the im-
portant discovery that when a copper disc is rotated in its own plane, and if a magnetic needle be freely suspended on a pivot over the disc, it will revolve in a plane perpendicular to the disc. If on the other hand the needle is fixed it will tend to retard the motion of the disc. This effect was termed Arago's rotations. Futil attempts were made by Babbage, Barlow, Herschel and others to explain this phenomenon. The true explanation was reserved for Faraday. He knew that electric currents are induced in the copper disc by the cutting of the magnetic lines of force of the needle, which currents in turn react on the needle. In 1827 George Simon Ohm (q.v.) announced the now famous law that bears his name, that is:

\[
\text{Current} = \frac{\text{Electromotive force}}{\text{Resistance}}.
\]

In 1831 began the epoch-making researches of Michael Faraday (q.v.), the famous pupil and successor of Humphrey Davy (q.v.) at the head of the Royal Institution, London, relating to electric and electromagnetic induction.

Faraday's studies and researches extended from 1831 to 1855 and a detailed description of his experiments, deductions and speculations are to be found in his compiled papers, entitled 'Experimental Researches in Electricity.' Faraday was by profession a chemist. He was not in the remotest degree a mathematician in the ordinary sense — indeed it is a quest on if in all his writings there is a single mathematical formula.

The experiment which led Faraday to the discovery of electric induction was made as follows: He constructed what is now and was then termed an induction coil, the primary and secondary wires of which were wound on a wooden bobbin, side by side, and insulated from one another. In the circuit of the primary wire he placed a battery of approximately 100 cells. In the secondary wire he inserted a galvanometer. On making his first test he observed no results, the galvanometer remaining quiet. On increasing the length of the wires he noticed a deflection of the galvanometer in the secondary wire when the circuit of the primary wire was made and broken. This was the first observed instance of the development of electromotive force by electromagnetic induction. He also discovered that induced currents are established in a second closed circuit when the current strength is varied in the first wire, and that the direction of the current in the secondary circuit is opposite to that in the first circuit. Also that a current is induced in a secondary circuit when another circuit carrying a current is moved to and from the first circuit, and that the approach or withdrawal of a magnet to or from a closed circuit induces momentary currents in the latter. In short, within the space of a few months Faraday discovered by experiment virtually all the laws and facts now known concerning electro-magnetic induction and magnet-electric induction. Upon these discoveries, with scarcely an exception, depends the operation of the telephone, the dynamo machine, and incidental to the dynamo electric machine practically all the gigantic electrical industries of the world, including electric lighting (q.v.), electric traction, the operation of electric motors for power purposes, and electro-plating (q.v.), electrotyping (q.v.), etc.

In his investigations of the peculiar manner in which iron filings arrange themselves on a cardboard or glass in proximity to the poles of a magnet, Faraday conceived the idea of magnetic *lines of force* extending from pole to pole of the magnet and along which the filings tend to place themselves. On the discovery being made, he experimented to accompany the passage of an electric current in a wire. It was also assumed that similar magnetic lines of force whirled around the wire. For convenience and to account for induced electricity it was then assumed that when these lines of force are *cut* by a wire in passing across them when the lines of force in rising and falling cut the wire, a current of electricity is developed, or to be more exact, an electromotive force is developed in the wire that sets up a current in a closed circuit.

Faraday advanced what has been termed the molecular theory of electricity which assumes that electricity is the manifestation of a peculiar condition of the molecule of the body rubbed or the ether surrounding the body. Faraday also, by experiment, discovered paramagnetic and diamagnetic phenomena in Electricity. The results of his experiments with sol' ds and liquids are either attracted or repelled by a magnet. For example, iron, nickel, cobalt, manganese, chromium, etc., are paramagnetic (attracted by magnetism), whilst other substances, such as bismuth, phosphorus, antimony, zinc, etc., are repelled by magnetism or are diamagnetic ('Phil. Trans.,' 1845). Brugns of Leyden in 1778 and Le Bailiif and Becquerel in 1827 had previously discovered diamagnetism in the case of bismuth and antimony. Faraday also rediscovered specific inductive capacity in 1837, the results of the experiments by Cavendish not having been published at that time. He also predicted ('Phil. Mag., March 1854') the retardation of signals on long submarine cables due to the inductive effect of the insulation of the cable, in other words, the static capacity of the cable.

The 25 years immediately following Faraday's discoveries of electric induction were fruitful in the promulgation of laws and facts relating to induced currents and to magnetism. In 1834 Lenz and Jacobi independently demonstrated the now familiar fact that the currents induced in a coil are proportional to the number of turns in the coil. Lenz also announced at that time the important law that, in all cases of electromagnetic induction the induced currents have such a direction that their reaction tends to stop the motion that produces them, a law that was perhaps deducible from Faraday's explanation of Arago's rotations.

In 1845 Joseph Henry, the American physicist, published an account of his valuable and interesting experiments with induced currents of a high order, showing that currents could be induced from the secondary of an induction coil to the primary of a second coil, thence to its secondary wire, and so on to the primary of a third coil, etc. ('Philosophical Magazine,' 1849). At this time many re-searches into the laws of these induced currents, but owing to their complexity the investigation was not productive of very notable results ('Ann. de Chimie III,' i, 385). About 1850
Kirchhoff published his laws relating to branched or divided circuits. He also showed mathematically that according to the then prevailing electrodynamic theory, electricity would be propagated along a perfectly conducting wire with the velocity of light. Helmholtz investigated mathematically the effects of induction upon the propagation of this current and deduced therefrom equations, which experiment conformed, showing amongst other important points the retarding effect of self-induction under certain conditions of the circuit ("Poggendorf Ann. 1851"). In 1853 Sir William Thomson (later Lord Kelvin) (n.v.) predicted as a result of mathematical calculations the oscillatory nature of the electric discharge of a condenser circuit. To Henry, however, belongs the credit of discerning as a result of his experiments in 1842 the oscillatory nature of the Leyden jar discharge. He wrote (*Proc. Am. Phil. Soc.,* Vol. II, pp. 193, 196): *The phenomena require us to admit the existence of a principal discharge in one direction, and then several reflex actions backward and forward, each more feeble than the preceding, until the equilibrium is obtained.* The oscillation was subsequently observed by Feddersen (1857) who using a rotating concave mirror projected an image of the electric spark upon a sensitive plate, thereby obtaining a photograph of the spark which plainly indicated the alternating nature of the discharge. Sir William Thomson was also the discoverer of the electric convection of heat (the *Thomson* effect). He designed for electrical measurements of precision his quadrant and absolute electrometers. The reflecting galvanometer, now generally used for submarine cable signaling, are also due to him. About 1876 Prof. H. A. Rowland of Baltimore demonstrated the important fact that a static charge carried around produces the same magnetic effects as an electric current. The importance of this discovery consists in that it may afford a plausible theory of magnetism, namely, that magnetism may be the result of directed motion of rows of molecules carrying static charges.

One of today's discoveries that electric currents could be developed in a wire by causing it to cut across the lines of force of a magnet, it was to be expected that attempts would be made to construct machines to avail of this fact in the development of voltaic currents. (See ELECTRIC MACHINERY; ELECTRIC DIRECT CURRENT; GENERATORS). The first machine of this kind was due to Pixii, 1832. It consisted of two bobbins of iron wire, opposite which the poles of a horseshoe magnet were caused to rotate. As this produced in the coils of the wire an alternating current, Pixii arranged a commutating device (commutator) that converted the alternating current of the coils or armature into a direct current in the external circuit. This machine was followed by improved forms of magnetoelectric machines due to Ritchie, Saxton, Clarke, Stockton, constant type. The open type in both type which operated on closed circuit becomes, after a short time, polarized; that is, gases are liberated in the cell which settle on the negative plate and establish a resistance that reduces the current strength. After a brief interval of open circuit these gases are liberated, the plate is filled, the gases are removed, and the cell is again ready for operation. Closed circuit cells are those in which the gases
in the cells are absorbed as quickly as liberated and hence the output of the cell is practically uniform. The Leclanché and Daniell cells, respectively, are familiar examples of the "open" and "closed" type of voltaic cell. The "open" cells are used very extensively at present, especially in the dry cell form, and in annunciators. The "closed" cells are used in the network of intimate electrical systems. Batteries of the Daniell or "gravity" type were employed almost generally in the United States and Canada as the source of electromotive force in telegraphy before the dynamo machine became available, and still are largely used for this service or as "local" cells. Batteries of the "gravity" and the Edison-Lalanne types are still much used in "closed circuit" systems.

The possibility of obtaining the electric current in large quantities, and economically, by means of dynamo electric machines gave impetus to the development of incandescent and arc lighting. Until these machines had attained a commercial basis voltaic batteries were the only available source of current for electric lighting. However, the cost of these batteries, however, and the difficulties of maintaining them in reliable operation were prohibitory of their use for practical lighting purposes. The date of the employment of arc and incandescent lamps may be set at about 1877. Even in 1876, however, the public had been made toward the general use of these illuminants; the rapid subsequent growth of this industry is a matter of general knowledge. (See ELECTRIC LIGHTING.) The employment of storage batteries (q.v.), which were originally termed "secondary" batteries and accumulators, began about 1879. Such batteries are now utilized on a large scale as auxiliaries to the dynamo machine in electric power-houses and substations, in electric automobiles and in immense numbers in automobile ignition and starting systems, also in fire alarm telegraphy and other signal systems.

In 1871 the electric telegraph had grown to large proportions and was in use in every civilized country in the world, lines forming a network in all directions over the surface of the land. The system most generally in use was the electromagnetic telegraph due to S. F. B. Morse of New York, or modifications of his system. (See TELEGRAPH.) Submarine cables (see CABLE) connecting the Eastern and Western hemispheres were also in successful operation at that time. When, however, at the present day (1918) one views the vast applications of electricity to electric light, electric railways, electric power and other purposes (all it may be repeated made possible and practicable by the perfection of the dynamo machine) it is difficult to believe that no longer ago than 1871 the author of a book published in that year, in referring to the state of the art of applied electricity at that time, could have truthfully written: The most remarkable of the uses which have been made of electricity consists in its application to telegraph purposes (Miller's 'Magnetism and Electricity,' p. 460). The statement was, however, quite accurate and perhaps the time could have been carried forward to the year 1876 without material modification of the remarks. In that year the telephone (q.v.), due to Alexander Graham Bell (q.v.), was invented, but it was not until several years thereafter that its commercial employment began in earnest. Since that time also the sister branches of electricity just mentioned have advanced and are advancing with such gigantic strides in every direction that it is difficult to place a limit upon their progress. For a more adequate account of the use of electricity in industry see ELECTRICAL MANUFACTURING INDUSTRY.

In 1864 James Clerk Maxwell of Edinburgh announced his electromagnetic theory of light, which was perhaps the greatest single step in the world's knowledge of electricity. (Consult Maxwell's 'Electricity and Magnetism,' Vol. II, Chap. xx.) As already noted herein Faraday, and before him, Ampère and others, had inklings that the luminiferous ether of space was also the medium for electric action. It was known by calculation and experiment that the velocity of electricity was approximately 186,000 miles per second; that is, equal to the velocity of light, which in itself suggests the idea of a relationship between electricity and light. A number of the earlier philosophers or mathematicians of the 19th century, held the view that electromagnetic phenomena were explainable by action at a distance. Maxwell, following Faraday, contended that the seat of the phenomena was in the medium. The methods of the mathematicians in arriving at their results were synthetic while Faraday's methods were analytical. Faraday in his mind's eye saw lines of force traversing all space where the mathematicians saw centres of force attracting at a distance. Faraday sought the seat of the phenomena in real actions given in the laws of nature, whereas Maxwell felt satisfied that they had found it in a power of action at a distance on the electric fluids (Maxwell's 'Electricity and Magnetism,' preface).

Both of these methods, as Maxwell points out, had succeeded in explaining the propagation of light as an electromagnetic phenomenon while at the same time the fundamental conceptions of what the quantities concerned are, radically differed. The mathematicians assumed that insulators were barriers to electric currents; that, for instance, in a Leyden jar the electric condenser the electricity was accumulated at one plate and that by some occult action at a distance electricity of an opposite kind was attracted to the other plate. Maxwell, looking further than Faraday, reasoned that if light is an electromagnetic phenomenon and is transmissible through dielectrics such as glass, the phenomenon must be in the nature of electromagnetic currents in the dielectrics. He therefore contended that in the charging of a condenser, for instance, the situation did not stop at the point that the "displacement" currents are set up in the insulating medium, which currents continue until the resisting force of the medium equals that of the charging force. In a closed circuit conductor an electric current is continued. This resistance may be likened to that met with by a ship as in its progress it displaces the water. The resistance of the dielectric is of a different nature and has been
ELECTRICITY, ITS HISTORY AND PROGRESS

compared to the compression of multitudes of springs, which, under compression, yield with an increasing back pressure, up to a point where the total back pressure is the initial pressure. When the initial pressure is withdrawn the energy expended in compressing the springs is returned to the circuit, concurrently with the return of the springs to their original condition, this producing a reaction in the opposite direction. Conversely, due to the displacement of electricity in a conductor may be continuous, while the displacement currents in a dielectric are momentary and, in a circuit or medium which contains but little resistance compared with capacity or inductance reaction, the currents of discharge are of an oscillatory or alternating nature. (See Oscillating Current; Telegraphy, Wireless.) Maxwell extended this view of displacement currents in dielectrics to the ether of free space. Assuming light to be the manifestation of alterations of electric currents in the ether, and vibrating at the rate of light vibrations, these vibrations by induction set up corresponding vibrations in adjoining portions of the ether, and in this way the undulations corresponding to light were thought of as an electromagnetic effect in the ether. Maxwell's electromagnetic theory of light obviously involved the existence of electric waves in free space, and his followers set themselves the task of experimentally demonstrating the truth of the theory. This honor was reserved for Prof. H. Hertz, who in 1887 in a series of experiments proved the actual existence of such waves. The discovery of electric waves in space naturally led to the discovery and introduction in the closing years of the 19th century, of wireless telegraphy (q.v.), various systems of which are now in successful use on shipboard, lighthouses and shore and inland stations throughout the world, by means of which intelligence is transmitted across the widest oceans and large parts of continents.

In 1891 notable additions to our knowledge of the phenomena of high frequency and high potential current were contributed by Nikola Tesla (q.v.). (Consult Proc. Am. Inst. El. Engrs., 1891.) Amongst the novel experiments performed by Tesla was the use of a glass tube in which the air had been exhausted, then bringing his body into contact with a wire carrying currents of high potential, the tube was surmounted with a pleasing bright glow. Another experiment was to grasp a bulb that was suspended from a single wire attached to a high potential, high frequency current circuit, when a platinum button within the bulb was brought to vivid incandescence, the experimenter at this time standing on an insulating platform and potential involved in the experiments made by Tesla at this time were of the order of one or more million cycles and volts. For further information relative to these experiments the reader may be referred to Tesla's 'Experiments with Alternate Currents of High Potential and High Frequency.'

The place of electricity in leading up to the discovery of those beautiful phenomena of the Crookes Tube (due to Sir William Crookes) (consult Proc. British Association, 1879), and later to the discovery of Roentgen or X-rays (q.v.), must not be overlooked, since without electricity as the excitation of the tube the discovery of the rays might have been postponed indefinitely.

It has been noted herein that Dr. William Gilbert was termed the founder of electrical science. This must, however, be regarded as a comparative statement. Up to the middle of the 19th century, indeed up to about 1870, electrical science was, it may be said, a sealed book to the majority of electrical workers. Prior to this time a number of handbooks had been published on electricity and magnetism, notably Aug. de La Rive's exhaustive 'Treatise on Electricity,' 1851 and (in the French) 1852; Beer's 'Einleitung in die Elektrostatik.' Wiedemann's 'Galvanismus,' and Reiss' 'Reibungssalzl. elektricitat.' But these works consisted in the main in details of experiments with electricity and magnetism, and but little with the laws and facts of those phenomena. About this time the Fleeming Jenkin's work on 'Electricity and Magnetism' and Clerk Maxwell's 'Treatise on Electricity and Magnetism' were published. These books were departures from the beaten path. As Jenkin states in the Preface to his work the science of the subject was similar from that of the practical electrician that it was quite impossible to give students sufficient, or even approximately sufficient, textbooks. A student he said might have mastered De la Rive's large and valuable treatise and yet feel as if in an unknown country and listening to an unknown tongue in the company of practical men. As another writer has said, with the coming of Jenkin's and Maxwell's books all impediments in the way of electrical students were removed, 'the full meaning of Ohm's law becomes clear; electromotive force, difference of potential, resistance, current, capacity, lines of force, magnetization and chemical affinity were measurable, and could be reasoned about, and calculations could be made about them with as much certainty as calculations in dynamics' (Introduction to 'Electricity in the Service of Man'). Since that time also the real science of electricity has rapidly advanced. Various units of electricity and magnetism have been adopted and named by the international electrical engineering institutes of the world, which units and names have been confirmed and legalized by the governments of the United States and other countries. Thus the Volt, from the Italian Volta, has been adopted as the practical unit of electromotive force, the Ohm, from the enunciator of Ohm's law, as the practical unit of resistance; the Ampère, after the eminent French scientist of that name, as the practical unit of current strength, the Henry as the practical unit of inductance, after Joseph Henry and in recognition of his early and important experimental work in mutual induction. See Electrical Units; Electrical Terms.

The theories regarding electricity are also undergoing change. Indeed it may with truth be said that the trend of experimental investigation now leads to the conclusion that matter in its final analysis is electrical in its nature—in fact is electricity; the theory upon which this view is based being termed the electronic theory, or the electric theory of matter. See Electron.

This theory (or better, hypothesis) in a word assumes that the atom of matter, so far
from being indivisible, as assumed under the older theories, is made up of smaller bodies termed electrons. That the electrons were electric in their nature, and consequently all matter ultimately is electrical, the atoms of the different elements of matter consisting of a certain number of electrons, thus, 700 in the hydrogen atom and 11,200 in the oxygen atom. This theory of matter though of comparatively recent origin in several of its important features is not altogether one of a day, nor is it due to the researches of one man or to the conception of one mind. Thus, as regards the view that the atom is not an indivisible particle of matter, but is made up of numerous electrons, many scientists have for years held that all the elements are modifications of a single hypothetical substance, protyle, the undifferentiated material of the universe. Nor is the theory entirely new in its assumption that all matter is electrical. Faraday, Weber, Helmholtz, Clifford and others had glimpses of this view; and the experimental work of Zeeman, Goldstein, Crookes, J. J. Thomson and others had greatly strengthened this view. Over 35 years ago Weber predicted that electrical phenomena such as light are due to the existence of electrical atoms, the influence of which on one another depended on their position and relative accelerations and velocities. Helmholtz and others also contended that the existence of electrical atoms followed from Faraday's laws of electrolysis, and Johnstone Stoney, to whom is due the term "electron," showed that each chemical ion of the decomposed electrolyte carries a definite and constant quantity of electricity, and inasmuch as these charged ions are separated on the electrodes as neutral substances are brought in contact, however brief, when the charges must be capable of existing separately as electrical atoms; while in 1887, Clifford (q.v.) wrote: "There is great reason to believe that every material atom carries upon it a small electric current, if it does not wholly consist of this current."

Whether the electronic theory will survive or will in turn be displaced by some more suitable theory remains for the future to determine. In the meantime, be that as it may, the practical application of electricity will go on apace. It is an every day saying of laymen that electricity is as yet in its infancy. This remark causes technical men to smile, for "electricity" is already a most prodigious infant. But in the sense that we may only be on the threshold of the possible utilizations of this most wonderful of nature's agents, the remark is perhaps true. Predictions that were with difficulty made in the closing decade of last century to the effect that within 100 years of that time people would probably speak to one another without artificial means of communication; that wires would be laid along every street and tapped into every house as gas pipes were then, for lighting and power purposes, have been for a decade facts accomplished. What the next 20 years shall bring forth with regard to the applications of electricity none can tell. Twenty years ago it would have been difficult to find one steam railroad engineer willing to admit that application of electric traction to steam railroads was a possibility. To-day much has been done in this direction in the improvement of railroad terminal facilities, and it is now difficult to find one steam railroad engineer that the electric locomotive will not be in general use within 20 years hence all the important steam railroads of this country may not be operated electrically. In other directions the progress of events as to the utilization of electric power may be expected to be equally rapid. In every part of the world the power of falling water, nature's perpetual motor, which is of course never to waste since the world began, is now being converted into electricity and transmitted by wire hundreds of miles to points where it is useful and economically employed. (See ELECTRIC TRANSMISSION OF ENERGY.) But the extensive utilization of falling water will not be limited to natural water falls. In hundreds of places where a fall of 40 to 400 feet extends over 10 to 50 miles, and where in the aggregate hundreds of thousands of horse power, by suitable hydraulic power, is possible, this power will be usefully employed, thereby in large measure conserving the limited quantity of the world's coal. It has for instance been proposed to dam Niagara River at the foot of the gorge whereby another source of water power equal to that of the falls would be made available. The Jhelum River in Kashmir, India, too, has a fall of 2,480 feet in 80 miles with a minimum flow of 30,000 gallons per second, and a beginning has been made to develop the 1,000-000 electric horse power here represented, a considerable portion of which it is proposed to utilize in the production of nitrate of lime for fertilizer purposes, by combining means of powerful electric currents the limestone that abounds in this region with the nitrogen of the air, a combination which Danish engineers have shown to be commercially possible, and which inexhaustible product may in time be economically available to replenish the failing powers of the farm lands of America and other countries. Within 10 or 20 years also that dream of the electrical engineer, the direct production of electricity from coal without the intervention of the steam engine with its wasteful methods, may be realized. Other means, now unknown, of developing electricity may be wrested from nature's storehouse. Indeed in view of the past progress of electricity, and especially in view of its marvelous progress in the last two decades, theoretically and practically, it requires no great exercise of the imagination to conceive that the time may not be far distant when the universal artificial source of the world's heat, light and power, will be electricity, and that what is now only surmise as to the sameness of electricity and matter will be demonstrated beyond reasonable doubt. Not only will wireless telegraphy be more perfected than at present, but wireless telephony, and "seeing by electricity" to a distance, may all be theoretically accomplished. Indeed it is difficult to find one of our successors of 25 or 30 years age who does not at our obtuseness in not perceiving the obviousness of things which to them may then be self-evident, virtually as we now marvel at the simplicity of our cleverest ancestors in so long
ELECTRICITY, ATMOSPHERIC—ELECTRICITY, CAUSE OF DEATH

failing to recognize the identity of frictional, animal, and voltaic electricity, or the more simple fact that the wind, by itself, regarded as a phenomenon, is merely air in motion.

WILLIAM MAYER, JR.,
Author of 'American Telegraph and Encyclopedia of the Telegraph'; Fellow, American Institute Electrical Engineers.

ELECTRICITY, Atmospheric. Experiments have shown that there is always free electricity in the atmosphere, which is sometimes negative and sometimes positive, but most generally positive, and the intensity of this free electricity is greater in the middle of the day than at morning or night and is greater in winter than in summer. In fine weather the potential increases with altitude at the rate, according to some writers, of about 30 volts per foot. To detect the presence of free electricity in the air a pointed metal rod projecting into the air several feet and connected at its lower end to a gold leaf electroscope may be used. When this rod is projected into the air a few feet the leaves of trees and balloons have also been used to detect and, so to speak, draw down the free electricity of the air. The origin of atmospheric electricity is still unknown. Some physicists have ascribed it to the friction of the air upon the ground, others to the gradual oxidation of plant and animal life, others again to evaporation, to induction from the sun, and to differences of temperature. Most authorities are agreed, however, that whatever may be the origin of free electricity in the atmosphere, the electricity of enormous voltages that disturbs the air and produces the phenomena of lightning (q.v.) is due to the condensation of the watery vapor forming the clouds; each minute vapor drop as it moves through the air collecting upon its surface a certain amount of free electricity. Then as these drops of vapor coalesce into larger drops with a corresponding decrease in the total surface exposed the electrical potential rises until it overcomes the resisting power of the air. This remark will be more clearly understood when it is considered that with a given charge of electricity its potential rises as the electrical capacity of the object holding the charge is decreased, which is the case when the minute vapor drops coalesce into larger drops. The similarity of lightning to the electricity developed by an electrical machine was demonstrated by Franklin in his memorable kite experiments.

Saint Elmo's fire (q.v.) is another phase of atmospheric electricity to be considered in this connection. It is otherwise known as the fire of Saint Elias, of Saint Clara, of Saint Nicholas and of Helena, as well as composite, composite or corposant (that is, corpus sanicinum). The phenomenon is observed, usually during a thunder storm, at the tops of trees, spires, etc., or on the heads of animals, as a brush or star of light.

ELECTRICITY, Cause of Death by. As is well known, one of the most important safeguards of the human body against the passage of electrical currents through it is its high degree of resistance. This degree of resistance, however, is subject to a considerable amount of variation, the resistance of the skin being at times as low as 500,000 ohms, while at others it may be as high as 100,000,000 ohms. In either event, the resistance is from 5 to 20 times as great as when the skin is wet. From what is known of the amount of electrical current necessary to cause death in man, it is probable that 1,600 volts of electromotive force, of a continuous current, is sufficient to bring about this end, and that an alternating current of half this voltage would probably be fatal. In fact, the general deduction has been drawn from the experiments conducted in electrocution work at the Sing Sing prison, that no human body can withstand an alternating current of 1,500 volts, and 300 has produced death, while for the continuous current it may be necessary that over 3,000 volts may be required to bring about instantaneous death. Some of the minor injuries due to lightning and electricity are severe burns, paralysis of some of the muscles, deafness, loss of smell and taste, hysterical phenomena, traumatic neuroses. Occasionally blindness has resulted, also insanities of the maniacal type have been known to occur following lightning stroke. As to the cause of death by lightning and electricity, modern research has shown that there are marked changes in the blood vessels of a hemorrhagic type, and minute alterations in the nerve cells, but these seem to be secondary to the pathological action that the electrical current has upon the fibres of the heart muscle. The electrical shock brings about a condition of delirium or fibrillary contraction of the heart muscle, causing a stoppage of that organ. This theory of the cause of death at present has the largest number of adherents.

As to what can be done for the treatment of electrical shocks, medical science is still somewhat in doubt. For all practical purposes, death, when it takes place, is instantaneous. The evidence derived from non-fatal cases is of great interest. In these, personal experience has shown that a number of individuals who have been rendered unconscious have recognized in the brief moments of consciousness the experience of a strange sensation, as if coming from the shock of electricity or lightning which have been severe enough to bring about unconsciousness are very common. As to the border lines which separate the recoverable from the fatal cases it seems difficult to determine. Promptness in the treatment is of the utmost importance. Artificial respiration and cardiac stimulants should be used simultaneously. It is of importance to remember that the body of a patient in contact with live wires must not be touched by the rescuer with naked hands, but should be dragged away by his clothing, or removed from contact with the earth by slipping a board under him, thus to break the connection with the live wires. Live wires may also be raised by a stick and thus take the body out of the circuit. Artificial respiration (q.v.) by the Sylvester method or by means of the Gibbon's pump should be performed and the body should be surrounded by hot bottles or bricks, and rubbed, and suitable cardiac stimulants should be utilized. Injections of large quantities of salt solution into the rectum may be of service and occasionally it may be necessary to infuse normal salt solution directly into the veins. Efforts at artificial respiration should not be discontinued under from three to six hours. Consult Jelliffe, 'Peterson and Hayden's Textbook of Legal Medicine and Toxicology.'
ELECTRICITY, Contact Theory of, a theory which assumes that the electromotive force of a voltaic cell, and perhaps the electricity produced by friction, is due to the difference of potential assumed by two dissimilar substances when placed in contact.

ELECTRICITY, Diffusion of. Electricity diffuses itself on the surface of a conductor. This may be proved very easily, by a simple apparatus devised by Faraday. An insulated spherical conductor has two hemispherical cups carefully fitted to it, each attached to an insulating handle. The conductor and its covering are charged with electricity, the cups are then removed and the conductor is brought near an electroscope. No divergence of the leaves occurs, indicating that none of the electricity has passed into the conductor. If the conductor has a spherical shape, the electricity distributes itself equally over the surface; in other words, the density is the same on every part of the surface. We may conceive the electric fluid to surround the conductor as an ocean of uniform depth. If the conductor be a brass disc, the electricity is found in greater quantity at the edges or rim. If it be a brass cylinder with rounded ends, the density is greatest at the ends. If the conductor have the shape of a cone, the density is greatest at the apex, and the sharper the apex the greater the density. Hence the remarkable effect of a pointed body in dissipating an electric charge.

ELECTRICITY, Dissipation of. The gradual loss of electricity from a charged body surrounded by non-conductors which takes place by means of them is called dissipation of the electric charge. A charged conductor, for instance, supported on a glass pillar, slowly loses its electricity. This is due partly to the creeping of the electricity along the surface of the glass, which, even if it be free from dust and dirt, is seldom absolutely free from an invisible film of moisture; and partly to the air that surrounds the insulating conductor, the electrified body charging the particles of air with similar electricity and then repelling them, by which means a gradual loss of charge occurs. Experiments extending over a period of several years show that this dissipation of electricity does not take place in a vacuum. Coulomb made a careful investigation into the laws of dissipation, by which he was able to allow for it in cases where he could not arrange his experiments so as to be undisturbed by it. Coulomb was led by his experiments to abandon the use of glass as a support for his conductors whenever it was possible, employing instead thin stems of shellac, and sometimes suspending small electrified bodies by well-dried silk fibres. He found that the amount of loss in a given time by means of the particles of air diminishes as the charge possessed by the conductor gets weaker and weaker, the losses in successive equal intervals of time being in geometrical progression.

ELECTRICITY, Experimental Researches in, by Michael Faraday (1839–55). A monumental work in the literature of science; not merely recording the results of experiments in what Tyndall called "a career of discovery unparalleled in the history of pure experimental science," but enriching the record with thoughts, and clothing it in many passages in a style worthy of exceptional recognition. In devising and executing experiments for passing beyond the limits of existing knowledge, in a field the most difficult ever attempted by research, Faraday showed a genius and an acumen remarking him as a thinker not less than an observer of the first order. In strength and sureness of imagination, penetrating the secrets of force in nature, and putting the finger of exact demonstration upon them, he was a Shakespeare of research, whose work has a permanent interest. He made electricity, in one of its manifestations, explain magnetism. He showed to demonstration that chemical action is purely electrical, and that to electricity the atoms of matter owe those properties which constitute them elements in nature. In language of lofty prophetic conception he more than suggested that the physical secret of living things, the animal and the plant, is electrical. He particularly dwelt on the amount of electricity forming the charging of an atmosphere, the oxygen of the air, which is the active agent in combustion and the supporter of life in both animals and plants, and only stopped short of definitely pronouncing vitality electrical. He urged very strongly as a belief, to which no test of experiment could be applied, that gravitation is by electrical agency, and that in fact the last word of discovery and demonstration in physics will show that electricity is the universal agency in nature. And among his far-reaching applications of thought guided by new knowledge was his rejection of the idea of "action at a distance," in the manner of "attraction." If a body is moved, it is not by a mysterious pull, but by a push. The moving force carries it. These ideas outran the power of science to immediately understand and accept. But Maxwell, Hertz and Helmholtz have led the way after Faraday, to the extent that his electrical explanation of light is now fully accepted. Fifteen years after his death, the greatest of his successors in physics, Helmholtz of Berlin, said in a Faraday lecture, that the later advances in electrical science had more than confirmed Faraday's conclusions, and that English science had made a mistake in not accepting them as its point of departure for new research. See LIGHT.

ELECTRICITY, Frictional. It was an observation made by the Greek philosopher Thales, 600 years before the Christian era, that, when amber was rubbed, it acquired the property of attracting light bodies. The cause of this attractive power was assigned to a principle to which the name of "electricity" was given — derived from the Greek word for amber. When a piece of wax is rubbed on the coat sleeves, an attractive power is awakened in it; it is capable of attracting small pieces of leaves, or minute particles of sawdust. Taking a warm glass tube closed at one end, and rubbing it with silk, the same thing is manifested. It is observed also that after contact with the wax or tube, the light bodies fall away, being seemingly repelled. If a stick of sealing-wax be rubbed with flannel and then balanced on a paper loop suspended by a silk thread and the knuckle be presented to it, the wax will in like manner follow the hand.
We have, therefore, the fact that an electrified body attracts or is attracted by an unelectrified body. Another experiment of a simple character may be mentioned. Take a piece of warm brown paper or sheet of foolscap, place it upon a window, rub it well over with a piece of india-rubber,—it clings to the board; or remove it from the board and apply it to the wall of the room, and it adheres to the wall and remains in its position till its electricity is dissipated. Observation of these phenomena led to the development of the electric machine (q.v.).

**ELECTRICITY FROM HEAT.** The deriving of electricity directly from the application of heat is interesting, though it has not proven of commercial value. Two different metals in contact usually show a difference of potential. This difference is most marked in the case of bismuth and antimony. When bars of these metals are soldered together at one end and the opposite ends connected by a copper wire, and a flame is applied to the point of junction a slight electric current is set up, flowing through the closed circuit thus formed. The cooling of the point of junction also sets up a current. An apparatus made on this principle is called a thermo-electric couple, and a series of such couples, arranged to work together, is called a thermopile; a still larger aggregation of thermo-electric couples arranged in rings superimposed has been styled a thermo-electric generator. With any of these contrivances the current obtained is so minute as to serve no purpose except experiment. The thermopile is valuable for experimental purposes because of the great constancy obtainable with a very slight current. Iron is not a good metal to use in a thermopile, because at certain temperatures its potential coincides with nearly all other metals, so that there would be no current when that temperature was reached.

Pyroelectricity is not to be confused with thermo-electricity because of the similarity of name. It treats of the phenomena of electric polarity in minerals on being heated or cooled. The quality of pyroelectricity is best shown in tourmaline, a crystal of which on being heated from about 10° to 150° C. displays positive electrification at one end and negative at the other; but on cooling the polarity is reversed and the positive and negative ends change places. Twin crystals of quartz also show the phenomena and other crystals in a lesser degree.

**ELECTRICITY IN MEDICINE.** See ELECTROTHERAPEUTICS.

**ELECTRICITY IN MINING.** See MINES AND MINING.

**ELECTRICS and NON-ELECTRICS.** The chief work of the earliest experimenters in electricity was to divide bodies into electrics, which they could excite by friction, like amber; and non-electrics, such as the metals, which they could not so excite. These names were given to the two classes by Gilbert of Colchester (1600). But Du Fay (1733-45) showed that electrics are identical with non-conductors, and non-electrics with conductors; and that the reason why non-electrics did not exhibit excitement by friction was that the electricity was conducted away from them as fast as it was produced. The distinction was thus broken down.

**ELECTRO-BALLISTIC MACHINES.** See GUNNERY.

**ELECTRO-BIOLOGY,** the science which treats of the electric currents developed in living organisms; also the department of knowledge which treats of the influence or control over the feelings, thoughts and actions of a mesmerized person. Very simple powers of observation show that the motions of a living being are under the direction of his will. He puts forth his hand because he wills to do so; he walks through volition, even though his mind be occupied with other things; and talks or is silent as his will directs. It follows that there is some method by which the will communicates with the physical mechanism of that wonderful machine, the human body. Through anatomy we learn that the muscles do the work, and that the nerves guide the muscles, and that the nerves all proceed from or centre in the brain. Through phrenology we learn that certain classes of nerves connect with certain portions of the brain, and thus certain brain areas are identified with certain physical, mental and moral capacities.

But the thing we cannot demonstrate—because we cannot see it—is just how the will connects with a portion of the brain and sends out its order, which we know travels through the nerves to the muscles. Therefore we have to theorize as to how this is done, and the best theory appears to be the electric or magnetic theory, that that which Mesmer called "animal magnetism" is the medium of exchange. This is not meant as an endorsement of all that Mesmer said and did—far from it—but simply that the force, process or thing used and little understood by Mesmer is the same force, process or thing that translates a man's will into brain action. The problem is elucidated by a study of hypnotism and mesmeric control. It will be remembered that mesmerism and hypnotism have been identified as based on the same natural laws, and that all authorities on the subject are in agreement that in hypnotism one person's will is replaced by another person's. The subject (or victim) of a hypnotist surrenders his will to the hypnotist, to the degree in which he is brought under the influence of hypnosis. This is why the subject obeys the commands of the hypnotist, even when told to do ridiculous and absurd things. The hypnotist has got control of the subject's "magnetism" for the time being, and he is helpless, a mere puppet or slave of his hypnotist's will. This is logical and rational, and for a fuller exposition of the subject the reader is referred to the article on HYPNOTISM. Mesmer apparently was right in his assumption that by mesmeric passes he gained control of his patient's magnetism. His theory was that there existed "a fluid universally diffused, continuous, and naturally susceptible of receiving, propagating and communicating all motor disturbances." (Binet and Pere, "Animal Magnetism," p. 5) This is exactly the sort of fluid that seems to be the requirements of transmitting one's will to one's brain and nerves; but to-day we do not use the word "fluid," rather "ether" to express the medium
through which electricity, magnetism, X-rays and similar manifestations are believed to travel. Mesmer considered that the human body was charged with this magnetism much as the earth is charged with electricity, and the theory stands analysis. He called it "animal magnetism," which is here used as the most familiar term, though it might better be termed "physical magnetism." That animals have it as well as humans is shown by the fact that animals can be hypnotized. As early as 1646 Father Athanasius Kirchner described his hypnotizing of poultry, and later this became a fashionable pastime in France. In 1872 Czermak repeated his experiments, and also hypnotized birds, rabbits, salamanders and crabs.

Whether this animal magnetism is identical with animal electricity, or whether — as is more probable — it is a separate form of some higher ethereal vibration than electricity, is interesting, but not all-important, and appears never to have been demonstrated. The vital fact of interest is that it is electric in its effect. The human organism is virtually a vitalized dynamo, that gathers charge from the air breathed, and which gives off energy through the muscles under the direction of the will. Electrical engineers commonly make this comparison, being struck with the similarity of the human organism with the electric dynamo. And the fact that the human organism gets its charge of magnetism through the air breathed suggests that human magnetism is either universal in space or at least existent in both the air and water in which men and fishes live.

Another proof of the reality of this thing we call "animal magnetism" is furnished by spiritualistic or mediumistic phenomena. The "animal magnetism" is believed to be the cause of the "aura," of which every student has read, but which few have seen. Spiritualistic mediums often speak of witnessing an individual's aura, but this evidence will satisfy only those who believe in mediumship. To actually see the aura or some other form of human magnetism this experiment is suggested: Arrange a perfectly black background and place a large, strong man about five feet in front of it, at dusk or twilight. Take a position 20 to 40 feet away, and gaze steadily on the scarcely visible form of the man. When the conditions and distances are right anyone of good sight will see a faint radiance or aura emanating from and outlining the man on the black background. It is claimed that the more moral the man the brighter the aura, and that this is why the old masters painted auras about the heads of pictures of saints and especially of Jesus Christ. Another evidence of the reality of this magnetism comes from the spiritualistic mediums. They claim that the work of mediumship is extremely exhausting, and deprives them of their magnetism, and that this is why they cannot give genuine exhibitions ad libitum as visitors may demand. And many who have investigated mediumship are convinced that this is so.

The term electro-biology was coined about 1850 to describe the relationship between electricity and life. We do not know what electricity is, and we do not know what life is; we have to judge both by their manifestations. We know little of the nature and nothing of the origin of either, although some scientific men and some theologians are apt to be dogmatic in asserting that this or that must be or cannot be possible. But we do know that through some medium the will controls man's sensory organism and physical functions, and we choose to call this thing "animal magnetism," as Mesmer called it, and to consider it of the nature of electricity. Reasoning analogously, that as the wireless telegraph conveys a certain vibration which may be picked up by an instrument hundreds of miles away through etheric vibrations, caught by a coherer or detector, so we conclude that the will also originates vibrations, which many call thought- vibrations, and sends them through the etheric magnetism that imbues all men and animals, and perhaps all nature. But ordinarily these vibrations are picked up and responded to only by the organism of the man who sends them out, presumably because his magnetic vibrations harmonize with his physical body. It is also logical to reason that this sort of magnetism exists everywhere, as we suppose electricity pervades the universe, and that the phenomena of telepathy or thought-transference, and mind-reading, are explainable through harmonic vibrations of the ether which this magnetism permits to pervade. Clairvoyance and clairaudience likely are closely related, so that in solving the problem of physical magnetism these will also be solved.

It is stated in 'The Great Psychological Crime' (p. 178) that "animal magnetism is an important factor in the development of mediumship," and that "the room in which the sittings are held must become thoroughly magnetized with the animal magnetism of the controlling intelligence." The reader who cares to pursue the subject further should consult this book.

ELECTROCHEMICAL EQUIVALENTS. The general principles of electrochemistry (q.v.) and especially Faraday's laws (q.v.) have shown us a definite quantitative relation between the amount of electricity passing in a given electrolysis, and the amount of decomposition resulting. According to Faraday's laws, the amount of any given element which will be deposited by a given amount of current is directly proportional to the amount of current passing, and to the chemically equivalent weight of the element in question. Quantitatively, it requires 96,500 coulombs of electricity (ampere-seconds) to deposit a chemically equivalent weight of any substance; or, to put it in a more practical way, it requires 96,500 coulombs to make a unit change of the atom of any substance. From this numerical relation one can then calculate the weight of any element that will be deposited by a unit amount of current in a unit time. This is called the Electrochemical Equivalent of the element. For scientific purposes it is usually stated in grams per coulomb or per ampere-hour; for commercial use larger units are convenient, such as kilograms or pounds per ampere-day, or per 1,000 ampere-hours.

These values are taken from 'Electrochemical Equivalents' by Hering and Getman (New York 1917).

G. A. ROUSH, Assistant Secretary, American Electrochemical Society.

### Electrochemical Industries

Electrochemistry may be defined as that branch of chemistry relating to the carrying out of chemical reactions by the means of or with the assistance of electricity. The word electrochemistry as here used includes the processes of electrometallurgy, the production and treatment of metals by means of electricity, there being no generic term covering both subjects.

The production or furnishing of chemical action by means of electrical energy may be secured in three ways: (1) By electrolysis — the action of an electric current upon a chemical compound in solution or in a fused condition; (2) by electrothermic action — the production of chemical changes by electrically generated heat; (3) by the discharge of electricity through gases.

The largest employment of electrolysis is in the production and refinement of metals, particularly aluminum and copper; but it is also used extensively in the preparation of a large number of chemical compounds of widely varying character.

In most cases a substance obtained by electrolysis may be prepared also by a strictly chemical process. The choice of methods then becomes simply one of cost. An example in point is the manufacture of metallic sodium; originally discovered by the electrolysis of caustic soda, it was for many years made commercially by the reduction of sodium carbonate with carbon, or of caustic soda by a mixture of iron and carbon; more recently the electrolytic process has replaced the chemical methods, because it is cheaper. In other cases certain products of electrochemical action have not yet been made by any other process.

A great saving of heat is found in most electrothermic processes, due to the fact that the electrically generated heat is applied inside the container, where it is effectively employed, no heat being wasted in heating the contents through the walls of the container, as in combustion processes. But even when produced by the cheapest water power, electric heat consciousness times more heat than heat produced by the combustion of coal, so that where large quantities of heat are needed at only moderate temperatures, the combustion processes are usually cheaper.

We shall here consider the chief electrochemical industries that have thus far attained commercial importance.

**Copper.** — The process of refining copper electrolitically consists in the transfer of copper from the anode to the cathode, by the selective action of the electric current, and in leaving the impurities behind dissolved in the electrolyte, or in the form of slime or sediment. The material at present subjected to profitable electrolyte refining is crude copper containing from 96 to 98 per cent pure copper, and varying amounts of silver, gold, platinum, palladium, nickel, iron, arsenic, antimony, sulphur, etc. This crude copper is obtained from various copper ores by smelting and is cast in copper molds into anode plates, which are several times thicker than any that are used, weighing 250 to 500 pounds. The cathode plates are of electrolytically refined copper, practically the same in length and width as the anodes, but only 1/32 to 1/16 inch thick. The electrolyte, or bath, in which the plates are suspended, is a solution of copper sulphate just short of saturation, with enough sulphuric acid to prevent the separation of hydrated cupric oxide, but not enough to cause hydrogen instead of copper to be separated at the cathode; the proportions are about 3-4 per cent of copper as sulphate and 10-13 per cent of free sulphuric acid. When silver is present in the anode a little salt or hydrochloric acid is added to the electrolyte. The bath is kept at a temperature of about 40-45°C (100-113°F). The oxygenating tanks are of wood, usually lined with sheet lead or carefully coated with a pitch compound, and of such dimensions that a distance of from 1.5 to 2 inches exists between the faces of the plates. In some cases the plates are arranged in series and in others in parallel or multiple. In the series system the anodes,
which are much smaller than in the multiple system, are suspended in the electrolyte from one-half to three-fourths of an inch apart, and only the end ones in the series are connected with the poles of the generator. With this arrangement the copper dissolved from the inner face of the first anode is deposited on the nearer face of the second plate; the farther face of the second plate is dissolved and deposited on the nearer face of the third plate—and so on through the series. When all the anodes are nearly exhausted the pure copper deposits are removed from the tank and the undissolved remnants of anode stripped from the back of the cathodes.

The series arrangement has the advantage of requiring electrical connections to be made at the first and last plates only, whereas the parallel system requires a connection at every plate; but in the series system the leakage of current due to the short-circuiting action of the sediment and sides of the tank is from 10 to 20 per cent, so that the parallel system is more generally used. The connections between the various plates and the circuit in the parallel systems are made by copper rods, which are run at two different levels along the edges of the tanks, one bar for each set of plates. In some instances these rods are arranged in a V shape, so that the edges will cut through any corrosion which may happen to form at the points of contact. The vats are arranged, with respect to each other, so that each is accessible from all sides and free circulation of the electrolyte is possible. This circulation is sometimes obtained by blowing a stream of air through the electrolyte, but more frequently by arranging the vats in steps, and piping so that the electrolyte may pass from the top of one vat to the bottom of the next, by the action of gravity. This maintains a uniform density of electrolyte, which is necessary for the proper formation of the deposit. The electromotive force required is from 0.2 to 0.4 volt per tank, with a current density of 15 to 20 amperes per square foot of cathode plate surface. The individual vats are connected in series so that the total voltage may be approximately the same as that which the generator furnishes, being usually 110 volts. One amper of current deposits on the cathode only about one ounce of refined copper in 24 hours, and the current density must be kept below 40 amperes per square foot to avoid mushrooming and consequent short-circuiting. In practice from 400 to 500 ampere-hours are required per pound of copper deposited, the theoretical amount according to Faraday's law being only 380.2 ampere-hours. The loss varies from 4 to 20 per cent according to the system employed.

The main product of refining is commercial cathodes, which are sometimes shipped to consumers, but more frequently cast into wire-bars, ingots, cakes or slabs of standard dimensions and weight. They usually assay from 99.86 to 99.94 per cent pure copper. The yield in commercial cathodes is from 97 to 99 per cent of the anodes treated, excluding the anode scrap which varies in weight from 7 to 15 per cent of the charge, depending on the type of the cathode. This scrap is not a loss as it is collected and recast into anode plates. Besides electrolytic copper most plants secure gold, silver, platinum and palladium from the slimes, and sometimes selenium, tellurium and other rarer metals. Nickel salts are usually recovered from the solutions.

There are in the United States 10 electrolytic copper refineries with a total capacity of 2,780,000,000 pounds per year; one refinery in Canada with a capacity of 14,000,000 pounds per year. The actual production in 1917 was about 2,300,000,000 pounds, representing approximately 35 of the world's production of copper for the year. Of the total production the amount that does not require refining, about 275,000,000 pounds from Michigan, the United States production amounts to over 81 per cent of the total production of refined copper. The other 19 per cent is produced in a number of plants of comparatively small capacity in England, Wales and Continental Europe.

Aluminum.—Practically the whole output of this metal for the entire world is now produced electrolytically. The only process used on a large scale is that invented independently in 1886 by Charles M. Hall in the United States and by Paul L. T. Héroult in France. This process consists in electrolyzing alumina dissolved in a fused bath of cryolite. The alumina is obtained from the mineral bauxite which occurs abundantly in Arkansas, Georgia, Alabama and Tennessee. The natural material, being a hydrated alumina containing silica, iron and titanium, must be treated in order to drive off the water and eliminate the impurities. This is accomplished by a chemical process. In practice it requires about two pounds of alumina for each pound of aluminum produced. The flux or bath in which the alumina is dissolved consists of cryolite, a natural double fluoride of aluminum and sodium (NaAlF₄) found in Greenland. This is melted in a large carbon-lined, sheet-iron tank which constitutes the negative electrode, a group of suspended carbon rods forming the positive electrode. A current of several thousand amperes at six to seven volts is used, only a portion of this voltage is required to decompose the alumina, the balance amounting to about four to five volts represents the heat required to keep the bath melted. The passage of the current causes the aluminum to deposit on the bottom of the tank as a fused metal, whence it is drawn off periodically. The oxygen set free combines with the carbon of the positive electrodes and passes off as carbonic oxide. The reaction is Al₂O₃ + 3C = 2Al + 3CO. About one pound of carbon is consumed for one pound of aluminum produced. An excess of alumina is kept floating on the bath so that it is saturated at all times. According to Faraday's law the weight of aluminum deposited by 1,000 amperes is 0.743 pound per hour. The actual yield of metal by the Hall process is about 85 per cent of this theoretical amount. The metal when drawn from the tanks is cast into rough ingots which are afterward remelted and converted into commercial shapes, such as sheets, rods, wires, etc. The United States in 1917 produced about 180,000,000 pounds of aluminum, which was about twice the capacity of the world. Before the European War the share of the United States in the total production was under 50 per cent.
1 Electrolytic process of copper-refining, showing tanks filled with a solution of copper sulphate and containing sheets of copper connected to the terminals of a generator.
2 Casting side of a furnace showing copper anodes placed radially on a Clark casting machine.
Zinc.—The very high temperature (1300° C. or 2370° F.) necessary to reduce zinc from its common ores, and its generation as a vapor, due to its boiling point being at 930° C. (1700° F.) present difficulties which offer an unusually open field for success to an electrolytic method of reduction. Several processes are in use. They all provide for the preliminary roasting of the ore — which is essentially lead sulphide, zinc sulphide and gangue — at a low red heat, so as to convert the sulphides and sulphates of the ore into the respective sulphates. The roasted ore is then treated with dilute sulphuric acid, the zinc being dissolved as sulphate, leaving the lead sulphate as an insoluble residue to be smelted by the usual dry methods. Most of the silver present remains with the lead, a small portion passing into solution with the zinc. It is in fact the recovered silver that sometimes makes the process profitable. It is necessary to free the zinc solution from iron, copper and other foreign metals — a matter of considerable difficulty. When sufficiently purified, the zinc sulphate is electrolyzed, the anodes being of lead, and the cathodes thin sheets of zinc. The operation is in reality a reduction of the sulphate, in no sense a refining process. As the reduction proceeds the electrolyte becomes more and more acid, and when hydrogen in quantity is evolved at the cathodes, the electrolyte is run off, and used again to leach roasted ore.

Lead.—The electrolytic refining of lead has never been as widely applied as in the case of copper, due to the fact that the operation is more expensive in comparison with the low price of the metal, and that the ordinary furnace-refined lead of commerce is 99.98 per cent pure. In some cases, however, the lead carries valuable impurities that are not readily recovered by furnace methods, and the process of electrolytic refining is resorted to. The principles involved are the same as for copper, the impure lead being used as anode in a solution of lead fluosilicate as electrolyte. The cathode is a rolled sheet of pure lead. The electrolyte ordinarily carries 60 to 70 grams of lead per litre, as fluosilicate, and 80 grams of free hydrofluosilic acid. Lead normally tends to give a fine crystalline deposit, but by the addition of 0.1 per cent of antimony to the electrolyte, the deposit is changed to a smooth, coherent deposit. The temperature has no effect on the deposit, but the current used is sufficient to maintain the bath at about 30° C. (86° F.). The current density used is 12-16 amperes per square foot, and the voltage per tank is 0.30-0.38. Tanks are arranged in series with the electrodes in each tank in multiple. The purity of the refined lead is about 99.995 per cent.

Silver.—The parting of the gold and silver when the silver is in excess, or the refining of auriferous silver, is also carried on by an electrochemical process. In this process the electrodes are arranged horizontally, the anodes above and separated from the cathode by a porous diaphragm. The cathode is a thin sheet of silver formed into an endless belt which travels horizontally below the series of anodes. The upper surface of the belt is smeared with graphite to prevent a close adherence of the crystals of deposited silver. These crystals are brushed off at the end of the belt by a conveyor belt and removed at once from the electrolyte. Another modification has a horizontal graphite plate for cathode, from which the silver crystals are removed by hand with a scraper. The electrolyte carries 1 to 3 per cent of silver, 4 to 6 per cent of copper, and one-tenth of 1 per cent of free nitric acid. A certain amount of the acid is consumed in dissolving the copper present in the silver — about one and one-half pounds to each 1,000 ounces of silver treated.

Gold.—The electrolytic process has been used in the recovery of gold from its solution in potassium cyanide, after cyanide extraction. The cyanide liquor is electrolyzed between iron anodes and sheet lead cathodes, using low current density. Chemical precipitation of the gold, using zinc or aluminium is usually preferred, however. In addition to this recovery process, electrolytic refining is practised to a considerable extent. The crude gold is used as the anode, in a solution of gold chloride with hydrochloric acid as the electrolyte. The cathode is a thin sheet of pure gold. A current density of 90 amperes per square foot at a low voltage (say 1 volt) is employed. The gold is deposited in crystalline form, leaving the impurities in the anode as a sludge, or dissolved in the electrolyte.

Antimony.—Antimony has been produced by an electrochemical process, but never on any extended scale. One process consists in leaching the sulphide ore with sodium sulphide, and extracting the dissolved antimony from the solution by electrolysis, using iron cathodes, from which the deposited metal is broken by hammering when it reaches a thickness of about one-tenth of an inch. The electrolyzing cell is separated into two compartments by a porous diaphragm, the anode being carbon in a solution of sodium chloride. The chlorine from the anode compartment is used in the manufacture of bleaching powder, and the exhausted sodium sulphide from the cathode compartment is used to leach more ore. One method of working up the slimes from the electrolytic lead-refining process gives a sodium sulphide solution carrying antimony, which is treated in a similar manner. Attempts have also been made to refine antimony in both sulphide and fluoride solutions.

Nickel.—While the electrolytic processes have not proved available for the commercial winning of metallic nickel from its ores, its electrolytic refining is successfully accomplished, though the details of the process employed are regarded as a trade secret. As is well known, electroplating with nickel is simple and easy. When, however, a thicker deposition is attempted, the metal scales off of the cathode in thin flakes which cannot be collected and melted into ingots at a commercial profit. The tendency of any iron and cobalt present in the crude nickel to be deposited on the cathode along with the nickel is a serious drawback — and incidentally compels attention to the fact that electrolytically deposited metal is not necessarily pure. It has been proved by experiment that nickel may be thus deposited in thick plates if the operation is conducted with a hot electrolyte — in the neighborhood of 65° C. (150° F.)) — and with a comparatively high current density. Difficulty is experienced under these conditions with the evolution of hydrogen from the cathode, causing pitting of its surface. An indirect method of refining nickel by electro-
Electrochemical Industries

The Seward and von Kugelgen process uses an electrolyte of fused sodium chloride, the melting point of which has been reduced by the addition of other salts less readily decomposed by the current.

Potassium.—There is little commercial demand for metallic potassium. Its production, however, is entirely practicable by the Castner process described for sodium, using caustic potash as the electrolyte.

Electroplating and Electrotyping.—Electroplating is the art of covering a metallic surface with an adherent, electrodeposited coating of the same or some other metal, the form of the original surface being retained. The metal coating may be added purely for decorative purposes, or because of its superior resistance to wear or corrosion. Electrotyping is the art of reproducing the form of an object by electrodeposition of a metal, usually copper, in a cast or molded impression of the original object. For further details of these processes, the reader is referred to the articles under these separate headings.

Caustic Soda.—The production of caustic soda (NaOH) and chlorine (Cl) by the electrolysis of a solution of common salt (NaCl) is readily realized experimentally (2NaCl + 2H₂O = NaOH + Cl₂ + H₂), but its successful accomplishment on a commercial basis is difficult because of the secondary reactions which take place, forming a mixed product of caustic, salt, and hypochlorite of soda. These difficulties are avoided by separating the caustic soda that is formed, either by a porous diaphragm, by drawing it off as soon as formed, or by absorbing the sodium deposited in mercury or melted lead. The most prominent system for the electrolytic production of caustic soda and chlorine from common salt is the Castner-Kellner process. The Castner process employed in this country at Niagara Falls is as follows: The electrolytic tank consists of a slate box, 4 feet long, 4 feet wide and 6 inches deep, the joints being set in rubber cement. Two slate partitions reaching within 1/16 inch of the bottom (under which are grooves) divide the cell into three compartments, each 15 inches by 4 feet, sealed from each other by a layer of mercury covering the bottom of the tank to a variable depth. The two outside chambers through which the brine is passed are provided with graphite anodes. These compartments are provided with gas-tight covers and exhaust pipes of rubber and lead, to lead the chlorine away. The central compartment has an iron cathode, of 20 upright strips, and is filled with pure water above the mercury. Whenever the specific gravity of the water rises to 1.26, from its absorption of caustic soda, it is drawn off and fresh water supplied. The liberated hydrogen is led from this chamber by means of pipes and used as a fuel for the concentration of the caustic. The tank is pivoted at one end on a knife blade and rests at the other on an eccentric, which raises and lowers that end of the tank about half an inch every minute and causes a circulation of the mercury between the outer and middle compartments. The current passes into the outer compartments, splits up the sodium chloride (common salt, NaCl) into sodium and chlorine (Na and Cl), the latter is liberated at the graphite anodes and passes through the exhaust pipe to the absorption chambers where
it combines with slacked lime to form bleaching powder. The sodium combines with mercuric ammonium amalgam, which by the rocking of the tank passes to the center chamber, where it serves as the anode, and combines with the water to form caustic soda (NaOH) and hydrogen (H₂), which appears at the iron cathode. Each of these tanks uses 630 amperes at 4.3 volts. The theoretical voltage required is but 2.3, the remainder being utilized in overcoming the ohmic resistance of the electrolyte and in keeping it warm. The output of this process per horse power per day is 12 pounds of caustic and 30 pounds of bleaching powder for each cell. The product contains from 97 to 99 per cent caustic, 1 to 2 per cent sodium carbonate, 0.3 to 0.5 per cent of sodium chloride, and traces of sodium sulphate and sodium silicate. A number of other processes have been developed for the electrolysis of salt solutions for the production of alkali and chlorine, all based more or less on the same general principles as those utilized in the Casner process.

The process is commonly used at Niagara Falls, but which has been discontinued, obtained caustic soda and chlorine using molten lead in place of mercury as a cathode, fused salt instead of brine as the electrolyte, and operated at a temperature of 850°C. (1560°F.). The containing tank was a cast-iron vessel 3 feet long, 2 feet wide and 1 foot deep, the sides above the molten lead being covered with magnesium so that the current must pass from the graphite anodes to the lead which acted as the cathode. At one end of the tank was a small compartment separated from the remainder of the vessel by a partition dipping into the lead to such a depth that nothing but this fused lead can pass from one compartment to the other. In the smaller compartment the lead was subjected to a stream of steam, which decomposed the lead-sodium alloy with the formation of NaOH and hydrogen and at the same time kept the alloy in circulation. At intervals the caustic, which was in a fused state, was drawn off and allowed to solidify, thus avoiding the evaporation of water which is necessary in the Casner-Kellner process. The current employed per vessel in the Acker process was 2100 amperes at from 6 to 7 volts, forming 54 per cent of the chemical action, and the remainder in maintaining the temperature. The output of each was 550 pounds of caustic soda and 450 pounds of chlorine in 24 hours.

Chlorine.—All processes making caustic soda from salt at the same time produce chlorine gas at the anode. In some cases this is absorbed in lime for the manufacture of bleaching powder, and in other cases it is compressed and liquefied. The liquid chlorine is shipped in pressure tanks for chemical purposes and for water purification. One of the most striking uses to which it has been put is as one of the poison gases used at the front in trench warfare. Hundreds of tons of gas have been used in a single attack.

Hypochlorites.—Another electrochemical industry that is widely distributed throughout the country is the manufacture of hypochlorite for bleaching purposes. For some time the use of hypochlorite as a bleach was confined to large installations where an enormous quantity of bleaching liquor was demanded every day, e.g., in the manufacture of paper pulp. Now hypochlorite plants are installed in small units, producing only a few pounds of bleach which is used in laundries. The types of cell used in hypochlorite manufacture vary widely, but are all alike in that they must have unattackable electrodes of some kind, usually either graphite or platinum. Many of the different types of cells have a number of electrodes in series, acting as bipolar electrodes. The electrolyte used is a 15 to 16 per cent solution of common salt, NaCl.

The efficiency of the operation in practice usually amounts to only about 20 to 25 per cent, but the simplicity and ease of working of the process commend it in spite of its low energy efficiency. The minimum requirement is 1.27 kilowatt hours for the production of 1 kilogram of active chlorine, while actual practice requires 6 to 7 kilowatt hours.

Potassium Chlorate is produced electrochemically in considerable quantities, both here and abroad. The obsolete process, used at Niagara Falls, consists in the electrolysis of potassium chloride solution, using a copper or iron cathode and a platinum anode. The current efficiency is high, being 500 amperes per square foot of anode. Each cell uses about four volts, of which 1.4 is required to convert chloride to chlorate, and the remainder produces the heat that maintains the electrolyte at from 50 to 70°C. (125 to 160°F.), which is necessary for the proper reaction. The whole commercial supply is thus produced. Perchlorates are made by electrolysing chlorates at low temperatures in the same type of cell.

Hydrogen and Oxygen.—One of the most widely distributed of the electrochemical industries, but one that is usually installed in fairly small units, is the electrolysis of water for the production of hydrogen or oxygen, or both. When only one of the gases is required it is often more economical to produce it by some other method, but if both gases are needed, it is better to use an electrochemical method, and often the conditions are such that the single gas can be produced advantageously by the electrochemical method.

Apparatus for the commercial electrolysis of water uses as electrolyte a solution either of sulphuric acid (H₂SO₄), or one of the alkalies (NaOH or KOH). With the alkalies the cells are usually constructed of iron, and with the acid, they must be lined with lead, whatever the body of the cell may be. With the alkaline solutions, a concentration of 10 to 25 per cent is used, and with acid, 20 to 30 per cent. The voltage needed to force a current through such a cell is composed of three factors—the voltage of decomposition of the water, the voltage necessary to overcome the resistance of the cell, and the voltage necessary to overcome the resistance of the gas layers on the electrodes, sometimes known as "overvoltage." The sulphuric acid solution has a much better conductivity than the alkaline solutions, but the resistance of the gas films is greater on lead than on iron, so that on the whole, cells using alkaline solutions have a lower working voltage than those using acid. The current efficiency in either case can be made to approach 100 per cent.

The total voltage required for the cells is 2.3 to 3.6 volts. The energy requirement for one cubic meter of mixed gases is 3.7 to 5.9 kilowatt hours, the alkaline cells giving the lower figure,
and the acid cells the higher. In the acid cells, lead anodes are used, which peroxidize, and the presence of PbO₂ causes the oxygen to contain some ozone. The chlorides in the alkaline solution allow the anodes, usually of iron or nickel, to be slowly attacked, requiring occasional replacement. The purity of the gases is usually 97 to 99 per cent.

Electric Smelting.—One of the earliest commercial processes in electrochemistry was that devised by E. H. and A. H. Cowles in 1884. A mixture of about two parts of alumina, one of iron oxide, and one of carbon was introduced into a brickwork chamber. Bundles of carbon rods inserted at the ends formed the electrodes between which a current of 3,000 amperes at 50 volts was maintained. At a very high temperature the alumina was reduced (Al₂O₃ + 3C = 2Al + 3CO) and the resulting aluminum combined with the copper to form aluminum bronze. This was the forerunner of the various types of electrothermal operation described in the following paragraphs.

Iron and Steel can be produced by reducing iron ore with carbon in an electric furnace. For example, a mixture of magnetite and carbon can be heated by passing a current through it, as in the Cowles aluminum bronze process, by passing the current through a carbon core in contact with the material as in the carborundum process; or by the action of an arc as in the carbide process. The reaction is simply Fe₂O₃ + 4C = 3Fe + 4CO. Pure iron, cast iron or steel may be produced, depending upon the proportion of carbon. The chief advantages are the directness of the process and the fact that no impurities (sulphur, silicon, etc.) are introduced in the fuel, besides a considerable saving of fuel over the ordinary steel furnace. On the other hand it is a question of location, whether the electric furnace can compete in economy with the blast furnace, the Bessemer converter, and the open-hearth furnace. Pig iron has been made in the electric furnace in places like California and British Columbia where the coal is available, and the production of iron is also very expensive. The grade of iron thus produced is equal to the best Swedish charcoal iron, and commands a higher price than ordinary pig iron.

The chief utilization of the electric furnace in the iron and steel industry, however, is not in the direct production of pig iron or steel, but in the conversion of low-grade metal from the Bessemer or open-hearth into a high-grade metal, or in the remelting and refining of scrap steel for high-grade castings. Ordinary metal from the Bessemer converter or the open-hearth furnace can, in the electric steel furnace, be converted into metal of crucible quality or better, at a lower cost than crucible steel, and in large quantities, up to 25 tons to the charge.

Ferro-alloys.—One of the most important developments in the steel industry in recent years has been the production of the various alloy steels,—steels in which some special property is secured by the addition of some other metal to the simple alloy of iron and carbon. The purpose of the alloy is to add or subtract from the iron some properties by the addition to ordinary steel of the proper amount of an iron alloy carrying a high percentage of the metal desired. This ferro-alloy is usually, though not always, made electrothermally by the reduction by carbon in an electric furnace of an oxide of the metal, in contact with metallic iron to take up the reduced metal. Sometimes a reduction is made of a mixture of iron oxide and the oxide of the metal in question, but this necessitates the supplying of electric energy for the reduction of the iron, as well as of the alloying metal; and the iron can usually be reduced more cheaply with carbon methods. Under these conditions the reduction of the oxide is much more readily accomplished than if there were no iron present, since the iron considerably reduces the melting point of the resulting mixture. The type of furnace used varies with the size of the charge, the production, but in general are quite similar to those used for the production of calcium carbide.

The alloys that are made in this way are: ferromanganese, ferrosilicon, ferrochromium, ferronickel, ferrotungsten, ferromolybdenum, ferrovanadium, and ferro-uranium.

Silicon Carbide.—Known under the trade names “carborundum,” “crystolon,” and “exolon” silicon carbide is produced in large quantities by the process invented by E. G. Acheson. It is formed by intensively heating a furnace mixture of about 35 per cent of ground coke, 52 per cent of sand, and about 11 per cent of sawdust and 2 per cent of salt, the yield being seven or eight tons of crystalline carborundum and a considerable amount of the amorphous material. The furnaces used at Niagara Falls consist of simple brick hearths 28 feet long and 11 feet wide, with brick walls at each end, these being about three feet thick and six or eight feet high. The side walls are built without cement or mortar to allow the escape of gases and because they have to be pulled down at the end of each run to discharge the furnace. In the middle of each of the end walls there are iron frames holding together a large carbon electrode built up from a number of small electrodes, through which the current is led to a core about two feet in diameter composed of broken coke and extending the entire length of the furnace. This core is raised to a very high temperature by passing through it a current, and thereby is heated up to about 1,600 kilowatts. The heat from the core permeates the mass and converts it at a temperature of about 2,200° C. (4,100°F.) for some distance around the core into silicon carbide. The unchanged material on the outside is worked over in the next charge. The coke of the core is converted into graphite. The shell of carbide is broken up after the furnace has cooled and is used in the manufacture of grinding wheels and other forms of abrasives. It is also used to a limited extent as a refractory material, since it is stable at high temperatures and is a good conductor of heat.

Siloxicon.—This substance is an oxygen-carbon-silicon compound, intermediate between silica and carborundum. It is formed in the electric furnace by reducing silicon with carbon, but not carrying the reduction so far as with carborundum. Siloxicon is an exceedingly refractory material, neutral toward both acid and basic slags, and insusceptible and insoluble in molten metals. It is used as a furnace lining, either made into bricks or as a protective wash with sodium silicate.

Silicon.—The production of metallic silicon (90 to 95 per cent pure) has been accomplished by the extension of the principles used in the production of silicon carbide and ferro-silicon.
It is made in an arc furnace consuming 1,200 to 1,500 horse power, having two electrodes dipping down into the charge, consisting of coke and sand. The principal impurities are iron and aluminum, with some carbon.

Titanium Carbide.—This compound can be made by a process exactly as for carbonium, but substituting the mineral rutile (titanium oxide) for the sand of the charge. Made into electrodes for arc lights, titanium carbide gives twice the light given by carbon electrodes.

Calcium Carbide.—The earliest of the large electric furnace industries to be established was the manufacture of calcium carbide. It is made in the electric furnace by the interaction of lime, CaO, and carbon, usually in the form of coke or anthracite coal. Charcoal can be used, and in fact, on account of its purity, is the most desirable of the three, but is always more expensive. The raw materials should be as pure as possible, in order to prevent the collection of impurities in the product. Phosphorus and arsenic are particularly to be avoided as impurities, and in the production of calcium carbide, these materials are extremely disadvantageous. The lime and fuel, coarsely crushed, are mixed and charged into the furnace, where they are heated to the reaction temperature mainly by the direct action of the arc.

The furnaces for the manufacture of carbide are all of the arc type and only a small portion of the heating is done by resistance. They may turn out the carbide either in solid blocks or as a liquid, to be tapped out as collected. Formerly the furnaces were of the block type, but now they are going over to the tapping furnaces.

The earliest form of furnace consisted of an electrode suspended in a car, which served as the other electrode and as a container for the carbide. This form of furnace was small and of low efficiency, 100 to 200 kilowatts at 40 to 70 volts, with a power consumption of 6 to 7 kilowatt hours per kilogram of 85 per cent carbide, an efficiency of only 40 per cent. The losses of raw materials were also high.

The modification of the block furnace for continuous operation is also undesirable. The material being drawn away from underneath the working zone of the furnace, made possible a decrease in power consumption to 4.5 kilowatt hours per kilogram of carbide. The size of the furnace was also increased up to 375 kilowatts.

Tapping furnaces are much larger, up to 1,200 to 1,400 kilowatts and have a power consumption of 4.2 to 4.5 kilowatt hours per kilogram of carbide. One ton of product requires 900 kilograms of lime and 600 kilograms of anthracite coal.

Three-phase carbide furnaces have been built up to 3,000 kilowatts per phase, or 9,000 kilowatts per furnace. This proved to be the limit in furnace extension for single units, as the limit for laboratory apparatus is also undesirable. A furnace of double this size was constructed by including two three-phase electrode systems in one furnace jacket. This gives an 18,000 kilowatt furnace with 6 electrodes, each electrode carrying up to 15,000 amperes. A furnace of this size will produce carbide with a power consumption of 4 to 4.2 kilowatt hours per kilogram. Using charcoal as a source of carbon, the power consumption can be cut as low as 3.8 kilowatt hours per kilogram, equivalent to about 69 per cent efficiency, but the extra cost of the charcoal over that of the coal will probably overbalance the extra saving in power.

Cyanamide.—A large portion of the calcium carbide now made is for use as a raw material for the manufacture of calcium cyanamide. The cyanamide after being finely ground is heated to temperature of about 1,000° C. (1,830° F.) in a special type of electric furnace, in the presence of pure nitrogen. The nitrogen combines with the carbide forming CaCN₂. This formula calls for 35 per cent of nitrogen in the product, but since the carbide is never entirely pure and since it is not entirely converted, the resulting product carries about 20 per cent of nitrogen.

The process was originally developed for the production of a fertilizer material to replace the more expensive sodium nitrate or ammonium sulphate, but processes have since been developed for the conversion of the nitrogen of the cyanamide into ammonia and for the oxidation of the ammonia into nitric acid. This process has largely been made means for the chemical utilization of the nitrogen of the air. This same result has been secured by the direct oxidation processes for atmospheric nitrogen, which will be considered later.

Graphite.—Artificial graphite was first considered as a commercial possibility when it was noticed that in the carbonium furnaces masses of graphite frequently resulted from the overheating of the carbonium in the center of the furnace, the carbonium being decomposed and the silicon volatilized, leaving the carbon as graphite. The process was then carried on with the intentional overheating of the entire charge, with the result that it was converted into graphite. It was eventually found that all carbides decompose with the formation of graphite and the volatilization of the metal, and that it was not necessary to make up a carbonium charge to secure graphite, but that any carbonaceous material could be graphitized that carried a uniform mixture of metallic oxides, for example coke or anthracite coal. The next step was the graphitization of molded carbon materials, particularly electrodes, it being only necessary to incorporate uniformly throughout the body, while in the process of manufacture, a small percentage of some metallic oxide, preferably Fe₂O₃, this being largely volatilized out in the course of the graphitization. The amount of amorphous graphite produced in this way now amounts to about ten million pounds annually, and the electrode material graphitized to at least half that amount.

Alumina.—Electrically fused alumina under the trade-names of "alundum" and "aloxite" is used mainly for abrasive purposes and to a lesser extent as a refractory material mainly for laboratory apparatus. These methods are in fusing down pure calcined bauxite in an electric furnace. The furnace is of the crucible type with two electrodes dipping into it. When the furnace is filled it is shut down, the sides stripped off and the block of alumina, weighing about five tons, is cooled slowly and then broken to lump form for shipment. The furnace works at 110 volts and 2,500 amperes, consuming 275 kilowatts. The energy consumption is about 2.1
kilowatt hours per kilogram of alumina. This is about half the power requirement for carboration, but the raw material is more expensive, so that the product is a trifle more expensive than carboration.

**Fused Quartz.**—Fused silica ware is now made by several manufacturers, and almost any shape can be secured that is made in glass, providing the size is not too great. The price of the material is still quite high. Pure silica is fused in a small electric furnace and the main difficulty encountered is the heating of the silica to a sufficient temperature for it to flow easily (2,000° C. or 3,600° F.) without excessive volatilization and without the silicon combining with the carbon electrodes to form silicoxon or silicon carbide.

**Phosphorus.**—The disadvantages of the old chemical methods for the manufacture of phosphorus were considerable, the reduction of phosphoric acid or a phosphate giving a very low yield. The operation is now carried on electrothermally, reducing a mixture of bone ash, calcined phosphate rock, and carbon. The phosphorus distils off and is collected under water, and the calcium or aluminum silicate slag is drawn off intermittently. The yield of phosphorus is 90 to 90 per cent and the furnace requires 11.6 kilowatt hours per kilogram of phosphorus.

**Carbon Bisulphide.**—The chemical manufacture of this substance was attended with considerable difficulty, but the electrothermal process in its very early stages supplies the entire demand of this continent. A current of electricity passing through a granular carbon resistor volatilizes sulphur to vapor, which passes up through a column of hot charcoal above the resistor, forming CS2, which is drawn off from the top of the furnace and condensed. The energy consumption is about 1.15 kilowatt hours per kilogram of CS2, an efficiency of about 35 per cent.

**Nitrogen Fixation.**—The direct oxidation of the nitrogen of the atmosphere for the production of nitric acid and ammonia is a result long sought by numerous investigators, but it is only within recent years that it has become a commercial possibility. This has now been accomplished in three types of processes. One of these, the direct combination of nitrogen with hydrogen to form ammonia, is more chemical than electrothermal, and so does not concern us here. The second type of process is a more or less indirect conversion of the nitrogen, largely electrothermal in character and is treated in the preceding paragraphs on Calcium Carbide and Cyanamide. The third type of process is the direct combination of atmospheric nitrogen and oxygen to form nitrous oxide under the influence of a high-tension electric discharge. This process is generally known as the cyanamide process, while the preceding process is known as the cyanamide process.

The arc process, while a very interesting development from an electrochemical standpoint and as the pioneer in the field, cannot cope with the cyanamide process either in cost of operation or in efficiency. One of the simplest forms of apparatus and at the same time one of the most satisfactory is that of Birkeland and Eyste. If an arc is struck between two high-tension electrodes, it immediately tends to break down to a low-voltage arc, at a high current, but if the arc is placed between two powerful electromagnets the electromagnetic force will bend the arc out from the line of the electrodes, in which form. As the arc spreads and becomes longer, the current drops and the voltage at the electrodes increases and soon reaches a point where a second arc strikes across between the electrodes in the same manner, to be immediately followed by others until the first arc formed reaches such a length that the voltage is no longer able to sustain it. Since an alternating current is used, the succeeding arcs form on opposite sides of the electrodes and, with proper regulation, maintain a circular set of flame, composed of a series of arcs progressing outward till they are extinguished either by becoming too long to be maintained by the voltage available or by the reversal of the electro motive force at the end of every half period of the alternating current. The disc of flame, which is about 1.6 metres in diameter, is enclosed in a furnace and a current of air is forced out radially on each side of the arc. Furnaces are in operation, taking 3,200 to 4,000 kilowatts at about 5,000 volts, of which 3,300 to 3,900 volts are across the arc, the remaining being the drop in the series inductances. The frequency is 50 cycles, the power factor is 0.6 to 0.8 per cent and the current 940 amperes. The gas from the furnaces contains one part per million of NO, the yield of HNO3 is about 0.7 grams per kilowatt hour.

The Birkeland process is similar in principle to the Birkeland-Eyste, but differs in application. Here the succession of arcs is produced not by magnetic deflection but by blowing the blast of air that is to be treated between the two electrodes, thus accomplishing the same end as the magnet of Birkeland and Eyste, except that the sheet of flame extends on one side of the electrodes only. The gas from the Birkeland-Eyste furnace is somewhat richer in nitrogen oxide than from the Birkeland-Eyste furnace, but the yields are somewhat lower. Each furnace contains two 200-kilowatt arcs in series, at 4,000 volts, taking 140 amperes at a power factor of 70 per cent.

In comparison with these processes, the Schönhell process is of interest, this being based on a different principle. Both the Birkeland-Eyste and the Birkeland processes recognize the difficulty of maintaining a high-tension arc, particularly when subjected to a current of air, and so means are provided for securing a rapid succession of arcs as fast as they are extinguished. As a matter of fact, the arcs are made to overlap, so several exist in parallel at the same time. Schönhell, however, attacked the problem of maintaining a stable high-tension, high-current arc, working on the principle that if the air current were so introduced that it did not deform the arc, the discharge could be maintained in a stable condition. Schönhell used the air current, at right angles to the arc, to draw the arc out to a greater length. Schönhell secured the arc without destroying the arc by introducing the air tangentially from all sides simultaneously so that it traveled with a helical motion in the direction of the arc. This neither deformed
the arc nor overcooled it, allowing it to burn quietly. Working on this principle, the commercial furnaces designed by Hessberger take 700 to 750 kilowatts, 3,500 volts and 290 amperes with a 66 per cent efficiency. The arc is carried from 5 to 7 metres (16 to 22 feet) in length. The gases carry 1.5 to 2 per cent NO and the yield is 68 grams HNO₃ per kilowatt hour.

Ozone is a polymerized form of oxygen which may be produced by a silent electric discharge from a static electric machine, induction coil or very high voltage transformer, through oxygen or air.

It has powerful oxidizing and bactericidal properties and is extensively used in water and air purification.

Other Compounds.—Many other compounds, too numerous to describe, are made by electrochemical processes of one kind or another. For details of the principles involved in the operations of such processes, see ELECTROCHEMISTRY, ELECTROLYSIS, ELECTRIC FURNACES and METALLURGY. For details on individual subjects, see under the name of the substance in question.

G. A. ROUSH,
Assistant Secretary American Electrochemical Society.

ELECTROCHEMICAL SERIES, the arrangement of the chemical elements in the order of their ability to replace one another in a solution.

ELECTROCHEMICAL SOCIETY, American. The American Electrochemical Society was organized 3 April 1902, at Philadelphia, Pa., the objects of the society, as stated in its constitution, being the advancement of the theory and practice of electrochemistry. The charter members of the Society numbered 337, while the membership at the close of the year 1917 was about 1600. Since its organization, the Society has held two meetings every year, in the Spring and Autumn, for the presentation and discussion of papers on electrochemical subjects. These meetings have been distributed as follows:—New York City, 9; Niagara Falls, 4; Atlantic City, 2; Boston, 2; Philadelphia, 2; Pittsburgh, 2; Washington, 2; and one each in Albany, N. Y.; Bethlehem, Pa.; Chicago, Ill.; Detroit, Mich.; Denver, Colo.; Ithaca, N. Y.; Saint Louis, Mo.; San Francisco Cal.; Toronto, Can. Since the membership of the Society includes practically all of the prominent electrochemists of the United States, as well as many in foreign countries, the Society has naturally played an active part in scientific developments in the years since its organization.

ELECTROCHEMICAL TELEGRAPH, a telegraph which records signals upon a paper sheet or strip moistened with a chemical solution, which is decomposed by the electric current. See TELEGRAPH—Chemical Automatic Telegraphs.

ELECTROCHEMISTRY. That branch of chemistry which treats of the utilization of electrical energy to facilitate or carry on a chemical reaction is known as electrochemistry. This field may be accomplished in one of three ways: by electrolysis, by electothermal action, or by the discharge of electricity through gases. Versely, electrochemistry also includes those reactions by which electricity is generated by means of chemical action. It was the Italian physicist Alessandro Volta (q.v.), a professor in the University of Pavia, who first discovered that when two metals and a liquid are combined in a circuit an electric current is produced. It was also Volta, who, for the first time, distinguished between the two classes of electrical conductors, recognizing the difference between metallic conductors and electrolytic conductors, which is the foundation of all electrolytic work. Soon after this he established what has been called the contact electromotive series, which is a table of metallic conductors arranged in such order that if any two of them be connected with each other and also with an electrolytic conductor, an electric current will flow through the liquid from the metal higher in the series to the one lower in the series, and the current increases in magnitude the farther apart the two metals are in the series. Following this, it was discovered by Ritter, that the order of the metals in this series was the same as the previously known order in which metals replaced each other in solutions of their salts. This discovery was the first bond of linkage between the newer science of electricity and the older one of chemistry, and marks the birth of our modern electrochemistry. Volta's contact electromotive series soon led to the development of the voltaic pile (q.v.), the first device for the generation of electric current, and one dependent entirely on electrochemical principles. In his work on the pile, Volta could hardly have failed to notice the formation of gas bubbles on the metals immersed in his solutions, and the fact that he makes no mention of these phenomena indicates that he did not appreciate the significance of the reactions that were taking place. It remained for Nicholson and Carlisle in 1800 to record the formation of hydrogen and oxygen on passing the electric current through water. In the study of the various decompositions it was soon noted that there was a formation of alkali at the negative pole in the electrolysis and of acid at the positive pole. Following up these observations led to the discovery by Davy in 1807 of the alkali metals, sodium and potassium, which he separated by electrolysis of the fused hydrates, thus laying the foundation for the development 100 years later of the Castner process of manufacture of metallic sodium on a commercial scale. (See ELECTROCHEMICAL INDUSTRIES.) It was Berzelius, the great Swedish chemist, who devised the first theory for the explosibility of chemical compounds, based upon electrochemical observations. The Berzelius theory dominated this new science and the parent
ELECTROCHEMISTRY

Science of chemistry as well for many decades, but in turn was supplanted by other theories. During its lifetime, however, it served as the basis for an enormous amount of valuable discussion and research. According to the Berzelius theory, chemical atoms behave similarly to a magnet, having a positive and negative pole, but in the case of some elements the positive pole is stronger than the negative, whereas with others the negative pole is the stronger. Consequently the atom behaves in accordance with the character of the predominating pole, and the positive or negative character of the predominating pole of the atoms, and its relative strength as Berzelius's law of definite composition, is the characteristic of the element. Atoms of an electropositive character can then combine with those of electronegative character, in proportions determined by their relative strengths, thus neutralizing each other more or less, but not necessarily completely. If complete neutralization does not result from the first combination the result is a compound which is more or less electropositive or electronegative, depending on which charge predominates, and compounds of this kind of composite part can still further combine for more complete neutralization. Combinations of certain elements thus gave compounds of an acid character while others gave compounds of a basic character, and these combine to form salts, which, if not completely neutralized, can still further combine to form double salts.

After the establishment of the Berzelius theory, no great progress was made along electrochemical lines until about 1835, when Faraday announced his discovery of what are now known as Faraday's laws, which will be discussed later. Faraday received his taste for scientific work and the training that led up to it while serving as a helper in the laboratory of Sir Humphrey Davy, and Davy is said to have once replied, in answer to a question, that his most important chemico-discovery was Michael Faraday. Besides the laws governing the quantitative relations of electrochemical reactions, we also owe to Faraday our system of electrochemical nomenclature. To explain the reactions taking place he assumed the passage of electricity to be the movement in the solution of particles of matter which he called ions; the poles themselves were in general termed electrodes, the positive pole being the anode and the negative pole the cathode; the ions that moved to the positive pole were anions, and those moving toward the negative pole were cations; the solution undergoing decomposition was the electrolyte, that surrounding the anode being the anolyte, and that surrounding the cathode the catholyte; the process of decomposition was called electrolysis.

When the decomposition of water was first noticed, an explanation was sought for the simultaneous appearance of hydrogen at one electrode and of oxygen at the other. In 1805 Grotthus proposed a theory to explain the mechanism of the conduction of the electric current through the solution and opened the discussion of a problem for which we still have no entirely satisfactory solution. According to the Grotthus theory, the current charges one electrode positively and the other negatively, and these charged surfaces in turn act on the molecules of water in such a way that the hydrogen of the water becomes positively charged and the oxygen negatively charged. The attraction of the negative pole for the positively charged hydrogen and of the positive pole for the negatively charged oxygen then causes the molecules to arrange themselves as shown in A of Fig. 1. If the charge on the two electrodes

![Fig. 1](image-url)

is then sufficient, the atoms $a$ and $a'$ have their charges neutralized at the electrode and become free gas; the atoms $b$ and $b'$ then recombine with $c$ and $c'$ and so on throughout the line, forming new molecules of water, as in B, which then, under the continued influence of the current, will reorient themselves as before and the whole process is repeated. This theory held its own for about 50 years, but as the science developed, imperfections were discovered that made it no longer tenable, and it was eventually replaced by the Clausius theory. Clausius assumed that the positive and negative portions of the molecule in the electrolyte were not firmly combined with each other, but were in a state of continuous vibration, which if it became vigorous enough would cause the positive part of one molecule to come within the sphere of influence of the negative part of another molecule, with which it would unite, the negative and positive particles thus left temporarily free in turn soon come within the sphere of other oppositely charged particles with which to unite, so that there would be going on through the solution all the time a continuous interchange between the particles. But when an electric current is sent through the solution, a force is generated in the direction of the flow of the current and the vibration and exchange is no longer irregular, and in all directions, but intensified in the direction of the current flow, thus causing a movement of positive particles toward the negative pole, and vice versa.

The Grotthus idea of fixed ions was thus replaced by the vibrating ions of Clausius, and in turn, some 30 years later, was replaced by the Arrhenius theory of free ions. This theory has probably given a greater impulse to electrochemical research and has, directly and indirectly, been an aid to more discoveries than any other conception in the field of electrochemistry. The Arrhenius theory, or as it is frequently called, the electrolytic dissociation theory (see SOLUTIONS) was based on the assumption that when an acid, base or salt was dissolved, yielding a solution that was a conductor of electricity, the molecules of the dissolved substance were by the act of solution de-
composed into part-molecules, or ions. At any finite concentration the solution will still contain a certain amount of undisassociated material, and only at infinite dilution can the substance be completely dissociated into ions. These dissociated ions are positively and negatively charged, and it is the ions that act as carriers of the current, the conductivity of the solution being dependent on the degree of dissociation of the dissolved substance.

The discrepancies that constantly cropped out in the development of the details of the Arrhenius theory led up to what is known as the Hydrate theory, which assumes that part of the water present in the solution is combined with the dissolved substance, thus leaving as free solvent only a portion of the total amount present, which from a concentration standpoint would bring about the same results as the assumption according to the Arrhenius theory of an increase of the ultimate particles in the solution by dissociation. And this idea, in turn, becomes the Solvate theory when its principles are extended from aqueous to all solutions, both aqueous and non-aqueous. This Solvate theory, supplanting the earlier, the Arrhenius theory, extends the latter from its former constricted field of dilute solutions to a theory of solutions in general. There are still, however, many points that need further development, particularly with regard to the exact relation between dissociation and solvation.

If the law of conservation of energy holds, there must necessarily be a direct relation between electrical energy and chemical energy on the one hand and heat energy on the other. This brings us first to the discussion of Faraday's laws (q.v.), two of the most fundamental statements in natural science. Faraday's first law states that the amount of chemical action produced by an electric current in a circuit is directly proportional to the quantity of electricity which passes through the circuit. The second law specifies that the quantities of different substances which are produced by the same amount of electricity passing are directly proportional to the chemically equivalent weights of the substances concerned. These effects are entirely independent of the concentration or temperature of the solution, the size or distance apart of the electrodes, and all other conditions. These laws hold with great exactness not only for ordinary aqueous solutions, but also for non-aqueous solutions and for fused salts. The quantity of electricity that is necessary to deposit the chemically equivalent weight of any substance is 96,500 coulombs (ampere seconds) and this unit quantity is known as a Faraday, after its discoverer. Another, and possibly better, way of stating this is to say that one Faraday of electricity, 96,500 coulombs, is required to make a unit change in valence of any element or radical. One Faraday then will deposit as metal 56.7 grams of iron from a solution of ferric ions (2 valences) or it will reduce 56 grams of iron from ferric to ferrous, a change of one valence. This holds equally well whether it is a decrease of valence accompanying a chemical reduction, or whether it is an increase of valence accompanying an oxidation. The fact that 96,500 coulombs will deposit one chemical equivalent of an element makes it possible to calculate from this relation the amount of any element that would be deposited by any given amount of current. According to this, one coulomb should deposit 1.008 grams of hydrogen or 96,500 coulombs 0.000010446 grams of hydrogen or

\[ \frac{63.57}{2 \times 96,500} = 0.0003294 \text{ grams of copper. These values are known as the electrochemical equivalents (q.v.) and can readily be calculated for any material. The ampere-second values are usually used for scientific work, but for practical work in the plant, larger units for the ampere hour or ampere day may be used. Faraday's laws refer only to quantities of electricity involved in bringing about certain changes, but say nothing about the quantities of electrical energy necessary for the change. To arrive at values for the energy involved, we must consider not only the quantity factor of the current used, but also the intensity factor. In other words, Faraday's laws deal with ampere changes, while the energy involved is concerned with ampere times volts, or watts. All chemical reactions can be compared from an energy standpoint on the basis of the thermochemical changes accompanying the reaction.}

1 calorie = 4.186 watt seconds
1 watt second = 1 coulomb \times 1 volt
or 1 volt-coulomb = 0.2389 calorie.

Then 1 volt-Faraday = 0.2389 \times 96,500 = 23,054 calories. Any given reaction involving one Faraday will then require as many volts as the heat balance of the reaction will contain 23,054. For example, the heat of formation of water is 69,000 calories, and to decompose it an equivalent amount of energy must be supplied. A molecule of water, \( \text{H}_2\text{O} \), includes two chemical equivalents, so per chemical equivalent, there must be supplied 34,500 calories. The voltage required for the decomposition will then be

\[ \frac{34,500}{23,054} = 1.495 \text{ volts. The decomposition of one molecular weight (18 grams) of water then by electrical energy would require 2 \times 96,500 = 193,080 ampere seconds of electricity at a voltage of 1.49 volts, or } \frac{193,080 \times 149}{3600 \times 1000} = 0.08 \text{ kilowatt hours of electrical energy. This same principle can be applied to the calculation of the electromotive force of primary or secondary batteries (q.v.) when applied to the thermochemical balance of the chemical reaction that takes place in the cell. The chemical reaction in the Daniell cell is } \text{Zn} + \text{CuSO}_4 = \text{ZnSO}_4 + \text{Cu. The heat of formation in dilute solution of CuSO}_4 is 197,500 cal. and of ZnSO}_4 is 248,000 cal., leaving an excess of 248,000 - 197,500 = 50,500 cal. for two Faradays, or 25,250 cal. for one Faraday, 1.094 volts supplied by the cell. The reaction on charging a lead storage battery is } 2 \text{ PbSO}_4 + 2\text{H}_2\text{O} = \text{PbO}_2 + \text{Pb} + 2\text{H}_2\text{O}.

215,700 \times (69,000) 63,400 \times (210,200)

This reaction shows a deficit of 569,400 - 473,800 = 95,600 cal. for 1 \text{PbO}_2 (two Faradays) or
47,800 cal. for one Faraday. It will then require
\[
\frac{47,800}{23,054} = 2.073 \text{ volts to charge the cell,}
\]
and since the reaction is reversible, when once charged, it will be capable of generating the same voltage.

Of the phenomena accompanying electrolysis with unattackable electrodes, two of the most interesting are polarization and over-voltage. With electrolytes that are more or less reversible, it may be noted that after the passage of the current has caused a determination, there is a tendency for recombination of the materials present at the electrodes. If the current is stopped, it will be noted that for a short time there will be generated a small current in the opposite direction from that of the current originally imposed. This is known as the polarization current and the voltage generating it is known as the polarization voltage. This polarization voltage, being in the reverse direction from the voltage causing the original electrolysis, will reduce the electromotive force of the cell and the current passing. In some electrolysis involving the separation of a free gas on an unattacked electrode, it is well known that the voltage required for decomposition is greater than that calculated from the heat of formation. This excess of voltage required over the theoretical is called over-voltage, or more recently, gas voltage. These voltages vary widely for various metals and an explanation of the differences has long been sought. Recent investigations seem to indicate that the difference is mechanical rather than chemical. Calorimetric measurements show that the amount of electrical energy disappearing as chemical work is the equivalent of the normal decomposition voltage for the reaction taking place, and that the over-voltage appears in the solution as heat. This would indicate that the nature of the over-voltage was mechanical, and the probable explanation is that it represents the amount of energy necessary to overcome the resistance of the film of gas on the electrode. The gas as first formed on the electrode is a thin film over the entire surface, and then as the amount of gas increases surface tension begins to act to form the film into bubbles of gas which detach themselves from the electrode and escape from the solution. The amount of energy necessary to force the current through the gas film over the surface of the electrode will of course increase with the thickness of the film, and in turn the thickness of the film will be dependent on the ease with which the gas mechanically separates itself from the surface of the electrode. This will naturally vary with the material of the electrode and with the condition of its surface.

When the products of an electrolysis are stable and can be removed from the cell in the form in which they were deposited, there is no reaction except the decomposition itself and this is said to be a primary reaction. In many cases, however, the products of electrolysis undergo further reaction and appear in some other form than that in which they were originally deposited. In this case the reaction is said to be secondary. These secondary reactions may be divided into two classes, depending on whether the products of decomposition react on the material of the electrodes, or whether they react on the electrolyte. If desired, each of these classes can be still further subdivided into two groups, the first as to whether the reaction is on the cathode or on the anode, and the second as to whether the action is on the catholyte or anolyte. For example, if a solution of sodium sulphate were electrolyzed the primary reaction would result in the deposition of sodium on the cathode and of the SO\(_4\) radical on the anode. The sodium would then react with the water in the electrolyte with the formation of NaOH and hydrogen, while the SO\(_4\) would react with the water, forming H\(_2\)SO\(_4\) and oxygen. On the other hand, if a solution of NaCl were electrolyzed with a mercury cathode and a silver anode the sodium set free at the cathode would react on it with the formation of an amalgam, and the chlorine set free at the anode would combine with it with the formation of AgCl. Since the electrolysis of the water of an aqueous solution results in the formation of hydrogen at the cathode and of oxygen at the anode, we can have in the solution as the result of secondary reaction either a reducing or an oxidizing action. Conditions which favor the absorption in the solution of whichever is desired. A large electrode and a low current density favor the absorption of the gas in the nascent condition as fast as formed, while a small electrode and a high current density tend to cause the throwing off of the gas as free bubbles almost as fast as formed and with only a limited opportunity for absorption. Low current density at the cathode and high at the anode will then give a strong reducing action, while high density at the cathode and low at the anode will give an oxidizing action. For further discussion of the phenomena accompanying the passage of a current of electricity through a solution, see the article on Electrolysis.

In electrothermal applications it is the heating action of the current that is sought rather than its chemical action at the electrodes during electrolysis. An apparatus for the utilization of the heating action of the current found in high-temperature reactions is known as an electric furnace. In case the combined action of the high temperature and the chemical action of the current are both used, the apparatus is called an electrolytic furnace. In the former, as a matter of convenience and economy in handling the current, alternating current is usually used; in the latter, since electrolysis is sought, direct current is a necessity. See Electric Furnaces and Electrochemical Industries.

Man's far-off present day commercial operations require temperatures higher than are attainable from the combustion of a fuel, and for operations of this kind electric heating is a necessity. In many other cases it has been found more economical to substitute electric heating for combustion heating. The particular economy in electric heating is due to the fact that the heat is generated within the charge being heated and does not have to be forced through the refractory wall of the container which, on account of its low conductivity, imposes a heavy loss in efficiency. It is also possible to secure certain electrochemical effects by the passage of a high tension electric discharge through gases. The two chief reactions
of this kind are the conversion of oxygen, $O_2$, into ozone, $O_3$, and the oxidation of atmospheric nitrogen to nitric acid. (See Electrochemical Industries). Both of these reactions were first noted in the early years of electrical development, the former by Van Marum in 1785, and the latter by Priestly in 1779, but in both cases nothing was done in the way of study or development of the reactions until many years later, mainly within the last 30 years.

G. A. Roush,
Assistant Secretary, American Electrochemical Society.

ELECTROCHRONOGRAPH. See Chronoscope.

ELECTROCIDES, the amber islands of Greek mythology, at the mouth of the river Eriranus. The name was applied also to the islands on the northern coast of Europe.

ELECTROCHEMICAL USE OF PLANTS, the employment of electric light in agriculture and horticulture. It was determined at the Agricultural Experiment Stations of Cornell University and of West Virginia, in experiments made with the arc and the incandescent lights, respectively, that certain crops are forwarded by the light. The most remarkable instance is that of lettuce, which was brought to maturity in from 5 to 10 days earlier than other plants grown in the same houses and under otherwise identical conditions. This discovery has led to the commercial application of the arc light, if not of the incandescent also, to the forcing of lettuce under glass in several of the larger New England forcing houses, with the result that a gain of about three weeks' time is calculated upon for the season, thus enabling the gardener to devote his benches to one more crop than formerly or to follow his lettuce crops with cucumbers, the favorite successor, much earlier than would otherwise be possible. Several flower crops, such as Easter lilies and sweetpeas, have been experimented upon, with the result that they were forced into bloom several days in advance of others grown without the stimulus. In such cases the plants are always grown without the light until within about a month of maturity, when the light is applied for about half the night. It has been found that unless the light pass through a glass globe or pane there is a noticeable "scorching" of the foliage or flower. It is concluded that this is due to the action of the ultra-violet rays of the spectrum rays, which do not pass through the glass. Consult various bulletins of the Massachusetts, Hatch, Cornell University and West Virginia Experiment stations. See Electric Vegetable Gardening.

ELECTROCUTION, capital punishment by the agency of electricity. See Electrocution, Cause of Death By.

ELECTRODE (Greek, hodos, "a way"), a term introduced by Faraday to denote the conductors by which electricity either enters or leaves an electrolytic bath or solution. He termed the electrode by which the current enters the bath, the anode (positive terminal), and the electrode by which the current leaves, the cathode, sometimes spelled kathode (negative terminal). The terms anode and cathode have been introduced generally in metallurgical practice, and also in connection with Crooke's tubes and X-ray work, and the terminology has become common in the more extended sense of signifying either of the terminals of an electric source, instrument or electrolytic bath or cell.

ELECTRODEPOSITION. See Electrochemistry; Electroplating.

ELECTRODYNAMIC INDUCTION. See Induction.

ELECTRODYNAMICS, that branch of electrical science which treats of the attractions and repulsions exhibited between wires or other conductors along which currents are passing. If two wires are parallel they will attract each other when currents are passing the same way along them both and will repel each other when the currents are opposite. If the wires are inclined to each other at any angle there is not only an attraction or repulsion but a still more marked tendency to rotation which is not satisfied until the wires have become parallel and the currents flow in the same direction along them both. When there are only two straight wires these forces are feeble and require delicate apparatus for their exhibition, but by employing coils of wire the forces are multiplied and an instrument constructed on this principle called the electrodynamometer has been much employed for the measurement of currents. The basic principles of electrodynamics were discovered by Ampere in 1821 by many ingenious experiments, the results of which he expounded in a series of statements known to this day as Ampere's Laws.

ELECTRODYNAMOMETER. See Dynamometers; Electrical Measuring Instruments.

ELECTROKINETICS. See Electric Direct Current; Electric Alternating Current Machinery; Electricity.

ELECTROLYSIS. With respect to their ability to conduct electricity, all substances are divided into the two general classes, conductors and non-conductors; there is, however, no hard and fast boundary line between the two, but a more or less gradual merging from one into the other. The conductors are again divided into two classes, those which conduct the current without apparent decomposition and those in which the conduction is invariably accompanied by decomposition. In this latter class, the conduction of the current with concomitant decomposition is called electrolysis, and the liquid subjected to decomposition is termed the electrolyte. These are the names originally proposed by Faraday. True electrolysis is almost entirely confined to liquids. Evidences of electrolysis have been found, however, in a few cases in solids and similar phenomena have been observed in connection with high-tension discharges through gases. A large number of liquids, particularly of organic na-
ELECTROLYSIS — ELECTROMAGNETISM

ture, fall in the class of non-conductors. Water, and a number of other liquids of inorganic origin are also non-conductors when carefully purified. Liquids that conduct without decomposition are limited to liquid metals. Liquids that conduct with decomposition—that is, electrolytes, may be a pure liquid, a fused salt, or a solution, either aqueous or non-aqueous. In the case of solutions the conductivity is not necessarily dependent on the conductivity of the constituents of the solution, but may be a property of the solution itself. A solution of one non-conductor in another may give a solution of good conductivity.

Also, in the case of a solution, the decomposition caused by the electrolysis may affect the solvent or the solute or both, and may vary with the conditions of electrolysis. If the constituents of the solute are obtained directly at the anode and cathode, the reaction is said to be a primary one; but if for any reason, these constituents react on either the electrodes or the solution, the reaction is said to be secondary. (See Electrochemistry). Primary reactions are dependent only on the amount of current acting, and are not subject to modification by physical conditions (see FARADAY'S LAWS), but secondary reactions may be modified by temperature, concentration, current density and other physical conditions and in this type of reaction with its various modifications lie many of the possibilities in the field of industrial electrochemistry. (See ELECTROCHEMICAL INDUSTRIES). The problem of the mechanism of electrolysis is one that has attracted more attention than any other in the field of electrochemistry. A brief discussion of the early history and the present status of this problem will be found in the article on ELECTROCHEMISTRY. This question is also closely related to, and to a certain extent dependent on, the problem of the nature of solutions, and a further discussion of the principles involved will be found in the article on SOLUTIONS.

G. A. ROUSH,
Assistant Secretary, American Electrochemical Society.

ELECTROLYSIS OF GAS AND WATER MAINS. In the system of street railway traction in which an overhead trolley wire is employed, with direct current, in which the tracks are utilized as a return circuit for the current to the power-house, it has been found that damage has almost invariably ensued to the gas and water mains adjacent to the tracks, from electrolysis. This is due primarily to the electric current leaving the tracks and following the gas or water mains for some distance. At the points where the current leaves these pipes to return to the tracks or to the power-house, if the soil is damp and contains soluble chlorides of magnesium, sodium or calcium, the current sets free acids or chlorine which attack the iron of the pipes; the rapidity and extent of the damage done thereby being dependent upon the strength of the current, the duration of its application and the constituents of the soil. The electrolytic action in "pitting" the pipes, and bursting of water pipes and leakage of gas pipes is not uncommon from this cause. (See Illustration). Experiments have shown that with as low a potential as 0.5 volt and a current of 0.03 ampere, noticeable electrolysis of an iron pipe has occurred in sand moistened with sea water. Pipes on which the difference of potential was found to be about six volts have burst in a few years. To prevent electrolysis due to this cause greater precautions are now taken, and with considerable success, to preserve the continuity of the rails by bonding, welding them in situ by electricity by providing separate metallic return circuits and by connecting the water and gas mains by means of heavy copper wire at places where the current would otherwise return to the tracks via the earth.

ELECTROLYTE. Any liquid which conducts the electric current with a consequent decomposition is called an electrolyte. It may be either a pure liquid, a fused salt or a solution, aqueous or non-aqueous. In the case of a solution, the decomposition may involve the solution themselves. The name of the liquid, incorrectly applied to designate a salt which when dissolved in water will form a conducting solution.

ELECTROMAGNETIC INDUCTION. See Induction.

ELECTROMAGNETISM. The art or practice of magnetizing by means of an electric current, as distinguished from so-called natural magnetism as in the lodestone, or transient magnetism, as established in a wrought-iron bar. A magnet not only attracts steel and iron in a less degree, but cobalt, nickel, manganese, cerium and chromium. Hans Christian Oersted (q.v.) is credited with being the first to recognize the identity of magnetic and electric phenomena. In 1820 he observed that wires connecting the poles of a voltaic pile affected the magnetic needle. In 1821 he wrote a long paper on electro-magnetism. Arago, Ampere, Davy and Faraday all studied and contributed to knowledge of the phenomena. In 1825 William Sturgeon of Woolwich, England, began to experiment. His two first electro-magnets were made in the shape of a horseshoe and a straight bar. The former was made of a bent rod of iron one foot in length and half an inch thick, around which a bare copper wire was wound 18 times, the iron having been previously covered with varnish to insulate the wire from the iron. The current was supplied by one large primary cell. This magnet was able to sustain a weight of nine pounds, though weighing itself only seven ounces. Subsequently Sturgeon constructed a horseshoe electromagnet 18 inches in length, 2¼ inches thick and wound with 980 feet of copper wire one-twelfth of an inch in diameter, which upheld 1,386 pounds. In 1831 Joseph Henry made electromagnets for both Yale and Princeton universities that lifted 3,000 pounds. Large electromagnets are now used in foundries and machine shops of a capacity of 12 or more tons.

The phenomena of electro-magnetism may be briefly described as follows: It is known that
when iron filings are strewn over a cardboard or glass, if a bar or horseshoe magnet be placed under the cardboard the filings will tend to arrange themselves symmetrically when the cardboard is tapped. This is due to magnetic lines of force which are assumed to flow from the north to the south pole of the magnet, and the iron filings, becoming temporarily magnetized by these magnetic lines of force, tend to set themselves parallel thereto. Similarly, when an electric current flows in a wire, the magnetic lines of force bend to conform to these electric lines of force, which surround the wire in circles or hoops which increase in density with the strength of the current. It is known that iron is a much better conductor of magnetic lines of force (or magnetism) than air, in the ratio of 1 to 100 or 130, depending on the quality or permeability of the iron. Hence when the wire is made in the form of a coil into which is inserted a soft iron bar, the magnetic lines of force, so to speak, use the iron as a circuit and the latter becomes a magnet having north and south poles. A simple form of electromagnet consists of a U-shaped bar of soft iron, around which a copper wire is coiled in spirals, beginning at one extremity and extending to the other. If the iron core is placed in this position, A, and winding begins at the lower left side, turning the wire around clockwise, the south pole of the magnetic will be at the starting point on the left.

The space between the poles of a magnet or where its magnetic lines of force extend, or in the space around a wire conveying a current of electricity, is termed a magnetic field. The substances through which the lines of force pass, including the iron of the magnet, constitute the magnetic circuit. The expression number of lines of force per square centimeter in the material, is at present used as a measure of magnetic density. The total number of lines of force in a magnetic circuit is termed the magnetic flux, and is obtained by multiplying the total cross-sectional area of the field in square centimeters by the density of a square centimeters of the circuit. The magneto motive force (that is, the force that, as it were, drives the lines of force through the circuit) is equal to the product of the strength of current in amperes per second by the number of convolutions of the coil. This is also termed the amper turns. The magnetic flux may be increased by increasing the magneto motive force or by decreasing the resistance (termed the reluctance) of the magnetic circuit. Hence the relation of the foregoing terms to one another is analogous to that between electromotive force, resistance and current, in an electrical circuit, and may be expressed by the equation:

\[ \text{Magnetic flux} = \frac{\text{Magneto motive force}}{\text{Reluctance}}. \]

It is to be noted, however, that the reluctance of a magnetic circuit containing iron is not a constant, but increases in other words, its permeability to magnetization decreases, after a certain degree of magnetization, which is termed saturation, has been reached.

Electro-magnets and electro-motors are used in electric bells, in telegraph and telephone apparatus, in dynamo machines, electric motors (q.v.), and for many other purposes. See ELECTRIC MACHINERY.
urements that it superseded the cruder instruments, and being later improved by Dolesealek and others became a standard instrument. See Electric Measuring Instruments.

**Electromotive Force.** Electric pressure or voltage, equivalent to difference of potential; the force that causes electricity to flow along a conductor: commonly abbreviated E.M.F. The force which gives rise to an electric current is called electromotive force and is in direct relation with the force exerted by water under pressure or "head,"* resulting from water seeking its level. In a somewhat similar way, electricity seeks a balance. When a conductor is earthed, that is connected with the earth, the electric potential becomes the same as the earth's, balance is restored and there is no flow of current and no electrical manifestation, the electromotive force being at zero.

**Electromotograph,** a name given to a peculiar telephone receiver invented by Edison and constructed virtually as follows: A short metal strip, fastened at one end to the center of a mica diaphragm, rests on a rotating cylinder, the surface of which is composed of moist gyspum impregnated with mercuric acetate and potash. The strip and cylinder are placed in series in a telephone circuit. When variations in current pass through the gyspum surface it is found that the friction between the strip and the cylinder varies directly with the current. When the current is weak the strip is drawn along in the direction of the cylinder's rotation against the natural tension of the mica diaphragm. When the current increases, the strip slips back in response to the pull of the diaphragm and in this way the diaphragm is set into vibrations corresponding to those set up by the telephone transmitter. An explanation of this phenomena is that the current electrolytically sets free a thin layer of gas between the cylinder and strip, reducing the natural friction.

**Electron Theory or Corpuscular Theory.** The physical theory that the atoms of bodies are composite systems consisting in part (at least) of corpuscles of a still higher order of minuteness. The theory has heretofore concerned itself mainly with the study of one special form of corpuscle, which is exceedingly prominent in sub-atomic phenomena, and which appears to constitute a sort of basic and omnipresent structural element in the architecture of material atoms of all kinds, inasmuch as it has identically the same properties in every respect, whatever the kind of matter from which it is obtained. These fundamental corpuscles usually occur in combination with structural elements of other kinds to form the atoms, but they are also capable of existing in the free state, and they can be isolated by suitable experimental means. Each corpuscle carries a certain definite and constant charge of negative electricity, which is the same for all of them; and many authorities believe that the corpuscles are, in fact, mere isolated, disembodied electric charges. Whether this be so or not, experimental evidence indicates that the charge ascribed to a corpuscle has one definite value, and that it is incapable of variation. An atom is supposed to consist of a certain number of these negative corpuscles, associated in some definite way with a positively- electrified nucleus,—there being, normally, just enough of the negative corpuscles present to neutralize the effects of the positive electrification of the nucleus. According to this view, bodies acquire positive charges by losing some of their negative corpuscles, and acquire negative charges by picking up additional negative corpuscles. If this hypothesis be correct, it is evident that communicating an electric charge to a body is not a continuous process. It is, on the other hand, essentially discontinuous, and consists in adding to the body (or subtracting from it) a number of definite (though exceedingly small) units of electricity,—being roughly analogous to filling (or emptying) a barrel by means of a bucket, instead of by the use of a hose. Moreover, the belief that the charging process is essentially discontinuous is no longer based upon theory alone, for Millikan has obtained direct experimental evidence of such discontinuity, in connection with the charges communicated to oil drops by friction. It happens that the investigation of the positive nucleus of the atom is more difficult than the investigation of the negative corpuscles that are normally associated with it, or perhaps it would be more accurate to say that the experimental methods thus far devised are mainly applicable to the study of the negative corpuscle. Under certain circumstances atoms can lose positive charges as well as losing or gaining negative ones, but the loss of a positive charge appears to involve a fundamental change of some kind in the nature of the atom. (See Molecular Theory.) That there is probably an exceedingly important difference between positive and negative electricity is plainly indicated by the fact that no positive charge has yet been demonstrably observed in connection with a mass smaller than that of the hydrogen atom, while negative charges (as will presently appear) are known to occur in connection with masses far more minute than this.

The definite charge carried by the negative corpuscle appears to be identical in magnitude with the charge carried by the hydrogen ion (or any of the corpuscles of a still higher order of minuteness). For this charge Dr. G. Johnstone Stoney, as long ago as 1891, proposed the name "electron,"* (Lord Kelvin preferred "electron," but his suggestion has not been followed); and this name has been applied quite generally, in recent years, to the negative corpuscles themselves, instead of being restricted to the electric charges that they bear. Present practice among authoritative writers, however, is toward the restoration of the word "electron" to its original sense as the name of a definite quantity (or unit) of electricity, and toward the adoption of J. J. Thomson's original name, "corpuscle," or "negative corpuscle," for the actual particle that bears (or consists of) a charge of one electron of negative electricity. In the present article we shall follow the tendency here noted, and shall call the particle itself a "corpuscle" or "negative corpuscle," and the charge that it bears an "electron" or "negative electron."

The corpuscular theory of matter has been developed in many directions, and its bearing upon the varied phenomena of physics has been extensively investigated by both mathematical and experimental methods. To indicate all its bearings and relations would require a volume,
and the present article will therefore be devoted to an explanation of the origin of the corpuscular theory, and to an account of the numerous results that have been obtained by studying the mass, charge, speed and size of the negative corpuscle. Further data concerning the application of the corpuscular theory to specific physical phenomena may be had from the references given below.

The corpuscular theory of matter, in its modern sense, originated in connection with the study of the discharge of electricity through rarefied gases. Previous to the experimental investigation of this subject it was customary to regard positive and negative electricity as being of the same general nature, but differing from each other somewhat as a right-handed helix or spiral differs from a left-handed one, or (more accurately) as a positive number differs from a negative one. The study of vacuum-tube phenomena indicated, however, that there is a far more profound difference than this between the two kinds of electricity. It was shown by the researches of Plücker, Hittorf, Crookes and others that when electricity is passed through a tube filled with rarefied gas, the discharge from the negative electrode (or "cathode") is wholly different from the discharge that takes place at the positive electrode (or "anode"). The negative discharge (when the vacuum in the tube is high enough) takes place along straight lines that are everywhere at right angles to the surface of the cathode from which they proceed, and the phenomena observed at the positive electrode are altogether different and far less striking.

The negative discharge that proceeds from the cathode (or negative electrode) at right angles to its surface, in a "vacuum tube," is called the "cathode ray," and special attention was naturally paid to this ray, in an effort to discover its nature. The most strikingly obvious fact about it is, that it excites a vivid fluorescence in the glass walls of the tube, where it strikes it. Hittorf, in 1869, showed that a solid object, placed in the course of the ray intercepted it and casts a shadow, its outline being plainly visible because there is no fluorescence on the part of the tube that is shielded by the obstacle. Crookes, following Hittorf, took up the study of vacuum phenomena in a fascinating and masterly way, and obtained many results that were not only beautiful and striking, but also exceedingly suggestive and stimulating to further inquiry. By placing a very light paddle-wheel in the tube, so that its paddles were within the cathode stream (or "ray") on one side, and out of it on the other side, he obtained mechanical rotatory effects. By giving the negative electrode a concave form, and thereby bringing the cathode ray to a focus at a point within the tube, he showed that marked heating effects could be produced by it. These phenomena, together with many others that were observed, suggested that the cathode ray consists of a stream of material particles, negatively electrified by contact with the cathode and then repelled from the cathode on account of the charge they have acquired. This fact was strongly urged by Varley (in 1871), and very likely by others also, as it was a fairly obvious inference, though it was not the only explanation possible. (In Germany the cathode ray was quite generally believed to be due to some form of wave-like disturbance in the ether, and this view was held by Goldstein, who first introduce... even the name) Katherodenstrahlen, or "cathode rays"). One difficulty was, to identify the nature of the charged particles that were thus repelled. There were reasons for believing that they are not ordinary molecules or atoms. It was known, for example, that when an electrically-charged liquid is evaporated, the vapor does not carry away the electrical charge with it, and this appeared to indicate that the individual atoms or molecules of a gas cannot be separately electrified. Moreover, if the cathode ray consists merely of electrified molecules, it was hard to understand why the effects that were observed in connection with the cathode were not also manifested in connection with the anode, or positive electrode. Crookes, as a result of his researches, concluded that the projectile theory (or charged-particle theory) of the cathode ray is correct, but as he fully realized the difficulties in the way of that theory, he announced his belief that in vacuum-tube phenomena we are dealing with molecules in an extremely rarefied condition, the discharge from the negative electrode (or "cathode") is wholly different from the discharge that takes place at the positive electrode (or "anode"). The negative discharge (when the vacuum in the tube is high enough) takes place along straight lines that are everywhere at right angles to the surface of the cathode from which they proceed, and the phenomena observed at the positive electrode are altogether different and far less striking.

Following the experiments of Crookes there was a lull in the activity with which the phenomena of vacuum tubes were studied, but intense interest in the subject was again aroused by two exceedingly striking discoveries. Lenard, in 1894, showed that the cathode ray can be made to emerge from the tube and pass into the outside air of the laboratory, if a "window" of very thin aluminum (instead of glass) is provided at the point at which the cathode ray strikes the tube. Two years later (namely in 1896) Röntgen discovered that a previously unknown form of radiation is emitted from the point at which the cathode ray strikes against the tube, or against any other solid obstacle. The prospective usefulness of the Röntgen rays (or "X-rays") to the surgeon gave them an intense practical interest, in addition to the interest that they had for purely physical reasons; and from this time onward the study of the electric discharge was prosecuted with renewed vigor and earnestness, and by a large number of physicists—further stimulation being presently added by the discovery of radioactivity (1896) and of polonium and radium (1898). Exceedingly prominent among the physicists who took up the study of the cathode discharge at about this time was Sir J. J. Thomson. Beginning his researches by investigating the general phenomena attending the passage of electricity through gases, and guided by a wonderful scientific imagination, supplemented by a profound knowledge of mathematics and marked experimental skill, he established the soundness of Crookes' views, generalized them amazingly, developed a new "corpuscular theory" of matter and placed that theory on a firm foundation.

It is not possible, in the present article, to give more than a superficial idea of the way in which the reality and general properties of the negative corpuscle have been established. The strength of the corpuscular theory lies in the
fact that it has been tested from many angles, and that the results obtained by approaching it from the most diverse viewpoints have, in the main, harmonized with one another astonishingly. Doubts that may be felt with regard to the legitimacy of the assumptions made in any one line of investigation tend to lose their force when confronted by cumulative evidence from widely different sources. It is true that inconsistencies and other difficulties have developed here and there in connection with the corpuscular theory, but that could only be expected, because the entire subject is still new, and progress in the application of the theory has doubtless been retarded and distorted to a considerable extent by the persistence of certain of our older conceptions and postulates that are no longer defensible, but to which we still cling because we have not yet learned wherein our error lies. In the main, the data that have been obtained are singularly consistent. Moreover, the corpuscular theory has proved to be extraordinarily rich in its suggestiveness, and has led to many lines of investigation that have been fruitful and productive of good results. This alone would justify us in following it still further to see where it will ultimately lead.

Prominent among the quantities that we should like to determine in connection with the negative corpuscles of which we may for the time being assume the cathode ray to consist, are the following: (1) The mass \( m \) of a corpuscle, (2) the electric charge \( e \) that it bears, and (3) the speed \( u \) with which the corpuscle is moving under given conditions. Let us see how these magnitudes were first obtained:

It has long been known, from the general theory of electricity, that a charged particle, when moving in a magnetic field and at right angles to the lines of magnetic force, is deflected so that it tends to describe a circular arc (instead of a straight line), in a plane perpendicular to the direction of the magnetic lines. It is, in fact, a simple matter to show that when the charged particle is moving freely in space, its charge per unit of mass (denoted in symbols by the ratio \( \frac{e}{m} \)) bears to its velocity the same ratio that the reciprocal of the radius of the circle in which it moves bears to the intensity of the magnetic field that causes the path to be circular. Now it is easy enough to subject the cathode ray to the action of a magnetic field, and the deflection of the cathode ray thus produced is quite marked even when the field is not very strong. The radius of the circular arc that is described by the ray in a field of known strength is also measurable without any special difficulty, and hence we can determine, with a fair degree of precision, the ratio of \( \frac{e}{m} \) to \( u \).

This, however, is only one step in the solution of the problem, for we do not yet know either \( \frac{e}{m} \) or \( u \), separately. Some experimenters, assuming that the ratio \( \frac{e}{m} \) of the charge on the particle to the mass of the particle is the same in the cathode ray as it is in the case of the ions that are involved in electrolysis, substituted this value and then proceeded to determine, by means of the experiment just cited, the value of \( u \) — that is, the speed of the particles in the cathode ray. By this means a value of \( u \) was obtained that was not greatly different from the speeds "appropriate to atoms of matter." This result was illusory, however, because the fundamental assumption that \( \frac{e}{m} \) is the same in the cathode beam as it is in electrolysis was wholly gratuitous, and was also, as the event proved, entirely wrong.

Wiechert succeeded in measuring the speed of the cathode-ray particles directly, by means of an exceedingly ingenious apparatus, which, although it is apparently incapable of giving results of any high order of precision, is at least competent to show the order of magnitude of the speed, and hence to check the validity of assuming that it is similar to the ordinary molecular speed, or that the ratio \( \frac{e}{m} \) in the cathode-ray particles is the same as it is in the ions that are concerned in electrolysis. His method depends upon the deflection of the cathode ray by a magnetic field, but he used two magnetizing coils, energized by a rapidly alternating current having a period commensurate with the time required by the cathode-ray particles to traverse a considerable length of the tube. The cathode was placed at one end of the tube and at the other end was a fluorescent screen, which, by its luminosity, showed where the ray came in contact with it. Between the cathode and the fluorescent screen two diaphragms were placed, so that the ray was wholly intercepted except for a small part that could pass through a central perforation in each diaphragm. The first magnetizing coil was placed between the cathode and the first diaphragm, and as the alternating magnetic field that it produced varied, the cathode ray vibrated to and fro across the surface of the first diaphragm. The apparatus was so adjusted that the ray passed through the opening in this diaphragm only when the magnetic field produced by the coil was at its maximum in one particular phase — the oscillation was then at the extreme end of (say) its upward swing. At this moment the ray would pass through the opening in the first diaphragm, proceed down the tube to the second diaphragm, pass through the central opening in this, and then register itself by producing a round, luminous spot in a fixed position on the fluorescent screen beyond — the alterations in the magnetic field being so rapid that the spot appeared steady, although the illumination was really intermittent, because the cathode ray, since it could pass the first diaphragm only when at the extreme upward part of its periodic sway, traveled down the tube in a series of spurts or pulsations. The second magnetizing coil was placed at or just beyond the second diaphragm, and in the absence of a certain special adjustment or relation (to which we shall presently refer) the alternating magnetic field produced by this second coil, acting upon the cathode ray as it passed the second diaphragm, would again deflect it, and cause it to impinge upon the fluorescent screen above or
below the spot at which it would strike if the second coil were absent or inactive. It is evident, however, that if the magnetic field of the second coil were always in the zero phase when the cathode-ray radiation reached it, there would be no second deflection produced, and the luminous spot on the screen would occupy the same position that it would have if the second coil were absent. With the apparatus disposed, as described, the densest magnetic field of the first coil was at its maximum phase when the cathode ray passed through the first diaphragm, and (if the second coil did not displace the luminous spot on the screen) it was also known that the magnetic field of the second coil was at its zero phase when the cathode-ray pulsation reached the second diaphragm. In performing the actual experiment the two magnetizing coils were made identically alike and were placed in the circuit in parallel and with symmetrically-arranged leads, so that the phase of the current at any given instant would be the same in each. The magnetizing current was furnished by a modified Tesla high-frequency coil, provided with a pair of condensers of known capacity; and from the known electrical constants the frequency of the transverse magnetic field in the two fields could be calculated. The experiment then consisted in determining the shortest distance by which the two magnetizing coils could be separated, consistently with the second one having no effect. (We say the "shortest distance" because it is evident from the nature of wave-motion that a similar zero effect would be observed whenever the time of transit of the cathode ray from one field to the other happened to be one-fourth, three-fourths, five-fourths or any odd number of fourths, of the time of a complete period of the current in the magnetizing coils). In one experiment this least distance was found to be 39 centimeters, and the number of complete oscillations of the magnetic field, from either coil, was found to be 39,000 per second. The time required for the cathode beam to travel 39 centimeters, in this case, was the 128,000,000th part of a second. Therefore its speed was 4,992,000 centimeters per second — or, to express it in the usual way, and to as high a degree of precision as the data will warrant, 50 x 10⁶ centimeters per second. (The symbol 10⁶ stands for the ninth power of 10. In the same way 10⁻⁶ stands for the reciprocal of the ninth power of 10. A notation of this kind is in common use in physics for expressing large numbers, as it avoids the use of long rows of ciphers, which are not only confusing to the eye but are also likely to lead to error from misreading, or from the accidental addition or omission of ciphers in copying or printing). It is evident from the foregoing result that the speed of the cathode-ray corpuscles is of an entirely different order of magnitude from the usual speed of translation of gas molecules. The average molecular speed in hydrogen gas, for example, at atmospheric pressure and at the temperature of melting ice, is only about 17 x 10⁶ centimeters per second; on the other hand, the velocity of light, in a vacuum, is about 3 x 10⁸ centimeters per second, so that the velocity of the cathode-ray particles, in this experiment, was about one-sixth of that of light, or about 30,000 times as great as the speed of translation of hydrogen molecules. It should be understood that no great degree of accuracy is claimed for the particular numerical result just quoted, and it should also be understood that the speed of the cathode-ray particles varies considerably with the degree of exhaustion in the tube, and with the intensity of the electric field in the vicinity of the cathode. It is evident, however, (1) that we are here in the region of phenomena entirely transcending anything previously known in connection with the translatory motion of matter, and (2) that Crookes was in all probability right when he expressed the view that cathode-ray phenomena bring us in touch with "matters" (in the ordinary sense) in a very different state from any with which we have had previous experience.

As might be expected, a large number of experimenters turned their attention to the investigation of the nature and properties of these cathode-ray particles or negative corpuscles, and many exceedingly difficult, beautiful and ingenious lines of research were carried out in this direction. One of the most interesting was Sir J. J. Thompson's determination of the speed of transverse magnetic fields in the cathode ray, by a method wholly different from that of Wiechert. By the aid of a magnet he deflected the cathode stream so that for a definite time it entered an insulated hollow vessel that was connected with an electrometer, which served to measure the aggregate electrical charge of the entering corpuscles. Inside the vessel the beam impinged upon a delicate thermoelectric couple of known thermal capacity, by means of which the total kinetic energy of the torrent of corpuscles that entered the vessel (in the form of heat). The curvature of the beam, outside the closed vessel and under the influence of the magnetic field, was observed at the same time. If \( N \) is the number of corpuscles entering the closed vessel in a given time, and \( \epsilon \) is the negative electrical charge on each one of them, then \( Ne \) is the total aggregate charge on all the \( N \) corpuscles taken together. This was one of the quantities measured. Let us represent it by \( Q \) and write \( Q = Ne \). Again, if \( \mu \) is the velocity of the corpuscle (assumed to be the same for all) and \( m \) is the mass of any one of them, the kinetic energy of each corpuscle will be \( \frac{1}{2} \mu v^2 \), and the total aggregate kinetic energy of the \( N \) corpuscles that entered the enclosure will be \( \frac{1}{2} N \mu v^2 \). This quantity, which we will denote by \( W \) (so that \( W = \frac{1}{2} N \mu v^2 \)), was given by the thermoelectric couple. Finally, if \( H \) is the intensity of the magnetic field (in electromagnetic units) and \( r \) is the radius of curvature of the cathode beam where it traverses this field, we have, from general electrical principles, that \( \frac{1}{2} Hkr^2 = \frac{1}{2} N \mu v^2 \). We find that it is possible, from these three equations, to eliminate \( N \) and to find the values of \( \mu \) and \( \frac{1}{2} v^2 \mu \), respectively. In fact, we have \( \frac{1}{2} v^2 \mu = \frac{2W}{Qh} \) and \( \frac{1}{2} v^2 \mu = \frac{2W}{Qh^2} \). When the experiment was performed and the observed values of the measured quantities were substituted on the right-hand side of each equation, the value of the speed, \( v \), proved to be about 10,000 miles.

(or 1.6 × 10⁻¹⁰ centimeters) per second. The value simultaneously found for \( \frac{e}{m} \) (or the electrical charge of a corpuscle, per unit of its mass) was about 10, the mass being supposed to be measured in grammes, and the electric charge expressed in absolute electromagnetic units. According to this result, the charge of the negative corpuscle, per unit of mass, is about the thousandth part of the charge observed on the hydrogen atom, per unit of mass in ordinary electrolysis.

It was, of course, highly important to confirm these extraordinary results in as many ways as possible. Another method that suggested itself for determining the speed of cathode-ray corpuscles depends upon the fact that a static electric field tends to deflect a moving electrified particle and cause it to describe a curved arc — circular or parabolic, according to the conditions of the experiment. By subjecting the cathode ray, simultaneously, to a static electric field of intensity \( E \) and to a magnetic field of intensity \( H \), it is possible, if the directions of the lines of force are properly chosen, and the respective intensities \( H \) and \( E \) are properly related, to cause the two to tend to neutralize each other, so far as the deflection of the cathode ray is concerned. An application of the principles of theoretical electricity shows that if the deflection of the ray is to be zero, the two fields acting on its particles must fulfill the relation

\[
E = H u,
\]

from which we obtain the very simple result:

\[
u = \frac{E}{H}.
\]

In other words, if we find, by experiment, a combined magnetic and electrostatic field in which the cathode ray remains sensibly straight, the velocity of the particles of the ray may be found at once by merely dividing the strength of the observed magnetic field by the strength of the observed electric field. The actual application of this method involves special difficulties, but J. J. Thomson overcame them all, and obtained numerical results indicating that the velocity \( u \) lay between \( 3 \times 10^8 \) and \( 2 \times 10^9 \) centimeters per second, and this, combined with the result obtained by applying the equation \( m u = \frac{e}{H} r \), which holds when the magnetic field acts alone (\( r \) being then the radius of curvature of the cathode ray), led to the further conclusion that the value of \( \frac{e}{m} \) lies between 0.7 × 10⁻¹⁰ and 0.9 × 10⁻¹⁰, if \( m \) is measured in grammes and \( e \) in absolute electromagnetic units.

It should not be inferred that all our information with regard to the negative corpuscle is obtained from the study of the cathode ray, because this is far from being the case. According to the views at present held, the negative corpuscle plays a leading part in many physical phenomena, and the study of various other departments of physics has led to confirmatory conclusions with regard to the properties of these corpuscles. The Zeeman effect, for example, affords a means of determining the ratio \( \frac{e}{m} \) and gives results that are in harmony with determinations obtained from the cathode ray. The Zeeman effect, in its simplest form, consists in the doubling of the spectral lines of substances, when the radiating source, from which the light giving the spectrum proceeds, is subjected to the action of a powerful magnetic field, in which the lines of force are parallel to the direction of radiation. There is much to be done in the way of clearing up our ideas of the mechanism by which radiation is effected (see Radiation and Molecular Theory), but for the moment let us assume that light-waves originate in the disturbances produced in the ether by negative corpuscles executing orbital motions within the atoms of the radiating substance. The planes in which the corpuscles perform these orbital motions will, in general, be distributed equally in all possible positions, and the projections of their orbits upon any selected fundamental reference plane will be described, by the corresponding projections of the corpuscles themselves, equally in a clockwise and a counter-clockwise direction. Now if the radiating source be subjected to a strong magnetic field, the lines of force of which are parallel to the direction of the ray under consideration, the negative corpuscles will be differently affected, according as their projections are revolving clockwise or counter-clockwise, in their orbits as projected upon a plane perpendicular to the lines of force. Those that are revolving in one direction will be accelerated and those that are revolving in the opposite direction will be retarded, in accordance with known principles in the theory of electricity and magnetism. But a difference in the periods of revolution of the corpuscles will mean a difference in the wavelength of the emitted light, and hence if the magnetic field is sufficiently intense, it will cause a visible separation of the spectral lines into doublets. Lorentz, basing his calculation upon considerations of this kind, has shown that if \( T \) is the original period of the undisturbed vibration causing any given spectral line and \( \tau \) is the difference in period corresponding to the two components into which the line is resolved by means of the magnetic field, we have

\[
\tau = \frac{e}{m} \frac{HT^2}{4\sigma},
\]

where \( e \), \( m \), and \( H \) have the same significance as above, and \( \pi = 3.14159 \). With the exception of \( e \) and \( m \), all these quantities are either known or obtainable by direct observation; hence the equation affords us an independent means of determining the ratio of \( e \) to \( m \). Upon performing the experiment Zeeman found values of \( \frac{e}{m} \) ranging from \( 1.4 \times 10^7 \) to \( 1.8 \times 10^9 \), which agrees fairly well with the results previously obtained from the study of the cathode ray.

Other methods, based upon the action of ultraviolet light, and upon radioactivity and phenomena of various other kinds, have been used for determining this ratio, and from the general agreement among the results obtained by different methods and different experimenters it has become evident that although the velocity with which the corpuscles move depends upon the circumstances under which they
are liberated or set in motion, the electric charge of a corpuscle per unit of its mass \( \frac{e}{m} \), is always the same, no matter what the condition of the corpuscle is, or from what source it is obtained. It is evident that this kind that has led physicists to conclude that the negative corpuscle is a fundamental and omnipresent constituent of matter of every kind. The best value of \( \frac{e}{m} \) that has been obtained up to the present time is certainly Buccheri's. He found

\[
\frac{e}{m} = 1.767 \times 10^{-10},
\]

if \( m \) is measured in grammes and \( e \) in absolute electromagnetic units. This is believed to be correct to within about one-half of 1 per cent. It applies only to slowly-moving corpuscles, however, and we shall presently see, the apparent mass of a corpuscle increases with the speed of the corpuscle, while the charge presumably remains unchanged. (Buccheri's value of \( \frac{e}{m} \) is \( 5.299 \times 10^{-10} \), if the electric charge is expressed in absolute electrostatic units.)

The fact that the ratio \( \frac{e}{m} \) is nearly 2,000 times as great as the charge per unit mass observed in connection with the hydrogen atom in electrolysis shows, most conclusively, that one of two things must be true: Either (1) the charge on the negative corpuscle is far greater than the charge accompanying an ion in electrolysis, or (2) the mass of a negative corpuscle is far less than the mass of any ion or atom previously known to us. Of course these may both be true, but certainly one of them is true, and as soon as this fact was recognized, it was also recognized that the discovery of the negative corpuscle was an event of fundamental importance in the history of physics.

In order to find out which alternative must be accepted, J. J. Thomson undertook to determine the electric charge on a single corpuscle — and hence also the mass of the corpuscle, since the ratio of the two was known. More accurate values of these quantities have since been obtained by other means, but Thomson, it should be remembered, was a pioneer in a new field, and the work that he did in solving his problem has justifiably been called by Sir Oliver Lodge "one of the most brilliant things recently done in experimental physics." We can only outline his method, but the procedure approved by Lord Kelvin in 1870, that the surface tension of small droplets of water, suspended in the air, tends to cause evaporation even though the degree of saturation is enough to cause condensation on a water-surface that is flat, or that has a large radius of curvature; (3) on the fact, announced by J. J. Thomson himself in 1888, that the electrification of such a droplet tends to neutralize the effect of the surface tension, so that condensation can take place on any water droplet, or on any other curved surface of exceedingly short radius, if this droplet or surface is electrified, even though no such condensation could take place in the absence of the electrification; (4) on the investigation, by Sir George Stokes in 1849, of the limiting speed at which small spherical bodies will fall, by their own weight, through a fluid of known viscosity; and (5) on the method devised by Mr. C. T. R. Wilson, in 1887, for precipitating, by adiabatic expansion, a definitely-known quantity of aqueous vapor in the form of mist, from saturated air.

Thomson's experiment consisted (1) in partially ionizing, in a closed vessel and by means of X-rays or ultra-violet light, air containing a suitable quantity of water vapor; (2) in causing the deposition of droplets of mist, by Wilson's method of quick adiabatic expansion, about the ions thus set free; (3) in observing the rate at which the mist thus formed subsides — a process which really consists in the falling of the individual droplets through the air; (4) in calculating the value of Stokes' formula, the diameter (and subsequently the weight) of the spherical droplets constituting the mist — this being made possible by the fact that he knew the viscosity of the air and had observed the rate of fall of the droplets; (5) in calculating the total mass (or weight) of water precipitated, in accordance with Wilson's method, from the known degree of expansion of the air; and (6) in dividing the total weight of precipitated water by the weight of a single droplet, and thereby determining the number of droplets. The number of droplets produced being assumed to be the same as the number of available ions about which condensation was theoretically possible, the experiment manifestly gave the total number, \( N \), of the ions present in each cubic centimeter of the air, under the conditions prevailing in the experimental apparatus. In one experiment \( N \) was found to be 30,000.

The total aggregate charge of the ions was determined by means of a set of parallel metallic plates in the vessel in which the mist was produced — one of them being insulated and connected with an electrometer. If the space between the plates contained positive ions, for example, then by suddenly communicating a strong positive charge to the non-insulated plate these ions could be quickly repelled against the insulated plate, to which they would give up their charges; and the aggregate charge that they were carrying could then be measured by the electrometer. By means of this principle the total charge on the ions in a cubic centimeter of the air in the mist-chamber was determined; and by dividing this total charge by \( N \), the number of ions in a cubic centimeter of the air, the charge on one individual ion became known.

The charge on each ion was assumed to be due to the excess or deficit of one electron, and hence the experiment gave an estimate of the charge, \( e \), associated with each corpuscle. The value of \( e \) at first obtained by Thomson in this way ranged anywhere from \( 8.4 \times 10^{-8} \) to \( 8.4 \times 10^{-9} \) electrostatic units, and he adopted \( 6.5 \times 10^{-9} \) as the concluded value. In 1903 he
ELECTRON THEORY

published a later determination of $e$, obtained
following the same general plan as before but with cer-
tain improvements in technique, and gave the value $e = 3.4 \times 10^{-19}$.

Beautiful and ingenious as this determination
of the charge on the individual corpuscle
was, the method was open to certain criticisms,
involving as it involved a certain assumption
which had not been shown to be valid, and which,
in fact, were only approximately true.

They were near enough to the truth for the
method to yield a rough estimate of the value of $e$,
but they were too imperfect to provide us
with an accurate and dependable determination.
It was not known, for example, that Stokes' form-
ula for the rate of fall of spheres in a
viscous fluid would apply with sufficient ac-
curacy in the case of droplets of the exceed-
ingly small size here under consideration.

Nor was it known that every ion actually did sur-
round itself by a liquid droplet, nor that there
were no droplets containing more than one
ion. Nor did the method make allowance for
the effect of differences in the sizes of the
drop and for paring evaporation from
their surfaces after they were formed. It is not
possible, in the present place, to discuss
these various points, but it must suffice to say
that they have all received the most careful
consideration in later researches, and Prof.
R. A. Millikan, of the University of Chi-
cago, has recently been able to publish a
definitive and probably very accurate value of $e$,
obtained by a method which apparently
leaves little to be desired on the score of
soundness or of experimental excellence.

It does not detract in any way from the admira-
tion that we must feel for Thomson's original
work, to say that Millikan's research was still
more ingenious and beautiful. He succeeded
in trapping single corpuscles, and in measuring
the value of the "electron" directly; and the
account of his work that he gives in his book,
'The Electron,' is extremely fascinating.

Millikan's fundamental idea was exceedingly
simple, but in its practical application it called
for an immense amount of ingenuity, experi-
mental skill and patient labor.

A tiny spherical droplet of oil was electrified and caused to take
up a position, suspended in the air, between
two horizontal metallic plates that could be
electrified or grounded, at will. The drop was
strongly illuminated from two opposite sides,
and was observed by means of a telescope di-
rected at right angles to the light-rays.

It appeared, in the field of the telescope, "like a
bright star against a black background." The
drop was first allowed to fall freely through
a known distance (approximately equal to half
a centimeter or one-fifth of an inch),
the limits of which were marked by a pair of
cross-hairs in the telescope. The time of fall
through this distance, in one set of experiments,
was about 13 seconds. Before the drop reached
the metallic plate, a pair of plates, electrified
by connecting them to the terminals of a
battery having a total electromotive force
from 5,000 to 10,000 volts, the charge of the
lower plate having the same sign as the elec-
tric field of the telescope, the lower plate was
then electrified. When the experiment
was rightly conducted, the drop (already
carrying an electric charge) would begin to
rise, under the influence of the electric field to
which it was exposed, and the time
required for it to make its upward journey from the
lower cross-hair of the telescope to the upper
one was noted. Before it reached the upper
plate the electric field would be destroyed
by grounding the metal plates. The drop would
then fall again, and the time of its descent
from the lower cross-hair was again
once more observed, and so the experiment
proceeded—keeping the droplet always in
the air, and continually recording the times of
its ascent and descent. (A single drop could thus
be kept under constant observation for hours.)

The size of the drop was determined from
the measured time of its fall by means of a modi-

fied form of Stokes' formula for the descent
of small spheres in viscous media—the original
formula having been studied with great care
(epecially by Dr. H. D. Arnold) with refer-
ence to its accuracy in connection with droplets
of the size used in these experiments. The
diameter of the droplet being known, its weight
was readily ascertained, because the density of
the oil of which it was composed was known.

Then from the means was found for calcu-
lating the electriﬁcation of the drop at will,
and in either direction, by ionizing the air
between the plates by means of an X-ray
discharge, and then throwing ions against the
drop by electric repulsion. The original posi-
tive electrification of the drop was reduced
every time a negative ion was taken in, and
increased every time a positive ion was re-
ceived. After a positive ion had been taken
in, the upward journey would be performed
more quickly than before, and the inclusion
of a negative ion would cause a corre-
Sponding slowing of the upward motion. It was
found to be quite possible to determine, from
the circumstances of the motion, the number
(as well as the sign) of the ions thus entering
the drop; and by calculating for all the different
upward journeys that were observed, it became evident that these various
charges either showed no change, or differed
from one another either by a certain constant
quantity, or by a low multiple of that quantity.
It was even found that the original charge
of the droplet was also an apparently exact
multiple of this same quantity. The doctrine
that electrification is a discontinuous process,
and that it consists in adding to a body (or
subtracting from it) a certain number of
small-sized yet finite and equal charges, or
"electrons," thereby received an exceedingly
striking and definite confirmation; and the data
available made it quite easy to calculate the
magnitudes of this elementary unit charge.

After several years plates were electrometa-
in two years of work with a special
apparatus constructed with exceeding care, the
final conclusion was, that the charge on the
electron is invariably $e = 4.774 \times 10^{-19}$ the
always alike and Meek's value of $4.805 \times 10^{-19}$
(apparently with good agreement) but the un-
certainty in this result is not greater than
the thousandth part of its own magnitude. (The

corresponding value of the charge, in absolute electromagnetic units is \( e = 1.592 \times 10^{-19} \).

Millikan obtained his oil drop by perforating the upper of the two metallic plates by means of a minute pinhole, and then sending a fine spray of the oil into the space above the plate, by blowing a puff of air through an atomizer. In the course of time one of the droplets of the spray would fall through the pinhole into the region between the plates, and the experiment could be started. The friction to which the oil was subjected in the atomizer electrified the droplets of spray positively, and, as has been stated above, the charge communicated to the droplet in this way was always found to be an exact multiple of the value given above. This fact is highly interesting, because here we have, for the first time, direct evidence that an electric charge communicated to a body by friction consists in an excess or deficit of a definite, finite number of electrons. In one experiment, for example, the positive charge communicated to the droplet by the initial friction of the atomizer was found to correspond to a loss (or deficiency) of nine negative electrons.

Millikan varied his drop-experiments in many ways with numerous substances (including mercury) for the drops, and experimenting with drops of widely different sizes, and with various gases between his electrified plates; and he concludes that the apparent value of the electron is not in general a function of the gas in which the particle falls, of the materials used, or of the radius of the drop on which it is caught. In other words, he strikingly confirmed the theory that the negative corpuscle has an actual, physical existence, apart from the existence of the kinds of matter before contemplated by the scientist.

The determination of the mass \( m \) of a free, slowly-moving negative corpuscle is an easy matter after \( e \) and \( e = \frac{1}{m} \) have been separately determined; for we have the simple relation

\[
e + \left( \frac{e}{m} \right) = m.
\]

With Millikan's value of \( e \) and Bucherer's value of \( e / m \) (both expressed in terms of absolute electrostatic units) we have

\[
m = (4.774 \times 10^{-24}) + (5.299 \times 10^{-24}) = 9.091 \times 10^{-27} \text{ grammes}.
\]

(Both magnitudes being rounded off)

It may be shown, from this, that it would require 1,845 slowly-moving negative corpuscles, to have a combined mass equal to the mass of one hydrogen atom.

We do not yet know the shape of the negative corpuscle, nor do we positively know that the word "shape" has any definite meaning when applied to it. Larmor, for purposes of definition, assumed the corpuscle to be a mathematical point endowed with a finite charge of electricity, which creates a certain type of strain in the surrounding ether; but the prevailing conception (in which Larmor would doubtless concur) is that the actual, physical corpuscle has some kind of spatial extension, though it may not have definite boundaries. Nicholson, in a paper read before the Physical Society of London in October 1917, suggested that the corpuscle is a region of strain in the ether, the strain being intense in the immediate vicinity of a certain central point, and diminishing with extreme rapidity as we pass away from that point. According to this view the corpuscle would have no definite boundaries, and therefore (in a strict sense) no definite shape, though on account of the intense localization of the region in which the strain is really significant, we might treat the corpuscle for most purposes almost as though it were a mathematical point. If we defined the outside a "radius" to such a corpuscle, we should have to define the radius arbitrarily, either as extending to a region where the strain is some definite fraction of the maximum central strain, or in some other way.

In the absence of data concerning the shape of the negative corpuscle, it is natural to try, first, the simplest assumption we can make with regard to it and to see how well this fits such facts as we have. The simplest shape, from a mathematical standpoint, is a sphere; and we find that the three best-known theories as to the shape of the negative corpuscle assume it to be spherical, at all events when it is at rest.

1. Abraham considers the corpuscle to be rigid and spherical at all times, whether it is moving rapidly or at rest.

2. Lorentz considers it to be spherical when at rest, but assumes that when it moves it becomes transformed into an ellipsoid of revolution with its equatorial radius unchanged, but with its polar radius (which is parallel to the direction of the motion) shortened to \( r \sqrt{1-x^2} \), where \( r \) is the original radius and \( x \) is the ratio that the speed of the corpuscle bears to the speed of light.

3. Bucherer and Langevin also consider the corpuscle to be spherical when at rest and assume that when it is in motion it takes the form of an ellipsoid of revolution with its polar radius shortened and directed parallel to the motion; but they assume that the polar radius becomes \( r(1-x^2)^{1/2} \) and that the equatorial radii are increased in consequence of the motion, so that each becomes equal to \( r(1-x^2)^{-1/2} \), where \( r \) and \( x \) have the same significance as before. (It is to be observed that these relations of Bucherer and Langevin leave the volume of the corpuscle unchanged, whatever the speed may be).

Each of these conceptions has something in its favor, and each has something against it, but they should all be regarded merely as convenient mathematical fictions for the present — fictions that are worth considering because they may serve to suggest further researches when their consequences are investigated. The experiments of Kaufmann (to which reference will presently be made) appear to be incompatible with Lorentz's conception of the corpuscle, while the theory of relativity suggests that those of Abraham and of Bucherer and Langevin are untenable.

The general theory of electricity, as applied to static charges moving rapidly through space, brings us face to face with an exceedingly interesting topic in connection with the negative corpuscle, — namely, that its apparent mass is doubtless in some measure of electrical origin, and that it is quite within the bounds of possibility that it is wholly electrical. Sir J. J. Thomson pointed out, as long ago as 1881, that a moving body (for example, a sphere) pos-
Electron Theory

sesses a somewhat greater apparent inertia, or mass, when it is electrically charged than it does when it is not charged. ('Recent Researches in Electricity and Magnetism,' p. 21.) This is due to the fact that the charged body has Faraday's 'tubes of force' radiating from it, and these tubes are supposed to carry a certain amount of ether around with them and to encounter a sort of hydrodynamic resistance from the surrounding ether. This resistance is not analogous to friction, however. It does not necessarily entail any dissipation of energy, but has the general effect (when considered mathematically) of increasing the apparent mass of the charged body. Thomson showed, for example, that a sphere having a radius of \( r \) centimeters, and bearing an electric charge of \( e \) absolute electromagnetic units, has an apparent mass equal to \( m + \frac{e^2}{2r} \) grammes, if it is stationary or moving with a speed that is small in comparison with the speed of light; \( m \) being its mass, in grammes, when the electric charge is absent.

When a charged sphere is caused to move with greater and greater speed, the Faraday tubes of force shift their positions in relation to it, and Heaviside showed (in 1889) that as the speed increases, each tube, whatever its original direction, will be displaced more and more toward a plane passing through the centre of the sphere perpendicularly to the line of motion. In other words, if we call the diameter that coincides with the direction of motion of the sphere its 'polar axis,' the tubes of force that radiate from the sphere will crowd closer and closer toward the equatorial plane, the faster the sphere moves. Moreover, the shifting of each tube (according to Heaviside's analysis) will take place in such a way that the original distance of every point in the tube from the equatorial plane will be reduced by the motion in the proportion of \( \sqrt{1 - v^2/c^2} \) to \( V \), where \( v \) is the speed of the sphere, and \( V \) the speed of light. (It is to be observed, in particular, that the tubes approach the equatorial plane in the same way, whether they lie in front of it or behind it, as the sphere moves through space.)

4 The effect of the ether upon a Faraday tube is very different when the tube is moving endwise than when the tube is moving side-wise (or perpendicularly to its own length); and in consequence of this fact, the part of the apparent mass that is due to the electriﬁcation increases when the speed of the sphere becomes great enough for the equatorial crowding of the tubes of force to become significant. It is not possible to deal with this phase of the subject more than superficially in the present article, but it should be specially noted that mathematical analysis has shown (1) that owing to the existence of the Faraday tubes of force that stretch out into the ether from an electrically body, that body, whether its charge be positive or negative and whether it be stationary or in motion, has an apparent mass greater than the mass it has when the charge is absent; (2) that owing to the crowding of the Faraday tubes toward the equatorial region when the speed of the body increases, the apparent mass of the body's motion; (3) that at any ordinary speed this increase in apparent

mass is insignificant and does not have to be reckoned with; but (4) that it becomes significant as soon as the body attains a speed equal to a few tenths of the speed of light, and (5) the apparent mass increases with extreme rapidity as the speed approaches closely to the speed of light, and (6) it would become infinite if that speed were fully achieved.

Now until the last few years this rather striking conclusion was of academic interest only and it had no practical bearing because we could not produce any such prodigious speeds, in electrified bodies, as were necessary in order to give rise to any sensible increase in their apparent mass. When, however, it was discovered that the negative corpuscles in high vacuum tubes are moving with speeds comparable with (though always materially less than) the speed of light, the conclusions summarized above began to have an important practical bearing and physicists asked themselves whether any increase in the apparent mass of these corpuscles could be detected, that could be assigned to the causes indicated—i.e., that the experimental evidence could be adduced, to show that the apparent mass of a swiftly-moving electrified particle increases with the speed with which the particle is traveling. The question became far more interesting than it had been when it was shown that the so-called 'beta rays' emitted by radium are identical with the negatively electrified corpuscles observed in vacuum tubes, because the speed of these beta particles is as high as from 95 to 97 percent of that of light in some cases, and hence they should show a marked increase of apparent mass, if the previous theoretical conclusions about the effect of speed upon mass were sound.

Partly with the object of testing this point, and partly with the broader idea of gaining a general insight into the nature of mass and inertia and into the constitution of the negative corpuscle, W. Kaufmann, of Göttingen, undertook to determine the ratio of charge to mass for these rapidly-moving particles, at various speeds. An interesting semi-popular account of his best-known experiments will be found in Sir Oliver Lodge's 'Electrons.' (For the original papers, see 'Comptes rendus,' Oct. 1902; 'Zeitschrift für Physikalische Erkenntnisse,' 1902-03; p. 55; 'Annalen der Physik, Vol. XIX, 1906.') The method employed by Kaufmann was a modification of the one outlined above for determining the speed of cathode-ray corpuscles by subjecting the particles simultaneously to magnetic and electrostatic fields of force, except that Kaufmann made use of a stream of beta particles, emitted by radium, and arranged his apparatus so that the magnetic field tended to deflect each corpuscle toward one point, while the electric field, instead of being disposed as to neutralize this effect, was arranged so that it tended to deflect the corpuscle (say) toward the east. The stream of beta particles impinging against a photographic plate in such a way that a small, round, single spot was registered upon it when neither field was active. When the magnetic field alone was excited, the spot would have been merely displaced toward the north if the beta particles had the same speed; but since they had a great variety of speeds, it was drawn out into a straight line, extending in a north-and-
ELECTRON THEORY

south direction. Similarly, the electric field, when acting alone, caused it to be drawn out into a straight line extending in an east-and-west direction. In the actual experiment, with both fields acting at once, the line that was observed was a curve; and from a study of the shape and position of this curve it was found to be impossible to determine, separately, the velocity, $\mathbf{u}$, of the particles impinging upon any given part of it, and the ratio $\frac{e}{m}$ for these same particles. If it is assumed (in accordance with all the other evidence that we have) that $e$ remains invariable, the data thus obtained show the relation between the mass, $m$, of a negative particle and the speed, $\mathbf{u}$, with which the particle is moving.

The relation between speed and mass, as revealed by these experiments, was very marked. For example, at the highest speed observed (which was about 97 per cent. of that of light) the apparent mass of a corpuscle was found to be about three times as great as the mass of the same corpuscle when at rest.

Kaufmann's experiments provide us with means of testing, to a certain extent, theories of the constitution of the negative corpuscle, inasmuch as for every theory concerning the general nature of the corpuscle there will be a corresponding law of variation of mass with speed. This was recognized immediately, and was, in fact, largely what led to the making of the experiments to which we have just referred. A curious fact that has to be reckoned with, in applying tests of this kind to the observational data, is, that every negative-corpuscle theory yet proposed indicates that the mass of a body moving at high speed is a vector quantity—that is, that the mass of the body, as measured in the direction of the motion (i.e., the so-called longitudinal mass) is different from the mass of the same body as measured at right angles to the direction of the motion (i.e., different from the so-called transversal mass). It is the transversal mass, as Abraham pointed out in 1902, with which we have to deal in discussing experiments such as Kaufmann's.

If $R$ is the ratio that the speed of a given negative corpuscle bears to the speed of light when the electrical part of the transversal mass of the corpuscle is $m$, and if $m_0$ is the electrical part of the mass of this same corpuscle when it is at rest, then for $m + m_0$ we have the following values for the respective theories of negative-corpuscle structure mentioned above:

\[
\frac{3}{4} - \frac{1 + R^2}{2R} \log \left( \frac{1 + R}{1 - R} \right) - 1 \quad \text{for the Abraham theory;}
\]

\[
\frac{1}{(1 - R)^{1/2}} \quad \text{for the Lorentz theory; and}
\]

\[
\frac{1}{(1 - R)^{1/2}} \quad \text{for the Bucherer-Langevin theory.}
\]

When the several hypotheses as to the constitution of the negative corpuscle are judged by comparing these formulas with Kaufmann's experimental data, it appears (1) that the Lorentz corpuscle, which is the only one of the three that conforms with the theory of activity, does not fit the data at all; and (2) that the experimental evidence agrees quite well with either the Abraham or the Bucherer-Langevin corpuscle.

From experiments of this nature we may obtain a certain amount of information with regard to the proportion of electrical mass to "real mass" in a corpuscle; for the experimental data reveal the law in accordance with which the total mass varies with speed, while the theory of the nature and constitution of the corpuscle yields a formula showing merely how the electrical part of the mass varies. If there is a "real mass" to the corpuscle, we may therefore reasonably hope, by comparing experiment with good theory, definitely to solve this question of the quantitative relation between the two kinds of mass. Kaufmann, soon after his original experiments were made, believed that they indicated that only a fraction of the total mass is electric; but he had not then taken account of the difference (noted above) between longitudinal and transversal mass. Later, when due allowance was made for this difference, he came to the conclusion that most and perhaps all of the mass is electric, and there is a growing tendency among physicists not only to accept this view with regard to negative corpuscles, but also to generalize it broadly, and to assume (at least tentatively) that mass, wherever it is found, is exclusively electrical in nature, and due to the motion, within the atoms of bodies, of electrified corpuscles moving with great speeds. This conception is as fascinating as it is revolutionary. Many of its advocates, however, overlook the fact that even if this should prove to be the case, we have "explained" mass only by shifting it to the ether, which, at the same time, we should apparently have to conceive as a medium far denser than anything we know of, in the visible and tangible world of direct experience.

Before attempting to estimate the size of a negative corpuscle, it is necessary clearly to understand what we have no way, as yet, to determine the dimensions of corpuscles, if we assume that the mass that they possess is only partially electrical and that the rest of it is mass in the usual or non-electrical sense. If, however, we assume that the mass is wholly of electrical origin, we can easily obtain an estimate of the size of the corpuscle. The value that we obtain will depend in some measure upon the views that we hold with regard to the shape of the corpuscle; but if, for present purposes, we consider it to be spherical, the estimate of size obtained will probably be of the right general order of magnitude, even if the spherical shape ultimately proves to be untenable, so far as concerns the relation of the negative corpuscle to phenomena in general.

To obtain the desired estimate of size (in conformity with the assumptions here outlined) we may make use of the expression given by J. J. Thomson, and already quoted above, for the electrical mass of a slowly-moving electrified sphere. Thus if $m$ is the mass of the (stationary or slowly-moving) corpuscle in grammes, $r$ its radius in centimeters and $e$ its charge in absolute electromagnetic units, we have

\[
m = \frac{2}{3} \frac{e^2}{r}, \quad \text{or} \quad r = \frac{2}{3m} \frac{e^2}{e^2} \quad \text{in centimeters.}
\]

Hence, with the values given above for $e$ and $m$, we have

\[
r = \frac{2}{3} \cdot \frac{(1.592 \times 10^{19})^2}{0.901 \times 10^{-19}} \approx 1.875 \times 10^{-4} \quad \text{centimeters.}
\]

In other words if $10,000,000,000,000$ negative
corpuscles were placed in a line and just touching one another, they would make a row about an inch and a half long. (An equal number of oranges, each three inches in diameter and placed in a row in like manner, would reach from the sun to the orbit of Jupiter.) Atoms differ in size, but in a rough and general way it may be said that it would require something like 100,000 negative corpuscles, placed in a straight line and in contact with one another, to reach across the diameter of an atom.

The corpuscular theory has developed marvelously in the last 15 years, and it has been applied, in one form or another, to the explanation of the mechanism of many phenomena, such as radiation, X-rays, radioactivity, and electrical and thermal conduction. It has also been pressed into service to explain chemical affinity and valency and to elucidate the structure of atoms and molecules. It has proved to be a fruitful conception, and some modification of it will no doubt remain with us, and may give rise to new and fruitful theories. It should be recognized, however, that when, in discussing particles so exceedingly small, we apply the general physical and mechanical laws and principles that we have deduced from observation in our grosser world of experience, we are very likely committing a serious error—an error which, though it will no doubt be corrected in the course of time, may be blinding us, meanwhile, to some very large facts. Many of the "laws" that apply to larger masses of matter are probably statistical laws, due to the averaging of millions of separate events that do not individually follow these laws. That the properties of the negative corpuscle are far different from those that we have heretofore assigned to "gross" matter is already sufficiently shown by what we have learned about the mass of such corpuscles. In a general way, however, it may be said that we have made progress enough in the study of the negative corpuscle to have become a real thing to us—or at least a symbol of a real thing; and J. J. Thomson has well said that although the negative corpuscle is a recent discovery, we already know more about it than we do about the atom. See also Electricity; Molecular Theory; Radiation; Radioactivity.

ELECTROOPTICS, a branch of electrical science treating of the relation of electricity to light. See LIGHT.

ELECTROPHORUS. See Electric Machine.

ELECTROPHOTO MICROGRAPHY, the art of photographing by means of the electric light, certain objects magnified by the microscope.

ELECTROPHOTOGRAPHY. See Photography.

ELECTROPLATING, the art of plating or covering solid objects with a coating of metal by electro-deposition. This is the most common method of applying silver or gold plate for ornament, or copper or nickel plate for rendering an article more durable. Given a solution of the salts of a metal, say, for instance, sulphate of copper (the constituents of which are sulphuric acid and copper oxide), in which are immersed a copper plate connected with the positive pole of the electromotive force and a metal plate connected with the negative pole; when an electric current is passed through the solution an action takes place which may be described as follows: First, the salt is decomposed into sulphuric acid and oxide of copper. At the same time a portion of the water of the solution is also decomposed, setting free hydrogen and oxygen. The oxygen of the oxide of copper is drawn to the negative pole, where it unites with a portion of the hydrogen just freed, forming water, and the metallic copper thus set free is deposited uniformly on the negative metal plate. Simultaneously with this action sulphuric acid and oxygen arrive at the positive plate, where the oxygen unites with a particle of the copper plate, forming oxide of copper, with which the sulphuric combines, forming sulphate of copper; the process is continued as long as there is any metal left in the positive plate. For each atom of copper thus dissolved at the positive plate another is set free at the negative plate. Actions analogous to these underlie all electroplating and electrotyping operations. If it is desired to deposit nickel, silver, gold or other metal on the object, salts of these metals instead of copper will be used in the solution or bath, as it is termed.

Silver is the easiest metal to use in plating. one ampere of current depositing 4.02 grams of metal per hour; with the same current copper deposits 1.17 and nickel 1.09 grams per hour. If 10 baths are worked in series of eight hours a day, depositing each 10 pounds of copper, they will require 4,830 amperes of current all the time; and with copper anodes the pressure will be about 16 volts for the 10 baths.

The art of electroplating is extensively practised. The decomposition of the electrolyte, in solution, is usually supplied by continuous-current dynamo machines which are specially designed to give large currents at low electromotive force, rarely exceeding three to five volts. Sufficient electromotive force must be provided to decompose the solution, but the amount of chemical decomposition depends altogether on, and is proportional to, the rate or amperage of the current. If too high electromotive force is employed the plating is uneven and granular. Storage or primary batteries may also be used for this purpose.
and are so used for planting on a small scale. Much care and special knowledge is required to obtain the best results in electroplating. The process is begun by thoroughly cleaning, as by pickling and scouring the article to be plated to remove all trace of oxide or other impurity from its surface. In the case, for instance, of gold, silver or nickel plating the bath or solution employed by some electroplaters consists of 100 parts water, 10 of cyanide of potassium and 1 of the cyanide of gold, silver or nickel, as the case may be. Plates of either of these metals are suspended in the bath as the positive pole, while the article to be plated is suspended in the bath as the negative pole. When the plating has proceeded to the desired depth or thickness the articles are taken out and burnished. Such parts of the article as it may not be desired to plate are covered with grease, oil or wax. When non-metallic articles are to be plated they are first given a coating of wax, over which is laid a film of powdered plumago, upon which is applied the bath.

**ELECTROPLATE.** See **BLOCK SYSTEM.**

**ELECTROPONIAT, a mixture of sulphuric acid, bichromate of potash and water used as the liquid for batteries in which zinc and carbon are the poles. See **BATTERY.**

**ELECTROPYROMETER.** See **PYROMETER.**

**ELECTROSCOPE, an instrument for detecting or determining the presence of electricity upon a conductor, and showing whether it is positive or negative. It has many forms, of which the simplest consists of pith balls hanging from silk threads in a dry, closed glass case. On contacting with an electrified body the piths are excited and swing apart. In the gold leaf electrometer there is a wide-mouthed vial stoppered with a cork, through the centre of which a metal rod passes into the middle of the vial. There is a brass knob at the top of this rod and its lower end is bent or hooked to support a narrow strip of gold foil, which is folded in equal lengths over the hook. When a rubbed glass rod is brought near the brass knob, negative electricity is attracted and positive electricity is repelled to the gold leaves, which diverge by reason of the repulsion of the similar electricity on the leaves. To show the kind of electricity with which the leaves are charged, or with which another body may be charged, a finger is placed on the brass knob while yet the glass rod is near it. This allows the positive electricity to escape. When next the finger and then the rod are removed the negative electricity is dispersed over the gold leaf system and the leaves again diverge. If now, while the leaves are charged with negative electricity, a negatively charged rod be brought near the knob, the leaves tend to diverge still farther. If a positively charged rod is used the negative electricity in the leaves is attracted and the leaves tend to collapse.

Electrosopes of this general type are now used, on account of their great susceptibility to the presence of electricity, to detect and measure the radioactivity of weakly radiating substances like uranium and thorium, advantage being taken of the ionizing properties of such substances by which the particles of gases become carriers of electric charges proportional to the radioactivity of the substances. For this purpose the gold leaf system is placed in metallic connection with the upper plate of a small air condenser, on the lower plate of which is spread a layer of the radioactive material. A source of electromotive force is connected with the lower plate and the movement of the gold leaf is noted. As the rate and extent of this movement vary with the radioactivity of the substance, comparisons can be readily made of different substances or with a standard. See **ELECTROSTATICS; ELECTROMETER.**

**ELECTROSOLTING.** See **ELECTROCHEMICAL INDUSTRIES.**

**ELECTROSTATICS, that branch of electrical science dealing with electricity at rest, or static; opposed to electrodynamics, which deals with electricity as a force, in action. In the period of early research the electrical phenomena produced by friction came to be called static electricity, and it has been convenient to retain the nomenclature although it is recognized that all divisional names of electricity are arbitrary, for in all of them we deal with the same unknown thing whose phenomena we observe largely through its high vibrations. The terms free electricity and atmospheric electricity (q.v.) were formerly much used to describe the electricity which we recognize as resident in the air and clouds above us; but to-day the term static electricity is the one most commonly employed to describe that drawn from the atmosphere on a kite-string; or that which accumulates in a pile of printing paper which has been subjected to some frictional contact that causes the sheets to adhere to each other; or to electrification in a driving belt caused by some accidental rubbing in the course of its travel.

The first discoveries regarding electricity were regarding its static qualities. In the handling of amber, which is a fossilized vegetable resin, it was found to display peculiar phenomena when rubbed, attracting light particles of matter. This phenomena came to be called electric, after Greek elektron, the name for amber. Later glass was found to display similar yet opposite phenomena on being rubbed, and there arose the terms "vitreous electricity, for the sort produced by rubbing glass or amber respectively, and which have since been identified as simply positive and negative electricity. It was also learned that there is always a balance maintained between positive and negative electricity, and that the development of a given amount of one means an equivalent amount of the other. For a fuller description of the development of knowledge regarding frictional electricity which we now call static electricity, see the article on **ELECTRIC MACHINE.**

An understanding of induction is essential to an appreciation of static electricity. Static induction is the production of an electrical charge upon one body by another body that is statically charged. It might be termed electrical influence.

\[

\end{array}
\]

If the circle \(a\) becomes charged by friction, so that it is positively and electrostatically
charged, as indicated by the sign +, then on being brought near to another body b, the near end of b will become negatively charged, as indicated by the minus sign —, and the far end positively +. By touching b with the finger the electricity may be drawn off, or "earthed" or "grounded," passing through the body of the toucher to the earth if he is not insulated. The electrophorus is the simplest device for illustrating this principle and is described under "Electric Machine." But it should be understood that the current producible by a static electric machine does not differ from that of a battery or a dynamo, except that it is naturally and usually much less in quantity, being a primitive form of apparatus. From these early experiments it was demonstrated that every body positively charged repelled another body of positive charge; and any negatively charged body repelled another negatively charged body, while attracting a positively charged body. It was soon apparent, however, that the forces of attraction and repulsion varied greatly when the bodies were exposed in some other medium than the ordinary atmospheric air. The word di-electric was coined to express the material medium, which a body was found to be in, when located, and the term has been extended by common consent to mean any non-conductor, as glass or mica. A static machine was sometimes termed a dielectric machine, and the transmitting of electric forces by induction instead of conducting was dielectric; while the power of a dielectric to resist stress caused by induction across it, as measured by difference of potential necessary to break through in a violent disruptive discharge, was denominated dielectric strength.

Referring again to the positively charged circle a, let it represent a sphere. The electric charges it has been determined by various experiments are on the outside surface of the sphere and not inside. This is apparent in the case of a cylinder or a sphere, for it is obvious that which something may be passed; and also in the transferring of a charge on a globe by enclosing it with larger hemispheres. If an electroscope be covered by a wire cage and insulated but a charge may be brought near or electrically communicating with any distant hance of the sensitive mechanism of the instrument. The surface being the thing affected, it becomes apparent that if one wishes to increase the capacity of a conductor, as a trolley-wire, the simple way is to increase its surface, as by making it twice as thick. Capacity may also be increased by filling the space through which the lines of force tend to pass with some dielectric other than air, as with petroleum, mica or glass. Large quantities of mica are so used in electric machinery.

To measure the force of electricity obtained in primitive electric experiments a delicate instrument was necessary, and Coulomb invented the torsion balance, using a needle suspended at the centre of its gravity by a very fine wire or silk thread, etc. A minute electrical force of repulsion allowed to operate against one end of the needle so as to twist the thread was therefore measurable as a mechanical force. This principle is used in the torsion electrometer and various other instruments, with a torsion balance, Coulomb demonstrated that the transfer of statical electricity by induction involved an expenditure of force, the force varying inversely as the square of the distance of the centre of the bodies affected. See "Electric Machine." "Static Electric Induction Machines" and "Electrotherapeutics," where various static machines are described and illustrated.

**Electrotaxis.** See "Electrocultivation of Plants."

**Electrotherapeutics,** or the treatment of disease by electricity, began to be a science with the work of Duchenne of Boulogne. Working chiefly with a faradic current he determined the motor points of the various muscles or the places upon the skin where the application of the current produces contraction of the individual muscles. And for a long time the testing and treatment of paralysed muscles was the principal function of the electrotherapeutist. The burning and sometimes fatal effect of lightning had always been known and our countryman Benjamin Franklin had charged a Leyden jar with electricity collected from the clouds during a thunder storm. Franklin, after whom static electricity is denominated Franklinism, was the first to experiment with the shocks and muscular contractions produced by static electricity.

One of the types of electricity employed in electrotherapeutics and electrodiagnosis is Galvanic or Voltaic electricity or the constant direct current. This is obtained from a voltaic battery or from a storage battery, or from the direct current electric light circuit (suitably controlled) or from the alternating current electric light circuit employed to actuate a motor generator of direct current.

For various purposes the strength of the current may be regulated in the case of a battery by selecting the proper number of cells, and in the case of the other sources of voltaic currents by rheostats or variable resistances placed in the path of the current at the ends through which which may be passed; and also in the transferring of a charge on a globe by enclosing it with larger hemispheres. If an electroscope be covered by a wire cage and insulated but a charge may be brought near or electrically communicating with any distant hance of the sensitive mechanism of the instrument. The surface being the thing affected, it becomes apparent that if one wishes to increase the capacity of a conductor, as a trolley-wire, the simple way is to increase its surface, as by making it twice as thick. Large quantities of mica are so used in electric machinery.
is essential for turning the current on or off. A pole changer alters the polarity of the electrodes by changing the connections at the control table by simply turning a switch. A pole detector is a necessary apparatus and a convenient one contains a colorless liquid which changes to red at the negative terminal.

**Effects of the Galvanic Current.** — One important effect is muscular contraction. This does not occur during the uniform passage of the current, but at the moment of any great variation in the strength of the current, as when a strong current is suddenly turned on or off. If the current were gradually increased from zero to the same maximum, no muscular contraction would result. In electrodiagnosis one electrode is called the indifferent one and is placed at some place remote from the region of the motor neuron itself. It occurs in poliomyelitis, labioglossopharyngeal paralysis, and paralysis accompanied by lesions of the motor roots or of the motor nerves. In its complete form there is (1) abolition of faradic excitability of the nerve; (2) abolition of the faradic excitability of the muscle; (3) hyper or hypoexcitability of the muscle with or without inversion of the normal formula, Ca C C > C C; (normally cathode closure of the anode, positive, closure contraction) but the muscular contraction is slow instead of the normal sharp jerk. The presence of the reaction of degeneration shows what nerves are affected and to what extent; and the return to a normal reaction indicates progress toward recovery of voluntary muscular power.

The auditory reactions to the application of electricity form a very delicate and important means of the diagnosis of lesions in the labyrinth of the ear. For example, one of the normal reactions is obtained when an electrode is placed in front of the tragus of each ear and a galvanic current is applied. The patient feels dizzy and the outside world seems to be moving toward the cathode and the head is inclined toward the anode. He may see sparks before the eyes and hear a noise in the ears, and if the current is quite strong there is nystagmus or oscillation of the eyeballs.

A sensation of taste accompanies any application inside the mouth and often applications to other parts of the face.

The heating effect of electricity is well known but suitable galvanic currents are so weak that the sensation of warmth or even the reddening of the skin in contact with the electrode is usually due to electrolysis and not to the frictional resistance to the passage of the current. Very heavy galvanic currents of over 100 milliamperes, applied inside the uterus in the Apostoli treatment for fibroid tumors, did produce a great deal of heat effects similar to those produced by radiotherapy (X-ray and radium) is now more usual.

**Galvano-cautery.** — **Instruments** which are connected with both poles of the battery so that no current passes through the patient, are arranged so that a certain part becomes red hot owing to the passage of a heavy current through a thin metal strip in the same way that the filament in an electric light bulb is heated by the passage of current. Only the portion which is to be applied to the diseased surface becomes appreciably hot because the conducting wires are larger and capable of transmitting the current with less resistance. Familiar examples of galvano-cauterization are in the treatment of growths in the nose and larynx.

Electrolysis is an effect of the passage of a constant current through an electrolyte such as the human body. A chemical compound such as water is separated into its elements such as hydrogen and oxygen, and in the case of the human body an accumulation of sodium hydrate and a liberation of oxygen take place at
the negative electrode and an accumulation of hydrochloric acid and a liberation of oxygen at the point of contact with the positive electrode. If the negative electrode is a fine needle thrust into a hair follicle, a current of about four milliamperes causes a liquefaction of the tissues and loosening of the hair, the root of which may be permanently killed. A needle connected with the positive pole of the battery would stick fast and could not be withdrawn until a negative current had been turned on for a short time to loosen it by liquefying the tissue around it. The anodal needle has a coagulating effect. Electrolysis is employed also for the destruction of warts, birth-marks and keloids, in the treatment of strictures of the urethra and oesophagus and such lesions as anthrax.

For most of these cases the "indifferent" electrode is a sponge electrode held in the patient's hand; but for a more extensive destruction of tissue, needles connected with each pole of the generator are used and the needles are near enough together for all the intervening tissue to be destroyed. Rhytophysma, a bulbous swelling of the nose, is removed in this way.

Iontophoresis, including Cataphoresis and Anaphoresis.—A galvanic current tends to separate the electrode itself or the solution with which it is moistened into ions and to carry these into the tissues, iontophoresis. Metals and alkalis are carried toward the negative electrode or cathode and the introduction of these ions by an electric current is called cataphoresis. For example the positive electrode may be moistened with a solution of a cocaine salt and the cocaine will penetrate the tissues; they leave the anode and pass toward the cathode but their anesthetic effect is upon the tissues into which they first penetrate.

Some of those who have experimented most with iontophoresis assert that it is a more reliable way of administering many drugs, than giving them either by the stomach or hypodermically. Two rabbits were experimented upon by Leduc, as in Fig. 2. Rabbit A died with symptoms of strychnine and rabbit B of cyanide poisoning. Two other rabbits were subjected to the same experiment except that the direction of the current was reversed so that the strychnine ions did not tend to enter rabbit A, nor the cyanions the rabbit B, and neither was poisoned.

Another example of cataphoresis is electric ionization of the root canals of devitalized teeth. The positive active electrode may be a zinc needle moistened with a solution of a zinc salt. The method is employed to remove infection from the root canal and the area of the jawbone below. Very extensive destruction of cancerous tissue is accomplished by the introduction of metallic ions from large zinc needles amalgamated with mercury and connected with the positive pole while the patient lies upon the large indifferent negative electrode.

Anaphoresis or the introduction of acid radicals which the current carries toward the anode, is illustrated by the introduction of salicylic ions from a cathode wet with a solution of sodium salicylate, in rheumatism and neuralgia.

The old theory about the use of electricity in paralysis was that the involuntary contractions produced by the abrupt makes and breaks of the galvanic current and especially as we shall see later by the faradic current, tended to maintain the nutrition of the paralysed muscles until regeneration of the nerve took place. Certainly the patient and friends could see that something was happening during the application. It is doubtful whether the contractions accomplish this and in some cases of paralysis it is thought that permanent shortening of some muscles, difficult or impossible to overcome by manipulation, may be aggravated by electrical treatment of a nature to produce marked muscular movements. The passage of the galvanic current also has a tendency to maintain the nutrition of the muscles and to aid in the regeneration of the nerves. And by means of the apparatus in Fig. 3, a galvanic current sufficiently strong to produce the maximum benefit may be applied without the disadvantage of electrolysis and possible skin irritation at the electrodes and especially without any noticeable muscular contractions.

This current is a slow sinusoidal current or a rhythmically varied galvanic current increasing from zero to a certain maximum, 18 or 20 milliamperes in one direction; then gradually decreasing to zero; then changing polarity and gradually increasing to 18 or 20 milliamperes; then gradually decreasing to zero where the polarity again changes. About 25 such cycles occur each minute under the influence of a variable rheostat and pole changer actuated by an electric motor. This type of current is useful in paralysis from poliomyelitis and asphyxia and also as a general tonic in brain conditions and also in cases with vertigo from affections of the cerebral or cerebellar circulation.

Another effect of the galvanic current is to stimulate the secretion of glands. Another is to promote the return of sensation in paralysis of a sensory nerve. By its sclerotic effect it aids in the treatment of pleuritic adhesions and of ankylosis or joints stiffened by some previous inflammatory condition. Galvanic electricity has a sedative or calming action in many general disorders and this effect is often best produced by hydroelectric baths. Its analgesic effect makes it valuable in the treatment of neuritis and neuralgia.

Faradic electricity is made up of alternating currents induced in a coil with a few turns of insulated wire surrounding a coil with few turns of wire through which passes a current rapidly made and broken by a vibrating interrupter. The faradic current is of very small electrical quantity as measured by its heating effect. A couple of dry cells supply the current for a portable faradic coil but for an office equipment the electric light circuit suitably controlled is best because it does not re-
quire renewal and affords also power for the galvanic, galvanofaradic and sinusoidal currents. It produces marked muscular contraction of a tetanic type continuous during the entire time the current is applied, not merely at the beginning and end as with a galvanic current.

Two electrodes are necessary for applying the faradic current; one of which may be at an indifferent place. And in contrast with the galvanic current there is usually no difference in the effect of the two electrodes, practically the Bergonié method is used for the treatment of obesity by producing marked muscular contractions without any effort on the part of the patient. Straps or weights prevent excessive movement of the patient's limbs. As a sensory stimulant it is used in sensory paralysis. It stimulates the secretion of glands. It is revulsive or counterirritant in the later stages of inflammatory processes. Lumbar may be treated by applying faradic electricity with a dry wire brush electrode. It is excitatory and tonic as a hydroelectric bath, in such diseases as gout, diabetes, obesity, neurasthenia, convalescence from a long illness, and muscular atrophies. And the same baths are useful in combating various toxæmias. It may be used as a sedative.

The same conducting cords and electrodes may transmit to the patient a combination of faradic and galvanic current, in series; the De Watteville or galvano-faradic current.

Galvano-faradic or De Watteville currents are applied by connecting a faradic and a galvanic apparatus in series with a conducting cord leading from one pole of each to the different parts of the patient. One example of its use is in the treatment of spasmatic constipation. Large electrodes are over the abdomen and back; the faradic coil has many turns and the interruptions are rapid, producing very slight muscular contractions; and the galvanic current is quite a strong one, perhaps 30 milliamperes.

Sinusoidal currents are so called because the graphic curve in which forward motion represents time and up and down motion represents strength and direction of the current makes a sine wave. In effect it is an alternating current varying gradually as described in one of the paragraphs on galvanic electricity, but these gradual alternations may be of any desired number up to 1,800 per minute. The alternating electric light current is a sinusoidal current of 1,800 cycles per minute and controlled by a suitable rheostat it can be used for treatment. The apparatus previously referred to and shown in Fig. 2 is used for changing the direct to a sinusoidal current of from 12 to 120 alternations per minute. It is useful as a local and general tonic application in a wide range of chronic general and local disease characterized by debility, congestion, motor atony and pain. It is applied from the same kind of electrodes as the galvanic current.

Static Electricity.—Lightning is an example of a discharge of static electricity and so is the spark which we produce by shuffling our feet on the woolen carpet as we cross the room in winter and then touch another person or a metallic object. A charge of static electricity upon a hard rubber comb rubbed over our hair or over wool or fur causes the comb to attract small light objects to it. By suitable means any object may be given either a positive or a negative static charge. Similar charges repel each other and unlike charges attract, and if the charged bodies are light and freely moveable, they will come together in the latter case and the two charges be neutralized with an accompanying discharge which would be a loud spark between two large metal balls, or a silent and almost invisible brush discharge between two sharp metal points. Static electricity is of small quantity but of
such high voltage that it tends to escape from a charged body; in fact no body can be charged at all unless it is more or less insulated. Condensers are sheets of metal separated from contact with each other by sheets of glass or other other insulating material. One metal sheet is charged from one pole of a static machine and the other is charged from the other pole. Owing to the great attraction which charges of the two opposite polarities have for each other, even in such close proximity each will receive a much greater charge than it could contain separately. And if both are disconnected from the source of electricity the two opposite charges are actually self retaining, so that either can be touched by a conductor without losing its charge; but if a person touches both of the metal coatings at one time he receives a loud spark. Leyden jars with a dozen or more square inches of condensing surface are charged with a very small quantity of high tension electricity from a static machine and their discharge is used effectively by the name of the static induced current. A single electrode passes to the patient from the outer coating of a Leyden jar whose inner coating is connected with one pole of the static machine. The outer coating of the Leyden jar at the other pole is grounded (has a metallic connection with the earth). The patient need not be insulated. The distance between the discharging rods determines the voltage and consequently the degree of effect upon the patient. A wide separation of the discharging rods makes the static induced current suitable only for the application of sparks which are powerfully stimulating to both striated and smooth muscles and to all other tissues.

Condensers having a great many square inches of condensing surface interleaved like a book may be charged from the two poles of a galvanic battery. They receive a very large charge at a low voltage; and when they are discharged through the human body they produce marked muscular contraction. Since the capacity of the condenser and the voltage to which it is charged can be regulated, these low tension condenser discharges form a very exact means of electrodiagnosis. They may be used for the treatment of paralysis, and for some of the same purposes as the static induced current.

The modern static machine, also called an influence machine, has its initial charge produced by friction upon a revolving glass plate. This is communicated to other glass or mica or fibre plates arranged in such a manner that as they revolve the mutual attractions of positive and negative static charges separated by insulating disks, result in the accumulation of very strong charges at the two poles of the machine. Static insulation or the static bath is applied by connecting one pole of the machine with an insulated platform upon which the patient is seated. A static breeze is a silent, almost invisible discharge from a metal crown with sharp points connected with one pole of the machine, suspended within 6 or 12 inches of the patient. The effect is increased if at the same time the patient is insulated and receiving a static bath from the other pole of the machine. Static sparks are applied by bringing near any part of the patient, either clothed or not, a metal ball having an insulating handle and connected by a flexible conductor with one pole of the machine. Here, again, the effect is intensified if the patient is insulated and receiving a static bath from the other pole.

The static induced spark is described in another section.

The Morton wave current is a bipolar application from the two poles of the machine by two wet electrodes, which make a very perfect contact with the patient to avoid any spark effect. The patient had better be upon an insulated platform. The discharged rods of the machine are only a fraction of an inch apart. The greater their distance, the more powerful and even intolerable the effect becomes.

Every possible connection with and without Leyden jars has been used in treatment. They all have distinctive names but the arrangements described are the most important.

Effects of Static Electricity.—A single spark produces a muscular contraction and a sensation of local shock which is not very disagreeable. It is used in the treatment of the central nervous system. When the shock is felt by touching the patient with the insulated metal ball and quickly withdrawing it; somewhat the motion of cracking a whip. A dozen separate loud sparks applied along the spine are easily received by the most sensitive patient. But it is a very different matter when the ball electrode is held near the skin and a steady stream of sparks is applied at one place. That is intolerable. Static sparks are used as a general tonic in debilitated states and as a counterirritant for removing any old inflammatory products. They are not suitable for electrodiagnosis or for the treatment of paralysis. The static bath is a general tonic in debilitated states including convalescence from illness or operation and exhaustion from the care and anxiety attendant upon the illness of some dear one. It is excellent in neurasthenia and in insomnia. It is frequently combined with the static head breeze, and, except for insomnia, with the application of sparks along the spine. The static induced current has effects similar to those of the wave current but less useful.

Morton's wave current produces a succession of muscular contractions which should be slight. It is of value in relieving hyperemia and swelling and pain, and is used in the treatment of a great many chronic conditions in which these are prominent symptoms.

High Frequency Currents.—When a condenser is discharged by touching its two metal surfaces, the result is not an immediate change to an uncharged condition in each metal surface. Taking the surface that was positively charged we find that its charge drops not only to zero but to a certain distance on the negative side then back to zero and a certain lesser distance in a positive direction and so through thousands of times a small fraction of a second it comes to rest at zero. The oscillations are analogous to the vibrations of a piano wire after being pulled out of a straight line and released. The static induced current is the simplest example of a high frequency current but the discovery of the D'Arsonval current and of the resonator current has lately added a method of wonderful value.

The D'Arsonval current may be obtained from an induction coil, static machine or transformer, capable of producing sparks four to
eight or more inches long. The two poles are connected with the inner coatings of two Leyden jars whose outer coatings are connected with the extremities of a solenoid or cylindrical spiral of fine wire about 1/4 inch apart. Conducting cords lead to the patient from each of the extremities of the solenoid or from any two turns of it. The apparatus but not its connection with the patient is similar to that shown in Fig. 4.

The inner coatings of the two Leyden jars are oppositely charged and are connected with the terminals of a spark gap of adjustable length or preferably, an adjustable number of short spark gaps in series. With each impulse from the induction coil, the Leyden jars are charged to such an extent that a discharge of their inner coats occurs through the spark gap. This releases the opposite charges in the outer coatings of the two Leyden jars and their high frequency discharge passes partly through the solenoid and partly through the part of the body passed by the patient's body.

One would suppose that with each discharge of the Leyden jars the current would almost all pass through the solenoid which is a relatively short length of thin wire whose resistance measured in ohms is trifling compared with that of the human body. However, a counter-electromotive force generated in a coil of wire at the making of the current which adds a great inductive resistance to the passage of the current and increases enormously the percentage of the current which will pass through any other path open to it. The current passing through the patient may be measured by a hot wire milliamperemeter and may be all the way from 50 to 1,000 or more milliamperes. It is also a current of much higher voltage than the galvanic and the fact that it does not cause muscular contraction or a shock of any kind is due to its very rapid oscillations, a million or more per second. The motor nerves respond actively to alternations of 20 to 2,000 or 3,000 per second but are inert in the presence of much higher than 5,000 oscillations per second. The oscillatory character of the current prevents the electrolysis which would render a constant current of 1,000 milliamperes intolerable. One principal effect of the passage of the D'Arsonval current through the tissues is the production of heat in the tissues themselves by ohmic resistance of the same nature as the production of heat by a current passing through a galvano-cautery wire or through the filament of an electric light bulb. Whether all of the other effects are due to this generation of heat or whether some are due to direct stimulation of the tissue cells, is uncertain but the effects themselves are of the greatest value in therapeutics. D'Arsonval high frequency current of moderate milliamperage may be applied by two wet electrodes or by bare metal electrodes; or by one glass electrode and a glass vacuum bulb or by autocondensation. Diathermy (or less properly called thermopenetration) is simply a D'Arsonval high frequency current of very great milliamperage tending consequently to produce a great deal of heat in the tissues. Two metal electrodes may be applied to a piece of raw meat and after the current has passed through for some time, the meat will be found to be cooked all the way through. The electrodes themselves do not become too warm to be touched by the fingers— are not warm at all until contact is made on the meat. This is the underlying principle of the Deforest Cold Cautery which is suited to all the purposes of a hot metal cautery.

![Fig. 4.—High frequency Autocondensation.](image)

Diathermy may be applied by two wet electrodes, for instance at opposite sides of a joint, for producing a local effect. Or it may be used for producing a constitutional effect by means of Autocondensation. One conducting wire passes to a very large metal surface close to the patient's body but separated from it by a thick sheet of some complete and impenetrable nonconductor. The patient may hold one or more metal terminals from the other pole of the D'Arsonval apparatus or may be in close proximity to a second insulated surface charged from the other pole. During the application currents of high frequency, medium tension and high milliamperage (about 1,000) surge through the patient's body. The application produces very little sensation except a slight warmth and no shock or muscular contraction. The metal terminal must, however, be grasped before the current is turned on and not released during the flow of the current. Otherwise the patient will receive a succession of exceedingly hot sparks.

**High Frequency Resonator Discharges.**—The Oudin resonator shown in Figure 5 is an apparatus for this purpose. The outer coat of one of the two Leyden jars is connected with the end of a wire spiral and the outer coat of the other with some part of the spiral between its two ends. With each discharge of the Leyden jars, a current passes through the turns of the spiral between the two connections and this induces a current passing toward the free end of the spiral and increasing in voltage until from its terminal a long spark or a violet colored effluve may be drawn; or a glass vacuum electrode may be used to affect this high tension high frequency effect. The application is a unipolar one. When the vacuum electrode is held near the surface of the body a shower of sparks passes to the skin and this may be more or less disagreeable. This spark effect is largely avoided by keeping the electrode in contact with the surface. But even then tiny sparks may be seen passing from parts of the bulb not in close contact with the skin. These are not disagreeable. A sensation of
warmth is produced and the entire glass vacuum tube becomes heated in proportion to the strength of the high frequency current. The glass stem where the current enters from the insulated handle and the surface in contact with the patient are hotter than other parts of the electrode. The bulb is filled with a violet and ultraviolet light. The latter is invisible but its presence is easily demonstrated by fluorescence induced in Willemitte. It doubtless is partly concerned in the effect produced upon the tissues.

High frequency currents have little or no tendency to produce muscular contraction and are not used for electrodiagnosis. The spark effect is useful as a general tonic, to stimulate sensory nerves, to cause constriction of blood vessels locally and vasodilatation generally. Sparks applied from a metal point held close to the surface have a counterirritant or a destructive effect depending upon the strength of the current and the length of time sparks are applied to one spot without intermission. D'Arsonval currents, locally, raise the temperature and increase the circulation, increase the activity of glands and are a sedative. Autocondensation increases the production of heat in the body, increases the urinary solids and acts as a sedative. And especially it reduces the blood pressure when that is unnaturally high. The vacuum electrode actuated by the Oudin resonator has the effect of heating the tissues and promoting cellular activity of every kind as well as increasing local circulation. It is a counterirritant when the current is strong or is so regulated as to produce considerable spark effect even with the electrode in contact with the surface. In this case its general effect is stimulating; but with the current adjusted to produce very little spark effect and a great deal of warmth from the vacuum electrode in contact with the skin it has a sedative effect, and tends to reduce unnatural high blood pressure.

Some of the conditions treated by high frequency applications are growths varying from warts to skin cancers; various skin diseases including acne; high blood pressure and arteriosclerosis or hardening of the arteries; rheumatism; gout; neuritis and neuralgia; angina pectoris; hemorroids.

Sinclair Tousey, M.D.
New York City.

ELECTRONIC STATE, a term invented by Faraday (q.v.) to designate the total magnetic flux due to a conductor conveying a current, which linked with any secondary circuit in the field or even with itself. In one experimental all-magnetic flux he proved that electromotive forces were set up in conductors by the induction of other currents in the field; were caused by the cutting lines of the secondary circuit. See ELECTRICITY.

ELECTROTHERMAL PROCESS, the term applied to electrometallurgical operations in which electricity is employed solely as a heating agent, to distinguish them from electrolytic processes. In special electrothermal processes, as the manufacture of calcium carbide, the mixture of substances is raised by the electric current to the temperature at which the chemical reaction desired will take place. In other electrothermal processes the heat is applied to produce molecular or physical changes, as in the manufacture of graphite from gas-carbon or coke. The continuous current only can be used in electrolytic work, whereas an alternating current is also available in electrothermic work. See ELECTROMETALLURGY.

ELECTROTROPISM. The sensitiveness of plants to cultivation by electricity. See ELECTROCULTURE OF PLANTS.

ELECTROTINT, a method of tracing drawings, etc., for printing, by the action of electricity on a copper plate. The design is drawn in some varnish not affected by acid and placed in an electro-bath, the lines being thus brought out in relief.

ELECTROTYPE, a metallic copy, made by electro-deposition, a form of type, a 'cut,' engraving, etc., and manufactured into proper shape for printing. Wax is heated in a kettle, poured out on a molding-case and placed in a press to receive a reverse impression of the form, engraving, etc. The mold is covered with plumbago to give it a conducting surface to which the metal will adhere. The negative pole of a battery is attached to the mold and the positive to a piece of copper (or occasionally nickel or iron) and both are placed in a bath of sulphate of copper in solution. The copper is deposited on the face of the mold in a thin film, which increases in thickness as the process continues. The shell having attained the thickness of a stout sheet of paper the mold is removed from the bath the shell detached and strengthened by a backing of electrotype metal, this being a composition of lead, tin and perhaps a little antimony. The electrotype shell being washed is laid face down
on a metal surface and a sheet of tin foil melted on to the back, after which the backing metal is poured on in a molten condition. After drying, the electrotype plate goes to a planer, shaver, trimmer, etc., until reduced to the proper form for printing. Later it is remounted on a base of wood or metal to bring it to the same height as type, that it may be printed in a form with type; or if the plate is curved in a bending machine for rotary printing. For details of the electric bath employed, see Electrochemistry. When the copper electrotype is faced with nickel it is sometimes called nickel-type, or if with iron, steeltype. The electrotype plate has almost wholly superseded the stereotype for book and miscellaneous printing, though the stereotype is retained for rotary newspaper printing.

ELECTRUM, a substance mentioned by Greek and Latin writers, with regard to the nature of which there has been much discussion. The term was used with different meanings; it originally meant gold, and was then applied specially to native gold, containing quantities of silver, copper and other metals. The term 'electrum' of this native alloy was transferred to the artificial alloy of gold and silver, afterward made, and was also applied to amber on account of its color and inferior lustre. The natural alloy occurring in placer County, Cal., and Humboldt and Nye counties, Nev., contains about 40 per cent of silver. It is the principal mineral in the ore at National, Humboldt County, Nev.

ELEGY, properly, a poem of mourning. The Greeks and Romans, however, employed the term to denote a poem written in elegiac verse, whatever its character. This elegiac verse was the distich, consisting of the hexameter alternating with pentameter. Catullus, Propertius, Tibullus and Ovid were masters of the elegiac style. In modern times the term elegy is usually applied to any serious piece in which a tone of melancholy pervades the sentiments, as in Gray's 'Elegy Written in a Country Churchyard.'

In music, the term is used to denote a sad or suppressed theme.

ELEGY WRITTEN IN A COUNTRY CHURCHYARD, a poem by Thomas Gray, often said to be the most popular piece of verse in the language. It is thought to have begun at Stoke-Poges in 1742, resumed at Cambridge in 1749 and finished at Stoke in June of the next year. Gray at once sent a copy to his friend Horace Walpole, who showed it about. Early in February 1751 the poet received a letter from the editor of a magazine announcing the intention to print it. Gray thereupon through Walpole arranged for its publication by Dodsley on 16 Feb. 1751. Its success was instantaneous. Eleven editions were published in speedy succession, translations were made into Latin and into numerous modern languages, and parodies and imitations flooded the world. Subsequent reprints, especially in books, have been numerous. They found great circulation, and, although it has not escaped the disarray sure to be vented upon what is hackneyed, it has retained an unparalleled hold upon public affection. It would be a rash critic who should attempt to deny classic rank to Gray and his best-known poem.

Three copies exist in Gray's handwriting, and a study of the readings and the suppressed stanzas, as well as of the poet's borrowings from himself and others, is a valuable exercise for the student of poetic style. Owing to the almost flawless felicity of the diction and to the admirable fitness of the pentameter quatrains to the purposes for which it was used, there are but few of the 32 stanzas that do not yield some memorable phrase or line, many of which have become stock quotations, such as "The short and simple annals of the poor," and "Far from the madding crowd's ignoble strife." As has been intimated, the 'Elegy' through its own popularity due to its own excellence, has contributed to its own decline in favor among those exiguous persons who feel that it is an offense against taste to praise what the masses like. A moment's thought, however, should convince even the most fastidious that the masses are right. The 'Elegy' is not profound, or subtle, or exceptionally imaginative, or full of ravishing surprises in phrase and cadence. Had it been it would have failed of its purpose to express with consummate dignity the thoughts and feelings common to humanity in the presence of death and its monuments. The 'Elegy' is popular because the honest critic will confess that he could not improve it if he would and because the average reader has never thought it needed improvement. It is about as perfect a poem of pensive melancholy as the world can show, and if all its predecessors and successors in the so-called churchyard poetry were lost and it alone preserved it would suffice to warrant all the pertinent reflections and emotions connected with "the great leveler." Consult editions of Gray's poems by Gosse, Rolfe, Bradshaw, Phelps, etc.

WILLIAM P. TRENTH.

ELEMENT, in chemistry, a primary substance that cannot be decomposed as may be done with compound substances. The different substances now admitted by chemists to be elements, together with those which are tentatively assumed to be so, until further evidence is accumulated, number (1918) 82. They are aluminum, antimony, argon, arsenic, beryllium, boron, bromine, cadmium, cesium, calcium, carbon, cerium, chlorine, chromium, cobalt, copper, dysprosium, erbium, europium, fluorine, gadolinium, gallium, germanium, gold, helium, holmium, hydrogen, indium, iodine, iridium, iron, krypton, lanthanum, lead, lithium, lutetium, magnesium, manganese, mercury, molybdenum, neodymium, neon, nickel, niobium, nitrogen, osmium, oxygen, palladium, phosphorus, platinum, potassium, praseodymium, radium, rhodium, rubidium, ruthenium, samarium, scandium, selenium, silicon, silver, sodium, stron- 
ium, sulphur, tantalum, tellurium, terbium, thallium, thorium, thulium, tin, titanium, tungsten, uranium, vanadium, xenon, ytterbium, yttrium, zinc and zirconium. Whether any of these apparently inorganic and indivisible substances have proved to be in reality compounds cannot be definitely foretold. The most that can be said is that up to the present time no force has been brought to bear on them sufficient to disrupt the atomic attraction which holds each in its individual form. Much speculation has been
indulged in concerning the fundamental structural differences that subsist between the atoms of the different elements, but no universally acceptable explanation has been offered to account for the fact that the thousands of compounds that have been studied are all composed of so small a number of essentially different constituents. The alchemists believed that every apparent "element" can be modified, or "transformed," into every other one, and much labor was expended in the effort to transmute the baser metals into the "nobler" or more valuable ones. We now know that the problem of transmutation, if it is capable of solution at all, is at any rate far more serious than it was believed to be in the early history of chemistry. But there are numerous indications which suggest a relationship among the substances that are now accepted as elements, and it may yet prove to be possible to transform lead into gold, or tin into platinum, after some years; past Sir William Crookes has been a consistent advocate of the theory which teaches that all matter is fundamentally the same, and he has shown that some of the "elements" can be resolved by fractionation into substances which exhibit spectra that differ from one another in a marked manner, any two consecutive members of the series showing close similarity in their spectra, while the extreme members of the series are completely dissimilar. (Consult his lecture before the Berlin Congress of Applied Chemistry, entitled 'Modern Views on Matter,' in Science for 26 June 1903.) The theory of matter which is in favor at the present writing teaches that all atoms are composed of electrons (q.v.), which are all alike, but which are grouped together in various ways, and in various numbers, to form the atoms of the elements. If this view stands the test of further research the possibility of transmuting the elements into one another may not be altogether fanciful. The element radium (q.v.), which appears to possess the singular power of continuously emitting streams of free electrons, occurs in nature in certain varieties of the mineral uraninite. It is notable that the inert gas helium (q.v.) also occurs in this same mineral, though it appears to be present in the free state and never in actual chemical combination. It has been suggested that we are here face to face with a real case of transmutation of elements, the electrons that are emitted by the radium being slowly built up, within the uraninite, into new systems, which are nothing less than atoms of helium. See MOLecULAR THEORY; PERIODIC LAW; RADIATION; RADIUM.

ELEMENTAL SPIRITS, beings who, according to the popular belief of the Middle Ages, presided over the four elements, living in and ruling them. The elemental spirits of fire were called salamanders; those of water, undines; those of the air, sylphs; and those of the earth, gnomes. Paracelsus wrote a treatise upon them, and they play a part in Pope's 'The Rape of the Lock.'

ELEMENTS, Conscious. As is the case with any other process of analysis, the analysis of experience must disclose certain component factors from which more complicated experiences are built, and these are called conscious elements. It is by no means obvious that the psychical fragments which form the elements in the psychology of the present day are not subject to further fragmentation, nor, for the matter of that, that there are any conscious elements which cannot be further fragmented. Furthermore, the subdivision of an experience into its elements does not exhaust its analysis any more than the analysis of a mosaic is exhausted by an enumeration of the constituent bits of stone. Just as the arrangement of the components of the mosaic is the vital part of a mosaic, so the arrangement of the constituent bits of experience is the vital part of a mental state. The tentative character of conscious elements and the inadequacy of a psychology which confines itself to cataloguing them are all but entirely overlooked by perhaps the majority of experimental psychologists.

The general consensus of opinion among psychologists is that the structural elements—the items—out of which experience at any one moment is built are sensations and affections (q.v.), and these alone. In determining what constitutes a single sensation, our knowledge of the physiological processes of the sense-organs often yields us indications which are contradictory to introspection, as in the case of the sensation of a color, which does not show upon introspection the division into separate light and color processes which is indicated by its physiology.

There is not so much agreement as to the nature of the simple psychological functions, or temporal sequences of psychological units. Stout assumes that the simple processes are cognition—i.e., sentience, simple apprehension, and belief and will—i.e., hedonic tone and desire or aversion. Brentano separates ideation or awareness from belief. Wundt regards all experience as a manifestation of the volitional process of impulse, which involves both sensory and affective factors. Consult Brentano, 'Psychologie' (Leipzig 1879); Stout, 'Analytic Psychology' (London 1896); Titchener, 'An Outline of Psychology' (New York 1907); Wundt, 'Grundriss der Psychologie' (Leipzig 1897); id., 'Physiologische Psychologie' (ib. 1902-03).

ELEMI, as commercially used at the present day, an oleo-resin obtained from the Canarium laurina of the Philippine Islands, also known as "Manila elemi." At the market it has the appearance of old honey, due to admixture with extraneous material, but when pure it is colorless, and has a pleasing fragrance. It is a mixture of resin with a volatile oil, the resin being compound, part (61 per cent) amorphous and part (25 per cent) crystalline; the latter known by the specific name, amyris. The amorphous resin dissolves in cold alcohol; the crystalline only in hot alcohol. The hard elemi, most abundant in the West Indies, is obtained from species of Bursera, and is either yellowish or greenish, sometimes opaque and sometimes translucent, has a fatty lustre, is easily pulverized and very fusible. It is heavier than water, in which it is insoluble, although it is readily dissolved in either turpentine or alcohol. The Oriental elemi of ancient times was a African elemi, an extract of Boswellia Frederana or Santiriois bartysenula. The Mauritius variety is obtained from Canarium paniculatum. A large part of the elemi of commerce is produced from trees of different genera of the same family growing in tropical America. Brazilian elemi,
or anime, is the product of *Hymenaea Courbari*. Mexican elemi, now rarely found in commerce, is the product of *Erythrophleum.* It was formerly the base of a highly valued lacquer. Elemi is a regular constituent of spirit varnishes, and the Manila kind is used in plasters and ointments, and in the preparation of certain high grade printing inks. In Eastern commerce, it is also known as " elemi gum," and is used as a principle in a volatile oil obtained by distillation.

**ELEPHANT,** the largest of living land animals, the two species of which constitute the family *Elephantidae,* of the sub-order *Proboscidea.* The better-known species (*Elephas* or *Elephas maximus*) is native to the jungles of India; while the other species (*Elephas* or *Loxodonta africana*) is found in the forests of Africa.

The elephant is a huge, ungainly creature with an enormously heavy body, mounted on four short, columnar legs, the hinder ones bending like knees when he lies down, as he doubles thumps with his fore feet, and often stands on his hind legs; his tail is long and tapered, ending in a bunch of coarse hair; otherwise the wrinkled bluish-gray hide is quite hairless. His head is large, with big pendulous ears, small eyes, and a nose, prolonged into a proboscis or "trunk," which reaches to the ground when he stands erect. The average male elephant is 8 or 10 feet high, and weighs five tons or more. There is a pigmy race of the African elephant, however, found in the Kongo, which is not over seven feet in height. The incisors of his upper jaw are prolonged into tusks, which are, however, less useful to him, as weapons, than is his trunk. This organ enables the animal to pick up things from the ground, and to reach fruits or leaves many feet above his head, and it also conveys water to the mouth. Indeed, so great is the tactile sense of this singularly flexible proboscis that it has been likened to a hand.

It is also its owner's chief weapon of offense and defense; for with it he can catch and crush a man with ease, or hurl aside the tiger. The nasal bones are rudimentary, to give room for the trunk. The powerful muscles of the trunk demand a large surface for their attachment, and accordingly the skull is very large, and yet is protected from being excessively heavy by the presence of large air spaces between the inner and outer tables. The end of the trunk forms a prehensile organ with two flaps in the Indian elephant, one in the African. The tusks are not present in all elephants, and vary much in size. They lack all coating of enamel. The digestive system is typical of that of the herbivorous animals in general, except for the long, narrow form of the stomach, and for a peculiar muscle attached to the gullet, which renders regurgitation of water possible. The female has a single pectoral pair of mammae.

Gestation lasts two years, and the young are suckled for two years more. The age which this huge creature attains is proportionate to its size; for captive specimens have been known to live a hundred years, and scientists believe that, in a wild state, it may live many years longer. True, until, and now again, the days (now) differ from the African in having smaller ears and a longer head with concave forehead and smaller eyes; in this species, also, the hind feet are often five-hoofed, whereas in the African they are never more than four-hoofed, though five digits are always present in both limbs. Though the two species present as to dentition, the special peculiarity in the structure of the molars is common to both. These teeth are of great size, and are formed of vertical plates of dental bone, separately covered with enamel, and welded together by a bony "cement," so that each tooth looks like a number of teeth, cemented together. In both species, also, there are no canine teeth, and no incisors in the lower jaw; while the incisors of the upper jaw are developed into tusks, often weighing 150 to 200 pounds each. These tusks furnish the ivory (q.v.) which is so much esteemed for ornamental purposes. The Indian elephant for thousands of years has been the servant of man. From the earliest ages he has borne the Oriental warrior into battle, has hauled his stores and ammunition, and has even been taught to wield weapons. In peace he has piled logs and huge blocks of stone as unremittingly as a derrick, and has been the main feature in the processions of the native princes. In these last and always splendid ceremonies the elephant's anklets, saddlecloth and trappings are often engraved with gold and jewels; and the prince who sits in the canopied howdah on his back is not more gorgeously attired than his elephant. In this connection, also, the albinos of the elephant are prized far more highly than the ordinary sort; in Siam, indeed, the white elephant is royal and venerated. The catching of these elephants singly, or in herds, is by no means an easy task. In former years they were caught in pitfalls, but this practice has been abandoned, because the creatures were frequently injured. Modern methods are varied. Sometimes male elephants are decoyed by tame females trained for that purpose, until they are in close proximity to the hunters. These entangle their unconscious victim's legs in stout ropes, and when, eventually he finds himself trapped, he fights until exhausted. When, however, herds are hunted, they are driven by an ever narrowing circle of hunters toward the mouth of a strongly built stockade, or "keddah." When, after many days, surrounded and enclosed by their pursuers, they rush into the stockade, the great gate is shut upon them. They are then tamed by a variety of methods, which differ as the stockades do, according to locality. Once caught, the elephant is easily trained, a few months being, usually, sufficient to teach him all he needs to know. Methods of training vary in detail; but, after the first severe lessons, the trainer usually finds gentleness effective. The driver or mahout sits upon the elephant's neck and manages him by words and by the use of a small iron-pointed stick. Once tamed, elephants, except in cases where they become "bad," and have to be shot like mad dogs, often are so gentle that children may be trusted to play with them. Besides the differences between the two species, already noted, the African elephant is not as amenable to domestication and confinement as the Asiatic, and is the chief source of the world's supply of ivory. Indeed, the African elephant generally succumbs to disease and dies in confinement, while the only change noted in the Asiatic under the same circumstances is that the species generally does not breed in captivity. The African elephant is peculiar in that the great tusks, twice
as large as those of the Asiatic species, are present in both male and female, while in the Asiatic species they are found only in the male. Because of the demand for these, the African natives have made war upon the female as well as the male, and this leads naturally to a diminution of the species, as the number of tusks shipped has increased rather than decreased each year. The African elephant is now never used as a beast of burden, though in ancient Egypt he may have been so utilized. Elephants generally live in large herds, each herd led, and apparently governed, by a leader, usually the largest of the party. So far a family resemblance exists between members of the same herd that, in India — where they are classed as 'high caste' and 'low caste' — different herds are easily distinguishable. The African elephants live in mountainous regions, the Asiatic in forests, whence they can issue to play in and drink from the waters in which they find so much enjoyment. Here, too, their trunks are serviceable. They are used to squirt water over the creatures' backs, or to spout it, playfully, at their neighbors. Elephants also use their trunks to gather by means of their trunks. The anecdotes illustrating the docility, affection, sagacity, irritability, capriciousness and revengeful spirit of the elephant are innumerable, and may be found in various well-known books on natural history. The natural enemies of the elephant, besides man, are the tiger and the rhinoceros, and the nasal horn of the latter often proves a more formidable weapon than the trunk and tusks of the elephant, and the sight of even a dead tiger is said to be enough to excite most of the white population of the transport of fury. Consult Anderson, 'The Lion and the Elephant' (London 1873); Hornaday, 'Two Years in the Jungle' (New York 1885); Kipling, J. L., 'Beast and Man in India' (London 1891); Lydekker, 'The Game Animals of Africa' (ib. 1906); Neumann, 'Elephant Hunting in East Equatorial Africa' (ib. 1898); Sanderson, 'Wild Beasts of India' (ib. 1893); Selous, 'A Hunter's Wanderings in Africa' (ib. 1890).

**ELEPHANT MOUND.** See Mound Builders and Mounds.

**ELEPHANT, Order of the,** an ancient Danish order of chivalry. It is said to have been instituted about the end of the 12th century by Canute V1 to perpetuate the memory of a Danish crusader who had killed an elephant in the Holy Land. It was renewed by Christian I in 1462, and placed on its present footing in 1693 by Christian V. It is the highest of the Danish orders. The number of members, not counting those of the royal family, is restricted to 30. Foreign sovereigns are exempted from these restrictions. The fête of the order is held on 1 January, when the knights meet in the chapel of the order in the castle of Fredericksburg, taking rank by seniority upon seats over which are suspended their arms and devices. The insignia of the order are an enameled white elephant, with a negro mahout, bearing on a blue housing, bordered with gold and crossed with white, a sculptured tower. On state occasions the elephant is worn attached to a chain composed of elephants and castles of gold, with a letter D in gold to represent Danio (Denmark). The device of the order is Magni animi pretium.

**ELEPHANT-APPLE,** a large and handsome East-Indian tree (*Feronia elephantum*). It belongs to the orange and citron family, and produces a large gray-colored fruit with a very hard rind.

**ELEPHANT BEETLE,** one of the great cetonine beetles of the genus *Megasoma* of Central and South America; especially *M. elephas*. It reaches a length of three to four inches, and is black, delicately pitted. A related species (*M. therisite*) occurs in California.

**ELEPHANT BUTTE, DAM,** the largest of the government's irrigation projects, located in Sierra County, N. M., in the valley of the Rio Grande, 120 miles above the point where the river strikes the Mexican border. The lake formed by this dam is about 45 miles long and averages 1/4 miles in width, submerging 40,000 acres and storing 2,642,902 acre-feet, or 862,200,000,000 gallons. The water is intended to irrigate 183,000 acres of very fertile land in the States of New Mexico and Texas and 25,000 acres in Mexico. The water stored is sufficient to irrigate all the crops which can be grown on this acreage for two years in case there should be no rainfall. The dam is of cyclopean concrete. It was begun in 1910 and completed in May 1918. The crest is 1,310 feet long and 305 feet above bed-rock at its lowest point, 10 feet below the bed of the river. At its base the dam is 215 feet thick and it tapers to 18 feet at the crest, which carries a permanent roadway. The masonry content of the structure is 695,000 cubic yards, making it the third largest dam in the world (see Dam). In addition to the irrigation feature it is estimated that from 25,000 to 30,000 electric horse power can be delivered at El Paso, besides the many smaller powers which will be developed when the high level canals are in operation.

**ELEPHANT FISH** (*Calorhynchus antarcticus*), a fish of the sub-class Chimeroidae or *Holocephali* (q.v.), found in southern seas, where it is the sole representative of its kind. The name alludes to the prominent projecting appendage of the snout. The young remain until an advanced stage of development within the remarkable seaweed-like horny egg-cases. The fish attains a considerable size and is sometimes eaten in New Zealand.

**ELEPHANT RIVER,** a river of Cape Colony, running into the Atlantic after a course of 140 miles.

**ELEPHANT SEAL,** the largest of the hair seals (*Macrorhinus leoninus*), usually over 20 feet long, with a circumference of 12 feet around the thickest part of the chest. The female is much smaller than the male. In color this seal is grayish; its body is covered with short hair, growing in patches, which gives a spotted look to the animal. The head is proportionately large, with prominent eyes and thick eyebrows; the whiskers are long; and the canine teeth are so large as to form heavy tusks. The nose of the males is prolonged into a proboscis about a foot long, which, seemingly useless, hangs loosely over the face. When this is dilated it gives a new character to the creature's voice. This species has been almost exterminated, owing to the demand for its oil, though less than a century ago it was plentiful in the southern hemisphere. The skin is not valued for its fur and the flesh is not edible.
ELEPHANT-SHREW — ELEPHANTS

The herds migrate southward in summer and northward in winter to avoid the extremes of temperature. The northern elephant seal *M. angustirostris*, is also nearly extinct, being confined to the island of Guadalupe, off Lower California. Consult Moseley, 'Notes by a Naturalist on the Challenger' (London 1869); Townsend, 'The Northern Elephant Seal' (Zoológica, Vol. I, No. 8, New York 1912).

ELEPHANT-SHREW, the typical species *Macroscelides*, of the family *Macroscelididae*, belonging to the order of insect-eating mammals. The body, in general appearance and size, resembles that of the shrew rather than that of the elephant. The popular name alludes to its peculiar, elongated nose, which looks like an elephant's trunk. The hind legs, which are long and out of all proportion to the length of the fore legs, fit the animal for jumping, giving it the additional name of jumping-shrew. This insect-eater is confined to Africa. It moves by jumps, lives on the sandy plains, makes burrows in the sand and finds its prey among the grass and bushes.

ELEPHANTA, él-e-fán'tá, or ELEPHANT ISLE, called by the natives *Gharipur*, a small island in the Bay of Biscay, seven miles northeast of Bombay. It consists of two long hills and an intervening valley. It is celebrated for a cave temple 130 feet long, 123 broad and 18 high, supported by pillars cut out in the rock. Many of these were cut down by the Portuguese. There are 36 columns in six rows and in the centre is a gigantic trunuri or three-formed god — Brahma the creator in the middle, with Vishnu the preserver on one side and Siva the destroyer on the other. There are also other rock-caves. The date of these constructions is not known. A large stone elephant, which once stood near the landing place, gave name to the island. Pop. of the island about 500.

ELEPHANTIASIS, properly speaking, a peculiar and rare disease, sporadic or endemic in warm climates, and characterized by an inordinate thickening of the skin and the underlying tissues, usually limited to a definite area, and subsequent to an impairment of the lymphatic circulation. The disease is of great antiquity and exhibits a great variety of forms, by reason of which it has received a large number of names, medical as well as popular. The term is now applied by the best dermatologists to one disease, and not to several as heretofore. Elephantiasis exists in an endemic form in Africa, India, the Indian Archipelago, the West Indies and South America. The extra-continental possessions of the United States bring this disease in their train. The endemic form of the disease commences rapidly. There is pain, heat, swelling and pain in the affected part. The skin thickens and blood vessels soon become involved and the part affected seems to be attacked by erysipelas. In a few days the acute symptoms may subside. A recurrence of the attack leaves the arm, or leg, or scalp, or face, or genitals somewhat thicker, and the deformities of the affected parts. In the most characteristic cases of the tropical countries the disease seems to be due to a blood parasite, the *Filaria sanguinis hominis*. This worm gets into the blood, at times through the agencies of mosquito bites, and blocks up the lymphatic channels. In other cases the disease is regarded as a form of chronic erysipelas. In a few instances it is congenital. The treatment will depend largely on the type of the disease. Rest in bed, elevation of the limb, quinine for the *Filaria* and prompt medical attendance are the essentials. See *Filaria*; *Parasitism*.

ELEPHANTINE, él-e-fán-tné (Arabic, *Djesret-æz-Zaher*; 'isle of flowers'), a small island in the Nile, opposite Cairo, remarkable for its ruins. The island is almost covered with ruins piled up on each other — Egyptian, Roman, Saracen and Arabic. At the beginning of the present century there were the remains of two temples in Elephantine, and a very interesting one built by Amunoph III. They were destroyed in 1822 by the governor of Assouan in order to obtain stone for building a palace. The greater part of the Nilometer, mentioned by Strabo, which stood at the upper end of the island, was restored in the 19th century. The quay built of blocks taken mostly from older monuments is from Roman times. Many fragments of pottery with inscriptions in Greek have been found, some of these being receipts for taxes.

ELEPHANTINE PAPYRI. Elephantine is a small island in the Upper Nile and the most southern of the old Egyptian fortresses. In the ruins of a small city which was on the southern end of the island Aramaic papyri in considerable quantities have been found. These reveal the fact that soon after the destruction of Jerusalem by Nebuchadnezzar a colony of the Jews found their way to the southern frontier of Egypt. In them is mentioned the house of Yahu which is probably Jehovah. They cover the period extending from 471 B.C. to 411 B.C. and bring much light to bear on Jewish customs and worship of the times of this important document. One contains a petition for the restoration of the house of Yahu which had been destroyed by Egyptian soldiers.

ELEPHANTS, Fossil. The present genus (or genera) of elephant had many now extinct representatives in the Pleistocene. Among these the best known is the hairy mammoth (q.v.) of Siberia and northern North America. The mammoth was smaller than the largest existing elephants, but a similar species, *Elephas columbi*, ranging over the entire United States, equaled the extant species in size. *E. imperator* from the Southwest stood even larger, being 13 feet high at the shoulder. Another Pleistocene elephant was *Mastodon Americanus*. This differed from the true elephants in its lower skull and breast, unlike molar teeth, of which several were in simultaneous use in each side of each jaw. The teeth were covered with enamel, but had no cement on the crowns. Straight traces of tusks remained in the lower jaw of the males. In Pleistocene beds contain beside several species of Mastodon, the genus *Stegodon*, with the molar teeth intermediate in character between those of Elephas and of Mastodon. In the Miocene the interesting genus *Gomphotherium* or *Teira*, *Helodon* is found. The skull of Mastodon, but is much lower and flatter. The mandibular symphysis is prolonged and bears the well-developed tusks. Upper and lower tusks alike are relatively short and banded with enamel. The molars have for the latter forms, three in the earlier ones. The height at the shoulder is less than six feet.
The body and limbs have their present structure.

The next earlier form in the line of ascent was *Palaeomastodon* from the lower Oligocene and upper Eocene of Egypt. The dentition was 

\[ 1 \, \frac{1}{1}, 0 \, \frac{3}{2}, 0 \, \frac{3}{2}, 2 \, \frac{3}{2} \]

Both lower and upper tusks were very short and banded with enamel. All the grinders were in use together. There was probably a snout more or less like that of a pig instead of a well-developed trunk. The lower jaw was longer than the upper. The occipital bones extended nearly to the top of the parietals. There was a third trochanter on the femur. The size varied between that of a small elephant and that of a tapir. There is a considerable gap between *Palaeomastodon* and any known ancestral form, but it appears that *Marshatherium* of the middle Eocene of Egypt is not very far removed from its line of descent. *Marshatherium* has the dental formula

\[ 3, 3 \]

\[ 3, 3, 5, 2 \]

Both first and third upper incisors and the canines are very poorly developed; the second upper and lower incisors form short tusks. The molars are quadrirugular.

The skull is quite unlike that of Palaeomastodon and is long and narrow, with enormous cheek bones. The cranial capacity is relatively large. There appears to have been only a very slight trace of a trunk. The body was essentially like that of the elephants, though less specialized. An aberrant offspring of the proboscidean stock is characterized by the possession of tusks in the lower jaw only. This offspring, containing the genus *Dinotherium*, is quite like typical elephants in its body and limbs. The tusks point downward and are curved to the rear. The molars resemble those of the tapirs. The skull is low and flat and probably bore a trunk (see *Mammoth*; *Mastodon*).

**ELEPHANT'S EAR**, a name frequently given to plants of the genus *Begonia* (q.v.). It is applied more frequently to a plant bearing the name *Caladium esculentum*.

**ELEPHANT'S FOOT**, or HOTTENTOT'S BREAD (*Testudinaria elephantipes*), a plant of the yam family (* Dioscoreaeae*), of which the rootstock forms a large fleshy mass, curiously truncate, or somewhat resembling an elephant's foot, and covered with a soft, corkey, rough and cracked bark, recalling the shell of a tortoise, whence its generic name. From this springs annually a climbing stem, which bears the leaves and flowers, the latter being small and yellow. The starchy rootstock is used as food by the Hottentots. The plant is not infrequent in hothouses. The American plants known as elephant's-foot belong to the genus *Elephantopus* of the *Asteraeae*. The genus comprises 16 species, natives of tropical or warm regions. Four are found in the United States, mostly to the south of Delaware. The best known is the Carolina elephant's-foot (*E. carolinianus*). This is an erect hairy herb, with large, lanceolate leaves and light or purple flowers in branching corymbs. It grows as far north as southern New Jersey and west to Kansas, and is abundant in all the region to the south. Another species is known in the Southern States as tobacco-weed and devil's grandmother.

**ELEUSINE**, *el-ū-sînē*, a genus of grasses comprising six species, all natives of the Old World. The genus is represented in America by *E. indica*, the crab-grass or yard-grass, which is found in waste places all over North America except in the extreme north, naturalized from Asia. In its native places it is an important article of commerce. *E. coroana*, called in the west of India nachtchee, nagla, ragie and mand, forms a principal article of diet among the hill people of the western Ghauts in India. It is cultivated also in Japan. *E. stricta* is also used for food.

**ELEUSINIAN MYSTERIES**, festivals held annually at Eleusis, a town of Attica, in honor of the goddess Demeter, or Ceres, the patroness of agriculture and procreative power of nature. According to some accounts, to Demeter, the festival was established by the goddess to commemorate the hospitality of King Celeus of Eleusis, who received her as a wayfarer. The usual opinion is that they were begun by Eumolpus, the first hierophant, 136 B.C. Great secrecy was observed in the celebration of the festivals, consisting of the greater and lesser mysteries. The greater mysteries were celebrated toward the end of September and the first of October, lasting nine days. The lesser mysteries took place at Agon on the Lissus during springtime. It was a capital offense to reveal any of the rites. They existed about 18 centuries and ceased during the invasion of Alaric, in 396. Consult Pater, Walter, *Greek Studies*; Demeter and Proserpina; Cooper, Jacob, *The Eleusinian Mysteries*. See MYSTERIES.

**ELEUSIS**, *ē-lū'sis*, a ruined village of Attica, but in ancient times a city of Greece, 12 miles from Athens. It was celebrated as the chief seat of worship of Ceres (Greek Demeter), whose temple here was the largest sacred edifice in Greece. The Greek government began here an elaborate series of excavations in the year 1882, with the result that many remarkable ruins have been discovered. Even the site of the ancient temples is a matter of debate, so completely have they vanished. There are not wanting, however, ancient remains, which include two propylaea, a sacred well, an ancient council hall and small temples. The great hall of initiation was a modest structure until after the Persian War when it was greatly enlarged, first by cutting into the rock at the back, and later by constructing another hall alongside the first. A plan was added by Philon in the 4th century B.C., making a common front to both, and during the Roman occupation the interior was made into one great hall 178 feet by 170, with seven rows of columns. A little Albanian village, poor and mean looking, called Leusia, stands on the site of what was once powerful Eleusis. Consult Diehl, *Excursions in Greece*; Philios, *Eleusis, ses mystères, ses ruines, et son musée* (Athens 1896); Frazer, *Pausanias* (2d ed., 1874). For a plan of the excavations consult Baedeker's *Handbuch to Greece* (4th English ed., Leipzig 1900).
ELEUTHERA, ɛ-lə-ˈthɪr-ə, British West Indies, one of the largest of the Bahama Islands, lying east of Nassau, near New Providence, the second most populous island of the group. It is, like most of the islands of the group, long and narrow, its length being about 70 miles and 164 square miles. It exceeds the neighboring isles in fertility, and produces more oranges, onions and pineapples than any. Its chief town is Governor's Harbor with a fort and good harbor. Pop. 6,533.

ELEUTHERA, el-ū-thēr-ə (Gr. Ἐλευθέρα, freedom), was the name of several places in the ancient Greeks a festival commemorative of deliverance from the armies of Xerxes. It was instituted after the battle of Platæa (479 B.C.) and celebrated annually at that place in the month Maimacterion, nearly corresponding to our September. At the dawn of day a procession marched through the town, at the head of which trumpeters blew the signal for battle. At midday a chariot was driven toward the altar crowned with myrtle and various garlands and leading behind it a black bull. In front of the altar the archon of Platæa implored the gods. The bull to Jupiter and Mercury, eulogized the heroes who had fallen at Platæa and sprinkled the ground with wine. Every fifth year these solemnities were attended by contests, chaplets being the reward of the victors. See GREEK FESTIVALS.

ELEVATED RAILWAYS. See RAILWAYS, ELEVATED.

ELEVATION, in the liturgy of the Roman Catholic Church, the act of lifting up by the celebrating priest and presenting to the sight of the faithful the Host and the Chalice immediately after the consecration; this is the elevation by eminence. There is both in the Latin and in the Greek Church liturgies another elevation shortly before the communion. Prior to the promulgation and condemnation of the teaching of Berengarius in the 11th century the elevation after consecration appears to have had no place in the Latin liturgy; but from the beginning of the 12th century, when this custom was introduced, it spread rapidly and became universal and obligatory. It was the Church’s way of confessing her faith in the truth of transubstantiation, attacked by Berengarius. In the 13th century in the 12th century began and in the next century became universal the custom of ringing a small bell at the moment of the elevation, as is the present usage. But the ringing of the great bells in the church steeples and towers at the elevation which was pretty general in the 13th century is now not common.

ELEVATION, in astronomy and geography, means generally the height above the horizon of an object on the sphere, measured by the arc of a vertical circle through it and the zenith. Thus, the elevation of the equator is the arc of a meridian intercepted between the equator and the horizon of the place. The elevation of the pole is the complement of that of the equator and is always equal to the latitude of the place. The elevation of a star or any other point is simply its vertical distance from the plane of the horizon, and is its maximum when the star is on the meridian. In architecture the term is applied to a geometrical delineation of the front or any face of a building in which all the parts are drawn according to the scale and not shown as they would appear in perspective. It is one of the three designs necessary in outlining any work of architecture, the other two being the plan and the section.

ELEVATORS. The modern elevator is a direct evolution from the machine which Elisha G. Otis exhibited in 1853 at the World’s Fair in the Crystal Palace, New York. Hoists of various kinds had been built before that time, but this was the first elevator wherein provision was made for stopping the fall of the car in the contingency of the breaking of the hoisting cables. During the next five years a number of companies were built similar to that exhibited, all being driven from line shafting. In 1859 the same inventor introduced an independent reversible steam-engine directly connected to the hoisting machinery, and from that time the era of the elevator as a separate institution of the age began. In 1871 the hydraulic elevator was introduced, soon to attain predominance in the elevator art and displacing the steam-engine. The year 1888 witnessed the first application of the electric motor to elevator machines, destined in turn to eclipse the hydraulic elevator. The first type of electric elevator machine, still in use to-day for low and moderately high buildings, consisted of an electric motor actuating a hoisting drum through the intermediary of worm gearing. Although this machine has been developed to operate satisfactorily at comparatively high speed, it could not satisfy the requirements imposed on the elevator art with the advent of the skyscraper. Thus in 1903 a new type of electric elevator machine was developed, known as the 1:1 gearless traction machine, which has since completely ousted the hydraulic machine from the field of high-rise, high-speed elevators. Another development in the electric elevator art is the so-called microdrive machine, first introduced in 1915. This machine is capable of accurately and automatically stopping an elevator platform level with the landing under any condition of loading. It is extensively used in all cases where heavy loads have to be wheeled on or off the elevator platform on trucks.

It is quite evident that the high state of development of the electric elevator to-day could not have been accomplished without improvements in the design of electric motors and controlling devices. At the time of the introduction of the electric elevator in 1888 the design of the direct-current motor was already well advanced, while alternating-current motors were yet in their infancy. In the next decade the energy of designers was mostly bent upon the further development of the application of direct current, resulting in 1897 in the introduction of the direct-current magnet controller. With this invention the direct-current electric elevator at once entered the field of high-speed elevator service and became a dangerous competitor of the hydraulic elevator.

The electric power systems at that time were mostly direct current, but began gradually to make place for the more economic two- or three-phase alternating current, and it is with polyphase induction motors that has been introduced and began to be applied to elevators. The first attempts were not very promising. It would seem for a time that the polyphase alternating-current elevator never would be suitable
ELEVATORS

for high speed, owing to the fact that the motor operated only at a fixed single speed and to the inability to design suitable alternating-current magnets. To-day all of these difficulties have been overcome; polyphase induction motors are now easily built for two or more speeds as well as alternating-current magnets of sufficient power to operate controller and brake. In fact, the number of alternating-current installations to-day equals the number of direct-current installations and is doubtless destined to exceed the latter in the near future. Safety appliances were developed hand in hand with the development of the various types of machines. Grips to arrest and stop a falling cage were first designed to operate upon the breaking of the hoisting rope only. These soon proved to be inadequate, since they remained inactive in runaway accidents from various causes not due to the parting of the ropes. This defect was removed with the introduction of centrifugal governors, which actuate the safety grips when the car speed exceeds a predetermined maximum. In 1890 steel began to be used for guide rails, which previously to that date consisted exclusively of wood. This brought about a new type of safeties. Other demands came with the increase in elevator speeds, necessitating the design of safety grips capable of arresting a falling car without shock or injury to the passengers. Other safety appliances gradually developed but which have now become part of the standard equipment are: automatic stop at the terminals of the travel; slack cable devices to prevent further motion of the machine in case the car is obstructed in its descent; door locks to prevent the starting of the cage as long as the door is open, and to prevent the opening of door unless the car is at rest at the landing.

According to the foregoing there are, therefore, four general classes of elevators—belt, steam, hydraulic and electric.

Belt-driven Elevators.—This class of elevator, Fig. 1, is usually installed for slow-speed freight service in factories, is reliable and yet low in cost. The speed seldom exceeds 75 feet per minute. The machine is usually bolted to the ceiling of one of the floors. The middle one of the three flat-faced pulleys shown in the illustration is tight on the shaft and is adapted to actuate the hoisting drum through the intermediary of a worm and worm gear. The two outer pulleys are loose on the shaft and are belted, one by straight belt and the other by crossed belt to a line shaft pulley. To operate the elevator in the one or other direction the straight or crossed belt is shifted onto the tight middle pulley. The machines are provided with brake, slack cable device and automatic stop at terminal landings.

Steam Elevators.—Steam machines for elevator service may be dismissed with the reference that they are no longer in use. This has been due to the very large consumption of power with no compensation for the disadvantage in the matter of ease of control.

Hydraulic Elevators.—The hydraulic elevator installed in large numbers up to about the year 1900 is the so-called vertical hydraulic type (Fig. 2). In this type a cylinder of a diameter of 8 to 24 inches is placed in a vertical position in the elevator shaft or in any other convenient location. Within this cylinder works a piston. The pull exerted thereon by the water pressure is transmitted through the piston rods to a number of sheaves, which in turn operate on the hoisting ropes. The sheaves introduce a gear ratio varying from 2.1 to 12.1 between the car and piston travel. The elevator is controlled by a lever placed in the car, which actuates the operating valve. For the ascent, the valve admits water to act on the piston, at the same time discharging the water underneath. The descent of the car occurs by reason of its unbalanced weight, the water above the piston being allowed to flow through a circulating pipe to the space underneath. About the year 1900 the plunger type of hydraulic elevator (Fig. 3), (before that date applied only to low rises) began to be introduced for high speed passenger service. In this type a cylinder of a length equal to the car travel is set vertically in the ground. In this cylinder works a piston or plunger of the same length, carrying the car on its top. The weight of car and plunger is partially counter-

balanced by a weight attached to the car frame. Although this type of elevator had a larger power per square inch, the pumps delivered the water into a weighted accumulator. The water discharged by the machines is collected in a discharge tank from which again the pumps are supplied.

In addition to the types of hydraulic elevators mentioned above, there are the so-called aero-hydraulic and hydro-steam elevators. The elevator proper may be of any one of the hydraulic types already described, but they differ in respect to the manner in which the hydraulic pressure is obtained. In the aero-hydraulic machine a tank partly filled with water is connected to a supply of air pressure. The elevator ascends by simultaneously admitting air into the tank and water into the cylinder. For the descent, the air is discharged, while the machine returns the water to the tank. In the hydro-steam elevator, steam is employed in place of air. All hydraulic elevators absorb the same amount of power in each cycle of their operation, independently of the live load and cage. The power consumption for this reason, notwithstanding an excellent mechanical efficiency, is quite large. In addition, the speed of the hydraulic elevators varies largely with the load in the car.

Electric Elevators.—These excel the hydraulic elevator by reason of a speed practically independent of the load and by a lower power consumption. They may generally be classed as having machines with winding drums or machines with traction sheaves. Further distinction is made in respect to the type of gearing employed, into worm gear, worm and spur gear, herring-bone gear, gearless or 1:1 and 2:1 gearless machines. Fig. 6 shows a typical worm gear machine with winding drum. The motor in the illustration is of the direct current type, but may be alternating of single or polyphase. The brake is placed between motor and gear housing and is of the shoe type with springs to hold the shoes in frictional contact with the brake pulley. The brake is released only upon the admittance of current to the brake magnet and is applied immediately upon the interruption of the current supply thereto. The hoisting cables lead from the cage to the face of the drum, where they are solidly anchored. At the opposite side of the drum a counterweight is attached, adapted to counterbalance the cage and live load. Frequently also a second counterweight is employed, suspended directly from the cage. The weight of the counterweight where one is used, or their aggregate weight where two are used, is made to exceed the weight of the cage by an amount of from 30 to 50 per cent of the maximum load. On account of this arrangement a relatively small motor can be employed since it will be subject only to from 70 to 50 per cent of the maximum load when lifting the same. When lowering the empty cage the load on the motor corresponds to from 30 to 50 per cent of the maximum load. The worm runs partially submerged in oil (preferably castor oil) and owing to the excellent lubrication the efficiency of worm gearing is higher than usually anticipated. The roping employed in a traction elevator installation is shown diagrammatically in
ELEVATORS

Fig. 7 and will also be evident from Fig. 8. The machine is usually and preferably located overhead. The ropes pass from the car to the traction sheave, thence to an idler or secondary sheave and again over the traction sheave to the counterweight. The tension due to the weights of car and counterweight and the approximately two half wraps of contact between the ropes and traction sheave furnish the necessary adhesion to transmit motion from the traction sheave to the elevator without slip. This adhesion is instantly destroyed if either car or counterweight is obstructed in its descent, in which case motion of the elevator must cease even though the machine keeps on revolving. This property is a most valuable safety feature of the machine with traction sheave. By arranging the car to land on an oil buffer at the lower landing and by similarly obstructing the further descent of the counterweight when the car is at the upper landing, the car travel is absolutely fixed between two limits. Another advantage of the traction machine lies in the fact that the width of the traction sheave is independent of the height of the building. For a given capacity therefore, a standard machine can be provided, irrespective of the elevator travel. In the 1:1 traction machine (Fig. 7) the traction sheave is mounted directly on the motor shaft. As the illustration shows, the construction of the machine is simplicity itself. It consists of an armature with extended shaft, carrying a brake pulley and a traction sheave, all supported on two bearings. At full speed the motor runs at about only 60 revolutions per minute. Reductions in speed are obtained by means of field control and by manipulation of resistance in series and parallel with the armature. Contrary to popular belief motors for such low speeds can be made with as high efficiency as high speed motors, although, of course, the motor frame assumes considerable dimensions. Owing further to the absence of gears, the 1:1 traction machine has the highest efficiency of any elevator machine yet designed. Wherever it has replaced existing hydraulic elevators, the saving in power consumption has paid for the new installation within a few years. The microdrive machine shown in Fig. 8 derives its name from the fine adjustments in the stopping, which can be made with this machine in a manner not unlike the action of a micrometer.

To obtain accurate stops level with the landing it is necessary to slow down the cage to an extremely slow speed. In the microdrive machine this is obtained by having a main machine (which may be of any desired type) for ordinary hoisting purposes and an auxiliary machine for the stop. The main and auxiliary machines may be coupled together by a magnetically operated clutch carried on an extension of the main motor shaft. At the start, the coupling is released leaving the main machine free to hoist the load. Shortly before the stop the current supply to the main motor is interrupted while simultaneously the auxiliary motor is started up and the interior winding applied. The effect of this operation is that the load is now transferred to the auxiliary machine, which drives the drum through its own and the main gear reduction. The cage therefore proceeds to the landing at extremely slow speed controlled by an automatic leveling device. The function of this device is not only to stop the cage flush at the landing, but to maintain the alignment between cage and landing during loading and unloading. If for example a heavy loaded truck is rolled onto the car, the stretch of the hoisting ropes will cause the platform of the truck to level by leaning down as soon as the front wheels of the truck rest on the car floor. This will cause the auxiliary motor immediately to restore the alignment between car and landing before the rear wheels pass onto the platform. The controlling device most in use with electric elevators consists of a lever in the car operating a number of contacts. These in turn energize magnets assembled on a controller panel near the machine. The operator controls only the direction in which the car is to travel, the fast and the slow speed. Operations such as releasing the brake and stepping on the starting resistance occur automatically. In push button controlled elevators, each landing is provided with a button to call the elevator to that landing. The cage is provided with a series of buttons to dispatch the cage to any desired floor. The passenger desiring to use the elevator presses the button placed near the elevator shaft, and the car, if not in use, immediately travels to that floor and stops automatically. When the car has come to rest, the door can be opened. The passenger enters, closes the door and presses a button corresponding to the floor to which he wishes to travel and the car at once proceeds thereto. It will be seen that the push button elevator is entirely automatic in its operation, having the advantage of not requiring an attendant.

Although this type of control was developed many years ago, it has in the past found application only to slow speed residence and apartment-house elevators for the lack of a machine capable of maintaining a reference level with the landing. With the advent of the microdrive machine, however, this type of control is receiving increased attention and it is safe to predict that it is destined to come into general use.

Safety Appliances. While the factor of safety in the standard make of elevators is such that accidents rarely occur and practically never where proper attention is paid to the machinery, still all elevators (except plunger elevators) are equipped with safety grips. Of the very large variety of safety grips, only those types which have found extensive application will here be described. With wood guides the type of safety generally used consists of an arrangement of planer teeth forced into the guides and producing resistance by planing or grooving the wood as the car descends. Figs. 9 and 10 show one form of this type of safety. With steel guide rails the types in use are the roll, wedge clamp and the flexible guide clamp safety. The roll safety — shown on Figs. 11 and 12 — employs a corrugated steel roller, adapted to be forced into the apex of an angle, formed by the guide rail and the interior portion of the safety block. The angle usually is small so as to make the roller self-locking. This in turn causes an abrupt stop, so that the safety can be used only for low car speeds. In the wedge clamp safety, the rails are gripped between the
ELEVATORS

As shown in Fig. 13 the safety is returned by a drum having a hub provided with right and left hand screw threads which engage with two screws. Rotation of the drum in the proper direction moves the screws outwardly, forcing the wedges at the ends of the screws between the rollers of the clamp levers and causing the jaws to grip the rails. The drum is provided with a few wraps of rope, one end of which is fastened to the drum and the other to the governor rope.

Let us now imagine a falling car, equipped with a wedge clamp safety as here described, and analyze what will happen. Let us further assume that the normal speed of the car is 600 feet per minute. The governor (Fig. 14) — so as not to interfere with moderate speed variations from natural causes — will be set to trip at 800 feet per minute; that is to say, as soon as the speed of the car reaches 800 feet per minute, the governor jaws will grip the governor rope, causing the latter to come to rest quickly. As a consequence, the rope on the safety drum, having one end fastened to the governor rope, will unwind while the car over-speeds, amounting in the present example to 1,800 feet per minute. This is decidedly a disadvantage. The jaws now grip the rail and, as a consequence, the rotation of the safety drum stops. The governor rope, previously at rest, is therefore suddenly accelerated to the car speed of 1,800 feet per minute and begins to slip through the governor jaws. The force then exerted on the periphery of the safety drum, which is a direct measure for the retarding force exerted by the clamp, is the sum of friction caused by the grip of the governor on the governor rope and of the force necessary to suddenly accelerate the same to car speed. Now it will be clear, that in the present example the safety should be designed to stop the car at any speed above 800 feet per minute. At a speed of 800 feet per minute, however, the effect of the sudden acceleration of the governor rope is small and most of the work is done by the friction caused by the grip of the governor on the governor rope. If, however, the car actually falls, action of the safety begins at a speed of 1,800 feet per minute with a very considerable effect of the sudden ac-

ANOTHER ADVANTAGE OF THIS TYPE OF SAFETY LIES IN THE FACT THAT IT IS PRACTICALLY NOT AFFECTED BY SLIGHT CHANGES IN THE THICKNESS OF THE RAIL. THIS IS, OF COURSE, DUE TO THE VERY FLEXIBLE ARRANGEMENT OF THE JAWS. A SLIGHT INCREASE IN

FIG. 13.—Wedge clamp safety.
the thickness of the rail will merely result in a somewhat higher spring compression without much increase in the retarding force of the clamps. The operation of a safety by means of a speed governor always has the disadvantage that no action occurs, except at a certain overspeed. If, for example, the hoist ropes break while the car is at rest, it is rather contrary to common sense to permit the car to fall and gather speed before the safety is applied. For this reason, the flexible guide clamp safety is arranged to be actuated in three different manners, viz., first, in the ordinary way by means of a speed governor; secondly, immediately upon the breaking of the ropes and thirdly, at the will of the operator.

Air Cushions.—An air cushion is the enclosure of the bottom part of the shaft to a height of from one-sixth to one-third of the car travel with just sufficient clearance for the

of the height of the shaft before entering the cushion. As a consequence, the speed of the car at the entrance of the cushion is enormous and large retardations—dangerous to life and limb—have to be allowed to bring the car to rest within a comparatively small distance. By actual tests, velocities as high as 10,000 feet per minute have been measured. Retardations observed have been as much as 10 times gravity, subjecting a person standing in the car to 11 times his weight. Air pressures have been measured as high as 16 pounds per square inch from which it will be evident that a heavy construction of the cushion and doors is required.

Oil Buffers.—With particular reference to high speed electric elevators, it is highly improbable, but yet conceivable, that all of the switches, which constitute the automatic stopping device at the terminal landings, fail. Under such conditions, the car will proceed at normal speed and since—in the absence of overspeed—the safety remains inactive, there is no agent to prevent the cage from striking the limits of its travel. Accidents of this kind are made impossible by the installation of oil buffers. One or more of them are placed in the pit and are struck by the cage as it overruns the bottom landing. Another buffer is usually attached to the counterweight and comes into operation when the cage overruns the top landing. The construction of an oil buffer is shown in Fig. 16. It consists of an outside casing with a cylinder within and a piston operating in the cylinder. Casing and cylinder are filled with oil. When the car strikes the buffer and the piston descends, oil is forced out of the cylinder through holes, so arranged in number and position that the resistance offered by the fluid is just sufficient to bring the car to an easy stop within the stroke of the buffer. The piston is returned to the upper position by a spring. ELEVENTH CENTURY, The. The 10th century is commonly said to have been an especially backward period in human achievement, due to the belief then prevalent that the world was coming to an end in the year 1000. This superstition is supposed to have placed an inhibition upon human effort which kept men from serious work. An interesting commentary on this generally accepted impression is to be found in the fact that the two men in the world’s most prominent positions that is as emperor and Pope, who lived over from the 10th to the 11th century, are distinguished in history for their intellectual abilities while their lives are striking examples of the deep mental interests of the time. The Pope was Sylvester II (999-1003) who before he became Pope was known as the famous Gerbert, the most distinguished scholar of the
period. Gerbert wrote a series of works on philosophical, mathematical and physical subjects which have been preserved and which serve to illustrate the breadth of intellectual interest of the men of his time. He was no merely academic scholar but a man of very practical ability; for he is said to have introduced the use of Arabic figures into western Europe and to have invented the pendulum clock. A great improvement in the organ is also attributed to him and he is said to have notably influenced the development of music. As Pope, he is known for his determined insistence on the elevation only of men of unblemished character to the episcopal office and his consistent reformation of abuses. He maintained Church discipline firmly, especially in matters of the moral law, even where it concerned kings and was undoubtedly a man of saintly character. In spite of this, his popular legend gradually attributed to him the powers of a magician in league with the devil and after some generations his name became a byword. The incident is illuminating because it demonstrates how little the Church was able to prevent such perversions on the part of the people of the real significance of scientific knowledge and original discovery.

The emperor of the transition to the second millennium was Otto III; an orphan brought up by his grandmother Adelheid, assisted by a civil and ecclesiastical council who assumed the government and made every effort to give the boy, who was destined to be the ruler of the larger part of Europe, a fitting education. No one, however, could clearly define for him the value of education, nor how well founded were the ideas with regard to it at this time, than the details of Otto's training as they have come to us. The council thought first about his body, and his physical training was entrusted to Count Heinrich of Salzburg. Mental education was begun under Berwand, later bishop of Hildesheim, known both as litterateur and artist, and famous for his interest in schools of the arts and crafts. To him the Bernward Cross and other beautiful objects of high artistic art were due. Later Otto's education was entrusted to the famous Gerbert, deservedly considered the greatest scholar of the period. Special provision was made for the teaching of Greek to the young prince, and John of Calabria, where Greek was still a spoken language, was chosen for this purpose. These measures were so successful that Otto III as a young man received the title of "wonder of the world." When he reached the age of 15 he assumed the imperial power, and his tutor, Gerbert, took the occasion to remind him "how much he had been given to him and therefore how much must be expected of him; by Divine Providence he was by birth a Greek (his mother was Theophano, the daughter of the Byzantine Emperor, Romanus II), by dominion a Roman, and he had the treasures of Greek and Roman wisdom; as a monarch he was obeyed in Germany, France and Italy as well as by the Slavs, and that he wore the greatest crown in the world."

Young Otto as he approached the age of 20 had two ambitions and desires of restoring the ancient glories of Rome so as to make it the capital of his empire and to surround it with the magnificent circumstance of the Byzantine court. Personally, however, he exhibited a humility in striking contrast to his position as a monarch and his talent as a scholar. He proclaimed himself the "slave of Jesus Christ and his Apostles," and on his visit to Rome insisted on remaining in the catacombs of the great church of Saint Clement in fasting and prayer. He spent some time in the cave of Saint Benedict at Subiaco in order to testify his admiration for the man who had begun the organization of modern civilization in the trying times of the transmigration of the nations, but also in order to ask for help in his own work as he looked forward to it of turning the attention of the world to higher things.

Unfortunately neither of these men was destined to live long to influence the new millennium. The young Emperor Otto died 23 Jan. 1002, and Gerbert followed him to the grave on 12 May 1003. Short as was his life and few his acts, Otto III is in one respect more memorable than any who demonstrated his importance, because of his deeds for him. None save he desired to make the seven-hilled city again the seat of dominion, reducing Germany and Lombardy and Greece to their rightful place of subject provinces. No one else forgot the present to live in the light of the ancient order; no other soul was so possessed by that fervid mysticism and that reverence for the glory of the past wherein rested the idea of the medieaval empire. (Bryce, 'The Holy Roman Empire'). Thus opened the second millennium.

Otto III was the last of the Ottos, and as he died unmarried three claimants to the throne brought confusion and warfare to the world of the time and opened a century that was to be full of war. Henry II the Saint who succeeded was the last of the Saxon emperors. His reign is a bright spot in the century and after him the crown passed to the Franks in the person of Conrad II who reigned for some 15 years and then was buried in the cathedral of Spires which he had founded. After him came Henry III and then Henry IV who succeeded to the empire at the early age of six years and is known in history for his recurring quarrels with Pope Gregory VII.

It is not surprising to find that a century which opened thus auspiciously for the intellectual life in its greatest representatives should have witnessed the development of what is practically the first university of modern times, that of Salerno. It was founded around a medical school largely under the influence of the Benedictines whose mother house of Monte Cassino was not far away. The greatest teacher of this century was Constantine Africanus who afterward became a Benedictine, withdrawing to Monte Cassino. According to an old document published by De Renzi in his 'Collectio Salermiana,' it is definitely recorded that the school was founded by four doctors, a Greek, a Saracen, an Arab, and a man of whom lectured in his native language. This is probably only a tradition invented to account for the wide interest in the school. The Greek influence as is not surprising here in southern Italy, which used to be called Magna Graecia, was the strongest. As has been pointed out by Gurlt in his 'History of Surgery,' the writ-
nings of the Salernitan physicians contain Grecisms and not Arabisms. The influence of the Arabs was comparatively slight and was due entirely to the fact that certain of the old Greek authors were available only in Arab translations and that these Arab physicians had a certain prestige. The medical school at Salerno became so famous that it attracted students and patients from even distant parts of Europe and Duke Guiscard sent his son Bohemund to Salerno for the cure of a wound which he was to be treated by extraordinary surgical treatment of the time. Robert, the son of William the Conqueror of England, is said to have passed some time in Salerno for a similar reason. From very early in its history Salerno not only permitted, but seems to have encouraged, women medical students, and the department of women’s diseases was placed entirely in their charge. As a consequence of the high standards maintained in medical education at Salerno the king of Sicily issued royal licences to the students there, and thereby lent a status and an authority to the practice of medicine “for the protection of the subjects of our kingdom from the dangers arising from the ignorance of practitioners.” The development of the history of medicine in recent years has shown that the Salernitan School made magnificent achievements in surgery and that its favorite remedial measures were fresh air, good food, water internally and externally and rest. The “Regimen Sanitatis Salernitanum,” the little book of abstracts from the medical advice of the teachers at Salerno, written originally just before the close of the 11th century, was for centuries the most popular medical book in Europe. It has been printed in more than 300 editions since the invention of printing and has been reprinted in most of the modern languages in our time.

The important political events of the century were due to the continuation of the incursions of the Northmen. King Aethelred II, “The Unready,” had tried at the end of the 10th century to buy off the Danes from further invasions of his territory in England, but the 10,000 pounds of silver only whetted their appetite for conquest. A second and third ransom were no more effective, and then an organized massacre of the invaders (1002), in which the Saxons tried to repel all the cruelty of their oppressors, only prompted organized reprisals. Sweyn invaded England time after time, and finally (1013) assumed the title of king of England. Edmund Ironside, son of Aethelred, fought with a heroism that has made his name forever memorable, but in vain. Canute after Edmund’s death (1016) established the Danish rule, and as he was the monarch also of Denmark, Sweden, and Norway as well as of most of Scotland, had an imperial domain. He proved an excellent ruler once he had securely established his power, and the familiar incidents related of him, as when he showed his flattering courtiers how little his personal appearance was a typical characteristic of the man. He made a visit to Rome, organized the government of his states and well deserves a place among the great rulers of history. His death was the signal for internal dissensions in his kingdom and it was not until rebellions had been put down that Hardicanute succeeded him.

The Irish suffered also from the invasions of the Danes, but the Northmen were definitely defeated by Brian Boru at the great battle of Clontarf not far from Dublin, 1014. Brian had secured his place of High King by previous defeats of the Danes and gave the example of military success as a claim for the position of ruler with very unfortunate effects during the next two centuries. Brian himself and his son and grandson were killed at the battle of Clontarf, and after this Ireland was plunged into internal dissensions. England was of necessity to have a quarter of a century of peace and good will in the reign of Edward the Confessor who on Hardicanute’s sudden death in 1042 was called by acclamation to the throne, at the age of about 40. There were no wars except to repel an inroad of the Welsh and to assist Malcolm III of Scotland against Macbeth the usurper. Edward devoted himself to the welfare of his people. His royal patrimony sufficed for even his generous donations to the poor and for religion without taxes. “Edward was the last saint in the English Church.” He often demanded by the English of subsequent generations in times of oppression. In their affection and reverence for him the people came to be touched by his hands in certain ailments and so “the touch” became a tradition for English royalty.

For the west of Europe the significant event of the century was the Conquest of England by the Normans, 1066. The duchy of Normandy, the district at the north of France which had been given over to the sea rovers from the Scandinavian countries in the hope thus to create a barrier against further invasion, had been growing in power and prosperity for several generations. William the Conqueror became one of the most important sovereigns by his acquisition of England. He led some 60,000 soldiers of fortune on the expedition. Emerson in “English Traits” sums it up as “these founders of the House of Lords were greedy and ferocious dragoons, sons of greedy and ferocious pirates.” The English people had given the crown to Earl Harold, “the Last of the Barons,” but on the strength of a promise made by King Edward the Confessor, who was through his mother a kinsman of the Duke of Normandy, claimed the throne. The English King Harold found himself compelled to defend himself against Harold Hardrada, king of the Northmen, so that he had two enemies to contend with. He defeated Harold of Norway, but was himself defeated and slain in the famous battle of Hastings or Senlac. The English still opposed the Normans after the victory but William succeeded in spreading his dominion over the country and the opposition, often fomented for the purpose, only served to give excuses to get the large estates and the highest offices in England into the hands of Normans and those on whom he could depend to support him in his policy. The Norman dynasty and its descendants have since ruled England. Britain which up to this time is typical of European affairs was now drawn into Continental politics. With a ruler who had domains on the Continent nothing else could well have happened. Royal claims on various parts of France and of England in war for centuries. Conflicts between sovereigns and various petty rulers continued to be constant.
during the century. More and more the nobility refused to acknowledge obligations to their feudal lords in the matter of abstaining from war, and private wars of various kinds became almost the rule. As a consequence, the religious and intellectual life as well as the commercial and agricultural life of the people suffered severely. Feudalism at the beginning of the 11th century had broken down as an instrument for maintaining peace. It is interesting to see what was accomplished, as we have seen how successfully, to put an end to this state of affairs. It is almost the last place at the beginning of the second millennium of modern history to find a great movement for peace, but here it is.

In order to save bloodshed and protect people generally, the Church succeeded in bringing about the introduction of the "Truce of God." Councils of the Church early in the 11th century forbade hostilities from Saturday night until Monday morning. This prohibition was subsequently extended to other days in the week, and Friday in honor of the Passion and Saturday the day of the Resurrection were declared illegal for military or judicial concerns. But about the middle of the century ecclesiastical regulations made it unlawful to fight during Lent and then during Advent. The Truce was first successfully proclaimed in France and spread to Italy and Germany to the great advantage of the people of the time.

The Truce required that people be allowed to go quietly to and fro on their business without being disturbed by soldiers on the designated days and special regulations were issued protecting the peasant and his cattle and his agricultural implements. Before this councils had proclaimed the Peace of God which protected consecrated persons, places and times from warlike invasion. This protection was extended to the poor, pilgrims, Crusaders, and eventually even merchants on a journey. The further development of the Truce of God gave the impetus to peace which was finally taken up by the public authorities, through leagues for the enforcement of peace, and municipal federations until war was restricted to occasional tribal wars.

One of the most noteworthy features of the history of the 11th century is its interest in architecture. This began at the very beginning. "About three years after the year 1000," said Rodulf Glaber, "the churches were renovated almost throughout the whole world especially in Italy and the Gauls, although the greater part were still in good enough condition not to need repairing." The movement included not only the churches, but also the public buildings of various kinds.

This interest in architecture naturally led to important developments and the creation of that form of architecture called Romanesque, which was to prove only a step but a very great one toward the magnificent Gothic architecture of the later Middle Ages. The supreme examples of Romanesque are the cathedral of Speyer, finished in 1030 as a mausoleum for the so-called Salian emperors; the cathedral at Treves or Trier, planned and conceived toward the end of the century; the new cathedral of Mainz, which followed the one erected by Willigis the Regent (who saved the empire from disintegration during the minority of the Emperor Otto III), but which was unfortunately burned down on the day of its consecration, but was immediately rebuilt and completed by Bardo von Oppertshafen in 1037. This Romanesque cathedral of Saint Martin at Mainz is one of the most interesting monuments in the history of architecture and has been the fruitful source of ideas for architects in our generation. The limitation of the width of the Gothic nave makes Gothic churches less suitable for preaching to large crowds, and even Boston and New York chose to have great churches modeled on Romanesque lines.

The 11th century witnessed some precious social development, especially in the establishment of hospitals, which at that time were not only for the ailing poor, but also for the crippled and needy of many kinds as well as lodging for strangers. Archbishop Lanfranc erected a series of hospitals and "the good Queen Maud," the wife of Henry I, who was the daughter of Saint Malcolm of Scotland, acquired a special repute in connection with her care for the ailing poor. King Henry, after the death of his son by drowning in the famous incident of "the White Ship," caught something of his lady's charity, and Matilda, their daughter, followed their example. The lepers particularly were cared for, and the beginning of the eradication of this disease, said to be as common then as tuberculosis is with us, was made through segregation, the hardships of which were mitigated to no inconceivable degree by the l.vely interest of royalty and the nobility in the afflicted and the spirit in which their ailment was taken.

The 11th century saw the beginning of the organization on a broad scale of the Christian nations against Mohammedanism. The first active reaction against them in the countries where they had maintained themselves for some centuries came in Spain where the Moors in possession since early in the 8th century felt themselves at home. Just about the beginning of the 11th century the three Christian kingdoms—Castile, Aragon and Navarre—began to play a rôle of importance in the northern part of Spain. Castile led the movement, and before the end of the century reconquered Toledo. The rivalry between the Christian countries hampered their progress for a time, but they grew stronger by the intermarriage of their royal houses and were able to advance their frontiers at the expense of the Moors. Aragon took possession of Barcelona and the valley of the Ebro. Nearly 500 years of struggle remained however before the Moors were finally expelled. The advantage to Spanish character of the ceaseless contest was seen in the rôle played by the Spaniards in the New World after its discovery and the magnificent development of Spanish power at home and abroad which followed the final expulsion of the Moors in 1492.

The great hero of the century's Ruy or Rodrigo Diaz de Bivar, known as The Cid (Arabic, master) or El Campeador (Spanish, the champion or challenger). His life fills the whole of the second half of the century and his exploits animated the Spaniards against the Moors for all the time until their complete expulsion. The romantic chronicle of 'The Cid' the substance of which was compiled by Alfonso the Learned only half
a century after the hero’s death contains much that is literal history, and the obviously legendary incidents can be rather readily eliminated. Soutey’s translation made the work familiar in English. The life of the romances is another creature entirely, quite as much the nucleus for myths as Charlemagne’s Paladins or King Arthur and the Knights of the Round Table. Undoubtedly Rodrigo’s real victories apart from all romance form the core of Spanish history to the time.

The other phase of Christian opposition to Mohammedanism is also the greatest event of the 11th century, the first Crusade. Jerusalem had fallen into the hands of the Arab Mohammedans shortly after the death of Mohammed in the 7th century. This Semitic race shared in the Christian reverence for the Holy Places and permitted the Christian pilgrims who came in large numbers during the Middle Ages to pursue their devotions without molestation. In the 11th century, however, the Seljukian Turks, receding from the Caucasus, now invaded the caliphate as the Germans the Roman Empire, replaced the Arabs as the rulers of Jerusalem and at once initiated a very different policy toward the Christians. Great hardships were inflicted upon the Franks, and the stench of the cruel ties imposed aroused the feelings of Europe. The Seljuks, continuing their victorious career, defeated the Eastern Empire in 1071 and thus became rulers of Asia Minor. They took possession of Nicaea, just across the straits from Constantinople, and the city itself was menaced. Pope Urban II, whose training as a churchman had come under Pope Gregory VII, after six years of wandering from the time of his election had, in 1094, at last succeeded in gaining entrance to Rome and set himself to the task of unifying Christendom. In spite of rather serious breaks with the Emperor Henry and King Philip of France who had repudiated their wives, Urban devoted himself to the great problems of arousing Christianity against the Turks.

The first incentive to the Crusades has often been attributed to Peter the Hermit, but it really came from Pope Gregory VII and was popularized by the address of Pope Urban at the Council of Clermont (in Auvergne). After excommunicating Philip of France for adultery in having taken to wife Bertrada, the wife of Fulk of Anjou, the urgent question of the East was taken up. The Council had attracted immense crowds of all classes, but particularly of the nobility and knights. The Pope’s address asking for an army to be sent to redeem the Holy Places aroused great enthusiasm, and all present exclaimed with one voice “It is the will of God.” The Pope declared that this should be their rallying cry, and all were to wear a cross as a sign of their acceptance of what hardships might be involved. It is from this cross that the word crusade is derived. Each participant was “crossed.” Pope Urban suggested that particularly those who were in the midst of contentions with brethren and relatives might thus find a holy vocation. He who took up the cross did so out of the highest motives of pure devotion. It would be idle to think that in so great a mass of men there should have been no hypocrites, but they must have been surprisingly few.

In his great-heartedness the Pope proposed that those who had been robbers and brigands might now become soldiers of Christ with the feeling that here was a chance for the redemption of such men from evil ways, though doubtless also with the conviction that no matter what their motives they could work less harm in the army than at home, and that at any rate all should have their chance in the great cause.

Many privileges were granted to the Crusaders by the Church, and these have sometimes seemed to modern historians a juggle with justice. The payment of debts for instance could be put off, and the Crusaders were even freed from the payment of interest upon their debts and permitted to mortgage their property for the purposes of the Crusade without the consent of their feudal lords, though this was required by the laws of the time. We in our time who have seen another great World War with its moratoria, its prorogation of rents and notes, its shutting up of stock exchanges and its taking over of national property are not likely to misunderstand similar events of the Crusade. Crusaders’ wives and children and property were taken under the direct protection of the Church and those who disturbed them found that they had to do with the ecclesiastical authorities. The youth of all the country gave themselves unstintedly to the cause quite as they have in our time and have always done for idealistic purposes. Within a year after the great wave of enthusiasm which had begun at Clermont had spread through Europe there was, according to the Pope himself, some 300,000 soldiers collected under the leadership of the great nobles of the time. It is recalled that at this period the European countries whose census of population we have, had much less than one-tenth as many inhabitants as in our time, the immensity of the effort thus put forth will be properly appreciated. The important leaders were Godfrey of Bouillon and his brother Baldwin, from Brabant, with Count Raymond of Toulouse who led a great army from Provence. The French troops were not led by Philip, who was in disgrace, but were joined with those of the Normans from southern Italy under the command of Bohemond, the son of Robert Guiscard, and of Rainald, who was the son of Otto the Good and of Emma, the sister of Robert Guiscard. Tancred came to be the rival in the later legends of the Crusades even of Godfrey of Bouillon and to be the centre of romances for centuries in modern European life.

After many hardships the army of the Crusaders succeeded in finding its way to Constantinople only to discover that the Greeks expected to turn the great Christian expedition into a military campaign for the benefit of the empire. The Crusaders entered the suburbs of the capital not only were not welcomed, but were actually declared enemies because they refused to take the oath of homage to the emperor. Contemporary documents which show the complaints of traitorous cruelty on both sides used to be held up as flagrant testimony to the essential barbarism of the people of the time, but recent experiences have demonstrated that the trait thus disclosed is human and not merely mediæval. The emperor’s daughter Anna, writing a history of the times, has made a
ELEVENTH CENTURY

Document almost as bitter in denunciation of the Crusaders as any that appeared on either side in our own great war. The Crusaders did not hesitate to call the Greeks traitors, cowards, liars and worse, but above all to depreciate their cruelty toward small parties of Crusaders unable to defend themselves. The Byzantines replied with accusations of attacks upon women and children and thieving depredations of various kinds.

It was not until the spring of 1099 that an army of 20,000 Crusaders under Godfrey of Bouillon reached Jerusalem. The Holy City was stormed and taken 15 July 1099. Elected king of Jerusalem Godfrey refused that title in deference to the higher King whose spirit reigned over the world from there, and chose the simple designation of Protector of the Holy Sepulchre. He completed the conquest of the Holy Land by defeating the sultan of Egypt in the plain of Ascalon, 12 Aug. 1099. Godfrey had been wounded during the siege of Jerusalem and died just a year later, 11 July 1100. He was succeeded by his brother Baldwin. Altogether four principalities were created by the Crusaders in Mohammedan territories, the capitals of which were Edessa, Antioch, Tripoli and Jerusalem. Baldwin succeeded in taking possession of Acre, Sidon and some other important towns along the coast of Asia Minor. The news of the fall of Jerusalem caused great rejoicing throughout Europe and brought many accession to the armed forces of the city's ruler. Unfortunately many of these were lost at sea and many were cut off in various ways by the Turks so that the consolidation of the recent conquests became very difficult. Luckily the Mohammedans were engaged in fighting among themselves and could not combine against the Franks as they called the Crusaders generally. Altogether at the end of the 11th century the Crusaders occupied a small strip of land not 50 miles wide and some 500 miles long from which the Turks were for long in danger to displace them.

This was the beginning of the great movement, the Crusades, which was destined to influence Europe so deeply for the next two centuries. There was scarcely a generation until 13th that did not witness the going out from some part of Europe of large bodies of men who had nobly taken up the task of securing the possession of the Holy Places to the Christians. In the meantime a great event which accomplished wonderful work for Christendom and a brand of Hell by those who declared that he was an influence for evil. There is no doubt at all that he exerted a deep influence over his own and succeeding generations. He was a self-made man of lowly birth, one of those who in President Wilson's words make it clear why government did not suffer dry rot in the Middle Ages under the aristocratic systems which then prevailed in Europe. There was no peasant so humble, that he might not become a priest and no priest so obscure that he might not become Pope of Christendom and every Chancellery in Europe was ruled by those learned, trained and accomplished men. As Pope he took up at once the reform of Church matters and the definite regulation of the relations of the Church to the State. By abuse bishops had come to be almost more state officials than Church dignitaries. Gregory labored to have them independent in their ecclesiastical functions except of the head of the Church, but it was difficult to correct long standing abuses. The most serious contest in this matter is between Pope Gregory and the Emperor Henry IV of Germany. Hildebrand dissolved the oath of allegiance of Henry's subjects and the nobility, glad of the opportunity to put down a tyrant, fell away from him and made Henry realize that unless he regularized his relations with the Church he could not hope to continue as a ruler. After many attempts to avoid the humiliation Hildebrand made the famous journey to Canossa to be reconciled with the Pope, when he was required to do penance so severe that Hildebrand's conduct in this matter has often been censured. But Hildebrand maintained the rights of the Church as he saw them and continued to purify the Church itself of abuses of various kinds and to uphold the moral law as binding upon rulers as well as the people. Reformers are not likely to be popular and Gregory was in constant trouble. His own last words sum up his life better than any others. He had been compelled to leave Rome and was dying in Salerno when he said I have loved justice and hated iniquity, therefore I die in exile.

Hildebrand both before and after his election as Pope did more than anyone else to lay that foundation of the ascendancy of the Papacy in Europe which culminated a century later in the pontificate of Pope Innocent III. During the time when popes were looked up to as guardians of the moral conscience of Europe, the best historians admit that there was a magnificent development of culture in the best sense of that word. Few if any epochs in the whole history of mankind present achievements higher than those of the 12th and 13th centuries. The loftiest arts and sciences of the mind were finely fostered. Beautiful architecture, painting that has never lost its interest, magnificent hospitals and great literature, charming arts and crafts all developed at this time and have come to be the loving study and reverent admiration of our generation. If a career is to be judged by its fruits, Hildebrand's influence in making the popes a moral centre as well as ecclesiastical power in Europe must be considered one of the great factors for a great era of human development.

A great scholar of the 11th century whose works are still republished in many languages
and whose influence continues to be felt is Anselm, archbishop of Canterbury. His little book, *Cur Deus Homo,* is still frequently read by those who are deeply interested in the philosophy of the Church and his *Monologium* and *Proslogium* are well known by philosophers and theologians. He was one of the most important links in the chain of philosophic thinking known as scholasticism, which has had a very interesting and significant revival mainly through Cardinal Mercier in our own generation. Though Anselm was the archbishop of Canterbury and had been the abbot of Bec in Normandy, he was neither Norman nor Saxon, but Italian, born in 1033 near Aosta. His father was a simple citizen of the little town and Anselm owed his rise entirely to his own abilities. He entered the abbey of Bec as a young man just when it had been made famous by the learning of Lanfranc and three years later became pr.or and filled that office and that of abbot for some 10 years when he was made archbishop. He succeeded Lanfranc as archbishop of Canterbury under most difficult circumstances, refusing the archiepiscopal at first as he had refused the election of abbot and continued to be honored only when it was made clear to him that he could probably do great good in the new office. Lanfranc had had serious difficulties with the king over the matter of investiture and Church revenues and Anselm inherited these. He succeeded in finding a mode of compromise and laying down the principles on which the relations between the Church and State could be safeguarded without violation of the rights of either. Historians have recognized the genius and character of the man, and Freeman did not hesitate to say "stranger as he was he has won his place among the noblest worthies of our Island." Curiously enough Anselm's contribution to the borderland between philosophy and theology, the ontological argument for the existence of God put forth in his *Proslogium,* was revived in modern times by Descartes, became the cardinal point of departure between Kant and Hegel at the end of the 18th century, to be revived by Rosmini in Italy and adapted by Emerson in America in the 19th century. An argument that sways such minds all down the centuries must surely have in it something that has a deep appeal to some essential quality of the human intellect apart from training and environment.

The rise of the Seljukian Turks gave a period of peace in Persia under the viziers of Toghrol Beg and his son and grandson, Alp Arslan and Malik Shah, during which a series of contributions of enduring interest to the intellectual life of humanity were made. At the beginning of the 11th century Abul Kasim Mansur of Tus in Persia (d. 1020), known as Firdusi or Firdausi "the Paraisiac," finished the Shahnahme, the great Persian epic of about 60,000 distichs, which sines the deeds of Persian heroes for 500 years. A little later Avicenna, "the prince of physicians" (d. at Hamaden, Persia, 1037), "at once the Hippocrates and the Aristotle of the Arabians" (Wheewell) wrote the books that for five centuries influenced medicine in Asia and Europe more than any others. They are only compilations of Hippocrates and Galen, but when Greek was no longer known they served as sources of ancient knowledge for a great many writers. Avicenna's work is typical of much of what the Arabs did. There is little of originality, he was merely a channel for the older medical writers and his *Arabian* and the second half of the century Al Gazali (b. Tus 1058) was for a time professor of Mohammedan theology in the school at Bagdad. In his earlier years some of his writings were sceptical and these have a special appeal to the moderns, but later he turned into Mohammedan apologist and continued to be studied for long afterward. Omar Khayyam, the Persian poet-astronomer, whose "Rubaiyat" attracted so much attention at the end of the 19th century was the fourth of these Mohammedan writers destined to an enduring influence. He corrected the calendar successfully and wrote books on algebra and astronomy, but these have had no influence beyond a generation or two in its own time, while his quatrains on life and death and love and God and the problems men face struck at all times, caught the vein of thought of the distant Western peoples eight centuries later. He had been the schoolmate of the vizier of Alp Arslan, and the third of a little trio who at school swore eternal friendship and to share whatever fate might befall them, the ambitious Hasan, "the Old Man of the Mountains," from whose name because of his infamous deeds very probably the word "assassin" in our modern languages is derived. Manifestly Omar's experience of life and its vicissitudes in person and through his friends as ample to enable him, if he had the mind to, to write of humanity's problems with fullness of knowledge.

There are two great women of the century whose names are still well known and lives of whom have been written in our generation. One of these was Matilda of Canossa, Countess of Tuscany and heiress of the Marquess Boniface of Tuscany. She knew Latin well, was fond of serious books, took a deep interest in the philosophical and religious discussions so common at the time and came to exert an immense influence, not only in Italy but throughout Europe. She was a great personal friend of Hildebrand before his election to the Papacy as Gregory VII, and constantly supported him in the conflicts which his reforms involved. It was in letters to the Countess and her mother that Pope Gregory discussed the question so dear to his heart of the organization of the Crusade for the winning back of the Holy Land. It was at her castle of Canossa that Pope Gregory received the repentant Emperor Henry. At her death Matilda bequeathed her estate in central Italy to the Church, feeling the necessity of strengthening the Pope's political situation and this bequest was confirmed by the Emperor Frederick II.

The other great woman of the century was Margaret of Scotland, whose life runs almost parallel with the second half of it. She was intimately related to many of the well-known characters of the time. She was the granddaughter of Edmund Ironside, and when exiled under Canute, Escotep moved to the care of St. Stephen of Hungary. She returned to be close to Edward the Confessor for a time, but, with her mother, set out for France
when the Normans won the battle of Hastings. Their ship was driven by storm to Scotland where Malcolm III, having defeated Macbeth, was king. Margaret became his wife and did so much to soften the barbarous manners of the Scotch that ever since she has been in benefaction. A favorite occupation was the securing of justice for the poor and a stone is still pointed out near Edinburgh, called Saint Margaret's stone, on which she sat to hear their causes. Her favorite son David is the Saint David of Scottish history, and the building of great churches and monasteries was initiated by Margaret. She was untiring in zeal for education and for the encouragement of book-making and is looked upon by the Scotch as one of the great founders of their civilization.

Author of 'The Thirteenth, the Greatest of Centuries.'

PRINCIPAL EVENTS OF THE ELEVENTH CENTURY.

1001. The Eastern Empire loses territory to the Bulgarians and is attacked by the Russians.

1002. Emperor Otto III of the Western Empire dies.

1003. Pope John XII, known as Gerbert, the greatest scholar of the age, dies.

1014. The Irish at the Boyne defeat the Danes at Clontarf.

1042. Edward the Confessor reigns over England.

1066. The Normans invade Sicily.

1071. The Turks defeat the Eastern Empire, occupy Asia Minor and threaten Constantinople.

1076. The Turks capture Jerusalem.

1077. Henry IV of Germany does penance at Canossa for disobedience to Pope Gregory VII.

1087. The Moors enter Spain to assist the Arabs and Saracens.

1094. Ruy Diaz de Brito the Castilian Cid Campeador defeats the Moors and becomes lord of Valencia, Spain.

1094. Urban II after six years of wandering re-enters Rome and actively engages in uniting Christendom.

1095. The European Truce of God proclaimed at the Council of Clermont by Pope Urban II.

1095. Peter the Hermit starts Europe to save Jerusalem from the Turks. Celibacy enjoined.

1096. The First Crusade.

1099. Christian Crusaders capture Jerusalem.

ELF-ARROWS, ELF-BOLTS, ELF-SHOT are the names given to implements of stone, especially flint, of various sizes and forms, which are found abundantly in many countries. They are the relics of arrow-heads, darts and other rude ancient weapons from the Palaeolithic period. They belong to the same class of ancient implements that are generally known as Celts (stone hatchets). These rude and ancient implements are objects of some extraordinary superstitions. The names given above are, of course, of popular and comparatively modern origin, and imply that those who gave them were completely ignorant of the real origin and use of those weapons. These names are found independently among the peasantry in Scotland, England and Ireland, and the superstitions associated with them are much more widely spread. According to the popular belief the stones are of supernatural origin, and various virtues are attributed to them. They are worn as charms, and used as a protection against lightning; but they are chiefly suspected of invoking ill-fortune. A cavern has been pointed out where the archfiend carries on the manufacture with the help of attendant imps, who rough-hew them while he finishes the work. Similar superstitions prevail in Italy, Africa and Turkey. Consult Evans, 'Ancient Stone Implements of Great Britain.'

ELGAR, Sir Edward William, English composer: b. Broadheath, Worcestershire, 2 June 1857. Among his compositions are 'The Black Knight' (1892); 'Chora Suite' from the Bavarian Highlands' (1895); 'Lux Christi,' produced at the Worcester Festival (1896); 'Te Deum,' sung at the Hereford Festival (1897); 'Caractacus,' produced at the Leeds Festival (1898); 'Sea Pictures,' for the Norwich Festival (1899); 'Dream of Gerontius,' for the Birmingham Festival (1900), which is considered his masterpiece. It was reproduced at the Niederrheinische Musik Fest in 1902. Other of his compositions are 'Coronation Ode' (1902); 'The Apostles' (1903); 'The Kingdom' (1906); 'Coronation March' (1911); a masque, 'The Crown of India' (1912); 'The Music Makers' (1912); 'Falstaff,' a symphonic study (1913), and 'Carillon' (1915). Besides these he has written symphonies, several concert overtures and a cantata, 'The Kingdom.'

ELGIN, James Bruce, 8th Earl of, and 12th Earl of Kincardine, English statesman: b. London, 20 July 1811; d. Durrumsala, North India, 20 Nov. 1863. He was educated at Eton and Oxford; in 1841 entered Parliament as member for Southampton, and in the same year succeeded to the earldom. In 1842 he was appointed governor of Jamaica. His rule in Jamaica was so successful that in 1846 he was appointed governor-general of Canada, and there he succeeded by a conciliatory policy in allaying the discontent which had broken out and for some time continued. It was through his efforts that reciprocity between the United States and Canada in natural products was established (1854-66). In 1849 he was raised to the British peerage as Baron Elgin; was sent in 1857 as special ambassador to China, where in the following year he succeeded in concluding the Treaty of Tientsin. He also concluded a treaty with Japan. When he returned to England he was given the office of Postmaster-General and elected lord rector of Glasgow University. In 1860, the Chinese emperor having manifested unfriendliness, Lord Elgin was sent to enforce the treaty, which he did by seizing Peking. The treaty which followed was successful in regulating Chinese relations with Europe until 1890. In 1861 he was appointed governor-general of India. He maintained internal peace and exerted himself unceasingly for the development of the country. His 'Letters and Journals' were edited by Walrond (London 1872).

ELGIN, Thomas Bruce. See ELGIN MARBLES.

ELGIN, Victor Alexander Bruce, 9th Earl of, British statesman: b. Montreal, 1849; d. Scotland, January 1918. His grandfather, the 7th earl, best known by his connection with the Elgin Marbles (q.v.), was British Ambassador at Constantinople from 1799 to 1822. Lord Elgin was educated at Eton and Oxford and entered Parliament as a Liberal under the banner of Gladstone. In 1893 he was appointed viceroy of India, a post which his father had held — and
died in — 30 years before. The five years of Elgin's administration, 1894 to 1899, were marked by numerous and serious problems, financial, economic, plague, famine and war. The difficulties were met by the viscerality and his advisers with courage, resource and success, and much was done to improve public works in general and railroad construction in particular. Lord Elgin was chairman of the royal commission appointed in 1902 to inquire into the military preparations for, and conduct of, the South African War. In the cabinet (December 1905) he became Colonial Secretary, in which capacity he was primarily responsible for framing the Constitution for the Union of South Africa. He retired in 1908, but his services were employed on important government commissions where judgment and impartiality were needed. As chairman of the Carnegie Trust he took a strong interest in the application of the fund. Lady Elgin, who died in 1909, had six sons and five daughters.

ELGIN, Ill., city of Kane County, 36 miles west by north of Chicago, on the Fox River. Two railroads supply adequate shipping facilities, the Chicago, Milwaukee and Saint Paul and the Chicago and Northwestern. It is also the terminus of the Aurora, Elgin and Chicago Railway, which is a third-rail electric line between Chicago and Elgin. Two products make Elgin famous — butter and watches. The dairy interests have probably had more to do with the development of the community than any other factor. Early in its history, the Borden Condensed Milk Company located a large plant here and since that time has established many more in the immediate vicinity. The current quotations of the Elgin Board of Trade fix the market price of high grade butter throughout the entire country. The other industry to which Elgin largely owes its growth and prosperity is the making of fine watch-movements. The watch factory was started in the spring of 1864 and has been a success from the beginning. There are many other industries in Elgin, all of which have been progressive and successful. There are two large publishing houses located here and there are several machine shops and foundries. The United States census of manufactures for 1914 showed within the city limits 91 industrial establishments of factory grade, employing 5,974 persons; 5,529 being wage earners, receiving annually $3,520,000 in wages. The capital invested aggregated $17,371,000 and the year's output was valued at $10,492,000; of this, $6,221,000 was the value added by manufacture. Elgin is sometimes called the "City of Churches." Nearly all denominations are represented and the various houses of worship are large and handsome. The city is noted for its public school system, which is highly developed and very efficient. The buildings are handsoms in architecture and a new high school is in the process of construction. The Elgin Academy, North Central College, and Northwestern University is a well-known preparatory school for the latter institution, which is located at Evanston, Ill.

Saint Mary's Academy is also well known throughout the State and bears a high reputation as a place of learning. The Illinois Northern Hospital for the Insane is located in Elgin. The Elgin Woman's Club has built and operates a large hospital; the Elgin public schools throughout the State for its high standing and great efficiency. Its cost was about $1,000,000. The banks are six in number, four national and two savings. They have a combined capital of over $650,000 and are prosperous and sound. The strong financial institutions. Founded in the spring of 1835, Elgin has grown rapidly in size and importance until it now is the most beautiful and the second largest city in Kane County. Elgin was incorporated in 1854 and Dr. Joseph Tefft was chosen the first mayor. The waterworks and sewer system and the electric-lighting plant are the property of the municipality. The city has commission form of government. Property is in demand, owing to the number of Chicago people who, on account of good transportation facilities, are seeking more room and pleasant homes within the confines of the beautiful city on the Fox River. Pop. 27,485.

ELGIN MARBLES, the name given to a peerless collection of antique sculptures brought from Athens to England by Thomas Bruce, 7th Earl of Elgin in the early part of the 19th century. While Ambassador at Constantinople (1799-1802) he conceived the plan of securing some portion of the ruins of ancient Athens and to that end secured permission of the Porte to take "any stone that might appear interesting to him." At his own expense (the British government having refused aid) he set a corps of artists to work who toiled for 10 years detached various specimens from the Parthenon, consisting chiefly of the colossal statues on the tympana of the pediments, the metopes and the frieze around the cella. Among the best preserved examples which this splendid effort brought forth were the tympanum representing the birth of Minerva, the 15 metopes showing in high relief the combat of the Centaurs and Lapiths, and the slabs from the cella frieze depicting in low relief the great Panatheniac procession. In addition to these Lord Elgin procured the colossal statue of Bacchus from the choragic monument of Thrasyllos, one of the caryatides from the temple of Pandrosus, a portion of the frieze from the Erechtheum and fragments of the columns of the Parthenon and Erechtheum; also numerous inscriptions, urns, etc., found in the neighborhood. When these treasures of antiquity arrived on the English shores they were received with a mixture of admiration and indignation — the latter because of supposed vandalism. It is said that Lord Byron was so outraged by the alleged depredations that when he visited the Parthenon he inscribed conspicuously: Quod non fecerunt Proles Sculi. However, as it afterward proved, had not Lord Elgin obtained these sculptures they would have been destroyed in the subsequent war of Greek independence and especially in the last siege of Athens in 1826-27. After much hesitation and bickering, the British bought, and, despite, too, of their value vouched for by experts, the British Parliament purchased the marbles from Lord Elgin for £50,000, easily a
third less than he had expended upon them. They are now to be seen in the British Museum as priceless examples of the highest in Greek art which matured under the genius of Phidias. Many casts have been taken of these unsurpassed reliefs and by which the city of New York possesses a set. Consult 'Ancient Marbles in the British Museum' (Vols. VI–IX, London 1830–39, 1842).

ELHORST, Hendrik Jan, Dutch biblical scholar: b. Wisch, Guelderland, 1861. He received his education at the University of Amsterdam. He entered the Mennonite ministry and held pastorates successively at Assum, Friesland, Arnhem, The Hague and Haarlem. In 1906 he was appointed to the chair of Hebrew language, antiquities and literature in the University of Amsterdam. He published critical commentaries on Micah (1891), Amos (1899) and 'Israel in Thet lichte der jongste onderzoekingen' (1906).

ELI, é-li, Hebrew judge and high-priest of Israel. After a turbulent rule of 40 years, he died 1116 n. C. Failing to punish the misdoings of his sons, Phineas and Hopnhi, the downfall of his house followed.

ELI PERKINS. See LANDON, MELVILLE DE.

ELIA, é-lé-a. See LAMB, CHARLES.

ELIE DE BEAUMONT, a-lé dé bů-mó̂n, Jean Baptiste Armand Louis Léonce, French geologist: b. Canon, France, 25 Sept. 1798; d. there, 22 Sept. 1874. He was educated in the Polytechnic School; became professor of the School of Mines (1829); professor of geology in the College of France (1833); chief engineer of mines (1833); member of the Institute (1835) and perpetual secretary of the Academy of Sciences (1853). He published 'Carte geologique de France' (1843); 'Notices sur les systems de montagnes' (1852); and with Dufrenoy, 'Voyage metallurgique en Angleterre' (1827), the record of a scientific journey he had made in England and Scotland in 1823. His principal services to science were the establishing of the geological survey of France and the stimulating of interest in mountain geology.

ELIGIUS, é-li-jůs, or ELOI, a-lů¿, Saint, bishop of Noyon: b. Cadillac, near Limoges, 588; d. Noyon, 1 Dec. about 660. Having in boyhood shown a decided aptitude for fine art he was placed by his parents under the direction of the master of the mint at Limoges and there acquired skill in the goldsmith's craft. Appointed coiner to the Frankish king, Clootaire, and to his son and successor, Dagobert, he executed at their order the bas-reliefs on the tomb of Saint Germanus, bishop of Paris, and other works in the precious metals which were regarded as the masterpieces of decorative art in that time. He was a favorite at court, which he was obliged to frequent because of his connection with the court; but he took more pleasure in relieving the needy than in the society of the worldly. He daily fed a large number of poor people, he buried the bodies of malefactors, and he ransomed captives, especially the Saxon slaves who were often sold in the market of Clootaire and his son Dagobert bestowed costly presents upon Eligius, but they could not make him rich, he gave so much to

the poor and to the founding of charitable institutions. At about the age of 50 he decided to abandon the world entirely and devote himself to the conversion of the pagans. Two years later he was ordained priest and in 546 was made bishop of Noyon. As bishop he gave special attention to the conversion of the Flemings and Frisians, and the greater part of Flanders was converted through his efforts. Consult Lebeuf, 'Histoire du diocese de Paris'; Fleury, 'Vita S. Eligius.'

ELIHU, a friend of the patriarch Job, introduced as speaking after the three intimate friends. His portion in chapters xxxii–xxxvii is supposed by many critics to be a later addition to the book. Lightfoot and others conjecture that Elihu was the author of the book of Job.

ELIJAH, whose name ('Jehovah is God') indicates his mission and his work, was one of the greatest prophets of Israel. His prophetic activity began in the days of Ahab, who ended in the days of his son, Ahaziah, or, as is on the whole more probable, in the days of his son-in-law, Jehoram of Judah. His first appearance is strange; the end of his life on earth still more strange. Throughout his career he comes and goes in an unusual and remarkable way. His special work was to save his nation from falling into heathenism, and thus making impossible the great history which has resulted in the Christian civilization of our own days. Ahab, the king of northern Israel, had married Jezebel, the daughter of Ethbaal, king of Tyre, and formerly a priest of the Tyrian religion. Among the Semitic peoples an alliance of nations meant a mutual honoring of gods. Thus the marriage of Ahab and Jezebel introduced into the kingdom of Israel the worship of the Tyrian Baal. Gradually, through the determined efforts of Jezebel, who was a fanatic for her faith, the worship of Baal displaced that of Jehovah, and seemed likely altogether to destroy it. Later, by the marriage of Ahaziah, the daughter of Ahab and Jezebel, to Jehoram, king of Judah, the same course of things began in the kingdom of Judah (2 Kings viii, 18). To bring back the nation to the worship of Jehovah, and to the recognition that God was the work of Elijeh. This work began with the sudden appearance of the prophet to Ahab, to announce to him the coming drought and famine, which the nature god Baal would be powerless to prevent (1 Kings xvii, 1). The life of the prophet up to this time had probably been spent in the lonely and wild region on the eastern side of the Jordan, although it is uncertain where his birthplace was. During the three years and more of drought and famine which followed Elijeh's mission, Ahab, the prophet found a home and the means of life, first by the brook Cherith, and afterward in the home of a widow in Zarephath, a city of Phoenicia. At the end of this time he had his great contest with the prophets of Baal on the Mount Carmel, where, in answer to his prayer, Jehovah revealed himself by fire, and was acknowledged by the people to be God. The same day the falling rain ended the drought and the famine (1 Kings xviii). The triumph of the prophet was followed by a flight to Mount Horeb to escape the wrath of the angered Jezebel. On this mountain he received
from God a revelation in regard to the real part his work had in the history of his nation, and was commanded by God to call Elisha to be his successor in the work for the nation. In obedience to this command, he went from Horeb to Abel-meholah, the home of Elisha. Having given to Elisha the call to be his successor, he disappeared for a time from the view of men (1 Kings xix). About six years later, the people being very angry with Ahab in the vineyard of Naboth, in Jezreel, to denounce him for his wicked disregard of the rights of his brother, made sacred by the law of Jehovah (1 Kings xxi. 17-24). The final work of the prophet on behalf of his people is recorded only in the book of Chronicles (2 Chron. xxi. 12-15). This was the sending of a letter to Jehoram, the king of Judah, to tell him that, because he had endeavored to introduce the Baal worship of the northern kingdom into Judah, and because he had cruelly murdered his brothers to make his own throne more secure, Jehovah would send great evils upon his people, his family and himself. How long the prophet lived we do not know (2 Kings ii, 1-12). Consult Milligan, 'Elijah: His Life and Times ('in Men and the Bible'); Parrar, 'First Book of Kings' (Chaps. xxxiii-xlvi., in the Expositor's Bible) 1893'; and 'Second Book of Kings' (in the same. Chaps. i and ii, 1902); Strachan, 'Elisha' (in Hastings' Dictionary of the Bible, 1899).

Sylvester Burnham,
Professor of Old Testament Interpretation,
Theological Seminary of Colgate University.

Elijah, The, an oratorio by Mendelssohn, first performed at Birmingham, England, 26 Aug. 1846. It is one of his best-known works and is more popular in England and America than any other oratorio, with the exception of Handel's 'Messiah.'

Elimination. In mathematics we often meet with instances where, given several statements concerning several distinct quantities, we wish to discover precisely what is affirmed of a smaller group of these quantities. For example, in the solution of simultaneous equations, such as

$$\begin{align*}
ax + by + c1 &= 0 \\
ax + by + c2 &= 0
\end{align*}$$

we obtain the value of $x$ we must derive from these two equations a single one not involving $y$. This process is called the elimination of $y$. In the case of linear simultaneous equations such as the above, the elimination may be performed by multiplying the first equation by $b_2$ and the second by $b_1$ and, subtracting or by solving the first equation for $y$ and substituting this value in the second, or by solving both equations for $y$ and equating the values thus obtained. All these methods give the result:

$$x = -\frac{c_1 b_2 - c_2 b_1}{a_1 b_2 - a_2 b_1}$$

(see Determinants), and throughout all forms of elimination determinants are very convenient. Elimination between equations not linear is apt to be very complicated and difficult. However, in the case of the elimination of a single unknown from two consistent algebraic equations, Sylvester's dialytic method forms an easy solution to the problem. This consists in obtaining from two equations in $x$ of the $m$th and $n$th degrees, respectively, the $n$ equations formed by multiplying the $m$th equation by the powers of $x$ from the $0$th to the $(n-1)$st and the $m$ equations formed by multiplying the second equation by the powers of $x$ from the 0th to the $(m-1)$st, and by eliminating from these the terms independent of the independent variables. We thus get $m+n$ equations in $m+n-1$ variables, and the condition (see Determinants) that these be consistent is that the determinant of the coefficients should vanish. For example, if our two equations are

$$\begin{align*}
a_1 x^2 + a_2 x + a_3 &= 0 \\
a_4 x^2 + b_2 x + b_3 &= 0
\end{align*}$$

we obtain from these the equivalent family of equations

$$\begin{align*}
a_1 x^2 + a_2 x + a_3 &= 0 \\
a_4 x^2 + a_2 x + a_3 &= 0 \\
b_4 x^2 + b_2 x + b_3 &= 0 \\
b_4 x^2 + b_2 x + b_3 &= 0
\end{align*}$$

which give the relation between the coefficients

$$\begin{array}{cccccc}
0 & a_3 & a_3 & a_3 & a_3 & a_3 \\
a_4 & b_3 & b_3 & b_3 & b_3 & b_3 \\
0 & b_4 & b_4 & b_4 & b_4 & b_4 \\
0 & b_4 & b_4 & b_4 & b_4 & b_4 \\
\end{array}$$

In certain cases an analogous method may be applied to systems of three or more equations. A method of similar application to that of Sylvester had been discovered previously by Euler. (See Algebra, Elementary; Determinants). Consult Burnside and Panton, 'Theory of Equations' (Dublin 1901); Dickson, 'Introduction to the Theory of Algebraic Equations' (New York 1903); Muir, 'Theory of Determinants' (London 1890); Young, 'Monographs on Modern Mathematics' (New York 1911).

Eliot, Charles William, American college president and educator: b. Boston, Mass. 20 March 1834. He was graduated from Harvard in 1853, was tutor in mathematics there 1854-58, and assistant professor of mathematics and chemistry in the Lawrence Scientific School, Harvard, 1858-63. After spending two years in Europe studying chemistry and investigating educational methods he was professor of analytical chemistry in the Massachusetts Institute of Technology 1865-69. In the last-named year he became president of Harvard University, which position he resigned in 1909. He is one of the foremost writers and speakers of the day upon educational and social problems and has exerted a strong influence upon the trend of American thought. During his incumbency Harvard College introduced what is commonly known as the elective system—a system since adopted by most American colleges, whereby students no longer must pursue a rigidly prescribed curriculum, but may choose (within certain groups) any of the subjects taught. Under President Eliot, too, Harvard's college course could be covered in three years instead of four, thus enabling students to complete both the college and a professional course in six, instead of seven, years. Numerous other educational reforms were advocated by Dr.
Eliot in his long career at Harvard, which have placed him among the greatest American educators and have won great prestige for the university over which he presided. He has published 'Manual of Qualitative Chemical Analysis' with F. H. Storer; 'Manual of Inorganic Analysis' (with F. H. Storer); 'Five American Contributions to Civilization and Other Essays'; 'Educational Reform'; 'More Money for the Public Schools' (1903); 'John Gilley' (1904); 'The Happy Life' (1905); 'The Road Towards Peace' (1915).

Eliot, George (the pseudonym of Mary Ann Evans Cross), the most distinguished of English women novelists: b. Arbury farm, near Nuneaton, Warwickshire, 22 Nov. 1819; d. Chelsea, 22 Dec. 1880. Her father, Robert Evans, who was of Welsh extraction, was agent on the estates of Francis Newdegate; and she was the second daughter and third child of his second marriage. When Marion was a few months old, the family removed to Griff, a "cheerful red-brick, ivy-covered house", and there the first 21 years of her life were spent. She was one of a large family and among a people that she was destined to immortalize. Her first school was at Attleborough, and from there she went to a boarding school at Nuneaton, one of the governesses at which, Miss Lewis, became a warm friend, and whose name excelled in awakening religious impressions that were deepened in the years she spent between the ages of 13 and 16, at Miss Franklin's school in Coventry. The death of her mother, to whom she was tenderly devoted, which occurred in 1836, was succeeded soon after by the marriage of her sister, and the care of her father's home then devolved upon her. The duties of the household were accompanied by lessons in Italian and German, Greek and Latin; she was already an omnivorous reader and one with a fine power of selection; she was passionately fond of music, and an excellent player on the piano on which instrument she might have attained some distinction as an executant but for the "agonies of shyness" with which she was afflicted during her youth. The active life was followed by her brother's appointment to succeed him, and Marian and her father removed in 1841 to Toleshill Road, Coventry.

Up to this time Marian was deeply imbued with evangelical religion, which had been stamped upon her mind at a very early age by the example and instruction of her teachers. Then with expanding intellect came vanishing faith. Among the new friends was Charles Bray, whose wife was a sister of Charles Hennell, the author of a work called 'An Inquiry Concerning the Origin of Christianity,' published in 1838, and rationalistic in tone. The reading of this and similar works effected a complete revolution in the inner life of Marian Evans; she abandoned the creed of her girlhood, and determined in the spring of 1842 not to go to church. This was the occasion of a temporary breach with her father, who was a churchman of the old school and little disposed to brook rebellion in his own household. After a short absence from home and through the efforts of friends a reconciliation was effected; Marian returned and resumed her attendance at church, and although she never retracted by a step the course she had taken, her works are witness to the insight and tenderness, born of understanding, with which she approached evangelical beliefs.

The years from 1842 to 1849 were devoted to attendance on her father during his recurrent illnesses, and by the translation of Strauss's 'Life of Jesus,' a work which entailed two years of exacting labor and was published anonymously in 1846, and for which she received the sum of £20. The completion of this work left her "Strauss-sick—it makes her ill discussing the beautiful story of the Crucifixion." After the death of her father (1849) she went to the Continent and passed about eight months in Geneva. On her return she took up work on the Westminster Review, acting as sub-editor, and in 1853 went to reside at the office of the magazine at 142 Strand. In the same year she published a translation of Feuerbach's 'Essence of Christianity.' Her only work published under her own name, and the leading idea in which is that man has made God in his own image—the spiritualized form of his hopes and desires. At this period she made the acquaintance of Froude, J. S. Mill, Carlyle, Harriet Martineau, Herber Spencer and George Henry Lewes (q.v.).

With Lewes, whom she describes as a "man of heart and conscience, wearing a mask of flippancy," she entered into a connection which she regarded as a marriage without the sanction of law. He had a wife already, from whom he was separated under circumstances that precluded the possibility of divorce. This alliance is regarded by many as the one fatal step in her life, and to it they attribute the somewhat abrupt self-consciousness that is apparent in some parts of her writings, and note that the novelist's own conduct does not square with her teachings. There is no doubt however that they lived happily together, and that their union exercised a profound mutual influence on their literary life and fortunes. Lewes undertook all business matters for her, acted as critic and mentor; and tactfully shielded her from the perusal of unfavorable or inept reviews. Indeed but for the constant encouragement and stimulus given by Lewes the success of "Silas Marner" and "Marian Evans would never have discovered herself as a creative artist, for although possessing singular robustness and health of intellect she was of low physical vitality, subject to acute fits of depression, and only by strong effort was able to undertake creative work. Lewes and Marian Evans left England in July 1854 and wintered in Germany. On their return she labored at a translation of Spinoza's 'Ethics' and wrote reviews for the Leader. An article contributed to the Westminster Review entitled "Evangelical Teaching: Dr. Cumming," in which the famous preacher of Crown Court was subjected to a criticism that was at once informed, witty, pointed and scathing, revealed to Lewes that he had mated with genius, and under his encouragement, 'The Sad Fortunes of the Reverend Amos Barton' was begun in September 1856, and appeared in Blackwood's Magazine in January 1857. This was followed by 'Mr. Gilfi's Love Story,' and 'Janet's Repentance,' the three stories being published in book form in 1858, under the pen name of "George Eliot." Discerning critics like Thackeray and Dickens recognized that a new force had arisen in England fiction, and the latter divined that the creator was a woman.
It may be questioned if the author ever bettered those faithful sketches of old-fashioned life in the Warwickshire of her girlhood, with their genial and kindly humor, warmth of sympathy, poetry of description and unforced pathos. 'Scenes of Clerical Life' could not be called a popular success, but with her next novel 'Adam Bede' (1859) written partly in England, partly at Munich and Dresden, the reading public was taken by storm, and it has remained the most popular of George Eliot's works. The genesis of the story came to the author through an aunt, a Methodist preacher, who had occasion to pass a night with a girl condemned for child murder, the aunt and girl respectively becoming the Dallas Morris and Hetty Sorrel of the novel. George Eliot was put to considerable annoyance by the claims made to its authorship, especially by one Liggin's in her native county, and only the intervention of Blackwood the publisher set the matter at rest. It then became known that Marian Evans, the Westminster reviewer, and George Eliot were identical. 'The Mill on the Floss' (1860) is to some extent autobiographical, the charming portraits of Maggie and Tom Tulliver drawn from her own and her brother-in-law, Isaac's childhood. 'Silas Marner', which many regard as her most perfect story, followed in 1861. In 1860 George Eliot had spent the summer in Italy collecting material for her great historical romance, 'Romola', first published serially in Cowpluff, for which she received the then unheard-of sum of £2,000, and which appeared in book form in 1863. In order to write this she went through a course of reading that would have qualified her to write a history. Her husband says that, "it ploughed into her more than she of her works," and she herself says she "began it a young woman, and finished it an old woman." Although it must be pronounced a masterpiece, reflecting her powers at their very highest, it cannot be regarded—in spite of the fine character drawing in it, especially of Tito Mocenigo and Tessa—as a faithful and lifelike reproduction of the Florence of the Renaissance. The appearance of 'Felix Holt the Radical' in 1866 seemed to betoken diminishing powers. She then essayed poetry, 'The Spanish Gypsy' and 'The Agatha' in 1869; and these revealed that her art did not lie in that direction. The only poem of hers that is certain to live is the noble piece beginning 'O may I join the choir invisible.' 'Middlemarch' (1871-72), a novel which may be regarded as inspired by her life at Coventry, as her early works drew their stimulus from childhood and girlhood, is notable for some fine characterizations of middle and upper class life in an English provincial town, and is replete with pregnant thought. The 'Legend of Jubal' and Other Poems appeared in 1874. 'Daniel Deronda,' her last great work, was published in book form, and in the opinion of at least one noted critic is the best of her novels and marks the culminating point in her career. On 6 Nov. 1880, Lewes died. This bereavement was a crushing blow to George Eliot; for weeks she saw no one and wrote no letters; and she busied herself preparing his unpublished work for the press, and founded a scholarship in his memory for scientific investigation. 'The Phra pipe' Sibb,' written sometime earlier, appeared in 1879. She never really got over the shock of Lewes's death. In the months of sorrow and depression following on that event she had been lifted somewhat by the forethoughtfulness and helpful sympathy of J. W. Cross, an American, and an old friend of her own and of Lewes—which, she died on 22 December of the same year. The first collected edition of her novels appeared issued at Boston in 1908. See Adam Bede; Middlemarch; Mill on the Floss, The; Romola; Silas Marner.

ELIOT, Sir John, English orator and statesman: b. Port Eliot, Cornwall, 20 April 1592; d. London, 27 Nov. 1632. He studied at Exeter, but did not take a degree. He then took up law, and traveled in Europe, where he became an intimate friend of George Villiers, later Duke of Buckingham. In 1614 he was sent to the "Addled" Parliament for Saint Germans. In 1618 he was knighted and in the following year, through the patronage of the Marquis of Buckingham, was made vice-admiral of Devon. In this capacity he was energetic in suppressing piracy. His arrest of a notorious pirate named Nutt brought him into collision with Nutt's protector, Sir George Calvert, then Secretary of State; and Eliot was imprisoned on trumped-up charges of treason and was married. The return of the Duke of Buckingham accomplished his release. He was returned to Parliament in 1624, where his remarkable independence and fluent oratory at once brought him into prominence. In 1625, during which session he opposed the leniency toward Catholicism and became an ardent supporter of constitutional rights. In 1626, the accumulated mismanagement and instances of the selfish policies of Buckingham completely undermined Eliot's faith in him and an impeachment followed. This, together with Eliot's opposition of forced loans, led to his imprisonment. At the protest of the Commons he was shortly released and returned to Parliament in 1628. He joined Coke in promoting the Petition of Right, which was signed by Charles on 7 June. In 1629, after the murder of Buckingham, Eliot devoted himself to the earnest support of Protestantism. His attempts to resist the king's tonnage and poundage taxes were met by the monarch with contempt and with the adjournment of Parliament. When this last measure was to be carried out a second time, Eliot insisted that the
GEORGE ELIOT

From the etching by Hajon
ELIOT, John, American colonial missionary, "the Indian Apostle": b. probably at Widdersford, Hertfordshire, 1604; d. Roxbury, Mass., 20 May 1690. He was graduated at Cambridge in 1622, and, after taking orders in the Church of England, quitted his native country for science's sake and landed at Boston, New England, in 1631. In 1646, after two years study of the Indian language, he delivered a long sermon in the native dialect at Nonantum, and other meetings soon followed. He shortly after began to establish his converts in regular settlements, his work meeting with approval both in the colony and at home; in England a corporation was founded in 1649 "for the promotion and propagating the Gospel among the Indians of New England," which defrayed the expenses of the preachers and the cost of printing translations. At one time there were over a dozen townships of "praying Indians" within the bounds of Massachusetts, and many more outside these limits, with numbers estimated in 1674 at 3,600; but, although the organization survived until the death of the last native pastor in 1716, the decay of the "praying towns" was rapid after the war with King Philip (1675), in which the converts suffered equal cruelties at the hands of their countrymen and of the English. There are monuments to Eliot's memory in the Indian burying-ground at South Natick, and at Newton, near the scene of his first Indian sermon. A man of earnest piety and devotion, warm-hearted and of a singularly attractive manner, he had a memory that it is honored among as the first in the history of New England. With Thomas Weld and Richard Mather, Eliot prepared an English metrical version of the Psalms, the "Bay Psalm-book" (Cambridge 1640), as the first book printed in New England; the following year, among other works, of "The Christian Commonwealth" (London 1659), suppressed by the court and now extremely rare; "The Communion of Churches" (1665), the first book privately printed in America; and of translations into the Indian tongue of Baxter's "Call"; Bayly's "Practice of Piety" (abridged); and Shepard's "Sincere Convert." But the great work of his life was the translation and publishing of the Psalms in the tongue of the Indians of Massachusetts (Algonquin), of which the New Testament appeared in 1661, and the whole work, with a version of the Psalms in metre and a page of liturgy, in 1663. The longest single work in it is "Utappesittukussunnoohehtunkuoh," signifying "kneeling down to him," in Mark i, 40; which illustrates the jest of Cotton Mather, who said he thought the words of the language must have been growing ever since the dispersion at Babel. Only 14 complete copies of the first and second editions are known to be in existence. A scientific study of Eliot's Indian Bible was made by J. H. Trumbull (q.v.), and his manuscript published 1903 as Bulletin 25 by the Bureau of American Ethnology, Washington. Its chief monument is "Natick Dictionary" and it is divided into two parts, the first giving the Natick words with English definitions and the second giving the English words with Natick definitions. While it is devoted to the Natick language it is practically a dictionary of all the Algonquian languages of Massachusetts, for the tribes of that part of the country spoke practically the same language, though each had its dialectic variations. Eliot's "Indian Grammar Book" was printed in his "Catechism" in 1669. The finest collection of unique and scarce copies of Eliot's works is in the Lenox Library, New York; many of them have been reprinted. The best "Life of Eliot" is that by Francis (Vol. V); Sparks' "American Biography" 1st series (1836); the earliest that by Cotton Mather (1691). Consult also articles in the "Cyclopedia of American Biography" (Vol. II, 1887); and the "Dictionary of National Biography" (Vol. XVII, 1889).

ELIOT, Sir John, English colonial clergyman: b. 7 Nov. 1685; d. 23 April 1763. He was a grandson of John Eliot, the "Apostle to the Indians," and was long a pastor at Killingworth, Conn. He was an able preacher, a botanist and a scientific and practical agriculturist; was the first to introduce the white mulberry tree into Connecticut, and discovered a process of extracting iron from ferruginous sands. He was also regarded as the first physician of his day in the colony; and such was his success in the treatment of insanity and chronic complaints, that he was sometimes sent for to Newport and Boston, and was more extensively consulted than any other physician in New England.

ELIOT, Samuel, American educator and historian: b. Boston, Mass., 22 Dec. 1821; d. Beverly, Mass., 14 Sept. 1898. He filled the chair of history and nationalism in the Indiana College, Hartford, Conn. (1856-64); was its president (1860-64); and lecturer on history at Harvard (1870-73), and head master of the Girls' High School in Boston (1873-76). From 1876-90 he served as superintendent of the Boston public schools; his principal works are "The History of Liberty" (1853); "The
ELIOT—ELIXIRS

Liberty of Rome" (1849); ‘Life and Times of Savonarola’ (1856); ‘Manual of United States History Between the Years 1492 and 1850’ (revised ed., 1873); and ‘Stories from the Arabian Nights’ (1879); ‘Selections from American Authors’ (1879).

ELIOT, Samuel Atkins, American Unitarian minister: b. Cambridge, Mass., 24 Aug. 1862, son of Charles W. Eliot (q.v.). He was graduated at Harvard College 1884; was pastor of Unity Church, Denver, 1889-93, and of the church at Bedford, Mass., 1893-98. He was secretary of the American Unitarian Association 1898-1900, becoming its president at the latter date. He is a member of the United States Board of Indian Commissioners; the president of the trustees of the Hackley School, an editor of the Hibbert Journal; vice-president of the Massachusetts Federation of Churches, etc. He holds the honorary degree of D.D. from Bowdoin and LL.D. from Western Reserve University.

ELIS, 'Elīs, (1) a country in the west of Peloponnesus, where Olympia was situated. It was bounded on the east by Arcadia, on the south by Messenia and ran along the coast, watered by the river Alpheus. There were three districts in their country—Colle, or Hollow Elis, Fixatis and Triphylia; the two latter being subject districts. It was the seat of the greatest national festivals. The Athenians were the first to raid the coast during the Peloponnesian War and frequent conquests followed. After the suppression of the games at Elis by the Emperor Theodosius in 394 A.D., the Eleans lost their prestige entirely. Elis and Arcadia now form a nomarchy of Greece with the capital at Pyrgos. (2) Elis, once the capital of Elis, is now called Kaloskopi. (See OLYMPIA.) Consult Curtius, 'History of Greece.'

ELISHA, a member of the tribe of Issachar, a citizen of Abel-meholah, was a disciple of Elijah, and his successor in the prophetic office. His prophetic ministry, which was exercised, as was that of Elijah, in northern Israel, began in the reign of Ahab, and continued through the reigns of Jehoram, Jehu, and Ahaziah, during a part of the reign of Joash, thus covering a period of more than half a century. He was a man of very different character and mode of life from Elijah, although master and disciple seem to have been most warmly attached to each other. Elijah was a son of the desert; Elisha came from a quiet farm in the Jordan Valley. Elijah lived apart from men; Elisha, for the most part, dwelt in the city, either at Jericho among the sons of the prophets, or in his own home at Dothan or Samaria. Elijah had nothing to do with kings except to rebuke them; Elisha was their friend and counsellor. Yet it is easy to make too much account of their difference of character and life and to suppose that it affected in any way the prophetic aim and religious attitude, so that these were quite different in the case of each prophet. But to claim that the work and spirit of Elisha were in marked contrast to those of Elijah would be to claim too much. The declaration of Jehovah to Elijah on Mount Horeb, "Him that escapeth from the sword of Jehu, shall Elisha slay" (1 Kings xix, 17), shows that it was Elijah's work of vengeance and destruction which Elisha was to continue. It was Elisha, moreover, who devised the plan for the destruction of the house of Ahab (2 Kings ix, 1-3). It was Elisha, also, who reproved King Joash for his lack of zeal for the utter overthrow of Syria (2 Kings xiii, 19). It is to be remembered in this connection that the accounts which we have concerning the career of Elisha, whatever the cause may be, relate rather to his deeds as a man, than to his work as a prophet.

For some six or seven years after his call to the office of prophet by Elijah at Abel-meholah (1 Kings xix, 19-21), he was a helper and disciple of Elijah. But we do not know just where he was in all this time, or the exact nature of his work. At the close of this time, after the ascension of Elijah, he began his own independent work as a prophet (2 Kings ii, 13-22). The character of the narrative in the Second Book of Kings makes it impossible to arrange the events of his life in chronological order. At the close of this time, after the ascension of Elijah, he began his own independent work as a prophet (2 Kings ii, 13-22). The character of the narrative in the Second Book of Kings makes it impossible to arrange the events of his life in chronological order. It is better, therefore, to group them under two headings: (a) his deeds in private life; (b) his deeds in public life.

Under the first class, we may put (1) the healing of the waters of Jericho (2 Kings ii, 19-22); (2) the punishment of the lads of Bethel (2 Kings ii, 23-25); (3) the saving of a widow's son from slavery (2 Kings iv, 1-7); (4) the restoring of the Shunammite's son to life (2 Kings iv, 32-36); (5) the rendering of some poisonous potion harmless (2 Kings iv, 16-41); (6) the miraculous feeding of a hundred men (2 Kings iv, 42-44); (7) the healing of Naaman the leper (2 Kings v); (8) the causing of the iron head of an axe to swim (2 Kings vi, 1-7).

Under the second class we may put (1) his helpful work in the campaign against Moab (2 Kings iii, 11-24); (2) his bringing of the Syrian army into Samaria, where they were made prisoners (2 Kings vi, 8-23); (3) his activity in the siege of Samaria (2 Kings vii, 24, viii, 2); (4) his visit to Damascus to announce to Hazael that he shall be king of Syria (2 Kings viii, 7-15); (5) the sending of a messenger to anoint Jehu to be king of Israel (2 Kings ix, 1-3); (6) the assuring of King Joash that Israel should be victorious over Syria (2 Kings xiii, 18-19). But the power of Elisha did not end with his life. Of him alone of all the prophets it is recorded that he wrought a miracle after his death. A dead man who was hastily cast into the sepulchre of the prophet, on touching the prophet's bones, came to life, and stood upon his feet (2 Kings xiii, 20-21). Consult Grove, "Elisha" (in Smith's 'Dictionary of the Bible,' 1868); Strachan, "Elisha" (in Hastings' 'Dictionary of the Bible,' 1899); Farrar, 'Second Book of Kings,' Chaps. iii-vii in the 'Expositor's Bible,' 1902.)

SYLVESTER BURNHAM, Professor of Old Testament Interpretation, Theological Seminary of Colgate University.

ELIXIRS, in pharmacy, are aromatic, sweetish, spirituous preparations, containing small quantities of active medicinal drugs. They are now mostly used as vehicles for other remedies and have very little potent action save that of the ingredient that escapes from the armaticum and Elixir glycyrrhizae (licorice) are the only two elixirs recognized by the 1917 revision of the United States Pharmacopoeia.
ELIZABETH, the wife of the priest Zacharias and mother of John the Baptist, and also the mother of Jesus. An angel foretold to her husband the birth of her son in her old age; and it was also foretold by the angel Gabriel to the Virgin Mary, as an assurance of the birth of the Messiah.

ELIZABETH, queen of England; b. Greenwich, 7 Sept. 1533; d. Richmond, Surrey, 24 March 1603. She was the daughter of Henry VII and of Anne Boleyn. After her mother had been beheaded (1536) both she and her sister Mary were declared bastards, but finally she was placed after Prince Edward and the Lady Mary in the order of succession. Thus, while the first two marriages of King Henry were both still held to be illegal, the children of both were legitimized. Elizabeth received a classical education, as was customary with women of rank in her time, and under her tutor, Roger Ascham, is said to have attained very considerable proficiency in Latin and Greek. During her father’s life, as well as in the reign of her brother, various negotiations were entered into for her marriage. The duke of Angoulême and Philip of Spain, who afterward married her sister, were among the matches proposed for her marriage. The air of this kind in which she may be supposed to have been personally interested was the suit of Lord Seymour of Dudley, the Protector Somerset’s brother. It is certain that even during the life of Catharine Parr, the widow of Henry VIII, whom he married, his attentions to the Lady Elizabeth were only too well encouraged. Both before this marriage and after the death of his wife he was a suitor for the hand of the princess; but his ambitious designs in this and other matters were not countenanced by the council, and ultimately ruined his life.

On the death of King Edward, Elizabeth vigorously supported the title of Queen Mary against the pretensions of Lady Jane Grey, by which her own title as well as her sister’s were backed. She rode to meet her sister, accompanied by 1,000 horse, and this bold proceeding was of no small service in confirming the doubtful in their allegiance; but Elizabeth gained little for herself by a policy in which it was well understood she had her own interest in view. After Wyatt’s conspiracy her life was in great danger, and was probably saved only by the intercession of Philip. She was committed to the Tower, from whence she was removed to Woodstock, where she was confined with great strictness. She afterward, through Philip’s intercession, obtained greater liberty; but throughout the whole reign continued an object of suspicion and surveillance. The danger she now incurred developed traits in her character which ever after continued conspicuous, her prudent self-control and power of dissimulation. She made every demonstration not only of conformity but of zealous adherence to the established religion. Her conduct in this must not be judged from the point of view of rigid Protestantism, which Elizabeth never professed; but there were some at least among the Roman Catholic ceremonies and customs to which she could not be supposed to give a sincere adherence. Nevertheless, her simulated zeal must have been well and ably sustained, for her conduct was not left to the report of friends, but carefully watched by spies and informers. Philip was most anxious to have her married out of the kingdom; and if the Duke of Savoy, whom he proposed, was unacceptable from the Catholicism, there was Eric, son of the king of Sweden, who long after continued to press his suit; but Elizabeth refused both. She felt in herself a capacity for rule, and her sister’s ill health opened up for her an early prospect of the throne, which she was unwilling to forfeit. Mary’s reign was not without advantage to Elizabeth. It tried her councillors as well as herself, and gave her the opportunity of selecting them to advantage. Her adviser throughout the whole of it was William Cecil, afterward Lord Burleigh, who had already been a minister under Edward VI, and continued for the rest of his life to be one of the chief councillors and ablest ministers of Elizabeth, to whom she was in many respects a congenial spirit.

On 17 Nov. 1558 Mary’s disastrous reign came to a close, and Elizabeth was immediately recognized queen by Parliament. On entering London she was met by the bishops, whom she permitted to kiss her hand, with the exception of Bonner, “whom she only allowed to kiss her fingers in token of the seversities in the time of his authority.” It was now that the caution and secrecy characteristic equally of Elizabeth and Cecil, and which enabled them to do such great things, appeared in spontaneous exercise. The Roman Catholic religion was still predominant in the House of Lords, and any attempt to overthrow it suddenly might have been attended with the greatest danger. Elizabeth made no immediate change in her habits. For a full month after the Roman Catholic Church were retained in all their state. A solemn funeral service was held for Queen Mary in Westminster Abbey, at her interment on 13 December. The Queen even intimated her accession to the Pope. She retained the greater part of her sister’s council, choosing only seven new councillors, who were Protestants, it is true, but not then known as such. Like Cecil and herself, they had all conformed, and possessed the necessary qualification for Elizabethan councillors of accomplished dissimulation. Such were her distaste and withstanding her great prudence, that at her coronation only one of all the bishops, Ogilthorpe of Carlisle, could be found to set the crown on her head. The obstacle lay in the terms of the oath of allegiance, which affirmed that the sovereign was the supreme head of the Church, and to which no loyal Catholic could subscribe. She had also before this authorized the reading of the liturgy in English. The first great object of her reign was the settlement of religion. A Parliament was immediately called to which this work was assigned. It met on 25 January, and was dissolved 8 May, but its object was already accomplished. The nation was prepared for a return to the reformed faith or rather to the via medii which is embodied in the Anglican Church—and Parliament by its law and bidding of the court. The reformation of religion in England was the work of Cranmer, and had already been accomplished in the reign of Edward VI; the re-establishment of the ecclesiastical system of the national Church on the basis on which it has remained to the present day was the work of Cecil and Elizabeth, and it was nearly completed in this Parliament. Elizabeth had less extreme opinions than many su-
porters of the new faith. She was tolerant, for instance, in regard to images and was fond of ceremonial and is said to have entertained scruples as to the extent of the royal supremacy in spiritual matters; but if she did, they must have been purely speculative. They certainly vanished on the first taste of power.

If the formal establishment of the reformed religion was easily completed, the security and defense of the settlement was the main object of the policy and the chief source of all the struggles and contentions of her reign. What made the position so difficult was the intolerance by which at this period and for long after all religious sects were characterized. No sooner were the Puritans freed from the restrictive measures of Mary's reign than they began to claim predominance for their own dogmas. But it was far from the intention of the Queen and the supporters of the Established Church, notwithstanding the common persecutions they had endured, to grant them even liberty of worship. Elizabeth's own determination, as expressed by her brother was that no church should be allowed to turn aside either to the right hand or the left from the drawn line of prescribed duty, and in insisting upon uniformity of worship she was not singular, but was acting in the spirit of her age. This principle was not less firmly held in her reign than in her sister's; and Roman Catholics on the one hand, and Puritans on the other, re- strained only by their dread and hatred of each other, were made the irreconcilable enemies of the existing order. Moreover, from the necessities of the struggle the severities of Elizabeth's reign went on increasing as time advanced. At first no one suffered death for his opinions; but eventually many were executed for this cause. The struggle against Roman Catholics was the most severe, chiefly because they were supported by foreign powers; so that while their religion was wholly prohibited, even exile was forbidden them in order to prevent their intrigues abroad. Simple non-conformity, from whatever cause, was pursued with the severest penalties. The fine imposed for non-attendance at church was £20 per month, while so strict were the lines of conformity drawn, that many more clergy men were driven out of the Church by differences about the position of altars, the wearing of rings and such like matters, than were forced to resign by the change from Rome to Reformation. These stringent measures were, however, the rigid consequences of the false position assumed.

Elizabeth's first Parliament approached her on a subject which, next to religion, was the chief trouble of her reign, the succession to the crown; they requested her to marry. She replied in a long speech, declaring her intention to live and die a virgin. It is certain, from her conduct both before and after, that this declaration was only a convenient affectation of prudery, which at once served to flatter her vanity and to veil her real indecision. She saw too clearly for her own interest the restraints to which each particular marriage might subject her, and so concluded that she must wait, thus leaving open the question of the succession.

On Elizabeth's accession the country was at war with France. Peace was easily concluded 1559; but the assumption by Francis and Mary of the royal arms and titles of England led to an immediate interference on the part of Eliza-
ELIZABETH

her government at home and abroad was sustained by such men as Burleigh, Bacon, Walsingham, and others who were all personal favorites of less merit who were often more brilliantly rewarded. It is sufficient to name Dudley, whom she created Earl of Leicester; and Essex, who was still more a personal favorite, though much less a courtier. The latter had some merit as a soldier; but his violence, temper, ill-suited to the Queen's haughty disposition, brought about his ruin. He was beheaded in 1601, and Elizabeth never forgave herself his death. Her own health soon after gave way, and she died, naming James of Scotland as her successor.

Besides its political glories, won in spite of the Queen's somewhat insular and narrow outlook, the reign of Elizabeth was the golden age of English literature. If all else could be forgotten, it would be remembered as the age of Spenser and of Shakespeare, not to mention a host of minor names. The naval achievements of Drake and the discoveries of Raleigh occupied the nation's mind. Thus it seemed to the world that round the name of Elizabeth, when regarded as a sovereign, and seen as she would be in her own day, especially by foreign beholders, through the drapery of state, criticism has expected some of the weaknesses of the individual woman who bore this burden, it must be remembered that the process is only half fair. As a sovereign she was entitled to her surroundings, and as an absolute ruler, as to a great extent she undoubtedly was, she must have her share of praise for the good that was done in her name. It is no small merit to select good councillors and to adhere to them. Elizabeth knew how to do both; and yet she was no puppet in the hands of her advisers. Though haughty and imperious to the Commons, she knew both when and how to yield. She studied with rare sagacity the temper of the people; and high as were her notions of prerogative, she may fairly be considered the first constitutional monarch of England.

ELIZABETH, empress of Austria: b. Possenhofen, Bavaria, 24 Dec. 1837; d. Geneva, 10 Apr. 1884. The only daughter of Duke Maximilian Josef of Bavaria, and married her cousin, the Emperor Franz Josef, on 24 April 1854. Together they were crowned with the insignia of Saint Stephen when the inauguration of the dual system was solemnized. She was greatly admired by Austrians and Hungarians alike. While visiting Geneva, Switzerland, she was assassinated by an Italian anarchist. Consult Friedmann, 'Kaiserin Elizabeth' (Berlin 1898).

ELIZABETH, Madame (ELIZABETH PHILIPPINE MARIE HÉLÈNE), French princess; b. Versailles, 3 May 1764; d. Paris, 10 May 1794. She was a sister of Louis XVI. She was the faithful friend and companion of her family in their flight to Varennes, and during their imprisonment was executed, on the pretext of corresponding with her other brothers, afterward Louis XVIII and Charles X.

ELIZABETH, Pauline Otille Luise, dowager queen of Rumania (pseudonym "CARMEN SYLVA"); b. Neuwied, 29 Dec. 1843; d. Bucharest, 2 March 1916. Her father was Prince Hermann of Wied and her mother, Princess Marie of Nassau. She married Charles of Rumania, 15 Nov. 1869. She was the patroness of arts and letters in Rumania, did much to promote native artistic industries and founded several charitable institutions. She is well known as a writer over the signature "CARMEN SYLVA," her works including "Sapho" (1880); "Hammerstein" (1880); "Stirme" (1881); "Leidens Erden" ("Sorrow on Earth") (1882); "Les pensées d'une reine" (1882); "Pelesch Märchen" (1883); "Le pie aux regrets" (1884); "Es klopt" (1887). She was very much interested in collections of Rumanian legend and folklore. In English she wrote "Pilgrim Sorrow," "A Real Queen's Fairy Tales" and "From Memory's Shrine." In 1882 she became a member of the Academy of Science at Bucharest, and in 1914 an honorary Fellow of the Royal Society of Literature of the United Kingdom.

ELIZABETH, Saint, of Hungary, daughter of Andrew II, king of Hungary, and Gertrude, daughter of the Duke of Canthia: b. Presburg 1207; d. Marburg, 19 Nov. 1231. Early in life she displayed a dislike for things worldly, as the pomp with which she was surrounded, ambition, avrice and vain pleasure, and she resolved to cultivate humility, piety and great charity. According to the custom of the times, when she was only four years old she was betrothed by her parents to Louis, the son of the Landgrave of Thuringia, who was about her own age. When Elizabeth was 14 years old they were married. Her husband admired his wife's piety and approved her great charity, especially during the famine in Germany in 1225, although members of his own family severely censured her. She founded hospitals in Marburg and other places within her husband's dominion. (Louis' father died the year after the betrothal, and he was the landgrave when he married Elizabeth). In 1227 Louis left home with Frederick Barbarossa to engage in the war for Palestine; but before reaching the Holy Land Louis died from fever. Great misfortunes soon befell Elizabeth. She was deprived of her regency by the brother of her deceased husband and driven out of her dominion on the plea that she was the true heir of the state by her charities. The inhabitants of Marburg, whose miseries she had frequently relieved, refused her any asylum, for fear of the new regent. At last she found refuge in the monastery of Kitzingen, where her aunt...
ELIZABETH — ELIZABETH, N. J.

was abbess, and later with her uncle, bishop of Bamberg, and when the warriors who had attended her husband in the Crusade returned from the East with his body, she gathered them around her, and recounted her sufferings and her child's fate. Steps were taken to restore to her her sovereign rights. She declared the regency, however, and would accept only the revenues which accrued to her as landgravine. The remainder of her days were devoted to almsgiving, mortifications and penance, and she became a member of the Third Order of Saint Francis, and in pictures she is often represented clothed in the Franciscan habit. She was canonized by Gregory IX, four years after her death. Consult Montalembert, 'Life of Saint Elizabeth of Hungary' (trans. into English by F. D. Hoyt 1904); Starr, 'Patron Saints'; Butler, 'Lives of Saints'; Bonaventure, 'Sermon on Saint Elizabeth'; Theodoric and Montague of Spire. There are extant manuscripts on her life, by contemporaries, Conrad of Marburg, Siegfried of Menz, and others.

ELIZABETH Farnese, făr-nē'sē, queen of Spain: b. 25 Oct. 1692; d. 1766. She was a daughter of Edward II, Prince of Parma. On becoming the second wife of Philip V she surprised those who had counseled the marriage by assuming the practical headship of the kingdom; her ambition to place her sons Charles and Philip in power over principalities in Italy and the aggressive policies of her Minister, Alberoni, disturbed the whole of Europe.

ELIZABETH PETROWNA, empress of Russia: b. 29 Dec. 1709; d. 5 Jan. 1762. She was the daughter of Peter the Great and Catherine, and ascended the throne on 7 Dec. 1741, as the result of a conspiracy, in which Ivan VI, a minor, who had reigned only one year, was deposed. Elizabeth is said to have rivaled her mother in beauty and to have surpassed her in her love of pleasure. Her reign was stained both by her unbridled licentiousness and the tyranny of her government, which was conducted by favorites. Banishment to the mines of Siberia and imprisonment in dungeons were awarded for the slightest political offenses. She was a patron of literature and corresponded with Voltaire, to whom she supplied materials for his 'Life of Peter the Great.' She also founded the University of Moscow and the Academy of Fine Arts of Saint Petersburg. Elizabeth sent an army, in 1748, to assist Maria Theresa in the war of the Succession, which contributed to bring about the Peace of Aix-la-Chapelle; and she joined in the Seven Years War against Prussia. Consult Bain, 'The Daughter of Peter the Great' (London 1899).

ELIZABETH STUART, queen of Bohemia: b. Falkland Palace, Fife, 16 Aug. 1596; d. London, 13 Feb. 1662. She was a daughter of James I of England and was married to the Palatine Frederick at Whitehall, 14 Feb. 1613. Her husband was then at the head of the Protestant interest in Germany, and in 1619 he accepted the crown of Bohemia offered to him by the revolted Protestants of that country. This he was only able to retain for a very short period; and after his defeat at the battle of Prague in 1620, he and his wife were obliged to flee, first to Brussels, and then to The Hague. Elizabeth had 13 children, several of whom died early. Charles Louis, the eldest surviving, was reinstated in the patrimony by the Treaty of Westphalia in 1648. His daughter, Elizabeth Charlotte, was the second wife of the Duke of Orleans, brother of Louis XIV. Her descendants were excluded by their Catholicism from the crown of England, but one of them was regent of France during the minority of Louis XV; and another, Louis Philippe I, ascended the throne after the Revolution of 1830. Her sons, Princes Rupert and Maurice, distinguished themselves in the civil war in England. Her daughter, Sophia, married into the house of Brunswick, became electress of Hanover and mother of George I. Elizabeth Stuart's cause was extremely popular with the English nation and after her husband was deprived of the crown of Bohemia she still retained among them the endearing epithet of Queen of Hearts. She returned to England at the Restoration with her second son, Charles II. Consult Green, Mrs. E., 'Lives of the Princesses of England' (London 1854).

ELIZABETH OF VALOIS, vāl-wē', or ISABELLA, Queen of Spain: b. Fontainebleau, France, 22 Nov. 1545; d. Madrid, 3 Oct. 1568. She was a daughter of Henry II, of France, and Catherine de Medici. She was intended to be the wife of the infante, Don Carlos, but his father, Philip II, being left a widower, became fascinated and married her himself. The story of a romantic relationship between Elizabeth and Don Carlos has furnished tragic subjects to Otway, Campion, Chénier, Schiller and Alfieri.

ELIZABETH, N. J., city, county-seat of Union County, on Newark Bay and the Arthur Kill, and on the Pennsylvania, Lehigh Valley, Baltimore and Ohio, Philadelphia and Reading and New Jersey Central railroads; 14 miles southwest of New York. Elizabeth has a good harbor admitting vessels of 25 feet draft. Coal and iron reach tidewater here from the Pennsylvania fields and are transshipped here. The city has steam power and is the residence of a commuter daily to the latter city. It has many fine homes and wide streets, well paved. The chief articles manufactured are sewing-machines (one of the shops of the Singer Manufacturing Company, employing about 300 people being located here), oilcloth, hats, saws, mill-machinery, stoves, hardware, edge-tools, harness, cordage, combs, leather and rubber works, oil refiners, foundries, chemical works, ship building plants, wire and cable, tools, electromotors, castings and bronze powder. The United States Census of Manufactures for 1914 showed within the city limits 184 industrial establishments of factory grade, employing 14,297 persons, 12,871 being wage earners, receiving $8,198,000 annually in wages. The capital invested in wages was $31,037,000, and the year's output was valued at $31,228,000; of this, $14,921,000 was the value added by manufacture. The shops of the Central Railroad, employing about 1,000 hands, and the Crescent Steel Works and shipyard are located here. There are three banks, one savings by the bank with a combined capitalization of $700,000 and deposits of $7,154,000, and building and loan
associations. Among public institutions are the Alexian Brothers' Hospital, General Hospital, Saint Elizabeth Hospital, Orphan Asylum, Old Ladies Home and Public Library. The educational institutions include the Battin and Pingry high schools, the town Day School, a business college and 11 public schools. The city has electric lights and street railways, many handsome churches and contains an old tavern where Washington stopped on his way to New York for his inauguration. Gen. Washington's house and the old Livingston Mansion are located here. It was settled in 1664 as Elizabeth-town and four years later the first General Assembly of New Jersey met here. For two years after 1755 it was the capital of the Colony of New Jersey. During the Revolution it suffered from its position between the contending forces. In 1789 it was chartered as a borough, as a town in 1796, and as a city in 1855. Its revenue averages about $2,250,000. In 1746 the college of New Jersey (now Princeton) was established here. Among its early citizens were the great rivals Alexander Hamilton and Aaron Burr. There are many fine types of architecture of the Revolutionary period still standing. Pop. 82,411. Consult Hefield, 'History of Elizabeth' (New York 1868).

ELIZABETH, Cape. See Cape Elizabeth.

ELIZABETH CITY, N. C., town, county-seat of Pasquotank County, on the Pasquotank River and the Norfolk and Southern and the Virginia and Carolina Coast railroads, about 145 miles northeast of Raleigh. A State normal school and United States custom-house are located here. The town has a good trade in the produce of the neighboring truck farms, also in cotton, fish and oysters. The region about is adapted for agriculture, lumbering and cotton raising. The manufactures of the town are varied, including cotton, saw- and planing-mills, shipbuilding, brick yards, carriage and wagon factories, shingle factories, hosieries, mills, flour and grist-mills, ironworks, machine-shops, barrels and baskets, boxes, etc. The town was founded in 1793 and now has a government consisting of a mayor, elected every two years, and a board of aldermen, and a board of control. A naval victory was gained here by the Federals, 10 Feb. 1862. Pop. 9,292.

ELIZABETH ISLANDS, Mass., group of 16 in number, forming the town of Gosnold, in Dukes County. They are situated between Vineyard Sound and Buzzards Bay; area, 14 square miles. In 1602 the first New England settlement was made on one of these islands, Butthunk, by Bartholomew Gosnold; but after a residence of a few weeks it was abandoned and Gosnold returned to England (see Gosnold, BARTHOLOMEW). The climate is healthful and the beaches are popular with anglers and as a vacation resort. Naushon and Nashawena are the largest of the group, which in 1864 were incorporated as the town of Gosnold. Pop. 164.

ELIZABETHAN ARCHITECTURE, a style of architecture, which began to prevail in England during the reigns of Elizabeth and James I. It was a mixture of interior Gothic with debased Italian, often very picturesque, but without purity and unity of design. It was characterized by deeply enlaid windows, galleries of great length, very tall and elaborate chimneys, strap work in the parapets and window-heads, and many dormer details of surface-carving characterizing the bizarre influence of the combined Renaissance influence from Germany and Holland. The names of Holbein and John of Padua are associated with this style of architecture in which they had hoped to revive classic models. The mansions erected for the nobility during the reigns of Elizabeth and James I are examples of this style of architecture, particularly the palace erected in the mixed style for Protector Somerset by John of Padua and the mansion of Longleat for his secretary, Sir John Thynne. Others which may still be seen near London and which represent the architecture of the 17th century are: Knowle, belonging to the Duke of Dorset, the Marquis of Salisbury's at Hatfield, Holland House, Campden House in Surrey, Bramshill in Kent, Sir T. Willy's at Charlton, Burton Agnes, Blickling, Montacute, Mogus Park, Aston, etc. This style was succeeded by the Jacobean in which Gothic details disappeared. The greatest architects of the Elizabethan period were Gerard Chrismas, John Thorpe, Thomas Holt and Rodolph Symonds. Consult Gotch and Muntz, 'History of English and English Architecture of the Renaissance in England' (London 1894); Richardson, 'Architectural Remains of the Reigns of Elizabeth and James I' (ib. 1840); Blomfeld, 'History of Renaissance Architecture in England' (ib. 1897).

ELIZABETH TOWN, Ky., city, county-seat of Hardin County, on the Louisville and Nashville and the Illinois Central railroads, about 40 miles south of Louisville. The city is the centre of the trade in asphalt for which the county is noted. It has flouring mills, stave and overalls factories, and dairying interests, and carries on a considerable trade in live stock, grain, flour, fruit, but it is not a coal center. It has municipal waterworks. Pop. 1,970.

ELIZAVEUTPOL, ě-lē-žë-vet-pol, or VELIZAVEUTPOL, Russia, (1) government of Transcaucasia, Asiatic Russia; area 16,991 square miles; pop. 1,998,000, of whom about 60 per cent are Azerbaijan Tartars, 30 per cent Armenians and the balance Kurds, Russians, etc. It is bounded on the north by Tiflis, Daghestan and Zakataly, east by Baku, south by Persia and west by Erivan. It belongs partly to the region of the Little Caucasus and is partly covered with steppes, in the west consisting of high mountains whereas the east is more level. The Kur River and several smaller streams are the chief waterways. Agriculture is the principal industry, the valleys being fertile and well cultivated. Wine is produced in considerable quantities; also cotton, the acreage in 1914-15 being 142,570 producing 23,652,500 pounds. The rearing of live stock is largely carried on in the steppes. The mountain slopes are well wooded and there are rich deposits of minerals, especially of copper, coal, and iron ore which are found and mined in large quantities. The Transcaucasian Railway crosses the government, which is divided into eight districts, Elizaveutpol, Zangial, Zareh, Jebraïl, Javanshir, Shawa, Kazakh and Nuka.
(2) A city of the same name is the capital of the government, located on an affluent of the Kur River about 120 miles by rail southeast of Tiflis. It is situated in a rich agricultural region and besides trading in the agricultural products and fruit, the inhabitants are extensively engaged in the silk-worm industry. The city consists of two sections, the old and the new; the former is poorly built with crooked streets and low-roofed houses and is occupied chiefly by Mohammedans; the latter is well built and contains several handsome buildings, churches, mosques, etc., and a bazaar. Ancient remains are found in the vicinity of the city and the old Turkish fortifications may still be seen. The city changed hands between Persians, Arabs and Khozars as early as the 7th century, later came into the possession of the Mongols, Georgians, Persians and Turks, was taken by the Russians in 1796 and finally annexed to Russia in 1813, receiving its name in honor of Elizabeth, daughter of Alexander I. In 1826 the Persians were defeated here. Pop. 60,500.

ELK, the name of various deer, but originally and properly belonging to the great, flattened-horned deer of northern Europe (Alces machlis), of which the American moose is substantially the counterpart, although regarded by naturalists as a distinct species. The European elk is now restricted to northern Russia, northern Scandinavia and the wilder forests of eastern Prussia; but in Pleistocene times it had a far more southerly range, together with other species now extinct. The great-antlered "Irish Elk," whose remains are found abundantly in peat-bogs and similar places not only in Ireland but in England and on the Continent, is not a true elk (Alces), but a deer of the genus Cervus related more nearly to our wapiti, despite the palmation of its horns. See MOOSE. The American deer called elk, by the ignorance or carelessness of early colonists, is the large, round-horned stag, related not to the true elk but to the red deer of Europe, and the white-tailed and other deer of this country, and would better be called, as commonly nowadays by its Indian name Wapiti. See WAPITI; DEER.

ELKESAITES. See ELCESAITES.

ELKHART, Ind., city in Elkhart County, at the confluence of the Saint Joseph and Elkhart Rivers, and on the Cleveland, Cincinnati, Chicago and Saint Louis, the Lake Shore and Michigan Southern and other railways, 101 miles east of Chicago. It is a railroad centre and shipping point for a large agricultural region. The rivers afford excellent water power. A large dam and power-house, erected in 1913 at a cost of $750,000, furnishes abundant power for its industries, which include railroad shops, musical instrument factories, automobile works, bridge and iron works, and establishments for the manufacture of carriages, invalid tables, machinery, gocarts, corsets, telephones, furniture, brass sundries, gas generators, paper boxes, rubber and paper. The United States census of manufactures for 1914 showed within the city limits 105 industrial establishments of factory grade, employing 3,815 persons; 2,993 being wage earners, receiving annually $4,382,000 in wages. The capital invested aggregated $9,511,000, and the year's output was valued at $8,649,000; of this, $4,267,000 was the value added by manufacture. The city has a Carnegie library and a fine high school building. Elkhart is the seat of Elkhart Institute and has public schools, business colleges, daily and weekly newspapers, gas and electric lights, electric railways, waterworks, two national banks. The control of the government is vested almost entirely in the mayor and there is a city council. Pop. 21,028.

ELKHORN, a river in Nebraska formed by the junction, in Madison County, of the North Fork, which has its rise in Brown County, and the South Fork, which rises in Knox County. The general course is southeast, 260 miles, when it flows into the Platte River. Logan Creek is the largest tributary.

ELKIN, William Lewis, American astronomer: b. New Orleans, 29 April 1855. He was educated at the Royal Polytechnic School in Stuttgart, Germany, and was graduated in 1880 at the University of Strassburg. He then went to the Cape of Good Hope on the invitation of Sir David Gill, English astronomer there, and took part with him in observations with the heliometer for the determination of stellar parallax; these determinations being the most accurate of the kind ever made up to that time. He became astronomer in 1884 and director in 1896 of the Yale College observatory. His work there was mainly in the lines of determinations of stellar parallax, the solar parallax from asteroids and the photography of meteor trails.

ELKINS, Stephen Benton, American politician: b. Ferry County, Ohio, 26 Sept. 1841; d. 4 Jan. 1911. He removed to Missouri when a child; was graduated at the University of Missouri in 1860; and admitted to the bar in 1864. During the latter year he went to New Mexico, where he was a member of the Territorial legislature in 1864-65; and the Territorial delegate in Congress in 1873-77. Subsequently he removed to West Virginia where he acquired large business interests. He married the daughter of Henry Gassaway Davis. He secured control of great coal fields in West Virginia and also became a large stockholder in several railroads, serving as president of the West Virginia Central and Pittsburgh Railroad. In 1891-93 he was Secretary of War and in 1894, 1900 and 1907 was elected to the United States Senate. The Elkins Railroad Law of 1903 bore his name. See ELKINS Act.

ELKINS, W. Va., city and county-seat of Randolph County, on both sides of the Tygarts Valley River and on the West Virginia Cincinnati and Pennsylvania (Wabash) and its branches, the Coal and Iron and the Coal and Coke railways, 60 miles southwest of Grafton and 130 miles northwest of Charleston. Elkins is in the centre of vast timber areas, and nearby are large deposits of coal, glass, sand, limestone, potter's clay, fire clay and shale. The city is in observations with the pressed brick and tiling. The industries include railroad car and machine shops, brick works, ice plant, foundries and machine shops, tannery, boiler works, pall factory, several planing mills, etc. The principal streets are paved with brick or macadamized and streets are laid with brick. The city owns the waterworks,
ELKINS ACT—ELLE ET LUI

which pump the water from the Tygart's Valley River. The streets are lighted by electricity and natural gas is furnished for domestic and manufacturing purposes. There are a national bank and a trust company in the city, with combined capital of $300,000 and deposits of about $1,200,000. The city contains several churches, reporting denominations. There are a graded public school and a high school. Elkton is also the seat of Davis and Elkton College and is home of the Odd Fellows home, two hospitals and an orphans' home. Under a charter of 1910 it is governed by a mayor, chosen annually, and a unicameral council. Pop. 6,000.

ELKINS ACT, a law enacted 19 Feb. 1903, to prevent secret railroad rebates and discriminations. The acceptance as well as the offer of a rebate or unlawful discrimination was a violation of the law; the published rate was declared to be the only lawful charge, and the United States Circuit Courts were authorized to enjoin carriers to charge only the published rates. The penalty was not less than $1,000 nor more than $20,000 for each offense, the corporation as well as the officer giving the rebate receiving the penalty. The law was most effective and with slight changes was incorporated in the Hepburn Act (1906) and the Mann-Elkins Act (1910). See DIFFERENTIALS IN RAILROAD TRAFFIC; SHERMAN ANTI-TRUST ACT.

ELKS, Benevolent and Protective Order of, a fraternal association, founded in 1868 in New York from an older social and benevolent society, the Jolly Coks. The grand lodge was incorporated 10 March 1871, and was composed of past members of New York Lodge No. 1, the premier regular association. In the same year it was empowered to form branch lodges. Lodges were formed in Philadelphia, San Francisco, Chicago, Cincinnati, Sacramento, Baltimore, Louisville, Saint Louis, Boston, Pittsburgh, Providence, Washington, and Denver and in every other city of any size throughout the country. The order has been noted for the prompt assistance given its members and also its ready response to calls for aid from the outside. In all great calamities of recent years it gave liberally of its funds to aid the needy. Its membership is close to 500,000, and its annual disbursements are about $600,000. There are 1,392 lodges, and subordinate lodges in Alaska and the island possessions of the United States. White male citizens of 21 years or over and of good character are eligible for membership. In any city there may be but one lodge, and the population of such city must be at least 5,000. On the first Sunday of December is held a memorial service for the deceased members of the order. Property and cash to the extent of over $11,000,000 are owned by the order. Its official organ is the Elks Antler, a monthly published in New York. Consult Ellis, C. E., 'Authentic History of the Benevolent and Protective Order of Elks' (Chicago 1910).

ELKUS, Abram Isaac, American lawyer and diplomat; b. New York, 6 Ate 1867; He was educated at the College of the City of New York and at Columbia. He has been prominent at the New York bar since 1888 and was considered by President Wilson for a place on the Federal court in New York. He is one of the leaders of the American Jewry and has frequently appeared for Jewish immigrants who have faced detention at Ellis Island and deportation because they had less than $25 in cash when they reached this country.

In 1896 he became a member of the law firm of James, Schell and Elkus. On the deaths of his partners he became senior member in the firm now known as Elkus, Gleason & Pros- maker. He has appeared in all branches of his profession. He was elected by the United States judges as a special United States attorney to prosecute fraudulent bid-collecting cases and met with great success in that work.

He acted as counsel for the Merchants' Association and president of the Hebrew Technical School and as trustee of the Baron Hirsch Fund. In July 1915 he was appointed by President Wilson as Ambassador to Turkey to succeed Henry Morgenthau, who had retired to become chairman of the finance committee of the Democratic national committee. He is the author of a treatise on 'Secret Liens and Reputed Ownership.'

ELL, an old linear measure, originally denoting the length of the forefoot and latter denoting different lengths. The English ell equaled one and one-quarter yards (45 inches).

ELLAGIC ACID or BEZOARIC ACID, C₂₂H₂₉O₄, is separated from Oriental bezoar stones (concretions found in the stomachs of goats and other animals which have fed upon plants containing ellagitannin) by dissolving them in cold strong potash, away from the air, passing a current of carbonic acid, and then treating the ellagate of potassium, washing and recrystallizing it, and then liberating the ellagic acid by hydrochloric acid. When crystallized from pyridine it forms prismatic needles. After washing these with alcohol ellagic acid becomes pale yellow, tasteless, crystalline powder, soluble in water, decomposing at 680°, at which temperature it has still refused to melt. With the bases it forms salts, which are not very well known; they are crystalline and insoluble or sparingly soluble in water. The lead and barium compounds are yellow. This acid can be prepared synthetically by oxidizing gallic acid with arsenic acid. Though not in itself a tanning agent it is considered of great value in the tanning industry.

ELLE ET LUI ("She and He") is a novel by George Sand which excited a good deal of comment and enjoyed a kind of celebrity because it was accepted as her version of her unfortunate love affair with Alfred de Musset. After the rupture which brought to a pitiful end their Venetian adventure (1834), many bitter accusations were brought against each by the friends and partisans of the other, and neither hesitated to exploit the experience for literary purposes. George Sand's "Lettres
ELLENBOURGH—ELLET

d'un Voyageur," written immediately afterward, 
already drew largely upon it and echoes of it 
are frequent in the subsequent poetry of Mus-
set (Nuit de mai, Souvenir) and in his "Con-
fession d'un enfant du siècle." The appearance 
of Ellenborough in 1859 (shortly after the poet's 
death in 1857) revealed its bittersweet nature, 
reminiscences of the affair. It was evidently 
substantially the story of their relations, under 
the transparent disguise of a novel, though 
George Sand's intention, as she tells us else-
where, was not to tell their story, but to create, 
under the veil of fiction, a certain situa-
tion in which others than they may have found 
themselves. It provoked from Paul de 
Musset, Alfred's brother, the answering volume, 
"Lui et Elle," in the poet's defense. The true story 
of "Eller et Lui" has been told by Spel-
berch de Louvenjoul ("La véritable histoire de 
Ell et Lui," Notes et documents, 1897). 
The original correspondence of George Sand and 
Alfred de Musset has been published by Félix 
Decori (1904).

ARTHUR G. CANFIELD.

ELLENBOURGH, Ellen-burr, Edward 
Law, Lord, English lawyer: b. Great Salkeld, 
1818. He was educated at Cambridge, became 
the pupil of the celebrated special pleader, 
George Wood, in 1771, and was called to the 
bar in 1780. In 1787 he was made a king's 
counsel. On the trial of Warren Hastings in 
1788, Erskine having refused to undertake the 
defense, Law served as leading counsel. It 
required no little courage to encounter such 
opponents as Burke, Fox, Sheridan and other 
eminent men of the time, who conducted the 
impeachment. Law, as is well known, obtained 
the victory. In 1801 he was made Attorney-
General and in 1802 became Lord Chief Jus-
tice of the king's bench and was created baron. 
In Parliament he opposed the emancipation of 
the Catholics. Believing that the criminal laws 
were not severe enough he succeeded in es-
ablishing 10 new capital felonies by the passage 
of the so-called Ellenborough Act, afterward 
repealed in toto. He held the office of chief 
justice for 15 years.

ELLENBOURGH, Edward Law, 1st 
Earl of, English statesman: b. 8 Sept. 1790; 
d. near Cheltenham, 22 Dec. 1871. He was 
educated at Eton and Cambridge; entered Par-
lament as representative of Saint Michael’s in 
1814, and in 1818 succeeded his father as 2d 
baron and entered the House of Lords. He 
was Lord Privy Seal in 1828, and in 1841 
accepted the governor-generalship of India. 
He arrived in Calcutta in time to take control of 
the Afghan war, which was brought to a suc-
cessful issue. Scinde was conquered by Sir 
Charles Napier and annexed in 1843. This was 
followed by the conquest of Gwalior. 
The conduct of the governor-general, however, 
gave great dissatisfaction at home. He was conse-
quently recalled by the East India Company early in 1844. Under Lord Derby’s govern-
ment in 1858 he held the office of President of the 
Board of Control from February to June, 
during which he wrote a dispatch censuring 
the policy of Lord Canning as governor-gen-
eral of India, which caused much discussion 
and led him to resign his office.

ELLENVILLE, N. Y., village of Ulster 
County, at the foot of Shawagunk Mountain, 
on the main line and on the Ellenville and 
Kingston division of the New York, Ontario 
and Western Railroad, 18 miles north of Mid-
dletown. The first house was built in 1803, 
a post office established in 1827 and the village 
incorporated in 1856. It has several denomina-
tional churches, a high school and other edu-
cational establishments, two national and one 
savings banks, and its industries include zinc 
mining, the making of cutlery, paints, cloth, 
corkers, chiefs and shirt waists, overalls, artificial 
stone, and wooden wares, employing about 300 
operatives. Ellenville is a popular summer re-
sort. It has finely shaded streets and is near 
several places of interest, including Mount 
Meenahiga, the Ice Caves, Sun Ray Spring and 
many beautiful waterfalls. The village owns 
its waterworks. Pop. 3,114.

ELLER, Johann Theodor, German chem-
ist: b. Plotzkau, in Anhalt-Bernburg, 29 Nov. 
1689; d. Berlin, 13 Sept. 1760. In 1721 he was 
appointed Anhalt-Bernburg physician; in 1724, 
professor of anatomy in Berlin; in 1735, physi-
cian to Frederick the Great; in 1755, privy 
councillor and director of the physical class of 
the Academy of Sciences. His papers were 
published in the Memoirs of the Berlin Acad-
emy, and among them is a long and interesting 
review of the opinions held respecting the ele-
ments from the earliest times down to his own 
day. He also published a series of curious 
microscopic observations upon the change of 
value in blood corpuscles by the addition of 
different salts, tinctures of plants and other 
solutions. Eller was undoubtedly a man of great learning 
and abilities, but his writings do not indicate 
a high degree of originality.

ELLERIANS, a sect of fanatics which 
arose in 1726, and had for its founder Elias 
Eller, a ribbon-weaver, who was born in 1690 
at Ronsdorf in Berg. He was influenced in his 
religious beliefs by reading the works of Jacob 
Böhme, and other mystical writings. The sect 
committed great excesses, and became very 
umerosous. See BÖHME, JACOB.

ELLERY, William, American patriot: b. 
Newport, R. I., 22 Dec. 1727; d. there, 15 Feb. 
1820. He sat in the Congress of 1776, and was 
one of the signers of the Declaration of Inde-
pendence. He became Chief Justice of Rhode 
Island in 1785 and in the following year com-
misssioner of the Continental Loan Office for 
Rhode Island. From 1790 till his death, he re-
tained the office of collector in his native place.

ELLESMORE LAND, the most northern 
portion of the continent of North America, dis-
covered by Baffin in 1616. The western part 
of this region was explored and mapped by Otto 
Sverdrup (q.v.) in 1899. Ellesmere Land is a 
high plateau, without human inhabitants; a few 
reindeer, musk-oxen and wolves find suste-
nance there. It is separated from Greenland 
by Smith Sound. Consult Sverdrup’s account 
of his discoveries: ‘Four Years in the Arctic 
Region’ (2 vols., New York 1904).

ELLET, Charles, American engineer: b. 
Penn’s Manor, Bucks County, Pa., 1 Jan. 1810; 
d. Cairo, Ill., 21 June 1852. He was educated 
at the Polytechnic School in his return to America held various responsible en-

ELLET — ELLIOT.

Eingle. He built at Fairmount, Philadelphia, the first wire suspension bridge in the United States, and in 1845 built at Niagara below the Falls a suspension bridge adapted for railway purposes. He constructed also the railway suspension bridge at Wheeling, W. Va., which is owned by the Baltimore and Ohio Railroad. In the Civil War he became colonel in the engineering corps and equipped nine Mississippi River steamboats as rams, and with them defeated a fleet of Confederate rams, but died of wounds on that service.

ELLLET, Elizabeth Fries Lemonis, American prose writer: b. Sodus Point, N. Y., Oct. 1818; d. New York, 3 June 1877. She was popular in her day, and among her books are a translation of Silvio Pellico's 'Euphemia of Messina' (1834); 'Poems, Original and Selected' (1835); 'Characters of Schiller' (1842); 'Pioneer Women of the West' (1852); 'Novelties of the Musicians' (1852); 'Queens of American Society' (1867); 'Court Circles of the Republic,' with Mrs. R. E. Mack (1869); 'The Practice of Housekeeping'; 'Evenings at Women's Clubs'; 'Women Artists of All Ages.'

ELLEGE, or LAGOON ISLANDS, a group of coral islands, situated north of the Fiji and northwest of the Samoan group between lat. 5° and 11° S. and long. 170° and 180° E. They extend for 300 miles in the direction northwest to southeast, and form nine groups, the largest islands being Sophia or Rocky Island, Nukualai or Mitchell, Ellige, Nukufetau, Vaitupu, Netherland and Lynx. The inhabitants almost all speak a Samoan dialect, and have traditions of a migration from the Samoan Islands. They have long been Christianized, and reading and writing are general. The islands are of coral formation. Guano, yams, fruit, coconuts and copra are the chief products. They were discovered in 1781 by Maurelle, and were annexed by Great Britain in 1892. Area, 15 square miles. Pop. 3,084.

ELLICHPUR, el-ich-poor', India, town in Amritsar, on the Jumna, 32 miles northwest of Amrasiot and was once large and prosperous. It contains manufactories of cottons and carpets, and is an important trading centre in linen. Imperial troops have a regular station here. The town contains many interesting ruins, including a palace and several fine tombs. Pop. 13,909.

ELICOTT, Andrew, American astronomer and civil engineer: b. Bucks County, Pa., 24 Jan. 1754; d. West Point, N. Y., 28 Aug. 1820. His father founded the town of Ellicott's Mills, Md., where the younger days of his son Andrew were devoted to the study of the sciences and practical mechanics. The latter's scientific attainments early attracted public attention, and from the Revolution to the day of his death he was employed in the fulfilment of trusts conferred by the general or State governments. In 1785 he removed to Baltimore, and represented the city in the State legislature. In 1789 he was appointed by President Washington to survey the land lying between Pennsylvania and Lake Erie, and during that year made the first accurate measurement of the Niagara River from lake to lake, with the height of the falls and the fall of the rapids. In 1790 he was employed by the government to survey and lay out the Federal metropolis. In 1792 he was made Surveyor-General of the United States, and in 1795 superintended the construction of Fort Erie at Presque Isle (now Erie, Pa.), and was employed in laying out the towns of Erie, Warren and Franklin. In 1796 he was appointed by President Washington commissioner on behalf of the United States under the Treaty of San Lorenzo el Real, to determine the southern boundary separating the United States territory from the Spanish possessions. The results of this service, embodied in a period of nearly five years, appear in his 'Journal' (published 1803). Upon the completion of this service he was appointed by Governor McKean of Pennsylvania secretary of the State land office, the duties of which he performed to the year 1808, and in 1812 became professor of mathematics at West Point. In 1817, by order of the government, he proceeded to Montreal to make astronomical observations for carrying into effect some of the articles of the Treaty of Ghent.

ELLICOTT, Charles John, Anglican prelate: b. Whitwell, Stafford, England, 25 April 1819; d. 15 Oct. 1905. He was educated at Saint John's College, Cambridge, and after being professor of divinity in King's College, London, Hulsean lecturer and professor of divinity at Cambridge, and dean of Exeter, was appointed bishop of Gloucester and Bristol in 1863. In 1897 the diocese of Bristol was separated from that of Gloucester, Bishop Ellicott remaining at the head of the latter diocese. He was for 11 years chairman of the scholars engaged on the revision of the New Testament translation, and published commentaries on the Old and New Testament, as well as 'Historical Lectures on the Life of Christ' (1860); 'Modern Unbelief' (1877); 'Some Present Dangers of the Church of England' (1878); 'The Revised Version of Holy Scripture' (1901), which is the best popular account of the work of the revisers, etc.

ELICOTT CITY, Md., city and county-seat of Howard County, on the Patapsco River, nine miles west of Baltimore, and on the Baltimore and Ohio Railroad. Saint Charles College (R. C.) in charge of secular priests, and Mt. St. Mary's College, in charge of Brothers of the Christian Schools, are located here. It manufactures of flour, cotton, silk and woolen goods. Founded in 1772, Ellicott City was incorporated in 1807.

ELLIOIT, Arthur Ralph Douglas, English lawyer: b. 17 Dec. 1846. He is second son of the 3d Earl of Minto, was educated at Edinburgh University and at Trinity College, Cambridge. From 1880 to 1892 and from 1898 to 1906 he was a member of Parliament. In 1903 he was Financial Secretary to the Treasury and from 1895-1912 was editor of 'The Naval Review. He has published 'Criminal Procedure in England and Scotland' (1878); 'The State and the Church' (1881; 2d ed., 1889); 'Life of the First Viscount Goschen' (1911).

ELIOTT, Benjamin, American jurist: b. Charleston, S. C., 1785; d. 1836. He was graduated at Princeton in 1800. He was admitted to the bar in 1810 and entered on his practice in his native State of South Carolina. He was the author of numerous literary,
historical and political productions. Among his works is a ‘Refutation of the Calumnies circulated against the Southern and Western States respecting the Institution and Existence of Slavery’ (1822). He also prepared and published ‘The Militia System of South Carolina,’ which was adopted as the military code for the State.

ELLIOIT, Daniel Giraud, American zoologist: b. New York, 7 March 1835; d. 22 Dec. 1915. He made zoology a special study from his youth; traveled in Europe, Africa and parts of Asia in 1859-78; subsequently in Canada, Alaska, South America and the greater part of the United States. He afterward became curator of zoology in the Field Columbian Museum. He has published ‘The Pheasants’ (1871-72); ‘Birds of North America’ (1897); ‘The Grouse’ (1865); ‘Birds of Paradise’; ‘Hornbills’ (1877-82); ‘North American Shore Birds’ (1895); ‘Gallinaceous Game Birds of North America’ (1897); ‘Synopsis of the Mammals of North America and the Adjacent Seas’ (1904); ‘A Review of the Frimates’ (Vols. I-III, 1913). He has been decorated 10 times by various European governments for his researches in natural science.

ELLIOIT, Sir Gilbert, Scottish philosopher and poet: b. Teviotdale, September 1722; d. Marriettes, 11 Jan. 1777. His song of ‘Amynta’ beginning ‘My sheep I neglected, I broke my sheep hook’ is famous; he also wrote occasional philosophical papers.

ELLIOIT, Charles, American Methodist clergyman: b. Glenconway, County Donegal, Ireland, 16 May 1792; d. Mount Pleasant, Iowa, 3 Jan. 1869. He came to the United States in 1814 and became prominent in the Methodist denomination. He was a professor of languages at Madison College, Uniontown, Pa., 1827-31, and president of Iowa Wesleyan University 1856-60 and 1864-67. He was editor of The Western Christian Advocate, Cincinnati 1856-48, The Central Christian Advocate, Saint Louis 1852-56. He published ‘Treatise on Baptism’ (1834); ‘Delineation of Roman Catholicism’ (2 vols., 1841); ‘Life of Robert R. Roberts’ (1844); ‘Sinfulness of American Slavery’ (1853); ‘The Bible and Slavery,’ etc. His most important book was ‘The History of the Great Secession from the Methodist Episcopal Church in the year 1845.’ ‘Southwestern Methodism’ was edited by L. M. Vernon (1868).

ELLIOIT, Charlotte, English hymnwriter: b. 17 March 1789; d. Brighton, 22 Sept. 1871. She wrote a number of religious poems, which were published under the titles ‘Hymns for a Week’; ‘Hours of Sorrow’; ‘Invalids’ Hymn Book.’ The last collection included ‘Just as I Am,’ a hymn which is widely used, and has been translated in ‘almost every living language.’

ELLIOIT, Edward Charles, American educator: b. Chicago, Ill., 21 Dec. 1874. He was graduated at the University of Nebraska in 1895, studied also at Jena and at Columbia University. In 1898-1903 he was superintendent of schools in The Maltings; he was a professor, and after 1907 professor of education at the University of Wisconsin, where after 1909 he also served as director of the pedagogical seminar. In 1906-10 he conducted special investigations for the United States Bureau of Education, in 1911-12 for the New York Board of Education and in 1913 for the State of Vermont. He has published ‘Some Social Aspects of Public Education in American Cities’ (1905); ‘State School Systems’ (3d ed., 1910); ‘Legislation upon Industrial Education in the United States’ (1910); ‘City School Supervision’ (1914).

ELLIOIT, Jesse Duncan, American naval officer: b. Maryland 1782; d. 1845. He entered the United States navy as a midshipman 1804, and in October of 1812 won the first American naval success on the lakes, capturing two British brigs, the Detroit and the Caledonia, near Fort Erie. He commanded the Niagara, in the battle of Lake Erie, September 1813, being second in command to Perry, whom he succeeded in October of the same year as commander of the Lake Erie fleet. In 1815, during the war against Algiers, he was in command of the sloop of war Ontario, under Decatur, being appointed captain in 1818. He was court-martialed and suspended for four years, after his service in the Mediterranean squadron. He resumed his duties in 1843 and was given charge of the Philadelphia navy yard.

ELLIOIT, Maud Howe, American novelist: b. Boston, Mass., 9 Nov. 1854. She is a daughter of Julia Ward Howe (q.v.), and was married to John Elliott, an artist, in 1887. Her writings include ‘A Newport Aquarelle’ (1883); ‘The San Rosario Ranch’ (1884); ‘Atlanta in the South’ (1886); ‘Mammas’ (1888); ‘Honor’; and ‘Phylida’ (1903); ‘Roma Beata’ (1904); ‘Two in Italy’ (1905); ‘Sun and Shadow in Spain’ (1908); ‘Sicily in Shadow and Sun’ (1910); ‘The Eleventh Hour in the Life of Julia Ward Howe’ (1911); ‘Life and Letters with Julia Ward Howe,’ with Laura E. Richards (1915).

ELLIOIT, Maxine, American actress: b. Rockland, Me., 5 Feb. 1873, daughter of Thomas and Adelaide Dermot. Making her début with E. S. Willard, she played Felicia Umfraville in ‘The Middle Passage’ and later in ‘The Professor’s Love Story.’ She was with Rose Coghlan, and in 1895 went to London with Augustin Daly’s company. A member of N. C. Goodwin’s company 1896, she played in Clyde Fitch’s ‘Nathan Hale’ (1896); was married to Mr. Goodwin that year, appeared with him in ‘When We Were Twenty-One,’ and played Portia in the ‘Merchant of Venice’ (1901). She starred in Fitch’s ‘Her Own Way’ in 1903 and thereafter appeared in several light comedies. She is owner and manager of the Maxine Elliott Theatre, New York, since 1908. She appeared there in ‘The Chaperon’ and ‘Deborah of Tods,’ etc. She has since appeared in the film drama and with the greatest success.

ELLIOIT, Sarah Barnwell, American novelist. She is a granddaughter of Stephen Elliott. Her best-known works are ‘The Felmeres’ (1879); ‘Jerry’; ‘John Pagent’; ‘The Dutch Sperratt’ (1888); ‘An Incident and Other Happenings’ (1899); ‘Sam Houston’ (1900). She was a member of the American Social Club and a play ‘His Majesty’s Servant.’ She is a member of the Society of Colonial Dames and the United Daughters of the Confederate.
ELLIPSE

ELLIPSE (Lat. ellipsis, from Gr. ellipse, omission), a plane curve of such a form that, if from any point in it two straight lines be drawn to two given fixed points, the sum of these straight lines will always be the same. The ellipse is a species of conic section (q.v.), and is obtained by a plane which cuts all the elements of one nappe of a right circular cone. Projectively considered, an ellipse is a conic which cuts the line of infinity in two distinct imaginary points. If these are the two circular points, the ellipse becomes the circle. These two fixed points are called the foci. In the ellipse \( A, B, C, D, E \) and \( F \) are the foci. If a straight line \( EQF \) be drawn joining the foci, and be then bisected, the point of bisection is called the center. The distance from the center to either focus \( (EQ \) or \( QF \) is called the linear eccentricity. The straight line \( GQH \), drawn through the center and terminated both ways by the curve, is called the diameter. Its vertices are \( G \) and \( H \). The diameter \( A \), which passes through the foci, is called the major axis; the points in which it meets the curve \( (A \) and \( C) \), the principal vertices. The diameter \( BD \), at right angles to the major axis, is called the minor axis. Practically, a tolerably accurate ellipse may be drawn on paper by sticking two pins in it to represent the foci, putting over these a bit of thread knotted together at the ends, inserting a pencil in the loop, and pulling the string tight as the figure is described. The importance of the ellipse arises from the fact that the planets move in elliptical orbits, the sun being in one of the foci — a fact which Kepler was the first to discover. The equation to an ellipse, referred to its centre as origin, and to its major and minor axes as rectangular axes, is

\[
\frac{x^2}{a^2} + \frac{y^2}{b^2} = 1,
\]

where \( a \) and \( a \) are the semi-major and semi-minor axes respectively. From this equation it may be shown, by the integral calculus, that the area of an ellipse is equal to \( \pi ab \); or is got by multiplying the product of the semi-major and semi-minor axes by \( 3.1416 \). It may also be shown that the length of the circumference of an ellipse is got by multiplying the major axis by the quantity

\[
\pi \left\{ 1 - \left( \frac{1}{2} \right)^2 - \left( \frac{1.3}{2.4} \right)^2 + \left( \frac{1.3.5}{2.4.6} \right)^2 - \ldots \right\}
\]

The eccentricity \( e \), is \( \sqrt{1 - \frac{b^2}{a^2}} \) and the eccentricity is the ratio \( a-b \) to \( a \). See GEOMETRY AND CONIC SECTIONS.

ELLIPSIS, in grammar, the omission of one or more words, which may be easily supplied by the connection. It is common, especially in colloquial language, for the sake of brevity, and frequently adds to the strength and perspicuity of the sentence; hence a more extended use of the ellipsis in rhetoric and poetry. In the hands of a genuine poet or orator the ellipsis has a very telling value. In natural language, from the brevity it affords, the ellipsis becomes in all its phases the language of passion, and especially of sudden and intense emotion; and the imitation of its natural use in this way is to the poet a powerful instrument for painting passion to the life. The works of all the greater poets, and especially the Hebrew poetry of the Old Testament, abounds with familiar instances of this use of the ellipsis.

ELLIPSOID, in geometry, a real quadric surface with no real points at infinity. Its equation may be reduced by a transformation of axes to

\[
\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1, \quad a, \quad b \quad \text{and} \quad c
\]

being real. Every real plane section of an ellipsoid is an ellipse. If \( a, b \) and \( c \) are not all distinct, the ellipsoid is a figure of revolution, and is known as a spheroid. An oblate spheroid is one where the axis of revolution is less than the chords of the spheroid bisecting it perpendicularly; a prolate spheroid is one where the chords are less.

ELLIPSOIDAL STRUCTURE IN IGNEOUS ROCKS. Certain extrusive igneous rocks when viewed at a distance seem to be made up of aggregates of bowlders varying from a few inches to several feet in diameter. If these masses are studied more closely, however, they are seen not to be bowlders at all, but merely ellipsoidal shaped masses of the rock that have a slightly different texture and color from the remaining mass. This difference is believed to be the result of certain differences set up during the cooling and solidification of the molten rock. The cause is obscure but there is some reason to believe that it is due to the lava being poured out into a body of water, as in a lake or the ocean.

ELLIS, Alexander John (originally Sharpe), English scientist and philosopher; b. Foxton, 4 June 1814; d. London, 28 July 1844. He was educated at Shrewsbury, Eton and Trinity, Cambridge, and devoted himself to mathematics, the scientific side of music, and more especially to philology and phonetics. His translation of Professor Helmholtz's 'Sensations of Tone' (1875) has taken a place as a standard work on scientific music. In 1848 he published two small works: 'The Essentials of Phonetics'; and 'A Plea for Phonetic Spelling,' and collaborated with Sir Isaac Pitman (q.v.) in framing a phonetic system. His magnum opus on 'Early English Pronunciation,' with special reference to Chaucer and Shakespeare, appeared between 1869 and 1889. His other works include 'Horse Taming' (1842); 'Phonetics' (1844); 'On Glosik, a New System of English Spelling' (1870); 'English Dyonisian and Hellenic Pronunciations of Greek' (1876); 'Logic for Children' (1882), which consists of two addresses; 'Original Nursery Rhymes for Boys and Girls' (1848); 'Algebra Identified with Geometry' (1874); 'Practical Hints on the Quantitative Pronuncia-
ELLIS, Alston, American educator: b. Kenton County, Ky., 26 Jan. 1847. He was graduated at Miami University in 1865 and from 1867 to 1892 was principal of schools at Cincinnati, Ky., and superintendent of schools at Hamilton and Sandusky, Ohio. From 1892 to 1900 he was president of the State Agricultural College of Colorado and for the greater part of that time served also as director of the Colorado Experiment Station. In 1901 he was chosen president of Ohio University. He was president of the Ohio Superintendents' Association in 1875, of the Ohio Teachers' Association in 1888, of the Ohio College Association in 1892-93, and of the Ohio Association of Presidents and Deans in 1910-11. He published a 'History of the Ungraded Schools of Ohio,' and many educational reports.

ELLIS, Edward Sylvester, American writer of school textbooks and juvenile literature: b. in Geneva, Ohio, 11 April 1840. For some years he was superintendent of public schools at Trenton, N. J. He has published more than 20 volumes, most of which have been reissued in London and are sold in every part of the world. He is joint author of 'The World's Great Events,' and of a school history of New Jersey. His 'History of the United States' (8 vol., Cincinnati 1887) has sold to the extent of 114,000 sets or 912,000 separate volumes. A number of his historical productions have appeared in the moving pictures. His latest literary work is the editing of some 60 translations, devoted to a full history of all the nations engaged in the great European War.

ELLIS, George, English author: b. London, England, 1753; d. 10 April 1813. He was educated at Westminster School and Trinity College, Cambridge, and was one of the junta of wits concerned in the well-known political satire, 'The Rolliad.' He published 'Specimens of Early English Poets, with an Historical Sketch' (1790); 'Specimens of Early English Metrical Romances' (1805); and was an intimate friend of Sir Walter Scott.

ELLIS, George Edward, American Unitarian clergyman and historical writer: b. Boston, Mass., 8 Aug. 1814; d. there, 20 Dec. 1894. He was pastor of the Harvard (Unitarian) Church, Charlestown, Mass. (1840-69); and held the professorship of systematic theology in the Cambridge Divinity School (1857-63). He was also a lecturer of Lowell Institute in 1864, 1871 and 1879, and was editor of the Christian Register and Christian Examiner. As president of the Massachusetts Historical Society he made valuable contributions to an early colonial history. He published 'A Half-Century of the Unitarian Controversy' (1857); 'History of the Battle of Bunker's Hill' (1857); 'The Red Man and the White Man' (1869); 'The Indian Age and Rule in the Colony of Massachusetts Bay, 1620-85'; various memoirs, and several biographies in Sparks' 'American Biography.'

ELLIS, Henry Havelock, English scientist and literary scholar: b. Croydon, Surrey, 2 Feb. 1859. He taught school in New South Wales 1875-79, and on his return to England practised medicine for a short time and then devoted himself to literary and scientific work. He was editor of the 'Contemporary Science Series' (1889); and of the 'Mermaid Series of Old Dramatists' (1887-89); and is the author of 'The New Spirit' (1890); 'The Mind and Man' (1890); 'Man and Woman: A Study of Human Secondary Sexual Characters' (1894); 'Sexual Inversion' (1897); 'Affirmations' (1897); 'The Evolution of Modesty' (1899); 'Analysis of the Sexual Impulse' (1903); 'Sexual Selection in Man' (1905); 'Errors and Symbolisms' (1906); 'Sex in Relation to Society' (1910); 'The World of Dreams' (1911); 'Impressions and Comments' (1914).

ELLIS, John, English naturalist: b. Ireland about 1710; d. 1776. He was the first who suggested the idea that the South Sea islands were constructed and raised from the bottom of the ocean by means of zoophytes or the polypli inhabiting different species of coral ('Essay towards the Natural History of Coralines' 1755). He was for some time agent for the colony of West Florida and the island of Dominica. Among his works is a posthumous one entitled 'The Natural History of Many Uncommon Zoophytes' (1786).

ELLIS, John Valentine, Canadian statesman: b. Halifax, Nova Scotia, 1835. He was educated in the public schools of his native city; worked several years in a printer's office and in 1857 removed to Saint John, New Brunswick, where he became a reporter. He bought the Globe of that city in 1862 and thereafter was its editor and publisher. In 1882 he entered the political arena, served in the New Brunswick legislature as Liberal for Saint John from 1882-87. In the latter year he went to the House of Commons as member for Saint John. In connection with his election court proceedings were instituted which involved Ellis in contempt of court and he was imprisoned and fined. His popularity was greatly increased by these proceedings and the fine was made up by public subscription. He sat in the Commons until 1891, was again elected in 1896 and in 1897 became a member of the Senate. In 1911 he was chairman of the Senate Committee on Debates and in the same year was also president of the Natural History Society of New Brunswick.

ELLIS, John Willis, American statesman: b. Rowan County, N. C., 25 Nov. 1820; d. Raleigh, N. C., 1861. He was graduated at the University of North Carolina in 1841, was admitted to the bar in 1842 and soon acquired a large practice. He was a member of the State House of Commons from 1844 to 1848, when he was elected a judge of the Superior Court of North Carolina. This office, in which he succeeded his former preceptor, R. M. Pearson, who was elevated to the Supreme bench, he held until 1858, when he was elected governor of North Carolina. He was re-elected in 1860 and died in office. On 2 Jan. 1861, Governor Ellis took possession of Fort Macon at Beaufort, took the works at Wilmington and the Federal arsenal at Fayetteville, professedly on behalf of the State. On 20 April he ordered the seizure of the United States mint at Charlotte. He was active in promoting the passage of the secession ordinance in North Carolina.
ELLIS, Mina A., Canadian explorer: b. Bewdley, Ontario, about 1875. She was graduated at the Brooklyn (N. Y.) Training School for Nurses; later became assistant superintendent of the S. R. Smith Infirmary (now the Staten Island Hospital) and superintendent of the Virginia Hospital, Richmond, Va. She married Leonidas Hubbard, journalist and explorer, in 1901; he perished two years later in Labrador. She organized an expedition and in 1913 succeeded in completing the exploration work undertaken by her husband by crossing the northeastern part of Labrador, now known as the District of Ungava, Province of Quebec. She was the first white person to cross the river dividing the Naskaupi and George water-sheds. An account of the expedition, which resulted in some important discoveries, is given in her 'A Woman's Way through Unknown Labrador' (1908) and in 'The Bulletin of the American Geographical Society.'

ELLIS, Powhatan, American jurist and politician: b. Virginia, about 1794; d. Richmond, Va., March 3, 1857. In 1823 he graduated from William and Mary College, settled in Mississippi while it was a Territory, gained a high reputation as a lawyer and in 1818 was raised to the supreme bench of the State, being one of the first judges of that court. He remained in office until 1827, when a law was passed by the governor to serve out the unexpired term of David Holmes in the United States Senate. He failed of election by the legislature, but at the next election he was chosen senator for a full term, but served only from 3 Dec. 1827 to 1832, when he resigned to take his seat on the bench as United States judge for the district of Mississippi. While in the Senate he joined Thomas H. Benton and William Smith in opposing the ratification of the Red and Arkansas rivers, thus leaving only Florida and Arkansas for the expansion of slavery. While on the bench he delivered more opinions than any contemporary judge. On 5 Jan. 1836 he was appointed by President Jackson chargé d'affaires in Mexico, and on 28 December he closed the American legation. President Van Buren appointed him minister to Mexico on 15 Feb. 1839, in which post he was succeeded by Waddy Thompson in 1842. After his return he resided in Virginia.

ELLIS, Robinson, English classical scholar: b. Barming, Kent, 5 Sept. 1834; d. 9 Oct. 1913. He was educated at Rugby and Balliol College, Oxford, and in 1870 became professor of Latin in University College, London. From 1883 till 1893 he was university reader in Latin literature at Oxford, and in the latter year he was elected as professor of Latin in that University. His name is chiefly associated with the elucidation of the poems of the Roman poet Catullus. In 1867 he published a critical edition of Catullus ("Catuli Veronensis Liber") and in 1871 "The Poems and Fragments of Catullus" in the metres of the original, these works being followed by a "Commentary on Catullus" (1876). Other publications of his include "Ovid's 'Ibis,' with commentary (1881); 'Fables of Avianus' (1887); 'Ovidii Carmina' (1887); 'Notes Manilius' (1891); 'The Fables of Phaedrus' (1894), and a new recension of 'Velleius Paterculus,' with commentary (1898); 'Actna' (1900); 'Appendix Vergiliana' (1907); 'Licinianus' (1908). Consult American Journal of Philology (Vol. XXXIV, pp. 494-496; 1913).

ELLIS, William Hodgson, Canadian chemist: b. Bakewell, Derbyshire, England, 1845. He came to Canada in early youth and was graduated at the University of Toronto in 1867, afterward studying medicine there and in Great Britain. On his return he became professor of chemistry in Trinity Medical School and lecturer on chemistry at Trinity University. Afterward he became instructor in chemistry in the Provincial College of Technology, and in 1900 was appointed to the chair of toxicology in the University of Toronto. He also served as official analyst of the Inland Revenue office at Toronto. He is widely known as an expert chemist.

ELLIS, William Thomas, American journalist: b. Allegheny, Pa., 23 Oct. 1873. He was educated in the public schools and until 1894 was on the staff of Philadelphia's "Inquirer," when he became editor of the International Christian Endeavor organ. In 1897 he became editor of "Forward" and in 1903-08 was editorial writer for the Philadelphia "Press." He investigated social conditions in foreign countries in 1906-07 and in 1910-11 in the interest of a news syndicate. He wrote Sunday-school lessons and also contributed to religious periodicals. He has lectured frequently before religious bodies and has published "Men and Missions" (1909) and "Foreign Missions through a Journalist's Eyes."

ELLIS ISLAND, small island situated in New York Bay, one mile southwest of the Battery, where the old immigrant station, Castle Garden, was located. The United States immigrant commissioner has his offices on this island. Immigrants detained for investigation as to compliance with the United States immigration laws are kept on this island until allowed to land or are deported. It was sold by New York State to the United States in 1808, and for many years was used as a powder magazine. In 1891 it was made into an immigration station. The present buildings were erected in 1897, when the original structures were burned.

ELLORA, ē-lórā, ELORA, or ELURU, ē-loo-rā, India, village in the province of Aurungshād Hyderābād State; situated in 20° 21' N., and 75° 10' E., about 15 miles northwest of Aurungshād city. Near by is the red stone temple of Ahalyā Bāi, the Rānē of Indore (1767-95), a good example of modern Hindu architecture. Ellora is celebrated for some remarkable cave temples, excavated in the solid rock, which in magnitude and perfection surpass all other constructions of the kind in India. The temples are divided into three series, Buddhist, Brāhmaṇical and Jain and are arranged chronologically. There are 12 Buddhist caves at the north end, 5 Jain caves at the opposite end, with 17 Brāhmaṇical caves between. Important inscriptions have been found in them, dating from the 5th to the 9th centuries. The Kailās temple at Ellora is a remarkable specimen of Indian architecture. Its court is about 154 feet wide by 276 feet long.
entirely cut out of the solid rock, backed by a scarp 107 feet high. A curtain of stone has been built at the foot which forms of Siva, Vishnu and the other gods are carved. Rooms inside face an entrance passage at the end of which are a colossal Lakshmi and her attendant elephant and lotuses. An inscription dates from the 8th century. A bridge leads to the temple by a path covered with pebbles. The temple was
built by Krishna I, the Râshrâkûta King of Mâlèed (760-83). Consult Fergusson and Burgess, 'The Cave Temples of India' (London, 1880).

ELLORE, El-Lôr', India, town, in the Godavery district of the Madras presidency, on the river Jammalere, once the capital of the Northern Circars. It has magisterial and judicial establishments, police station, post office, etc., a number of Christian missions and a garrison. There are some manufactures of carpets and saltpetre. Pop. 33,500.

ELLSWORTH, Ephraim Elmer, American soldier; b. Mechanicsville, N. Y., 22 April 1837; d. Alexandria, Va., 24 May 1861. He organized about 1859 a zouave corps which became noted for the excellence of its discipline. In March 1861 he accompanied President Lincoln to Washington, and in April he went to New York, where he organized a zouave regiment of firemen, of which he became colonel. Ordered to Alexandria, he lowered a Confederate flag floating over a hotel, for which act the hotelkeeper shot him dead.

ELLSWORTH, Oliver, American jurist; b. Windsor, Conn., 29 April 1745; d. there, 26 Nov. 1807. He was graduated at the College of New Jersey in 1766, and soon after commenced the practice of law. In 1777 he was chosen a delegate to the Continental Congress, and in 1780 was elected a member of the council of Connecticut, in which body he continued till 1784, when he was appointed a judge of the Superior Court. In 1787 he was elected to the convention which framed the Federal Constitution, and was afterward a member of the State convention, where he earnestly advocated left at the front of that important instrument, which his exertions had essentially aided in producing. In 1789 he was chosen a Senator of the United States, which station he filled till 1796, when he was nominated by Washington Chief Justice of the Supreme Court of the United States. In 1799 he was appointed envoy extraordinary to Paris, and with his associates successfully negotiated a treaty with the French. He resigned his office of chief justice in 1800. In 1803 he was made a member of the governor's council of Connecticut, and in 1807, chief justice of that State. His biography was written by W. G. Brown (New York 1905).

ELLSWORTH, Maine, city, port of entry and county-seat of Hancock County, on both sides of the Union River, and on the Maine Central Railroad; 30 miles southeast of Bangor. It is the trade center of the country, and has extensive timber, ship-building and fishing interests, exporting over 50,000,000 feet of lumber annually. It has shoe, woolen, leather, carriage, sails, gasolene engines and other manufacturing industries. The city contains a court-

house, custom-house, public library and a city hall. The Union River is crossed by several bridges, and furnishes good water power for manufacturing purposes. The town is maintained here by the Federal government. The city was settled in 1763, was incorporated as a town in 1800 and as a city in 1869. A mayor and a board of aldermen administer the affairs of the municipality which controls the water-supply system and the electric plant. Pop. 3,549.

ELLWOOD, Charles Abram, American sociologist: b. near Ogdenburg, N. Y., 20 Jan. 1873. He was graduated at Cornell University in 1896 and studied also at the Universities of Chicago and Berlin. For one year he was lecturer and instructor at the University of Nebraska and in 1900 became professor of sociology at the University of Missouri. He became also advisory editor of the American Journal of Sociology and associate editor of the Journal of Criminal Law and Criminology. In 1904 he served as president of the Missouri Chartered Education. He has published 'Sociology and Modern Social Problems' (1910): 'Sociology in its Psychological Aspects' (1912); 'French trans. 1914); biographies and special articles on social psychology.

ELLWOOD, Thomas, English Quaker: b. Crowell, near Thanet, Oxfordshire, 1639; d. Amersham, 1 March 1714. About 1660 he was induced to join the Society of Friends, and subsequently became reader to those who had improved himself in the learned languages, but was soon obliged to quit London on account of his health. In the year 1665 he procured a lodging for Milton at Chalfont, Bucks, and was the occasion of his writing 'Paradise Regain'd' by the following observation: 'A friend has written the 'Paradise Lost' which the poet had lent him to read in manuscript; 'Thou hast said much of paradise lost, but what hast thou to say of paradise found?'. In 1705 he published the first part of 'Sacred History, etc., of the Old Testament'; and in 1709 'Sacred History, etc., of the New Testament.' His other works are numerous; among them 'Davidides, the Life of David, King of Israel, a poem, which is more distinguished for piety than poetry. His life, written by himself, and published the year after his death, affords many interesting particulars of the history of his sect.

ELM, Ulmus, a genus of trees and a few shrubs of the family Ulmaceae. The species, of which about 20 are known, are natives of the North Temperate zone and the southern portions of the Arctic zone. Their southern limits seem to be the Himalayas in Asia and the mountains of southern Mexico. None are natives of the Pacific slope of North America. They are characterized by short petioles, alternate, rough, usually deciduous leaves with serrate edges; axillary racemes of perfect, apetalous flowers which appear in early spring before or with the leaves; and compressed, winged, dry fruits. Many of the species are of wide economic importance. Their hard, heavy, tough, pliable wood is largely used in the manufacture of barrels, agricultural implements, boats, wagon wheels, buildings, etc., and for fuel. The inner bark of some species furnishes an article of food, and that of others a tough
Famous New England Elms
bast fibre used for cordage and cloth making. The outer bark of some is used in dyeing and sugar refining. Various parts of several species were formerly popular remedies employed in medicine, but except in domestic and local practice are rarely prescribed. Most of the species are highly valued as ornamental trees in street and park planting, those specially popular being the straight-trunked, tall-growing, vase-formed species, which quickly over-arch the streets and cast an abundant shade. Many cultivated varieties of fantastic form, color of foliage, or habit are also planted as ornamentals.

The best-known American species is the white, water, or American elm (U. americana), which grows in rich moist woods, especially on the shores of streams, from Newfoundland to Florida and westward to the eastern side of the Rocky Mountains. It is a tall tree, often attaining a height of 120 feet when growing in the forest, and with a wide-spreading, less lofty top when growing in the open, where it may be seen in several different forms, popularly known as "slippery" elm, "scotch" elm, or "korky" elm. Some of the arrangements of the branches. Some specimens of each develop numerous twiggy growths upon the trunk and main branches, which are thus rendered very attractive because of their feathery appearance. The most common form is the vase, in which the main branches develop at about 20 feet or more, and at their bases gradually, and toward their extremities widely diverge. This is probably the most popular street form in America. Another well-known American species is the slippery or red elm (U. fulva), which attains a height of 70 feet in rich soils and is found from Quebec to Florida and westward to Texas and the Dakotas. It is called red because the bud scales are reddish and conspicuous when unfold. g. in spring; and it is called slippery because of its mucilaginous inner bark. Its wood is less valued than that of the English elm, but more than that of the white elm. The cork or rock elm (U. racemosa), which grows on river bars from New England to Nebraska and as far south as Kentucky and Tennessee, attains a height of 100 feet and is noted for its corky developments resembling wings on the smaller branches. Its wood is specially valued for its glistening varnish. Another species with corky, winged branches is the wahoo or winged elm (U. alata), which ranges from Virginia to Florida and westward to Texas and Illinois. It rarely exceeds 70 feet in height, is very attractive in habit, and is planted for ornament in the South, but not in the North, as it is not sufficiently hardy for the rigors of winter.

The most noted European species is the English elm (U. campestris), which ranges through middle and southern Europe, northern Africa, and eastward to Japan. It reaches 100 feet in height and has a rather round-topped or open head, on account of its spreading branches. It is frequently planted for ornament at home and abroad, and in America is valued both for its own beauty and for its resistance to disease. It has several distinct varieties, which are sometimes considered as distinct species, and of which there are a large number of horticultural varieties. The next most important European species is probably the Scotch or wych elm (U. scabra), which has much the same range as the preceding species, like which it attains a height of about 100 feet. It is a variable species with many cultivated varieties, one of the best-known of which is the Camperdown elm, which has long, pendulous branches, on account of which the tree is fungicide (q.v.). Another is the semi-evergreen shrub or small tree, a native of eastern Asia, which has proved hardy in America as far north as Massachusetts.

Elm is readily propagated from seed which ripens in late spring or early summer and should be sown at once. The seedlings are easily managed, both as to cultivation, transplanting and pruning. The trees do best in rich soil, especially if moist. The choice varieties are generally grafted. The trees, especially of the American or white elm, are specially liable to the attacks of certain insects and diseases, which often defoliate them. The latter may be kept in check by the timely and proper application of a standard spray.

The name elm is also given to various unrelated trees, the best-known of which are probably the following: Water elm (Planera aquatica); Spanish elm or Bois-de-Cypré (Cordia gerascanthus). Several Australian trees are also known as elms, such as Duboisia myoporoides and Aphananthe philippinensis, each of which is valued for its timber.

ELM, Slippery, in medicine, the bark of Ulmus fulva, is widely used as a demulcent. It is probably the ancient Indian inhabitants of the country introduced it into medicine. Slippery elm bark is noted for the large amount of mucilage which it contains, thus rendering it a pleasing demulcent for sore throat, diarrhoea, dysentery, and inflammation of the intestinal tract in general.

ELM-INSCTS. Few ornamental trees are more subject to the attacks of insects than are the elms, and especially the American elm. The European species are, however, attractive to the European insects, of which many have been brought over unintentionally, and have spread remarkably because of the absence of their enemies. One of the most troublesome plant-louse known as Colophos ulmcola, which produces the cockscomb galls upon the foliage. It is rarely very troublesome, and has usually done its damage before it can be attacked. Kerosene emulsion, if applied in time, will prove effective. (See Insecticide.) A spiper (Spærda trimederna) is sometimes troublesome, but there seems to be no satisfactory way to control it, though it has been suggested that the trunk should be washed with lime or soft soap during June and July. Most of the other insects that attack the elms are beetles, their larvae, or the caterpillars of various moths. These all bite their food, and hence may be attacked with arsenites or other stomach poisons sprayed upon the foliage. Among these insects are the four-horned sphinx (Sphinx quadrifasciata or quadriconinis), a green caterpillar with four little horns near the head and the long anal horn characteristic of the sphinx-moth. The bag-worm (Thrydopteryx ephemeraeforuscis), the gypsy-moth (Oecria disfpar), the tussock-moth (Notoptus or Orgyia leucostigma),
and several other general feeders are frequently troublesome. But the most important leaf-eating enemy of the elm is the elm-leaf beetle (Galeruca anthophila), a reddish-yellow, two-winged insect which appears and eats the leaves in spring. The bottle-shaped yellow eggs are laid in rows on the underside of the leaves, and the hairy, black-spotted, yellow larvae eat circular holes between the leaf veins. Spraying with arsenites is effective, but when a new brood is produced the sprayings must be repeated frequently throughout the summer. Consult Marlatt, *Elm Leaf Beetle*, Circular 8, Division of Entomology, United States Department of Agriculture (Washington 1895).

ELMAN, Michail, Jewish violinist: b. Talnoye, Russia, 1802. He showed such remarkable talent that at the age of six he was taken by his father to Odessa and there studied under competent masters for four years. He met Leopold Auer in 1902 and so impressed the latter that he secured the permission of the Tsar for Auer's admission to the Imperial Conservatory at Saint Petersburg, hitherto closed to members of the Jewish race. Elman spent two years there under Auer and at his debut in 1904 he was at once acclaimed as an artist of first rank. He toured Germany and everywhere scored a triumphant success. He visited the United States in 1908 and again in 1911, 1912, 1913 and 1914, being eminently successful on every occasion. On the violin he is now recognized as a veritable genius.

ELMENDORF, Theresa Hubbell West, American librarian: b. Pardeeville, Wis., 1855. She was graduated at Miss Wheelock's Seminary, Milwaukee, in 1874 and from 1880 to 1896 was deputy librarian and librarian of the Milwaukee Public Library. In 1896 she married Henry Livingston Elendorf (d. 1906), and in 1906 was appointed vice-librarian of the Buffalo Public Library. In 1903-1913 she was president of the New York Library Association and in 1911 became president of the American Library Association — the first woman to fill that office. She was also coeditor of the *American Library Association Catalogue* and has published many articles in library periodicals on professional topics.

ELMINA, El-mé-ná, or SAINT GEORGE DEL MINA, West Africa, town belonging to Great Britain, formerly the capital of the Dutch settlements on the Gold Coast, five or six miles west of Cape Coast Castle. The Castle of Saint George del Mina was the first European establishment on the coast of Guinea, having been erected by the Portuguese in 1481. The castle is the residence of the government officials of the district. It is the chief outlet for the trade of Ashanti. It came under English control in 1872, when it was claimed by the King of Ashanti the result being the Ashanti wars of 1873-74. Pop. about 4,000.

ELMIRA, N.Y., city, county-seat of Chemung County, on both sides of the Chemung River, and on the Delaware and Lackawanna, the Lehigh Valley, the Northern Central and the Erie railroads; 100 miles southeast of Rochester, 149 miles east-southeast of Buffalo, and 46 miles south-southwest of Ithaca. Among the more important establishments are railroad-car shops, iron and steel bridge works, steel-plate works, valve and radiator works, manufactories of boots and shoes, automobile parts, tables, bicycles, glass, fire engines, tobacco and cigars, boilers and engines, doors, sashes and blinds, hard-wood finishing works, silk and knitting mills, tobacco warehouses, dyeworks, breweries and aluminum works. The district is fertile, and there are also stone-quar ters in the vicinity. Here are located Elmira College (q.v.), a State Normal School (see *ELMIRA REFORMATORY*), the Arnot-Ogden Memorial Hospital, the Steele Memorial Free Library, a Federal government building housing the Federal courts, the post office, etc., and various charitable institutions. The park system includes Wisner, Riverside, Eldridge and Hoffman parks. Elmira is finely laid out and has an excellent water supply, and gas and electric lighting. Elmira was permanently settled in 1783, was incorporated as the village of Newtown in 1815, and in 1828 was reincorporated as the village of Elmira. In 1836 it became the county-seat of Chemung County, and in 1864 obtained its city charter. During the Civil War it was the State recruiting and military rendezvous, and in 1864-65 one of the Federal prisons for Confederates whose terms of war was here situated. Near the present site of Elmira the battle of Newtown was fought, 29 Aug. 1779. General Sullivan, with an American force numbering 5,000, defeating a combined band of Tories and Indians commanded respectively by Sir John Johnson and Joseph Brant (Thayendanega) and numbering approximately 1,500. The battle-ground is now marked by a memorial to Sullivan. Elmira is governed, under a charter of 1906, by a mayor, who is biennially elected, and a common council, which is unicameral. In addition to the aldermen who are chosen by wards for terms of two years, the recorder, municipal judge and 12 supervisors, to act as a county board, are also elected by a popular vote. Pop. 37,816.

ELMIRA, Battle of, 29 Aug. 1779, in the Revolution. See CHEMUNG, BATTLE OF.

ELMIRA COLLEGE, at Elmira, N.Y. The first college founded exclusively for women in the United States (1855). Under the auspices of the Presbyterian Church, its course of study from the first demanded as high a grade of work as is usual in first-class colleges. The degrees conferred are bachelor of arts, bachelor of science, bachelor of music and master of arts. The college maintains a graduate department and also a summer session. The average enrollment is about 260, with 20 members in the faculty. There are 11,000 volumes in the library. The annual income is about $90,000, and the productive funds amount to $140,000.

ELMIRA HEIGHTS, N.Y., village in Chemung County, adjoining Elmira, on the Delaware, Lackawanna and Western, the Erie and the Lehigh Valley railroads. Bridgeworks, machine shops, knitting mills and pump factories give employment to a very great number. Pop. 2,732.

ELMIRA REFORMATORY, State institution, located in Elmira, N.Y. It is a reformatory to which may be sent only males between the ages of 16 and 30 who have not served a period in a State prison. The court
of the State of New York, in sentencing a prisoner to this institution, has no authority to limit the time; that is determined by the managers of the institution, and is almost a matter of policy depending on the conduct of the prisoner. However, the term of imprisonment shall not, according to the law of the State, exceed the maximum term provided by law for the crime for which the prisoner was convicted and sentenced; (it is reformatory, which takes the place of a State prison for male offenders who have not become hardened in crime, has effected a radical change in methods of dealing with the class of law-breakers intended to benefit. Although the law authorizing the institution was passed in 1866 it was not until 1876 that the institution was opened. The plan has been a splendid success and has had many imitators. About 22,000 prisoners have passed through its regiments. About 1300 is the average detained there. Consult Winter, 'The Education of the Reformatory'; New York State Laws of 1877, sec. 2, ch. 173. Wines, 'Punishment and Reformation' (1895); and the Yearbooks of the Reformatory.

ELMO, ERMO, or ERASMUS, Saint, a martyr, who suffered death at Formizia, a town of ancient Italy, during the persecution under Emperor Diocletian, in 303. He is considered the patron saint of sailors, and is usually invoked by Italian sailors during a storm. His feast is kept on June 3.

ELMO'S FIRE, Saint, is the popular name of an electric appearance, especially in southern climates during thunderstorms, of a brush or streamer of light at the tops of masts, spires, or other objects. Greek superstition embodied this phenomenon in the story of Castor and Pollux.

ELMORE, Alfred, Irish artist: b. Clonakilty, Ireland, 18 June 1815; d. London, 24 Jan. 1881. He studied at Royal Academy, London, traveled through Europe to Rome, where he lived two years, returning to England in 1844, becoming an associate of the Royal Academy, 1845, and Royal Academician, 1856. Among his works are: Martyrdom of Thomas A. Becket (1840); Saint Antony, which Charles Dullin; 'The Novice' (1843); 'Rienzi' (1844); 'Death of Robert, King of Naples' (1848); 'Griselda' (1850); 'Charles V at Uthe' (1856); 'Marie Antoinette in the Temple' (1861); Louis XIII and Louis XIV (1870); 'Ophelia' (1875); 'Mary Queen of Scots and Darnley' (1877); 'Pompeii,' 'John Alden and Priscilla' (1878); 'After the Ruin,' and 'Lenore.'

ELMWOOD PLACE, Ohio, village of Hamilton County, adjoining Cincinnati, to which it has repeatedly refused to be annexed, and on the Cincinnati, Chicago and Saint Louis and the Dayton and Cleveland railroads, the Miami River and the Erie Canal. It contains large steel manufacturing plants and extensive railroad freight yards. Pop. 3,423.

ELOBEY ISLANDS, a-lo-bay. The native of this island off the coast of Guinea, in Africa, belonging to Spain. Elobe Chico is the smaller and Elobe Grande the larger. Pop. 350.

ELOCUTION (Latin elocutio, e, out, loqui, to speak), the science and art of expression by voice and action. Though expression is dependent upon the thought or emotion to be given, elocution applies only to the manner of delivery. In a larger sense it relates to all forms of expressive art, such as music, painting, or sculpture; but the treatment here is confined to its uses in human action and speech. As a science it discovers and sets forth the elements or principles of expression; as an art it embodies these elements in the portrayal of our physical, mental and emotional nature, and their proper use constitutes that naturalness so desirable in public speech. The laws governing the use of these elements are as fixed and definite as those of other well-established sciences, and a violation of these laws results in unnatural and ineffective expression.

The relation between psychic conditions and the elements and laws through which impressions are received and expressed presents a useful and consistent philosophy by which all students of the art of expression in any of its forms may be guided.

Man is endowed with a vital, a mental and an emotive nature. Through these three natures he receives all impressions, and through the elements of elocution corresponding to these trune natures he must communicate all expression.

P A R T I.—E L E M E N T S OF V OC A L EXPRESSION.

There are four generic vocal elements of elocution, namely, Quality, Force, Time and Pitch, all of which are embodied in every utterance, while, in turn, every shade of human expression may be traced in its various subdivisions and combinations. A tabular view of the vocal elements is given on p. 262, etc.

I. QUALITY.—Quality is the tone-color or kind of voice, the purity or impurity of the tone, and is dependent upon the size, shape and physical condition of the vocal organs and cavities. Broadly speaking it is an emotive element which subordinates the other varieties, each having a definite correspondence to man's trune nature. Each quality is determined by its resonance, which Helmholtz defines as 'the strengthening or reinforcing of sound' in the cavities of the head, throat and chest. By changing these resonances at will the speaker can employ the qualities to express his various moods and emotions.

(1) Normal.—The normal is the ordinary, predominant, characteristic quality of voice peculiar to each individual. Its resonance is in the upper and back part of the mouth, and the tone should be pure. By this quality we recognize the voices of different persons. It belongs to the mental division and is the natural expression of our ordinary thoughts, such as solemnity, tranquillity, mild pathos, conversation, didactic thought, gladness, and joy.

(2) Oroton.—The oroton is a strong, clear, deep, voluminous quality, the resonance of which is in the upper part of the thoracic cavity. It represents about equally the mental and vital natures and is used to express thoughts and emotions of a lofty nature, such as reverence, sublimity, grandeur, courage, patriotism and oratorical intensity.
(3) Oral.—The oral is a thin, feeble, shallow quality with the resonance in the forward part of the mouth. It is the physical result of a low state of inherent or excited vitality and logically belongs to the vital division. It is generally used by a speaker in a personative sense to express sickness, feebleness, idiocy, timidity and fatigue.

(4) Nasal.—The nasal is an impure twanging, head-tonal quality in the resonance in the front nasal cavities. It represents a vital condition and belongs to that division. As an habitual

(6) Guttural.—The guttural is a harsh, grating, impure quality the resonance of which is in the upper part of the throat. It represents a very strong condition under a strong emotion and belongs about equally to the vital and emotive natures. It is used to express the malignant passions such as malice, scorn, anger, revenge, violent hate and rage.

(7) Pectoral.—The pectoral is a hollow, hoarse, sepulchral quality with the resonance in the lower part of the chest. It is emotive in nature and is never used except under the influence of the deepest emotions such as vexation, dread, amazement or horror.

(8) Aspirate.—The aspirate is a hissing, breathy, whispered quality in which intensity of emotion forces out more breath than can be vocalized. It belongs to the emotive division. The resonance varies according to the position of the organs and resonant cavities; and its use ranges from the gentlest whisper of secrecy or caution to the intense, half-whispered emotions of fear, terror or consternation.

II. Force.—Force is the power or energy with which sound waves are sent forth from the vocal organs. Figuratively speaking, it is the exploding powder back of the projectile and clearly represents the vital nature in speech. It has three divisions.

(1) Form.—Form is the manner of exerting force, the smoothness or abruptness with which a sound or word is begun or ended. It reveals the sentiment or emotion implied and belongs to the emotive division. It has three divisions which also correspond to the three nature of man.

(a) Effusive.—The effusive is that form of voice in which the sound flows forth smoothly and evenly without abruptness of force either in the beginning or the ending of the tone. It represents the emotive nature and is used to express such gentle and solemm emotions as pathos, tranquillity, reverence, awe or suppressed fear.

(b) Expulsive.—The expulsive is that form in which the force is applied abruptly causing the sound to rush forth from the vocal organs. It is the ordinary form and represents the mental nature in the expression of narration, didactic thought, gladness, patriotism, etc.

(c) Explosive.—The explosive is that form in which the force is exerted very abruptly, causing the sound to burst forth from the vocal organs. It belongs to the vital nature and is used to express the emotions in which great physical vitality is aroused such as in the excitement of ecstatic joy, great earnestness, defiance, alarm, anger, etc.

(2) Degree.—Degree of force is the measure or power with which sounds are uttered. Its subdivisions are subdued, moderate and energetic, all of which correspond to the vital nature and mark the degree of energy used. This scale of degrees is relative and dependent upon individuality and the acoustic properties of the auditorium which, in turn, depend upon the size and shape of the room and whether or not it is filled with an audience.

(3) Stress.—Stress is the application of force to the different parts of a sound or syllable. Any change of the location of the strongest impulse of force from one part of a word to another invariably changes the meaning of the utterance; hence stress responds to

quality it is a grave defect in a speaker. Under control of the will it may be used in an impersonative way to express laziness, mockery, burlesque or drollery; and in more serious thought, it is often employed to give pungency to irony, insinuation or contempt.

(5) Falsetto.—The falsetto is a pure, shrill, penetrating quality ranging above the ordinary pitch. Its resonance is in the upper part of the pharynx and is foreign to the vital division. Its use shows a lack of physical poise and expresses great excitement, fright, yelling, screaming, calling, etc.
the mental division of man's triune nature. There are six varieties of stress.

a. Radical.—In the radical stress the force is applied strongest in the first part of the sound. It is the ordinary stress representing the mental nature and is expressive of didactic thought, narration, gaiety, patriotism, courage, etc.

b. Compound.—In the compound stress the main force is put upon the first and the last parts of the sound. It represents the mental and emotive natures and expresses any irony of purpose or insinuation of statement such as mockery, satire, sarcasm, taunt, derision, etc.

c. Median.—Median stress represents the placing of the force chiefly upon the middle part of the sound. It belongs to the emotive division and is used to express pathos, sorrow, wailing, reverence, awe, etc.

d. Final.—In the final stress the force is placed mainly upon the last part of the sound. It represents the emotive and vital natures and expresses self-assertion, determination, stubbornness, courage, amazement, hate or revenge.

e. Thorough.—The force continues in about the same intensity throughout the sound in the thorough stress which represents the vital nature and is appropriate in the expression of calling, command, triumph, shouting, apostrophe, lofty appeal, etc.

f. Intermittent.—In the intermittent stress the force is placed upon periodic parts of the sound which represents a physical unsteadiness or trembling of the body; hence it belongs to the vital division. It is used to express laughter, crying, ecstatic joy, deep sorrow, tenderness, sympathy, extreme fright and defiant courage.

III. Time.—Time is the duration of utterance and relates to the length of vocal sounds, syllables and words, the rests which occur between them and the rate of speed with which they are given. It is one of the vital generic elements with three specific divisions which represent the pitch.

1. Pause.—Pause is the time spent between the impulses of the voice in the utterance of sounds and syllables or between words or groups of words in speech. By correct pausing words get to their ideas, hence the element belongs to the mental division of the triune nature. Rhetorical pauses should be used (a) Before relative pronouns always and conjunctive words, prepositional phrases and infinitive phrases generally; (b) between words of a series, words marking an ellipsis and clauses; (c) after nominative phrases, words or phrases used independently and words of strong emphasis or emotion; (d) before and after words or phrases transposed or used in apposition, direct quotations and parenthetical expressions.

2. Quantity.—Quantity is the length of time given to the utterance of sounds, words and syllables. It is especially adapted to the vocal utterance of the different shades of feeling or emotion and belongs to the emotive division. It naturally divides into (a) long quantity which expresses sorrow, pathos, reverence, sublimity, apostrophe, command, calling, etc.; (b) medium quantity which is ordinarily used to express narrative, descriptive and didactic thought and all emphatic words of unemotive language; and (c) short quantity which is the shortest prolongation of sound consistent with the requirements of articulation and is expressive of joy, laughter, impatience, contempt, fright, excited anticipation, etc.

The use of the various lengths of quantity depends upon the length of the inherent phonetic sounds composing the words. Long quantity, especially, should never be placed on a short sound.

3. Movement.—This is the rate or degree of rapidity with which a series of sounds or words or a sentence is given. Since the various degrees of movement are but an expression of the physical activities of speech this element belongs to the vital division of man's triune nature. Its degrees are slow, moderate and rapid, and are dependent upon the individuality of the speaker and the acoustic conditions. Very naturally the inner or reflective life requires a slow utterance, while the impulsive, lively, joyous moods find their expression in rapid movement, and the ordinary states of mind require the medium degree.

IV. Pitch.—Pitch is the range or compass of voice and relates to the location, variation and succession of notes upon the scale of degrees. It has three specific divisions which may be subdivided to convey a degree of meaning in expression. Broadly speaking, it is mental in significance and belongs to that triune division.

1. Degree.—The degree of pitch is the range of voice from the lowest to the highest tone, and the position in that range given to a particular note or word. Its subdivisions are high, middle and low, which may be further subdivided; and like all other scales of degrees in elocution depends upon individuality and acoustic conditions. The degrees of pitch mark plainly the speaker's emotive state, and the scale ranges from the deeply serious to reverential emotions of low pitch, through the ordinary thought of middle to the cry of excitement, joy, alarm or defiance of high pitch.

2. Change.—Change is the transition from one degree of pitch to another and is accomplished by a concrete glide or a discrete step. By changes of pitch we convey the various shading of meaning in expression and thus represent the mental nature. There are three varieties of change or transition which correspond to the triune classification.

a. Infection.—Which corresponds to the mental nature is a simple concrete change of pitch of which there are two varieties, rising, expressing anticipation or questioning, and falling, which denotes decision and conclusion.

b. Waves.—Waves are emotive and consist of two or more inflections united in a continuous concrete movement. They may be single, composed of two inflections; double, composed of three; or continued, made up of four or more inflections, all of which are used to extend the vocal quantity without oversteping the interval of pitch that the sentiment requires; and they represent the vital nature. Waves are also equal, expressing pleasantry; or unequal, implying irony; both of which represent the emotive; and direct, expressing assertion, and inverted, indicating anticipation, both of which are representative of the mental nature.

c. Intervals.—An interval is the distance between two points on the scale and marks the
length of the vocal slide or step taken. As a measure of the physical act of vocalization it belongs to the vital division. The five relative intervals of pitch are: Semitones, expressing plaintiveness or sorrow; seconds, reverence and sublimity; thirds, ordinary conversation and oratorical thought; fourths, animated conversation and triumph; and octaves representing extreme surprise, horror or impassioned exclamation.

(3) Melody.—Melody is the succession of speech-notes in utterance and represents the vital nature in the vocal placing of all degrees and changes of pitch upon the scale. There are two divisions.

a. Current melody relates to the body of the sentence and is made up of monotonous, dittones, tritones and polytones, all of which show the vital notation of intervals and notes and record the vocal trend in speech or song.

b. The cadence, which is that part of melody which gives repose at the close of a sentence when the thought is complete. Its technical varieties are (a) the monad, in which the lowering of pitch occurs on one syllable; (b) the first and second dyads, on two syllables; (c) the rising and falling triads, on three syllables; (d) the tetrad, on four; and (e) the pentad, on five syllables.

The distance over which the line of repose is reached is dependent upon the range of the current melody.

PART II.—THE PRINCIPLES OF ACTION.

Action in elocution is that part of delivery which addresses itself to the eye. The main principle of posture and position, the common property of students of expression since the days of the ancient Greeks, was set forth in the 'Chironomia,' a voluminous work of a century ago, by Dr. Gilbert Austin, of London; but the eminent French psychologist, François Delsarte, was the first to show the relation of the whole physical activities to man's triune nature and present anything like a philosophy of actional expression. More recent writers have presented the subject in textual form and made it practical for the student. Combining the expressional use of the eyes, the feet, as explained in the 'Chironomia,' with the zonal correspondencies of Delsarte, we dismiss the subject by referring to the diagram.

For the history of elocution and its relation to the material used in speaking, see ORATORY.

Bibliography.—Bartle, B. R., 'The Practical Speaking' (New York 1822); Basset, 'A Handbook of Oral Reading' (Boston 1917); Belle, A. M., 'Essays and Postscripts on Elocution' (New York 1886); Brewer, J. M., 'Oral English' (Boston 1916); Burgh, J., 'The Art of Speaking' (New York 1875); Fulton, R. L., 'Practical Elements of Elocution' (Boston 1883); Jennings, H., 'Voice and its Natural Development' (New York 1911); Kliser, G., 'How to Develop Power and Personality' (New York 1909); 'How to Read and Declare' (New York 1911); 'How to Speak in Public' (New York 1906); Knowles, A., 'Oral English' (Boston 1916); Pertwee, E., 'The Art of Effective Public Speaking' (New York 1911); Porter, E., 'Rhetorical Reader' (New York 1835); Rush, J., 'The Philosophy of the Human Voice' (Philadelphia 1885); Sheridan, T., 'A Course of Lectures on Elocution' (Troy 1883); Staley, D. M., 'Psychology of the Spoken Word' (Boston 1914); Winans, J. A., 'Public Speaking' (New York 1916). Among the organs devoted to elocution is The Quarterly Journal of Public Speaking (official organ of the Society of Teachers of Elocution, published at Menasha, Wis.).

ELOHIM, 'el-ō-him or e-lō-him (plural of Eloah), one of the Hebrew names for God, of frequent occurrence in the Bible, especially in those parts of the Pentateuch attributed to the earliest writers in the northern domain of the Semitic race. Elohim is used in speaking both of the true God and of false gods, while Jehovah is confined to the true God. The plural form of Elohim (literally signifying 'the great Eloah' or God) has caused a great deal of controversy among critics. By some it has been considered as containing an allusion to the doctrine of the Trinity, others regard it as the plural of excellence, while others hold it as establishing the fact of a primitive polytheism. This word, together with 'Jehovah,' has played a great part in modern criticism. Critics have professed to find in the comparative frequency of the two terms an evidence of the date of the manuscripts in which they occur; but on this controversy we cannot enter. See ELOHIST.

ELOHIST, 'el-ō-hist, also called Yahwist, both used in contradistinction to Jehovah (q.v.), one of the biblical writers, hypothetically assumed to have written part of the Pentateuch, who habitually, if not exclusively, used only Elohim for God. The Elohist passages in the Old Testament, as determined upon by biblical scholars, are simple, straightforward, and bear no signs of rhetoric or poetic effort, therein contrasting with the Jehovistic paragraphs. Gen. i, 27 is Elohist; Gen. ii, 21-4 is Jehovistic.
ELOISE—ELSIE VENNER

ELOISE, El'ë-zh, Mich., a hospital settlement in Wayne County, on the Michigan Central Railroad, 15 miles from Detroit. Here are situated a large hospital, an infirmary and a sanitarium. These are controlled by the Wayne County Superintendent of the Poor, a board established in 1832. Pop. 1,750.

ELON COLLEGE, a coeducational institution, situated at Elon College, 64 miles north of Raleigh, N. C. It was founded under the auspices of the Moravian Church in 1842, succeeded the Graham Normal College, founded in 1865. Courses are given leading to the degrees of bachelor of arts, music, philosophy and literature; and master of arts. The advanced degrees of doctors of literature, divinity and laws are also awarded. Certificates are given in music, art, expression and domestic science. The instructors number 27, the students 400. The library contains 10,000 volumes.

ELONGATION, in astronomy, the angle that measures the apparent distance of two stars as seen from the earth. The term is, however, by usage confined exclusively to the distance of a planet from the sun, and of a satellite from its primary. The greatest elongation of Mercury amounts to about 28 degrees 30 minutes; that of Venus to about 47 degrees 48 minutes, and that of the superior planets may have any value up to 180 degrees. When two fixed stars or planets are spoken of the word "distance" is employed.

ELOPEMENT, in law, an act of unlicensed departure, especially when a wife forsakes her husband and flies with a paramour, or when a daughter or ward accepting the protection of a lover leaves her natural or legal guardians. In almost every one of the States, the male principal in an elopement is held guilty of an abduction provided his associate in the act is under age. Marriage, however, checks all subsequent criminal proceedings unless the female alleges coercion. All persons guilty of aiding or abetting an elopement of a male with a female are deemed in law accessories, and liable to legal proceedings. Elopers themselves are not safe from another arrest after their act comes within the purview of the criminal statutes.

ELOTHERIUM, an extinct scull-lim animal of the Lower Miocene Epoch, remotely related to the hippopotami and pigs. The skull suggests that of the hippopotamus, but it has a narrow elongated muzzle; and the fruit teeth resemble those of the carnivora rather than the shearing tusks of the hippopotami and pigs. The limbs and feet are tall and stilted, the lateral toes reduced to small rudiments, as in ruminants. Different species ranged in size from that of a sheep to that of a rhinoceros.

ELPHINSTONE, Mountstuart, East India, b. Scotland, 6 Oct. 1779; d. Limpfield, Surrey, 20 Nov. 1859. He joined the Bengal civil service in 1795; was Ambassador to the Afghan court in 1808; resident at the court of Poonah from 1810 to 1817; and British commissioner to that province from 1817 to 1819, when he became lieutenant-governor of Bombay. In 1820 he established a code of laws, lightened taxes and paid great attention to schools and public institutions. He resigned in 1827. A college established by the natives was called after him Elphinstone College. He twice declined the governor-generalship of India and devoted the remainder of his life to literary pursuits. He was the author of an 'Account of the Kingdom of Cabul and Its Dependencies' (1815); and a 'History of India' (1841).

ELPHINSTONE, William, Scottish prelate: b. Glasgow 1431; d. 25 Oct. 1514. Having gone to France he studied law for three years, and, as was appointed professor of law, first at Paris and subsequently at the University of Orleans was later made general of the diocese of Glasgow (1471); rector of that university (1474); archdeacon of Lismore (1478), and commissary of the Lothians, and in 1479 became archdeacon of Argyll, and Privy Councillor. Soon after he was made bishop of Ross; and in 1483 was transferred to the see of Aberdeen. In 1488 he was appointed Lord High Chancellor of the kingdom. In October of that year he assisted in the coronation of James IV. He was afterward sent on a mission to Germany, and on his return was installed in the office of Keeper of the Privy Seal, which he held till his death. In 1494 he obtained a papal bull for the erection of a university at Aberdeen, and King's College and University soon came into existence. He was the author of 'Breviary of the Kingdom Aberdeen' (1509-10, reprinted London 1850).

ELSBERG, Elz'berg, Louis, American physician: b. Gerlohn, Prussia, 1836; d. in the United States in 1885. His family settled in the United States in 1849 at Philadelphia. He introduced the art of laryngoscopy in the United States; wrote many papers on the throat and its diseases, notably, 'The Throat and the Production of the Voice'; was the first to illustrate the character of ound tones and divisions of sound in articulation, and invented many instruments which are used in surgical treatment of the throat and ear.

ELSHEIMER, Elz'hem-er, Adam, German painter: b. Frankfort-on-the-Main 1578; d. probably at Rome 1620, called the 'Roman Painter of Germany.' He studied in Rome and settled there while still very young. He painted many biblical and mythological subjects, became a master of landscape, being the chief German artist of the end of the 16th century to acclimatize Roman art in Germany. Among his principal works are 'Jupiter and Mercury with Philemon and Baucis,' 'Joseph in the Pit,' and 'Judith' (at Dresden); 'Martyrdom of Saint Lawrence,' and 'Flight into Egypt' (Munich); his portrait and 'Triumph of Psyche' (Florence); many landscapes at Naples, Venice and Madrid; 'Good Samaritan,' and another 'Flight into Egypt' (Louvre) and a large collection of drawings.

ELSIE VENNER, the first novel of Oliver Wendell Holmes, was originally published as 'The Professor's Story' in the Atlantic Monthly for 1860, where it followed 'The Professor at the Breakfast Table.' The story centres about a young woman whose nature has a strange element not human, which she acquired before birth when she bitten by a rattlesnake. The author aims to enforce his ideas regarding heredity, and especially regarding heredity as modifying moral responsibility.
— ideas which he had advanced in the ‘Autocrat,’ and the ‘Professor at the Breakfast Table,’ and which had been vigorously challenged by the so-called New England moralizers. His moralizing is not, however, obtuse, and his strange heroine is fascinating and not in the least repulsive. As in all Dr. Holmes’ novels, the plot is of the old-fashioned, obvious sort, and some of the incidents are almost melodramatic. The humorous and realistic picture of New England village life, and of a young ladies’ boarding school are delightful, and some of the more serious scenes are portrayed with force. The work has the limitations that might be expected from an author who began to write fiction at the age of 50, and who was by nature an essayist and a social philosopher rather than a novelist; but the conception is striking, and the execution not unworthy. The story has a strange power of impressing itself on the reader and is usually remembered longer than many novels of far greater technical merit.

WILLIAM B. CAIRNS.

ELSINORE, él-sí-nöör, or ELSINBUR (Danish, Helsingør), Denmark, seaport, on the island of Zealand, 24 miles northeast of Copenhagen. The town has a charming site, with several interesting buildings, notably the town hall and the hospital. Its inhabitants are engaged chiefly in commerce and seafaring. The castle of Kronborg, built about 1580, is the chief defense of the town. It is a Gothic-Byzantine edifice built by Frederick II in the boldest of that style, and is said to be one of the finest structures of its kind in Europe. Until 1857 tills were exacted of all ships navigating the strait. Scenes in Shakespeare’s ‘Hamlet’ are laid here. It is now chiefly used as a prison, and was the place of confinement of the unfortunate Matilda, sister of George III of England. The manufactures are chiefly fishing-nets and a coarse cloth, iron founding, shipbuilding, marine engines and net weaving. It has a good harbor with excellent dry-docking facilities for repairing vessels. Coal is imported in great quantities. To the northwest lies the bathing place of Marienlyst, once a royal summer residence. Pop. 15,783.

ELSON, Arthur, American musical critic: b. New York City, Nov. 18, 1852. Son (q.v.). He studied music with his father and with Prof. J. K. Paine, at Harvard. He has degrees from Harvard and the Massachusetts Institute of Technology, and has been prominent as a teacher. His chief works are ‘A Critical History of Opera’ (1901); ‘Orchestral Instruments and their Use’ (1902); ‘The Woman’s Work in Music’ (1903); ‘Modern Composers of Europe’ (1904); ‘Musical Club Programmes from all Nations’ (1907); ‘The Book of Musical Knowledge’ (1915), and ‘The Pioneer School Music Course’ (1916). He is editor-in-chief of the ‘Musician’s Guide’ (10 vols., 1913) and author of many musical essays. He contributes occasional concert reviews to Boston ‘Advertiser’ and many articles to magazines.

ELSON, Henry William, American author: b. Cincinnati, Ohio, 29 March 1857; spent early life on farm; took classical college course at Thiel College, Greenville, Pa., after which he spent three years in the Lutheran Theological Seminary at Philadelphia and later two years in the University of Pennsylvania. After six years in Lutheran pastorates, at Kittanning and Philadelphia, Pa., he left the active ministry and took up the work of writing for historical subjects and lecturer in the University Extension Society of Philadelphia. In 1912 Dr. Elson was elected a member of the Constitutional Convention of Ohio in which he took a very prominent part. He also engaged in proceedings, especially as champion of the short ballot and as one of the leaders in bringing about a reform in the judicial system of the State. He introduced and piloted through the proposal to enable three-fourths of a jury to render a verdict in civil cases. This was made a part of the constitution of the State. Since 1905 Dr. Elson has been the head of the history department in Ohio University at Athens, Ohio. He was president of the Ohio Valley Historical Association in 1915-16.

He published ‘Side Lights on American History’ (2 vols., 1896-97); ‘History of the United States’ (1 vol., 1904); ‘History of the United States’ (5 vols., 1906); ‘Guide to American History’; ‘Guide to English History’ (1906-07); wrote music for volumes of the 10-volume set of the ‘Photographic History of the Civil War’ (1911).

ELSON, Louis Charles, American writer on music: b. Boston, Mass., 17 April 1848. After studying music at Leipzig he returned to Boston and has been a teacher and lecturer on music there from 1888. He has been musical editor of the Boston ‘Advertiser’ since 1888. He has published ‘Curiosities of Music’ (1883); ‘German Songs and Song Writers’ (1886); ‘Our National Music and Its Sources’ (1896); ‘Theory of Music’ (1890); ‘Realm of Music’ (1892); ‘European Reminiscences’ (1893); ‘Great Composers’ (1897); ‘Shakespeare in Music’ (1900); ‘Famous Composers and Their Works,’ new series (1901). His later activities have been wide-spread. He has twice been a Lowell Institute lecturer, giving one course of eight and one of 10 lectures before that institution. He has been city lecturer of Boston, giving about 250 lectures on music to the general public of that city, assisted by an orchestra, and he has traveled over the United States and Canada with musical lectures. His ‘Shakespeare in Music’ and ‘Great Composers’ have been reprinted in London. He has written a ‘History of American Music’ (1905) and a revised edition of the same (1915); ‘Mistakes and Disputed Points of Music’ (1912); and he is editor-in-chief of ‘The University Musical Encyclopedia’ (10 vols.). He has written two musical dictionaries, numerous magazine articles, and is teacher of the advanced courses in theory of music at the New England Conservatory of Music, Boston.

ELSSSLER, él-së-lér, Panny, Austrian dancer: b. Vienna, 23 June 1810; d. there, 27 Nov. 1884. She was the daughter of Johann Esslser, Haydn’s factotum, and was educated at Naples for the ballet, with her elder sister Theresa (b. 1808; d. 1878), who in 1851 became the morganatic wife of Prince Adalbert; in 1874 she was ennobled. Panny Esslser during her visit to the United States gave an entertainment in order to raise money for the Bunker Hill Monument. She retired in 1851.
ELSTER, čl'estr, two German rivers. (1) The White, or Great Elster, rising in the west of Bohemia, flows north into Saxony, receives the Pleisse and Parde at Leisnig, and joins the Saale between Halle and Merseburg, after a course of about 115 miles. It is navigable for small vessels as far as Leipzig. (2) The Black Elster, rising in Saxony, flows north into Prussia, and on the north bank, near Fulda, joins the Roda, and joins the Elbe between Wittenberg and Torgau, after a course of about 130 miles. It is navigable for 40 miles.

ELSTRACKE, Reginald or Ronald, English engraver: b. probably in London and lived there early in the 17th century. His plates were made with the graver solely, their chief value being historical. He executed portraits of Mary Queen of Scots, Darnley and Queen Elizabeth. Among his works was a volume of 32 plates called 'Basilioxia: a Book of Kings, being the true and lively effigies of all our English Kings from the Conquest until this present' (1618).

ELSICK, čl'swik, England, suburb of Newcastle, containing the great ordnance works of Sir William Armstrong, Mitchell and Company. These works are probably the largest of their kind in Europe, employing in normal times about 14,000 persons. Pop. 58,352.

ELTON, Charles Isaac, English jurist and archaeologist: b. Somerset 1839; d. Chard, Somerset, 23 April 1900. He was educated at Oxford and was called to the bar in 1865. He represented West Somerset in Parliament as a Conservative from 1884 to 1892. On legal subjects he published 'Tenures of Kent' (1867); 'Commons and Waste Lands' (1868); 'Copyholds and Customary Tenures' (1874-93); 'Improvement of Commons Bill' (1876); 'Custom and Tenant-Right' (1882); and 'Robinson on Gavelkind' (1897). Other works of his are 'Norway, The Road and Fell' (1864); 'The Career of Columbus' (1892); 'The Great Book Collectors' (1893); and 'Shelley's Visits to France' (1894). His greatest work, however, is 'Origins of English History' (1892). It is chiefly characterized by its thorough investigation of the evidence furnished by Greek and Roman writers regarding the condition and circumstances of early Britain, by its discussion of the ethnology, and prehistoric archaeology of the country, and by the importance assigned to the Celtic and even pre-Celtic element in forming the English nation.

ELTON, James Frederick, English explorer: b. 3 Aug. 1840; d. 13 Dec. 1877. He entered the Indian army in 1857. In 1871 he found himself in the Transvaal and Natal; in 1873 he was vice-consul at Zanzibar, two years afterward as consul in Mozambique he explored the coast of East Africa for the sake of repressing the slave trade. With Cotterill he reached Lake Nyassa in 1877 and scaled the Ksonga range of mountains at the north end of the lake, to the height of 10,000 feet. After his death Cotterill published his journal under the title 'Travels and Researches among the Lakes and Mountains of Eastern and Central Africa' (1879).

ELTON, Oliver, English literary historian: b. 1861. He was educated at Marlborough School and at Corpus Christi College, Oxford. From 1890 to 1900 he was lecturer on English literature at Owens College, Manchester, and in the latter year became professor of English literature at the University of Liverpool. He published an edition of Milton's 'Comus and other Poems'; 'The Mythical Books of Saxo Grammaticus', 'Historia Danica', translated for the Folklore Society; 'The Augustan Ages' (in 'Periods of European Literature', 1889); 'Michael Drayton' (1906); 'Life, Letters and Writings of Frederick York Powell' (1906); 'Modern Studies' (1907); 'Survey of English Literature from 1780 to 1830' (1912); contributions and reviews in the Manchester Guardian, the Quarterly Review, etc.

ELTON, a shallow lake in the government of Astrakhan, in Russia; area, 60 square miles. Eight salt-water streams flow into this lake, and it has no visible outlet; thus a large salt deposit rests on the bed of the lake. From about the middle of the 17th century for 100 years, the salt from this lake was in demand; but since the opening of the salt fields in the southern part of Russia (1860) the Elton salt has not been on the market.

ELTZACHER, Elts'bah-er, Paul, German jurist: b. 1868. He was educated at the universities of Heidelberg, Leipzig, Strassburg and Göttingen. He was appointed a judge; in 1900 privatdozent at Halle, and in 1916 professor of law at the Berlin Handelschulch. He has published 'Ueber Rechtsbegriffe' (1900); 'Die Handlungsfahigkeit' (1903); 'Die Uterlassungsklage' (1906); 'Gross-berliner Mietvertrag' (1913). His best-known work is 'Anarchismus' (1900; Eng. trans. by Byington, 1908), the most complete and unbiased treatment of the subject; it has appeared in most modern languages. The article in 'Handbuch der Politik' on anarchism was written by Eltzacher in 1910.

ELVAS, el'vás (Rom. Alpesa; Moorish, Balesh), Portugal, the strongest fortified city of the republic, in the province of Alemtejo, near the Spanish frontier, 10 miles west of Badajoz. Standing on a hill, it is defended by seven large bastions and two isolated forts. The city contains a 15th century garrison, in which are housed some fine paintings; a theatre, hospital and an ancient aqueduct of remarkable construction. It was completed in 1622. Fire arms and jewelry are the only articles manufactured. The Moors fortified the place and the city suffered from the wars between the Moors, Portuguese and Spaniards. It fell to Portugal in 1226, was taken by the French in 1808, but was ceded to Portugal after the Convention of Cintra. Pop. 14,018.

ELVES (O. Eng. elf; Germ. Alp; phant., spirit), imaginary creatures of the northern mythology, forming, according to some classifications, with the undines, salamanders and gnomes, groups of elementary sprites identified respectively with the water, fire, earth and air. The elves are of the air, and have been more widely received in the faith and poetry of Europe under this name than under that of sylphs, invented by Paracelsus. They are capricious spirits, of diminutive size but preternatural power. Their stature is less than the size of a young girl's thumb, yet their limbs are most delicately formed, and when they will they can hurl granite blocks, bend the strongest man or shake a house. They are divided in the sagas
into good and bad, or light and dark elves, the former having eyes like the stars, countenances brighter than the sun, and golden yellow hair, the latter being blacker than pitch, and fearfully dangerous. The elves ordinarily wear glass shoes, and a cap with a little bell hanging from it. Whoever finds one of these slippers or belts may do many things to the person who has cast it off, anything which he asks for. In the winter they retire to the depths of mountains, where they live in much the same way as men, and in the first days of spring issue from their grottoes, run along the sides of hills, and swing upon the branches of the trees. In the morning they sleep in blossoms or watch the people who pass by, but at the evening twilight they meet together in the fields, join hands and sing and dance by the light of the moon. They are generally invisible, but children born on Sunday can see them, and the elves may extend the privilege to whosoever they please. In England and Scotland they became fairies in the former, and brownies in the latter country, and were a king subject to a The islands of Stern and Rugen, in the Baltic, are especially subject to the king of the elves, who rides in a chariot drawn by four black horses, and whose passage from island to island is recognized by the neighing of the steeds, the blackness of the water, and the bustle of the great aerial company who follow in his train. The elves sometimes become domestic servants, and would be valuable as such if they were less easily offended and less dangerous after taking offense. As long as their caprices are gratified, their food and drink regularly left at an appointed place, and no attempt made to interfere with their freedom, the furniture is sure to be dusted, the floor to be swept and every chamber to be perfectly in order. But the brothers Grimm, in their 'Deutsche Sagen,' have chronicled the misfortunes of many a young girl, who, having called an elf to her aid, repented too late of having offended it.

ELVIRA COUNCIL OR SYNOD—ELY

This council was held at Illiberis or Elvira in Granada, Spain, at the beginning of the 4th century. Three dates are assigned, May 15, 303, 305, 309. Felix, bishop of Accis, presided. The town is no longer in existence. The council was attended by 19 bishops and 26 priests. Hostus of Cordova, adviser of the Emperor Constantine, was the most important personage present. Eighty-one canons were adopted, which reveal the fact that the Spanish Church was largely influenced at the time by Noratian and Montanist teaching. The regulations are many of them very stringent and are largely negative in character. They deal with idolatry, marriage, usury, prophecy, and the prohibition of communion to specified classes.

ELWELL, Frank Edwin, American sculptor: b. Concord, Mass., 15 June 1858. His early instruction in art was from May Alcott and Daniel C. French. He studied subsequently at the School of Fine Arts, Paris, the Ghetto Academy, and with Falguière of Paris. He settled in New York soon after his return home in 1885. His principal works are: 'Death and Strength' at Edam, Holland; 'Diana and the Lion,' now in the Chicago Art Institute; statue of General Hancock at Gettysburg battlefield; 'New Life,' in the cemetery of Lowell, Mass.; monument to Edwin Booth, Cambridge, Mass.; 'Charles Dickens and Little Nell,' at Philadelphia; statues of Greece and Rome on the New Customs House, New York; busts in the Senate, Washington, D. C.; 'Water Boy of Pompey,' in the New York Metropolitan Museum. From 1902 to 1905 he was curator of a department at the Metropolitan Museum, and in 1910 was chosen director of the School of Applied Design for Women, New York.

ELY, Richard Theodore, American political economist: b. Ripley, N. Y., 13 April 1854. He was educated at Columbia College (A.B. 1876, A.M. 1879, Fellow in Letters, 1876-79), and studied at the universities of Halle, Heidelberg, (Ph.D. 1879), and Geneva, Royal Statistical Bureau, Berlin, 1789-90; L.L.D. Hobart College, 1892. He was head of the department of political economy at Johns Hopkins, 1881-92, when he became professor of political economy in the University of Wisconsin. He was member of the Baltimore Tax Commission, 1885-86; of the Maryland Tax Commission, 1886-88, and founded the American Bureau of Industrial Research in 1904 and has since been one of its directors. He was one of the founders of the American Economic Association, 1885; its secretary, 1885-92; its twelfth president, 1890-1901, and was first president of the American Association for Labor Legislation, 1907-08. In 1913 he was appointed lecturer at the London University; has traveled in Great Britain and Ireland and Germany investigating land problems; was invited in 1914 by the New Zealand government to visit New Zealand; member of the International Statistical Institute. He published 'French and German Socialism in Modern Times' (1883), 'Taxation in American Cities and States' (1884), 'Outline of Economics' (1893), 'Monopolies and Trusts' (1893), 'Socialism and Social Reform' (1894), 'Studies in the Evolution of Industrial Society' (1903), 'Property and Contract in Their Relation to the Distribution of Wealth' (1914), editor of 'Macmillan's Citizen's Library of Economics Politics and Sociology,' also 'Macmillan's Social Science Text-books.'

ELY, Theodore Newell, American civil engineer: b. Watertown, N. Y., 23 June 1846. He was graduated at the Rensselaer Polytechnic Institute in 1866. From 1868 to 1910
he was a member of the engineering department of the Pennsylvania Railroad. He also held directorships in the Pennsylvania Steel Company and the Cambria Steel Company; was treasurer of the Cambria Steel Company; was treasurer of the Pennsylvania Railroad; was president of the Philadelphia Academy of Fine Arts; was a director of the Pennsylvania Academy of Fine Arts. He is honorary member of the American Institute of Architects and vice-president of the American Academy in Rome. In 1904 he was president of the Eastern Railroad Association.

ELY, England, an episcopal city in the country of the Cambridgeshire, about 15 miles northeast of Cambridge, on the Ouse. The place is noted for its cathedral, one of the most remarkable edifices of the kind in England. It was founded in 1083 and displays in itself all the styles of architecture from early Norman to late Perpendicular. It is a cruciform building, 537 feet long and 190 feet across the transepts. The nave is 208 feet long and the tower 215 feet high. It occupies the site of a monastery founded about the year 673 by Saint Etheldreda (or Audrey), daughter of Anna, king of East Anglia, and Saint Aldreda. In 1071, Hereward, the noted English outlaw, defended Ely against the Normans. (See HEReward). Market gardening and fruit preserving are among the important industries. Pop. 7,917. Consult Van Rensselaer, 'English Cathedrals'; Bond, F., 'English Cathedrals'; Stewart, 'Architectural History of Ely Cathedral'.

ELY, Minn., city and summer resort in Saint Louis County, 115 miles northeast of Duluth, on the Duluth and Iron Range Railroad. It is in the centre of the Vermilion Iron Range, and nearby are several lakes and waterfalls. There is a large trade in fish, furs, lumber and iron. The government is vested in a mayor, elected annually, and a board of aldermen. The city has a fine high-school building and city hall, and owns the waterworks and electric-lighting plants. Pop. 3,572.

ELY, Isle of, a district in England, in the county of Cambridge, separated on the south by the Ouse from the remaining portion of the county and forming in itself an administrative county; area, 283,073 acres. It rests about 100 feet above the general level of the fen country, and was formerly surrounded by marshes, which at times became sheets of water. The whole has by drainage been converted into fertile fields and is a most productive fruit-growing district. Pop. 69,752.

ELYMAS. See BAR-JESUS.

ELYOT, Sir Thomas, English author: b. Wiltshire not later than 1490; d. Carlton, Cambridgeshire, 20 March. 1546. In 1511 he became clerk of assize, in 1523 clerk of the king's council. In 1531-32, as Ambassador to Charles V, he visited the Low Countries and Germany, having orders to procure, if possible, the arrest of Tyndale. 'The Boke named the Gouernour, deuised by Sir Thomas Elyot, Knight,' was published in 1531. It may be described as the earliest treatise on moral philosophy in the English language, the author's principal object being to instruct men in such virtues as shall be expedient for them which shall have authoritie in a weale publike.' An elaborate 10th edition appeared in 1880, with life notes and glossary by H. H. S. Croft. Elyot's 12 other works include 'Of the Knowledge which maketh a Wise Man' (1533); 'Pasquale the Playne' (1533); 'Isocrates', 'Doctrinal of Princes' (1534); 'Picus de Mirandola's Rules of a Gentleman' (1534); 'Castel of Helth' (1534); 'The Bankette of Sapience' (1534); 'Bibliothea' (1538), the first Latin-English dictionary; 'The Image of Government' (1540); 'Defence of Good Women' (1545); and 'Preservative against Deth' (1545). These books were all printed after edition in their author's lifetime, and have now become among the rarest treasures of book collectors.

ELYRIA, Ohio, city and county-seat of Lorain County, on the Black River and on the Baltimore and Ohio and Lake Shore and Michigan Southern railroads, 25 miles southwest of Cleveland. It has a public library, a hospital and a fine natural park. Agriculture is the chief industry of the surrounding country; the sandstone quarries furnish employment to a number of people. The chief manufactures in the city are supplies for automobiles and bicycles, saddles, telephones, home-lighting plants, flour, feed, canned goods, concrete blocks, moldings, paints, metal polish, switchboards, screws, machine parts, iron pipe, angle iron, strip steel, etc. The United States census of manufactures for 1914 showed within the city limits 63 industrial establishments of factory grade, employing 3,236 persons; 2,735 being wage earners, receiving $1,759,000 annually in wages. The capital invested aggregated $9,985,000, and the year's output was valued at $8,792,000; of this, $3,776,000 was the value added by manufacture. The waterworks are owned by the city. Pop. 17,396.

ELYSÉE, Palais de l', pâ-la dé là-lé-zâ, the official residence of the President of France, in Paris, on the Rue du Faubourg Saint Honoré, with its garden extending to the Champs Elysées. It was built in 1718 for the Count d'Evreux; in the reign of Louis XV it became state property and was the residence of Madame de Pompadour. It was also used as a residence by Napoleon I and by Louis Napolecon, and became the presidential residence in 1871.

ELYSIAN FIELDS, or ELYSIUM, in classical mythology, the residence of the blessed after death. Elysium was supposed by Homer to have been at the western end of the earth; other poets placed it in the Fortunate Isles; later it was supposed to be in the under world. It was represented as a region of perfect happiness, where the sky was always cloudless and a celestial light shed a magic brilliancy over every object; where each one was free to follow his favorite pursuit, and cares and infirmities were unknown.

ELYZÉ, öttsē, Karl, German historian of literature: b. Dessau, 22 May 1821; d. Halle, 22 Jan. 1889. His specialty was English literature, and he was professor of English philology in the University of Halle 1875-89. One of his first works was a compilation entitled 'Treas-

ury of English Slang.' He produced critical editions of Shakespeare and other English dramatists, and wrote biographies of Byron and other English authors. Specially noteworthy is his 'Grundniss der englischen Philologie.'
ELZEVIR — EMANCIPATION

ELZEVIR, ėlzé'vīr, name of a notable family of printers descended from Ludovicus Elzevirus, a native of Louvain: b. 1540; d. 1617. Having learned the bookbinders' trade, he practised it for some years in his native town, but in 1580 he removed to Leyden in the United Provinces and there set up a printing press. His five sons, Marinus Egidius, E. Elzevirus, Joost and Bonaventura, were also printers and booksellers; but it was the youngest of the five, Bonaventura, born 1583 at Leyden, that gave the name Elzevir its great celebrity. The first work published by the house of Elzevir appeared in 1583, the 'Elnaire Questiones et Responsiones' of Drusius, not the whole three books, but only the second and third. In 1608, nine years before his father's death, Bonaventura Elzevir founded a separate printing and publishing establishment in the same city and then commenced the issue of works in Greek and other languages which have ever since been regarded as models of correct and elegant typography. He conducted the business of his house more than 42 years, till his death in 1652, having had as partner from 1626 Abraham Elzevir, his nephew, whom he survived one month. He was succeeded by his son Daniel and Abraham's son John; this partnership was soon dissolved.

John carrying on the business in Leyden, Daniel migrating to Amsterdam in 1655 and entering into partnerships there with another of his cousins; both of these were dead 1680. The last of the Elzevirs to figure in the history of typography was Abraham, son of Abraham, one of the five sons of Ludovicus; from 1681 to 1712 he was printer to the University of Leyden. The Elzevir editions of the ancient classics, especially Latin, while admirable in point of typography, are mostly reproductions of the texts adopted by previous printers and hence are inferior from the critical point of view. The number of works published by the different Elzevir houses nears the 2,000 mark.

EMANCIPATION, the act by which freedom of various kinds is granted to individuals, races or nations. In Roman law the dissolution of paternal authority (patria potestas) in the lifetime of the father. It took place in the form of a sale by the father of the son to a third party, who manumitted him. The Twelve Tables, the foundation of Roman law, required that this ceremony should be gone through three times. In general, the son was at last resold to the father, who manumitted him, and thus acquired the rights of a patron which would otherwise have belonged to the alien purchaser who finally manumitted him. In the case of daughters and grandchildren one sale was sufficient. This form of emancipation continued to exist in the time of Justinian, who substituted a declaration by the father before a proper tribunal. This emperor also changed the succession law, by making kinship by blood decisive. According to Teutonic law the marriage of a minor, who afterwards fled her father's parental control and a son became free upon setting up a home of his own. In modern states liberty from parental authority comes on attaining full age. If a person receives his freedom before attaining full age he is said to be emancipated. For full information on this question it is necessary to consult the various codes. The Catholic Emancipation Act was the act signed 13 July 1829, which removed the most galling of the Roman Catholic disabilities in England. See Emancipation, Catholic; Emancipation Proclamation; Slavery.

EMANCIPATION, Catholic, the customary designation of a measure of relief from penalties and civil disabilities granted to professors of the Catholic religion in England and Ireland by acts of the British Parliament 1829: the act did not extend to Scotland. The necessity of granting relief to the Catholics of Ireland became apparent soon after the outbreak of the war against the American colonies, and the first relaxation of the penal laws against the professors of the Catholic religion was made in 1780. At that time it was high treason for a priest, native of the kingdom, to perform any of the duties of his office. Catholics could not own land in Great Britain and titles to land antedated the penal laws were ousted if the legal heir professed Protestantism. A Catholic could not practise law, nor conduct a school. In 1780 a bill for removal of some of the disabilities was passed for England and Ireland. When the act of union of the kingdoms of Great Britain with that of Great Britain was passed in the Irish Parliament 1800, solemn pledges were given by the British Cabinet that the disqualifying statutes should be repealed; but after the Union the promise was ignored. In 1824 in Ireland was formed the Catholic Association to agitate for civil rights, such as the right to vote for members of the Parliament, to be elected members of the same and to occupy various offices in the government, national and local. In 1829 it was seen by English statesmen that to withhold these rights and franchises any longer would provoke a rebellion in Ireland; and a bill of relief was introduced in the Parliament 5 March, and passed in both houses and approved by King George IV 13 April, permitting Catholics to elect and be elected to the Parliament, and to hold offices under the Crown; but they remained still expressly excluded from certain high offices — that of lieutenant-governor of Ireland, that of regent of the universal kingdom or lord chancellor of the United Kingdom, or of Ireland, etc. In 1857 the last named disability was removed, as was, many years after, the disability of a Catholic to be lord chancellor of the United Kingdom. But the Act of Grace of 1829 contained a clause forbidding Catholic ecclesiastics, monks, friars and nuns from wearing the attire or habit of their respective station or order in public under a penalty of $250 for each offense. This proviso was ostentatiously violated in Ireland, and with impunity, for, like the $200 forftight the time of Justinian, all Ecclesiastical Titles Acts (q.v.), no penalty was ever exacted. Another clause of the Catholic Emancipation Act, which was also ignored and condemned, required that Jesuits and members of religious orders of the Roman Catholic Church living within the kingdom should register in the office of the clerk of the peace of the county under a penalty of $250. (See O'Connell, Daniel.) Consult Butler, 'Historical Memoirs'; Milner, 'Supplementary Memoirs'; Lingard, 'History
SIGNING THE EMANCIPATION PROCLAMATION
of the Church in England'; Green, 'History of England.'

**EMANCIPATION IN LATIN-AMERICA**, the Manumission of Slaves in Relation to the several Declarations of Independence. In Haiti, when African slavery was first introduced into America, the negroes received as a gift "the full liberty, equality, and fraternity" of the French republic in 1794, and by fighting established their independence in 1804. In Central America (when Guatemala, Salvador, Honduras, Nicaragua, and Costa Rica were united in the Central American republic), the laws of 31 Dec. 1823 and 17 and 24 April 1824 emancipated all slaves, and made free, slaves of other countries coming to Central America. The slave trade was prohibited, under penalty of forfeiture of the rights of citizenship. H. H. Bancroft, in his 'History of the Pacific States,' says "Of all the nations of North America, to the Central American republic belongs the honor of having first practically abolished slavery." What we angrily show, however, that this distinction fairly belongs to Mexico. Ecuador, which made its first effort to gain independence at Quito, 10 Aug. 1809, and actually threw off the yoke of Spain on 9 Oct. 1820, abolished slavery during the presidential term of General Urquiza, 1852-56. The Argentine nation began its struggle for independence 25 May 1810, and at the Congress of Tucuman, 9 July 1816, the formal separation from Spain was declared. Article XV of the constitution of 25 Sept. 1816 provides that "there shall be no slaves in the Argentine nation. Those few who now exist in it shall become free at the very moment this constitution goes into effect. The indemnification which the declaration may involve shall be provided for by special law. Any contract involving the purchase or sale of a person shall be held to be a criminal offense. . . . Slaves introduced in any way whatsoever into the country shall become free by virtue of the fact that they have trodden the soil of the republic." In Colombia (New Granada) the number of negroes was never very great; it was estimated at 80,000 in the middle of the 19th century. The struggle for independence, beginning 20 July 1810, or as a vigorous insurrection in 1811, was continued after the union with Venezuela (December 1819), and the republic of New Granada was formed in 1831. In 1821 a law was passed by the republic of Colombia for the gradual manumission of slaves, and all born after that date were declared free at the age of 18,—that gradual process applying, of course, to all the territory of the Greater Colombia at the time of the law's enactment. (See COLOMBIA, History). A law of 1851 abolished slavery entirely in New Granada, by giving liberty to all who remained slaves on 1 Jan. 1852, provision being made for the payment of indemnity to the owners. The beginning of the war for independence in Mexico dates from 16 Sept. 1810 (see DOLORES, GI Grito de) ; on 6 Nov. 1813 the first Mexican Congress, installed in the town of Chihuahua, issued the declaration of independence and decreed the emancipation of slaves. This, therefore, was the starting point of emancipation on the mainland of America. Venezuela's declaration of independence (5 July 1811) was followed after 10 years by the law for the gradual manumission of slaves which we have mentioned above, that is, the law of the Greater Colombia of 1821. The Paraguayan independence should be dated from 11 June 1811, when an assembly of deputies began its sessions; for the resolution passed by this assembly, renouncing allegiance to Spain, was ratified as a declaration of independence by the Paraguayan Congress of 1 Oct. 1813. The question of African slavery was comparatively unimportant in Paraguay. In 1865 there were negroes and mulattos at Emboscada, Tabapy, and Aregui; but the negroes have now almost completely disappeared ("Handbook of Paraguay," September 1902, issued by International Bureau of the American Republics). Chile entered upon a contest with Spain on 18 Sept. 1810, and the independence of the country was proclaimed 12 Feb. 1818. The negro problem did not weigh upon that country, the population being recruited from Europe quite largely. The independence of Peru was declared at Lima 28 July 1821; that of the Dominican republic 1 Dec. 1821; that of Brazil 7 Sept. 1822; and Bolivia became an independent republic 6 Aug. 1825. In Brazil the emancipation act was passed by the Statesman, Silva Paranhos, obtained from the Parliament the passage of a bill (28 Sept. 1871) for the gradual extinction of slavery, which provided that thereafter every child born of a slave mother should be free, and created a special fund for emancipation by redemption. Private philanthropy, largely directed by the Masonic lodges, effected more than the fund created for this purpose; and the number of slaves began to decrease. A bill for the immediate and unconditional abolition of slavery in Brazil was signed by Princess Regent Isabel 13 May 1888; the monarchy was overthrown 15 Nov. 1889; the new constitution approved 24 Feb. 1891. In Cuba the slaves were emancipated on the conclusion of the Ten Years' War, that is, in 1878, and Cuba became a republic 20 May 1902. The experiences of the French, Danish and British possessions may be referred to briefly in conclusion. Napoleon restored slavery in French Guiana, Martinique and Guadeloupe, although his efforts to accomplish this result in Haiti were, as mentioned above, frustrated by the resistance of the blacks themselves. The freedom of all who were held in bondage throughout the French dominions was declared in 1848. Slavery in the Danish West Indies (Saint Thomas, etc.) was abolished also in 1844. The act to abolish slavery throughout the British colonies, providing £20,000,000 for compensation of the owners, was dated 28 Aug. 1833, and its effect was to free 770,000 slaves on 1 Aug. 1834, the number thus emancipated in Jamaica being 309,000.

HARRIOT WILCOX.

**EMANCIPATION PROCLAMATION**, the announcement issued by Abraham Lincoln 1 Jan. 1863 abolishing slavery in all military sections of the South except those territories occupied by Union arms. The Republican administration at the outbreak of war was awkwardly placed for dealing with slavery. To assimilate it in its own territory was not only to belie the past professions of the party, but to alienate so much Northern support as to assure failure; nor indeed had the great bulk of the party any thought beyond lettering the slave
power for future aggression. On the other hand, to leave slavery untouched was not only to chill the energies of the most reliable supporters of the War, but to give foreign countries a pretext for asserting that the North was fighting merely for dominion, and that the Southern cause was that of liberty and morally entitled to help. The former horn of the dilemma in the South was not; and the government moved very cautiously, restraining its subordinates like Fremont (30 Aug. 1861) and Hunter (9 May 1862) from forcing its hand by emancipation orders. On 9 Aug. 1861 an act had declared masters employing slaves against the government hanged from further dealing with them; but that was a mere warning and rule of court. The first embarrassing problem was how to deal with slaves in conquered districts, or who had come within its lines: was the government to act as slaveholders' trustee and re-unite them to their owners? The growing resentment against slavery as a convertible term for the rebellion, and disgust at being slave-catchers to the behoof of their enemies, supplied the answer, and on 13 March 1862 all army officers were ordered to return all slaves; this surrender from any quarter was made harder (though the Fugitive-Slave Law was not formally abolished till 28 June 1864); on 17 June 1862 all captured, deserted or fugitive slaves of owners in rebellion were freed. As to the main body, it was plainly unjust not to help in unchallenged status as the core of a fresh abscess, Lincoln's wish was for compensated emancipation; he sent a special message to Congress 6 March, and that body passed a joint resolution 10 April, declaring that the United States ought not to allow any State in which would adopt gradual abolition, by paying for the slaves, and on 16 April those in the District of Columbia were thus emancipated; but despite his repeated urgencies, the border States would take no measures of the kind. On 19 June the slaves in the Territories were freed.

The final blow came, as John Quincy Adams 20 years before had forecast that it would, by using the President's war power to suppress insurrection. As the second year of the conflict wore on, the majority demanded the crippling of the rebellion by the most efficient means, and very many believed that a threat of general emancipation would bring about a general surrender. Lincoln wished for a great victory first, that it might not appear the selfish resource of an overmatched power; but the discouraging Peninsular campaign obliged him to satisfy his supporters by holding this bludgeon over the enemy. On 22 Sept. 1862 he issued a proclamation announcing that 100 days after, on 1 Jan. 1863, the Executive would issue another proclamation designating the States or parts of States then deemed in rebellion, evidence to the contrary being the presence of bona-fide representatives in Congress, that all slaves in the designated sections should be permanently free, and that the civil and military authorities of the United States would maintain their freedom, and would not repress any effort of theirs to make it good. The only result was a retaliatory proclamation by Jefferson Davis 23 December, ordering that captured negro Federal soldiers and their officers should be turned over to the States, and that Gen. B. F. Butler should be hanged if captured. On the 1st of January the threatened proclamation was issued, as "by virtue of the power in me vested as commander-in-chief of the army and navy of the United States, and as a fit and necessary war measure for repressing said rebellion." It designated Arkansas, Texas, Louisiana except 13 parishes or counties, Mississippi, Alabama, Georgia, Florida, South Carolina, North Carolina and Virginia except West Virginia and seven other counties, as in rebellion, emancipated all the slaves in them; enjoined these freedmen to abstain from all violence except in self-defense, and to work faithfully for reasonable wages; announced that suitable members of them would be received into United States military and naval service, and for this act invoked "the considerate judgment of mankind and the gracious favor of Almighty God."

The curious feature of this proclamation is that it abolished slavery only in the sections not under the military power of the United States, and left it untouched in those which were, namely, the ones specially excepted by it, "which are, for the present, in insurrection." If this proclamation were not issued," Hence it was argued by the Democrats that it had no legal force whatever, and emancipated no one; a question the Supreme Court never passed on. It was always accepted by the majority party, however, as a continuance of the emancipation as fast as any of that territory fell into the Union power, and not necessary to repeat. Politically, the results were enormous. Recognition of the Confederacy henceforward meant a flat maintenance of slavery instead of freedom, the entire anti-slavery sentiment of France and Great Britain was thrown against those countries' interference, which at once became unthinkable. It drove away many lukewarm Northern Republicans, and brought many local and State defects to the administration; but it took the party "off the fence" and made it a coherent organization with one firm, open principle, for many years unassailable. In the South, as defeat meant emancipation by their enemies and it would be nothing to them, some of the leaders (as Lee) seriously thought of offering freedom to slaves to fight in their armies in the latter part of the war, hoping to save independence and the control of their own destinies at least.

EMANTS, éman's, Marcellus, Dutch poet and descriptive writer: b. Voorburg, near The Hague, 12 Aug. 1848. His volumes of travels display his keen observation and his poetical imagination. Among his best are 'A Journey Through Sweden' (1877); 'Monaco' (1878); 'Along the Nile' (1884); 'From Spain' (1886). He holds a permanent place in the literature of the Low Countries through his charming narrative poems, 'Lilith' (1879); 'The Shimmer of the Gods' (1883).

EMANUEL THE GREAT, king of Portugal: b. 31 May 1469; d. Lisbon, 4 Dec. 1521. He ascended the throne of Portugal a child, under the regency of his mother. During his reign were performed the voyages of discovery of Vasco da Gama, of Cabral, of Americus Vespucius and the heroic exploits of Albuquerqu, by whose exertions a passage was found to the East Indies (for which the way was prepared by the discovery of the Cape of
Good Hope in 1486 by Bartolomeo Dias), the Portuguese dominion in Goa was established, the Brazils, the Moluccas, etc., were discovered. The commerce of Portugal under Emanual was more prosperous than at any former period. The treasures of America flowed into Lisbon and the reign of Emanuel was justly called "the golden age of Portugal." It is lamented by his subjects, but hated by the Moors and Jews, whom he had expelled. As a monument of his discoveries Emanuel built the monastery at Belem, where he was buried. He was a friend to the sciences and to learned men. He wrote "Memoirs on the Indies."  

**EMBA, ēmbā, a river in the district of Orenburg, Asiatic Russia; the Russians call it Jamba, the Kirghiz, Dchem. It rises at three sources in the western slope of the Mugodzhar foothills, flows sluggishly through an area of steppes, is about 200 feet wide and 500 miles long, and forms a delta at its embouchure in the Caspian Sea. It is not navigable, but abounds in fish. The fortress Embinsk is built on its upper waters.**

**EMBALMING, the art of preserving the body after death. It was probably invented by the Egyptians, whose bodies thus prepared for preservation are known as mummies, but it also prevailed among the Assyrians, Scythians and Persians. It is at least as old as 4010 B.C. The Egyptian mummies were placed in costly coffins ready for sepulture; but were frequently kept some time before being buried — often at home —and even produced at entertainments, to recall to the guests the transient lot of humanity. The usual method of embalming among the ancients was as follows: The intestines and brains were taken out, and the cavities filled up with a mixture of balsamic herbs, myrrh, cassia, etc.; the arteries and other vessels were injected with balsams. The ancient Egyptians filled the cavities of the trunk with aromatic, saline and bituminous stuff. The clothes in which the mummies were swathed were saturated with similar substances. So effectual were some of the processes that after 2,000 or 3,000 years, the soles of the feet are still elastic and soft to the touch. By 700 A.D., when embalming practically ceased in Egypt probably 730,000,000 bodies had been thus treated; many millions of them are still concealed. In 1851, upward of 30 mummies of potentates, including that of Rameses II, were discovered together at Deir-el-Bahari. (See MUMMY.) The Persians employed wax for embalming; the Assyrians, honey; the Jews aloes and spices. Alexander the Great was preserved in wax and honey. Desiccated bodies, preserved by atmospheric or other influence for centuries, have been found in France, Sicily, England and America, especially in Central America and Peru. The art of embalming was probably never wholly lost in Europe. The body of Edward I, buried in Westminster Abbey in 1307, was found entire in 1770. The body of Canute, who died in 1036, was found very fresh in Winchester Cathedral in 1776. The bodies of William the Conqueror and of Matilda, his wife, were found entire at Caen in the 16th century.

Chaussier's discovery, in 1800, of the preservative power of corrosive sublimate, by which animal matter becomes rigid, hard and grayish, introduced new means of embalming; but, owing to the desiccation, the features do not retain their shape. The discovery of the preservative power of a mixture of equal parts of acetate and chloride of alumina, or of sulphate of alumina, by Gannal, in 1834, and of arsenic by Tranchini, pyroxylic spirits by Babington and Rees in 1839, and of the antiseptic nature of chloride of zinc, have led to the application of these salts to the embalming of bodies required to be preserved for a limited time. The latest method common in the United States is an injection of a fluid into the femoral artery and the cavity of the abdomen. The most efficient agents are mercuric chloride, arsenic and zinc chloride. Embalming has taken the place of ice in preserving the dead until funeral services are ended. The reasons for this are its preservation of the body for transportation and leisurely disposal and its absolute prevention of communication of infection, either before the body is buried or after it has crumbled and mingled with earth in a cemetery. Consult Budge, 'The Mummy' (2d ed., London 1894); Dhonan and Nunnamaker, 'The Mummy and Military Science' (Cincinnati 1913); Eckles, 'Practical Embalmer' (Philadelphia 1904); Gannal, 'Traite d'embauemment' (Paris 1838; trans. by Harlan, Philadelphia 1840); Myers, 'Champion Textbook of Embalming' (5th ed., Springfield, Ohio 1908); Pettigrew, 'History of Egyptian Mummies' (London 1834); Smith, G. E., 'A Contribution to the Study of Mummification in Egypt' (Cairo 1906); Suceet, 'Embaumment' (Paris 1872). See DEAD, DISPOSAL OF THE MUMMY.

**EMBANKMENT. See LEVEE; MISSISSIPPI LEVEE SYSTEM.**

**EMBARGO IN THE UNITED STATES.** Prohibition of foreign commerce, to distress foreign countries and obtain the revocation of hostile measures; "peaceful war," intended to be cheaper than actual warfare and equally efficient, but in fact injuring ourselves deeply and the others little, and ending in real war at last. Our embargoes belong exclusively to the French-English wars of 1794-1814. Their ultimate cause was that the agricultural classes, who controlled the administration, lived in commerce, and preferred abolishing it to spending anything for its protection; moreover, they were mainly Southern and Democratic, the commercial interests mainly New England and Federalist, and the former were not loath to spare themselves the cost of war by impoverishing the latter. The first embargo was for 60 days, due to mutual orders of France and England for seizure of neutrals which placed the United States between hammer and anvil. Jay's Treaty (q.v.) of 10 Nov. 1794, for 12 years, measurably protected our commerce, but near its end conditions became infinitely worse. In 1806-07 the thronging mutual blows of England and Napoleon, ending in the former's Orders in Council of 11 November, and the latter's Milan Decree of 7 Dec. 1807, made practically every neutral vessel good prize to one or the other. Even more intolerable were the rights of search and impressment claimed by Great Britain, which swept several hundred American sailors every year out of the British fleets, and in one massacre (see CHESAPEAKE AND LEOPARD) outraged and humiliated this country beyond forgiveness. But aside from the reasons above given, few landmen believed

**VOL. 10—18**
till the victory of Old Ironsides (see Consti-
tution). True that American ships could fight
English on equal terms, and it was the general
conviction that in case of war our entire fleet
would at once be "Copenhagened" (that is,
captured bodily and added to the British fleet,
as was the Danish). At Jefferson's recom-
men dation, therefore, The Embargo was passed
22 Dec. 1807, forbidding all foreign com-
merce till the obnoxious decrees were repealed.
The havoc not only in trade but in the interior
life of the people was terrific: the exports fell
from $110,084,207 in 1807 to $22,430,960 in 1808.
The farming sections were dismayed to find
that commerce meant part of their daily bread
as well as the carrier's profits and that they
raised and sold much of that $97,000,000; but
they clung all the more stubbornly to their anti-
war recipe, though England and France ap-
proved it highly. Napoleon was glad to see his
enemy drifting into war with a western power;
England was glad to regain her carrying trade
and see Canada and Nova Scotia receive Ameri-
can capital. Meantime New England fought
it with the ferociousness of a struggle for life;
evaded it largely by sea and sent armies of
smugglers overland to Canada. Congress then
extended the act to rivers, lakes and bays, and
allowed collectors to seize on suspicion; and
the next Congress, 9 Jan. 1809, passed a savage
enforcing act with all the fury of hallowed doc-
tr inaires, imposing enormous fines, forfeitures
and bonds and making the collectors supreme
despots of their districts. New England was
nearly in insurrection; the collectors were in
danger of the fate of those under the Stamp
Act, some resigned, others were sued in the
State courts; the judges would give no findings
against smugglers; finally the States threatened
nullification and John Quincy Adams (a victim
to its support) declared that they had resolved
to withdraw from the Union at least tempo-
rarily, if force were used, and had opened nego-
tiations with Great Britain. A Federalist de-
clared in the Senate that blood would flow.
The Democrats were frightened and hastily
fixed (20 Jan. 1809) 4 non-intercourse act 8 to
influence its existence. But the next month they had regained
courage and passed a "non-intercourse act" to
take its place; still prohibiting intercourse with
France or Great Britain, but restoring it with
other nations and removing the coating tri
This policy was continued till the War of 1812
opened. The hostility of New England to the
war, only less destructive than the embargo and
against her political feelings, induced the British
government ostentatiously to relieve that section
from the blockade, to sow discord and make a
base of naval supplies; and on 17 Dec. 1813 a
new embargo was laid to 1 Jan. 1815, which,
however, was repealed 14 April 1814. Jefferson
always asserted that the policy was the best and
the embargo would have accomplished its object if
now the Embargo had only have helped. It is
now pretty generally agreed that the laying of
the embargo was a great political and economic
mistake and it is certain that, as a result of it,
American shipping sustained between 1807 and
1815 almost irreparable damage. Consult the
history of the United States through this period,
like Schouler, McMaster, etc.; especially Henry
Adams' "History," covering 1801-15, devoted
to the causes and consequences of these measures.

EMBASSY (embassy, from O. Fr. am-
bass., from low Lat. Ambass., a servant, vas-
al) in its strict sense, signifies a mission pre-
sided over by an ambassador, that is, a diplo-
matic agent of the first rank, as distinguished
from a legation or mission entrusted to an en-
voy or agent. The difference between the pow-
ers and the legation is that an ambassador's en-
voy is, that the former, as the representative
of the person of his sovereign, can demand a
private audience of the sovereign to whom he
is accredited, while the latter must communicate
with the Minister for Foreign Affairs.

EMBER-DAYS, called in the Roman Mis-
sal and Breviary Quattuor Tempora (the four
seasons) and in the Anglican Book of Com-
mon Prayer, *Ember-days at the four seasons,*
are in the Roman and in the Anglican calendar
the Wednesdays, Fridays and Saturdays which
come next after 13 December, the first Sunday
of Lent, the Feast of Pentecost (Whitsunday),
and 14 September, respectively. In both the
Latin Church and the Anglican these days are
days of fasting. The Quattuor Tempora
were observed at Rome in the time of Saint Augus-
tine (the bishop of Hippo, early in the 5th cen-
tury) and doubtless the observance was an old
practice of ancient date. The custom was brought into
Britain by that other Saint Augustine who was
the herald of the gospel to the Anglo-Saxons.
It was anciently the custom for bishops to hold
ordinations only on the Saturdays of the Quat-
tuor Tempora. The origin of the phrase Ember-
days cannot be definitely ascertained; but it is
probably a corruption of Quattuor Tempora, as
in German Die Quattember signifies the Ember-
weeks.

EMBEZZLEMENT (O. Fr. beszeler, to
ribe, lay waste) is the fraudulent appropriation,
as by a clerk, public officer, agent or other per-
son of property entrusted to him. It must not
be confounded with larceny, which is the
wrongful taking and carrying away of the per-
sonal property of another, with the felonious
intent of converting such property to one's own
use without the disconnection of the owner. This "taking" implies a trespass, which does not ex-
ist in embezzlement. By common law, embe-
zzlement was not a crime, but it has been uni-
versally made so by statute both in the United
States and Great Britain. The earliest statute
recognizing the offense was that of Henry VIII.
C. 7 (1529). This act was passed with the ob-
ject of remedying an admitted defect in the
existent criminal law, by which persons who had
fraudulently appropriated goods or money,
coming into their possession legally, escaped all
punishment, although their moral guilt was
great. Obviously they could not be convicted of
larceny, as their offense lacked some of the
essential elements of that crime. The above-
named statute, however, was limited to serv-
ants and in 1799 another statute was passed extending it to include clerks. This act, not
proving completely satisfactory, the Lar-
ceny Act, passed in England in 1901, which
amended sections 75 and 76 of the Larceny Act
of 1861, further amended the offense to include
trustees, directors of companies and others.
This act makes the offense a misdemeanor and
provides that the punishment therefor shall be
penal servitude for a term not exceeding seven
years, or imprisonment, with or without hard
1 French. Louis XV
2 English. Period, Charles I. A fine example of "stamp-work" (see article) characteristic design: figures, castle, animals, flowers and birds. (In Metropolitan Museum, New York)
labor, for a term not exceeding two years. In Scotland certain designated courts have inherent jurisdiction to punish all offenses, even when not declared to be crimes by statute, with the result that no legislation on the subject has been found necessary in that country.

Most of the statutes in the United States are based on the English act of 1799, but are much broader in their scope. In this country embezlement is a misdemeanor or a felony, depending usually on the value of the property appropriated. Although in some States embezlement by an officer of a corporation or embezlement of certain animals is a felony irrespective of the value of the property converted. Statutes often define embezlement and mention is frequently found therein of the persons who may be guilty of the crime, as administrators, guardians, trustees, public officials, servants, agents and others who occupy fiduciary relations. It is essential to constitute the crime that the person charged therewith should have come into possession of the property by virtue of his employment and that he intentionally violated some confidence. There must also be a criminal intent to appropriate the property of another. Thus one holding property which is legally in his hands in the honest though mistaken belief that he owns it cannot be convicted of the crime. In some States, as Massachusetts and New York, embezlement is included in the offense of larceny. The punishment differs in the various States, usually being imprisonment for a term varying from 2 to 10 years.

EMBLEMENTS (O. Fr., embläçment, from embläcer, to sow with grain), a term applied to the growing crops of land when the lease of a tenant for life has expired by the death of the tenant, or when an estate at will has been determined by the lessor. In either case the emblements belong to the tenant or his executors. But when the tenant puts an end to his occupation by his own voluntary act, he will not be entitled to the crops.

EMBOLISM, emból-lizm (Gr. emboléasis, intercalation, 'wv in, and bálës to cast). In the intercalation of a day, as the second month of our year in leap-year, or of a lunar month, 28 days, in the Greek calendar. In medicine, the blocking up of a blood-vessel by a clot of blood that comes from some distance till it reaches a vessel too small to permit its onward progress. The immediate cause or clot is called thrombus and the disease is known as thrombosis. See PATHOLOGY; THROMBUS; THROMBOSIS.

EMBOSSING (Fr. bosse, a protuberance), the art of producing raised figures upon plane surfaces, such as leather, paper, cardboard, metal, textiles, etc., by means of powerful presses furnished with dies of the desired pattern. Color embossing is done by two processes: (1) By applying the color to the raised part of the design, in which case the color is spread on the dies with a brush and the whole surface cleaned, leaving the ink in the depressed parts of the engraving only; (2) by leaving the design uncolored and applying the color with a printing-roller to the flat portions of the die. For large designs, engraved plates or electro-types are used with a counterpart of mill board faced with gutta-percha. Book-binding makes extensive use of the art of embossing. Embossed wall-paper designs are effected by means of copper cylinders on which the design has been engraved, with counter parts of rollers of a softer surface. These are mounted on calendar frames. A common type of embossing machine has been adapted from the fabric printing cylinder machine, by engraving the cylinders in a suitable fashion. For some purposes the cylinders must be heated and kept at a high temperature while being used. Metal ornaments are likewise often made by an embossing process and finished and polished later. See CHASING; REPOUSSÉ.

EMBRACERY (O. Fr. embraser, to set on fire), an attempt to corrupt or influence a jury by money, promises, letters, threats or persuasions. This offense in the United States is punished by fine and imprisonment.

EMBRASURE, em-bra'sür, in fortification, an opening made in the breastwork or parapet of a battery or fortress, to admit of a gun being fired through it.

EMBRO, a corrupted form of the name Edinburgh.

EMBROIDERY, the art of working on an already existent material a decoration with needle and thread. Form and shading are expressed by means of stitches; and it is essential in embroidery that the stitches must be frankly visible. Stitches are never concealed, nor disguised.

Technique.—A stitch is the thread left on the surface of the cloth after each ply of the needle. A piece of embroidery may be worked in one kind of stitch only, or a number of different stitches may occur in the one article. Embroidery stitches are ancient and have special names: Canvas (including cross, tent [petit-point] and cushion), crewel (also outline and stem), chain (simple, twisted, cable, zigzag and chequered), button-hole, feather, rope, fern, herring-bone, back, satin, basket, brick, braid, interlocking, overcast, plait, rococo, running, split-stroke, tambour, coral, darning, insertion, sail-trail, leviathan, ladder (Creton), two-sided Italian, trellis, old English knot, German knot, French knot, Rumanian, Hol-bein and many others.

Couching is the word used to define the method by which one thread is sewn down by another thread upon the material. Cord and braid, or a bundle of tiny threads, may also be "couched." Couching is much used in gold thread embroidery. Geometrical Upon fillings of leaves and backgrounds are often composed of lines of threads thrown across and couched down at regular intervals. The basket-stitch, which imitates wicker-work, is much used for couching.

Laid-work is an elaborate kind of couching. The stitches are laid down loosely on the surface of the material and then sewn down by cross lines of stitching. The Japanese use laid-work more extensively than any other nation. The Chinese, on the other hand, prefer to sew through the material, and, as a rule, their decoration is as beautifully embroidered on the wrong side of the material as on the right side.

"The Chinese and Japanese," writes Mr. Townsend, "are remarkable for flat treatment of plant-forms and are supreme in effects produced with one or two shades, partly through
their skill in placing the stitches. Constantly changing the direction of the stitches, they work for a pleasant play of light and shade acquired by the placing of the silk. They shade with the intention of showing where one shade ends and another begins. They are also fond of voiding, i.e., leaving the ground to show between the petals of flowers, similar to the use of a stem of a flower.

Raised-work is formed by a layer of padding placed on the material and worked over with threads. It was popular in the 14th century and was carried to excess in the 18th century (particularly in England), when stump-work, in which figures were stitched with thick thread in a dramatic manner, was introduced. Turkey-work, in imitation of Oriental rugs and carpets, appeared in the 16th century. It was worked in worsted and was used for table-covers, cushions and chair-seats. Eastern patterns were shaped like floral ones, characteristic of the Renaissance; and these, in turn, by 18th century designs. Turkey-work chair-seats were plentiful in American homes in the 17th and 18th centuries. Petit-point or tent-stitch, is often used generically to describe the needlework that most early stove screens enjoyed. It was favored in the 16th, 17th and 18th centuries. Bargello, or Florentine, work is produced by the cushion-stitch on a canvas foundation, a blunt needle being used. Sometimes the satin-stitch is employed in combination with the cushion; the one for the pattern and the other for the background. Zigzag patterns are characteristic. Bargello was much used in the 17th century. It has lately been revived and is now very fashionable. Delicate line-work and color in mass are sought for by the expert and artistic embroiderer, who also takes delight in producing effects in shading and a beautiful finish by a perfect control of the stitches. Occasionally the worker uses a frame on which the material to be embroidered is stretched. The tambour-frame, shaped like a sleeve or drumhead, said to have originated in China, gave its name to the tambour-stitch. Chinese embroidery, exquisite in design and workmanship, has been unchanged for centuries. The devices and motives resemble those on porcelain wares and cloisonné enamels. Nothing more beautiful than the embroidery on the robes of mandarins and noble ladies has ever been produced. Sometimes to the dragons, phoenix, flowers, butterflies, pagodas, clouds and temples the embroiderer adds something from his own fantastic imagination. The treatment of flowers in Chinese embroidery, in color, form and technique, is alone worthy of special study. The most beautiful Japanese work is on ceremonial robes on sashes for women and on the squares, called fukusa, used for covering fine presents. The best Japanese embroiderers live in Kyoto. In the Mikado’s collection at Nara there are specimens of Indian embroideries worked 1,200 years ago. India is said to have had some influence upon Japanese embroidery, though the chief source of inspiration was China.

Indian embroidery is done on silk, velvet, cotton, wool and leather. Most famous of all is the embroidery on wool, both loom-wrought and hand-woven of cashmere, as in the Cashmere shawl. Muslin embroidery is done at Dacca, Patna and Delhi. Rich embroidery in colored silk and gold and silver is made in Hyderabad and other places in Sindh. The embroidery of Nauanagar and Gondal in Kathiwar (of which Cutch gets the credit) resembles that of Resht on the Caspian. Gold is also used in Cutch for embroideries in the Persian style of Isphahan and Delhi. The gorgeous gold-embroidered velvets of Lucknow, Gulbarga, Aurungabad and Hyderabad in the Deccan, used for canopies of state, umbrellas of dignitaries, elephants’ cloths and state-housings, have remained unchanged from the earliest periods of Indian history; but their sumptuous gold-scroll ornamentation resembles Italian design of the 16th century. The Portuguese used to send satin to India to be embroidered in European designs and Oriental workmanship. Of such exquisite material were made many of the beautiful coats and waistcoats worn in the European courts in the 17th and 18th centuries. The embroidered native apparel of Cashmeres, Anitsar, Lahore, Delhi, Lucknow, Murshedabad, Bombay and Vizagapatam are highly prized.

History.—Whether embroidery originated in China or India is a disputed point. The Chinese claim to have practised it 3,000 years B.C. India also boasts an antiquity in this beautiful art. All ancient nations carried embroidery to perfection; for the art of the needle was developed before that of the brush. Thousands of years before the Bayeux Tapestry (q.v.) was worked with the Norman Conquest (1066 A.D.), if Homer may be believed, “Helen embroidered in her palace a large cloth, white as alabaster, with the story of the conflicts in which Trojans and Greeks contended for love of her.” Embroidery was, therefore, not only an artistic enrichment of material, but it was used for centuries as a means of record and commemoration. Sacerdotal vestments, draperies and curtains for temples, robes of ceremony, clothes for ordinary use and household articles were embroidered with appropriate symbols and designs in colored wools, silks and threads of gold in every country of civilization. The Egyptians excelled in embroidery, rivaling the gorgeous work of the magnificent Babylonians. The Jews learned the art from the Persians, by the veil that Moses had made for the Holy of Holies “of fine linen embroidered with cherubim of blue and purple and scarlet.”

The Greeks attributed the invention of embroidery to Athene; and a magnificently embroidered peplos hung behind her statue by Phidias in the Parthenon, and was renewed every five years. Persia was also famous for this art. Strabo speaks of the impression made upon the Greeks by the aerial and delicately embroidered fabrics, as well as the heavy and magnificent ones. Phrygia was so celebrated that all splendid embroideries were known in Rome as “Phrygian.” Roman emperors were not behind others in patronizing the art. Even more sumptuous were the Byzantine emperors, whose robes were stiff with gold and of enormous weight with wads. The favorite scheme of Byzantine embroidery consisted of pairs of birds or animals (often enclosed in circles), separated by the sacred tree of Persia, a kind of palm—the “tree of life.” This Byzantine style dominated ecclesiastical embroidery throughout Europe in the Middle Ages when monasteries and convents had special rooms for male and female em-
Ecclesiastical English Embroidery of the 15th Century ('opus anglicum), representing orphrey (name given to this golden embroidery). The background is completely overworked and hidden by the needlework in gold, silver and silks of various colors in the style of the illuminated manuscripts of the period. (In Metropolitan Museum, New York)

(Metropolitan Museum, New York)
broderers. Embroidery was also one of the most important subjects of instruction, ranking in dignity with painting and sculpture. Superb articles were worked on linen grounds with worsteds, silk and gold threads. Sometimes the entire material was covered with embroidery in the style of the miniature paintings in the illuminated manuscripts of the time; and it is noticeable that the great period of church embroidery, from the 12th to the 14th century, is also the great period of the illuminated manuscripts. "A needle," as contemporary writers call them, the English were the most celebrated. Their special work was known as Opus anglicum. It became so famous that great lords had to have specimens in their collections and many churches throughout Europe received gifts of this artistic production. The Syon Cope, now in the South Kensington Museum, is the most celebrated specimen in existence.

Embroidery was lavished not only on copes, chasubles, mantlets, robes and shoes for church ceremonies in the Middle Ages, but was also used to decorate the costumes of men and women and for draperies and householddesignations. Beds were magnificently embroidered and draperies were counterpaned. Nor was it sufficient to embroider one set of bed and window hangings, but several sumptuous "sets of hangings" were produced to suit the changing seasons and various occasions. Hangings for tents were also marvelously embroidered and so were the armorial bearings of the knight on his surcoat and on his banner. Much of this work was done in the convents and monasteries and by the groups of embroiderers supported in wealthy homes and much of it was done by the accomplished and noble ladies. We know from allusions in contemporary literature and in the detailed and descriptive entries in inventories and wills.

In the 16th century embroidery was no less used. It submitted, however, to Renaissance influence. In Spain, Italy, France and England. Beautiful specimens exist in private and public collections and in the treasuries of cathedral and abbey churches; and, moreover, we have the paintings of the old Italian, Flemish and Spanish masters who show what gorgeous embroidery people wore. Household articles received much work from the embroiderers and also such small articles as purses, bags, handkerchiefs, gloves and covers for books. Sets of hangings for windows and beds were embroidered and "Turkey work" and petit-point chair-seats and cushions were made. Queen Mary and Queen Anne, like Queen Elizabeth and their Stuart ancestor, Mary Queen of Scots, were expert embroiderers. They followed in their designs the general taste of the day, led by the artists Leonardo and Raphael and inspired by the growing Eastern influence. Still employed to adorn costume, the art of embroidery grew ever more and more delicate; and in the days of Louis XV, when there was a rage for Chinese decoration, the handsome coats of courtiers and men of fashion were often sent to China to be embroidered according to order with European patterns. Floss and spun silks were now made up into various new threads, such as the fluffy velvet chenille, or caterpillar cord. Delicate gold and silver threads were also produced; and with these pretty materials beads and spangles were often mingled to make the fantastic and graceful designs even lovelier by their added brightness and sparkle.

Embroidery was still exquisite in the days of Louis XVI and in the time of Napoleon. Josephine favored delicately embroidered and filmy muslins, which shared their vogue with Cashmere shawls. French, English and American fingers were soon able to produce lovely flowered and figured muslins and to decorate tulles and nets with tambour until machinery was invented to make their beautiful work unnecessary.

Within the last 30 or 40 years there has been a revival of artistic needlework—a movement in which Walter Crane and William Morris took the lead. Many art schools have been formed in the United States similar to that of the South Kensington Museum in London in which the stitches and styles of ancient and decorative embroidery are taught.

ESTHER SINGLETON.

EMBRUM, ōn-brûn (ancient Eburodunum Caturum), France, town in the department of Hautes-Alpes, on a rocky eminence in the centre of a large plain watered by the Durance, 20 miles east from Gap. It is an ancient place, surrounded by walls and ditches, and of very picturesque appearance. The principal buildings are a cathedral and the archiepiscopal palace. It was pillaged successively by Vandals, Huns and Saxons, and its inhabitants were terminated by the Moors in 966. It is still a bishop's, and was once an archbishop's seat. The manufactures consist of broadcloth, hats, yarns and farm tools. Pop. 3,812.

EMBRYO. See EMBRYOLOGY.

EMBRYOLOGY, that branch of biological science which is concerned with the development of the organism from the egg. The term is applied to the development of plants as well as animal organisms, but in the present article only the latter will be considered. Though every species of metazoa or multicellular animal produces eggs, not every individual arises directly from the egg. Indeed, in some groups asexual reproduction may be the usual method. It may occur by fission, or division of the organism into two or several individuals, as in certain flat-worms and annelids, or by gemmation, where new individuals bud or sprout out from the older ones, and either separate completely, or remain attached, forming colonies as in hydroids and bryozaos. However, strictly speaking, embryology applies only to the development of the organism from the zygote or fertilized egg-cell, or in some cases from eggs which develop by partheno-
genesis, i.e., without fertilization by a male gamete.

Historical.—Before the invention of the microscope observations on development were of the most superficial sort and the genesis of the animal was a problem for the philosopher. The relation of the embryo to the two parents was not in any sense comprehended and as late as the middle of the 17th century spontaneous generation was believed to occur in some animals, even by so great a physiologist as William Harvey. During the 17th and 18th centuries the theory of "evolution," later known as preformation, of which Bonnet, Leibnitz and Haller were among the greatest exponents, was the dominant view.

Evolution in this sense denotes mere unfolding, like the flower from the bud, and has no relation to evolution in the sense of a theory of descent with modification. In brief, preformation is the doctrine that all the structures of the adult body are present in miniature in the germ and that development consists merely in their unfolding and growth. According to this theory nothing arises anew; as a corollary, known as the "embryosteron" or box-within-box-theory, the germ must contain in diminishing series the germs of all succeeding generations. Naturally, most of the preformationists believed the germ to be contained in the egg, but after the discovery of the spermatozoa by Hamm in 1677, a new school arose known as the spermists or animallucists, who adopted the view that these minute motile bodies, so obviously living, contained the germs, the egg serving merely as a nutrient medium in which the minute but fully formed offspring of male origin was enabled to grow. Some of the spermists even published figures showing a miniature human body, the homunculus, enclosed in the spermatozoan.

An important advance was made in 1759 by C. F. Wolff, who demonstrated, from observations on the developing hen's egg, that bodily parts are not performed but actually arise anew in an orderly sequence, a theory which had been advocated though not proved by a century earlier. This was stated by Aristotle. This conception, which is termed epigenesis, shortly supplanted the purely speculative preformation theory, but what regulated this epigenetic differentiation remained a problem and still remains the great problem of embryology, notwithstanding a vast amount of observation and experimental research. During the 19th century great progress was made in morphological or descriptive embryology and if space permitted many important discoveries might be enumerated. The greatest of the early investigators in this field is generally admitted to be Karl Ernst von Baer (1792-1876), sometimes called "the father of embryology," who, working mainly on the chick, was the first to give an orderly account of the chief phenomena of development, including cleavage of the egg, formation of germ-layers and the distribution of organ rudiments. In some respects the normal morphology, even though very early established, is readily alterable, in other cases it is not. As to the general factors of differentiation, the majority of physiologists undoubtedly incline toward a purely mechanistic explanation, or interpretation, and in some instances the preformation theory, though not seriously interfered with, is not altogether abandoned. A more extreme view is that of the "phylotypists," who hold that all parts of the body have an underlying fixed form, independent of the environment, and that the various conditions alter this form in different ways. This is the theory of recapitulation, or the idea that the embryo goes through a series of stages corresponding to the successive stages of the ancestor. This theory, however, is opposed by the idea that the ancestors must be seen in the adult animal, and that the embryo is a miniature of the adult.

The cell theory, formulated by Schleiden and Schwann in 1838, which has so completely revolutionized biological thought, led only gradually to the recognition of the unicellular character of the gametes, egg and spermatozoan, and despite the much earlier germ theory of the spermists it was not until nearly the middle of the 19th century that the spermatozoa were generally recognized as the agents of fertilization; indeed by many naturalists they were regarded as parasites. The spermatozoa, accidentally present in the fertilizing fluid. In 1843 Martin Barry witnessed the penetration of the rabbit's egg by the spermatozoan, but strange to say the unicellular character of the two gametes, a fact of fundamental importance, was not clearly demonstrated until after 1860. As a consequence of the rapid development of comparative embryology during the middle and latter part of the 19th century, together with the newly awakened interest in organic evolution, came the recognition of embryology as one of the greatest sources of evidence of phylogenetic relationship, and it is not surprising that a generalization known as the "recapitulation theory," namely, that the individual in its development repeats in brief its racial history, should have been developed. Though this theory has been abandoned by many, even more than the facts warrant, it is unquestionably true that embryology has yielded highly important data as to the relationships of classes and smaller groups within the same phylum, thus confirming in many instances evolutionary evidence from comparative anatomy and paleontology. The latter part of the 19th century and the earlier years of the 20th witnessed the development of a school of experimental embryology, concerned with the physiology and the philosophy of development, with the old problem of what makes the egg develop and what factors regulate the progressive differentiation of the embryo. In this field of morphogenesis some of the leaders have been Roux, Herbst and Driesch in Europe, and Loeb, Morgan and Lillie in America. Experimental studies have shown that while organs are not formed in the egg, still in many cases the egg substance is differentiated into formative zones at, or even before, fertilization, that it exhibits in greater or less degree "germinal prelocalization" of material for future organs, but not the organs themselves, and that even after fertilization the egg has been termed "promorphology." In eggs of some animals this is so definite that removal of a portion of the egg will result in the building up of an incomplete embryo, while in other cases a fragment of an egg, or each of the first four or eight cells of the segmenting egg if artificially separated, will give rise to an entire dwarf embryo; hence it is not possible to make categorical statements regarding promorphology in general. It is, however, a very different conception from the old preformation theory and does not imply a negation of epigenesis. In some respects the normal promorphology, even though very early established, is readily alterable, in other cases it is not. As to the general factors of differentiation, the majority of physiologists undoubtedly incline toward a purely mechanistic explanation, or interpretation, and in some instances the preformation theory, though not seriously interfered with, is not altogether abandoned.
EMBRYOLOGY

MALE

Spermatogonia
with diploid number of chromosomes X
(X = 4 in this diagram)

SYNAPSIS
union of chromosomes in pairs,
forming 2n (haploid number) of bivalents

bivalents longitudinally split
FIRST MATURATION DIVISION

\( \frac{n}{2} \) split chromosomes
SECOND MATURATION DIVISION

\( \frac{n}{2} \) single chromosomes
Spermatids become spermatozoa

Mature Ovum

in man and other species. These are always of the same sex. Ordinary or dissimilar twins, of course, arise from different ova and may or may not be of the same sex, as is the case in ordinary litters of young in mammals. In the nine-branded armadillo a litter contains four young, all of the same sex, and these have been conclusively shown to come from a single egg, and in a related species the polyembryonic litter contains eight or nine. In certain hymenopterous insects (chalcids) a single ovum precedes, in protecting this hun-
dreds of individuals. It follows from the method by which sex is determined at fertiliza-
tion that all embryos thus arising from a single zygote must be of the same sex.

The Germ Cells.—The great generalization on which modern embryology is based is the cell concept as applied to the gametes. This is the fact that the ovum and spermatozoon are single cells of the parent organisms, and cor-
related with this the relatively new knowledge of the physical basis of heredity as located in the chromosomes. It is essential to realize not only that the gametes are true cells, but that they are exactly equivalent as regards their chromatin content and consequently their heredity-carrying capacity (with the exception of the sex-chromosomes, which are not always the same in different species). It is their great diversity in size and form represents only a physiological differentiation by which the spermatozoon, minute and capable of locomotion is enabled to reach the egg, which as it is sup-
pplied with foodstuff for the future embryo is much larger and non-motile. It is scarcely pos-
sible to conceive of two types of cells more widely different in form and appearance, yet both are the descendants of similar primordial germ cells, and their differences, except for the sex-chromosomes above mentioned, are entirely in the extranuclear structures. The sperma-
tozae are proliferated in the testis in enormous numbers. In their commonest form, often de-
scribed as tadpole-shaped, there is a head com-
posed of the nucleus with a tubule piece containing a centrosome, and a vibratile flagellum or tail by means of which the spermatozoon is actively propelled and enabled to reach the egg. Frequently also a pointed body, called the acrosome, is present at the anterior end and facilitates penetration into the ovum.

There is no relation between size of sperma-
tozone and size of organism. In man the entire length is 32-62 thousands of a millimeter. In many manute invertebrates it is very much greater. In a few animals, the spermatozoon are non-motile and not of the usual flagellated form. The ovum, or egg, is always much larger than the spermatozoon, non-motile and usually of spherical form. During the elaboration of the egg in the ovary granules of inert food-yolk or delectable substance are spread up in the matured divisions, becalmed in the protoplasm. This food-yolk is rich in protein, fats, lecithin, etc., and serves during develop-
ment as food for the embryo. The difference in size of eggs of different species is largely a difference of yolk of different species, and according to distribution of this substance eggs are described as (a) aleithal or holomeithal, hav-
ing very little yolk evenly distributed as in the minute ova of mammals; (b) teleolecithal, with the yolk massed toward one pole of the egg, the condition in most vertebrate eggs; and

(c) centroleithal, in which central mass of yolk is surrounded by a superficial layer of protoplasm, a type occurring in some arthropods. The amount of yolk affects the develop-
ment of the egg profoundly. The largest eggs are those of sharks, where the yolk is of extreme teleolecithal type and comprise the largest cells known. Those of placental mammals are very minute, that of man only 17 hundredths of a millimeter in diameter. In oviparous animals the eggs are usually en-
plosed in a protective envelope which are formed in the ovary and others secreted by the lining of the oviduct. In the hen's egg, to cite a familiar example, the delicate mem-
brane surrounding the yolk is of ovarian origin, while the albumen, shell membrane and shell are oviducal secretions. Frequently, as in in-
sects and bony fishes, the egg membrane is pierced by one or more minute pores, micro-
pyles, which permit ingress of the spermatozoan at fertilization.

Maturation.—A phenomenon long known to be of almost universal occurrence in the his-

tory of the egg is the successive extrusion from it coincident with or shortly preceding fertilization, of two minute globules known as "polar bodies." The significance of these bodies long remained a problem, the solution of which dur-
ing the later years of the 19th century constituted one of the most brilliant discoveries of cellular biology. It invested chromatin with a new importance, rendered possible a new under-
standing of germ-cells and fertilization and opened a new avenue for the investigation of the mechanism of heredity. It is a well-established fact that the cells composing the body (somatic cells) of every animal contain a definite number of rods of chromatin called chromosomas, this number characteristic of the partic-
ular species; also that these chromosomes are in even number and composed of two equiv-
alent groups derived respectively from the two parents (an exception to this occurs in the case of the sex chromosomes. See articles on Cell and Heredity). By a series of researches beginning in 1883, in connection with which the names of E. Van Beneden, Theodor Boveri and Oscar Hertwig are especially identified, it was demonstrated that the ripe germ-cells of both sexes have only one-half the number of chromosomes, though in the earlier primordial germ-cells the full somatic number occurs. This reduction is accomplished through a phe-
omenon known as "synapsis" or union in pairs of the chromosomes of paternal and maternal origin. Thus the somatic or diploid number of singles chromosomes becomes reduced in germ-
cells to the haploid number of bivalent or double chromosomes, this reduction occurring in the spermatocyte or oocyte cell generation prior to the last two cell divisions known as meiosis, in which the haploid gametic cells are formed. During the matura-
tion divisions the bivalent chromosomes are twice divided and the resultant univalent chromosomes distributed, still in haploid num-
ber, to each of the four resulting cells. In the male these four cells all develop into func-
tional spermatozoa, but in the female the di-
visions are as unequal as to consist merely in the successive extrusion from the egg of two abortive eggs or polar bodies. In some cases the first of these bodies again divides so that
the end result is one functional egg and three polar bodies, which differ from the egg only in the smaller amount of cytoplasm and yolk, their chromatin content being exactly equivalent. The racial significance of the reduction of the number of chromosomes to one-half in both gametes will be obvious in connection with the union of these cells in fertilization. Fig. 1.  

Fertilization.—Fertilization as applied to the union of gametic cells is a somewhat indefinite term, a relic of earlier days when it was supposed that the male semen merely activated the germ contained in the egg. While it is quite true that the spermatozoon does initiate development of the egg and thus fertilizes it in the same sense in which artificial treatment with chemicals may fertilize many kinds of eggs, another essential fact of the conjugation of the two gametes is the combination in the new zygote of two equivalent groups of chromosomes from the two parents. In many invertebrates and some aquatic vertebrates, eggs and sperm are shed in the water, where conjugation occurs, but in many other animals the spermatooza are transferred to the genital ducts of the female and fertilization is internal. Only one spermatoozon is normally concerned in fertilization of the egg, though polyspermy, or the penetration of several into the egg-cytoplasm, frequently occurs, especially in forms having large eggs, but such supernumerary sperms always degenerate eventually and take no part in the formation of the embryo. When a spermatoozon comes in contact with the ovum it penetrates the cytoplasm and in many cases a delicate membrane, the fertilization membrane, is instantly secreted from the surface of the egg, thus preventing the entrance of any more sperms. At the same time other marked evidences of disturbance of the physico-chemical equilibrium occur, often with violent streaming and new arrangement of formative zones in the protoplasm, and in some eggs the sperm morphology is rapidly established at this time. While in the majority of forms the egg has reached the fertilized condition and is left outside. The head upon entrance speedily enlarges and assumes a vesicular appearance, becoming the male pronucleus. The egg nucleus for the first maturation division is called the female pronucleus. Each of these pronuclei, as a result of previous reduction, has the haploid or halved number of chromosomes and by the union of pronuclei to form the zygote nucleus the normal diploid number characteristic of the species is restored. Thus reduction maintains the specific number of chromosomes from generation to generation. A centrosome, the function of which is to initiate the process of cell-division, is also introduced by the spermatoozon, usually in the middle piece, replacing the egg centrosome. The last maturation division of the zygote, as the fertilized ovum is called, is now a complete cell, really a new individual in the stage of a unicellular embryo, with its chromatin, the vehicle of heredity, derived equally from the two parents.  

Cleavage.—Development of the zygote may be defined briefly as a progressive differentiation accompanied by cell-division and sooner or later by growth, but it must not be assumed that differentiation is determined by the cell division, for experimental embryology indicates rather that the converse is the case. The term cleavage or segmentation is applied to the mitotic divisions by which the zygote is divided into numerous cells or blastomeres. When this process involves the entire zygote, it is described as total or holoblastic. In some cases the cells may for some time be equal in size, but where there is a unipolar aggregation of yoke, cleavage is mechanically retarded at the vegetal pole, the result being unequal cleavage, well shown in the egg of the frog. For a very abundant cleavage may be partial or meroblastic, limited to a small disc of yolk-free protoplasm at the so-called animal pole, as in the hen's egg. In such cases this small disc, the blastodisc or blastoderm, gives rise to the entire embryo which gradually encloses, digests and absorbs the inert mass of yolk. In centroleithal eggs of arthropods the cleavage is superficial over the entire egg. As a result of cleavage the egg in most cases soon attains the form known as the blastula, which in its most typical condition is a hollow sphere of cells containing a central segmentation cavity or blastocel. Where yolk is very abundant the blastula is greatly altered and in some forms there is no true segmentation cavity and strictly speaking no egg.  

Gastrula and Primary Germ Layers.—The single-layered blastula becomes transformed into a gastrula, a two-layered sac-like stage, in which there is an outer cell-layer called ectoderm (or ectoblast) and an inner layer, the endoderm (or endoblast). This two-layered stage is variously formed; in some cases, as in certain cestodates, cells wander inward from one pole of the blastula forming a solid inner mass which later becomes hollowed out, but a far commoner method of gastrulation is that known as the embryonic type, in which a part of the gastrula wall, generally the part richest in yolk, becomes turned in or invaginated as a result of unequal growth to form a cup-like endoderm. The new cavity thus formed in the endoderm (or entoblast) is the entoblast or entoblastic cavity; the mouth of the sac is the blastopore, which in various animals may form the mouth or the anus or neither. This simple sac-like gastrula is found only in eggs which have very little yolk, thus among vertebrates it is met with in typical fornicate forms readily recognizable in lamprey, amphibian and some other forms, while in most vertebrates the abundant yolk masks the sac-like character of this stage. Frequently in eggs with abundant yolk invagination of endoderm is mechanically impossible and in such cases gastrulation may be effected by an overgrowth of the ectodermal layer which surrounds the large yolk-filled portion of the egg. Such overgrowth is termed epiboly in contradistinction to embly, or inverting of endoderm. If not arrested, the gastrula has considerable differentiation and foretells the orientation of the future body and some of the great organ systems. Its ectoderm is the source of the epidermis and the nervous system. The endoderm forms the lining of the gut and later gives rise to outgrowths which become the chief digestive glands. These two layers are called the primary germ layers and are of well-nigh universal occurrence. In those vertebrates which have very abundant yolk and complete partial cleavage, as well as in mammals, which seem to
retain the developmental mode of forms with large eggs, the two-layered stage is so modified as to be scarcely recognizable as a gastrula and in such cases the blastopore becomes confluent with the blastocoele to form a longitudinal primitive streak which is almost the earliest evidence of the body axis.

Mesoderm.—In all animals above the coelenterates a third germ layer called the mesoderm (or archembryoblast) develops between the two primary layers and gives rise to the connective tissue, muscles, blood system and gonads. This layer arises in very diverse ways. In many worms it is segregated very early in deavage as special mesoblast cells. Usually it appears much later as a differentiation from the endoderm or in rare cases even from the ectoderm. In its origin from the endoderm it either delaminates as a sheet of cells from the outer surface of that layer, or arises as a series of hollow, sac-like outgrowths from the endoderm called enterocysts or gut-pouches. When formed by the latter method the mesoderm from the beginning contains cavities which were originally parts of the primitive gut cavity. In cases where it splits off as solid masses similar or associated with the mesoderm the mesoderm becomes the coelome or true body cavity. In animals in which the body is segmented or metamerically, such as the annelid worms, arthropods and vertebrates, the first evidence of segmentation appears in the mesoblast. In certain embryos a rather ill-defined tissue appears composed of loose cells and called mesenchyme. It may be produced very early, before the true mesoderm, or it may be proliferated from that layer. In general it gives rise to connective tissues.

Germ-Layer Theory.—All metazoa, excepting sponges and coelenterates, exhibit three germ layers, a fact to which great significance has been attached by many embryologists. The sponges are so aberrant in their development that it is impossible definitely to identify their two layers with ectoderm and endoderm; while the coelenterates, as suggested by Haeckel, may be regarded as a primitive group which has not progressed morphologically beyond the gastrula stage. The question of the homology of the three germ layers in the other phyla is one which has evoked much discussion and has led to considerable difference of opinion. As comparative embryology became known, the higher universal occurrence of the three layers and the general similarity of their respective derivatives naturally led to the assumption of their homology, a generalization known as the “germ-layer theory,” though, as stated above, the middle layer differs greatly in its mode of origin in different groups. In nearly all cases, however, the ectoderm gives rise to the epidermis, the lining of the mouth and anal region, the nervous system, and in some invertebrates, to the kidneys. The endoderm, with which from the beginning the nutritive yolk is especially identified, is the lining epithelium of most of the alimentary canal and the chief digestive glands and in vertebrates gives rise to the germ cells which later wander into the mesoderm. The mesoderm, as the last to appear, is the source of the connective tissues, including the internal supporting hard parts when such are present, the blood and blood vessels, the muscular system, the gonads with the germ cells in most cases, and usually the kidney system. The methods by which germ layers become differentiated into their derivative tissues and organs are so varied that limited to their present discussion, but it may be stated that common accompaniments of histogenesis are thickening, folding and delamination (splitting) of layers and also localized proliferation of free cells. The assumption of homology of the germ layers in different groups was quite natural, but of late years evidence has accumulated which indicates that many of the developmental resemblances of different phyla are to be interpreted rather as similar but quite independent reactions to like environmental factors; or in a word, as homoplastic rather than truly homologous.

Nutrition of Embryo.—Throughout the entire course of development the mechanical effect of food-yolk is very marked, not only in its retardation or prevention of cleavage, but in certain parts of the egg but in its mechanical effect on the formation of the germ layers and its physiological relation to development of the nutritive system. In general, though there are many exceptions, larvae rich in yolk develop slowly and the resulting embryos hatch in an advanced state, often with essentially the adult form, while small eggs poor in yolk must early develop some means of securing food and usually in such cases the embryonic period is very brief, the embryo hatching in the form of a larva, often totally different from the adult. Such larvae are especially common among marine invertebrates, in which usually they have the form of minute free-swimming organisms, often with no resemblance to the adult either in form or habit. Examples are the trocophores of annelids and molluscs, the nauplius of the crustacean, bipinnaria of the starfish, etc. In some cases the larva represents only a small portion of the future adult animal, occasionally only a portion of the head precociously equipped with an alimentary system and means of locomotion. These larvae feed on various micro-organisms and eventually become made over into the adult form by a more or less complete metamorphosis.

Extra-embryonic Membranes.—In some animals extra-embryonic membranes are produced which subserve a temporary function in the protection or nutrition of the embryo and which are lost at hatching or at birth. In the higher vertebrates such structures include the chorion, a membrane forming the outer wall of the entire embryonic vesicle; the amnion, a closed water-sac lined with ectoderm and completely enclosing the embryo, and the allantois, an extension outside the body of the urinary bladder which in reptiles and birds and also in the primitive egg-laying mammals known as monotremes spreads its vascular wall inside the chorion close to the porous egg shell and serves physiologically as an embryonic respiratory organ. In the marsupial the young are nourished during the very brief period of gestation by uterine milk, a secretion of uterine glands which the embryo absorbs by means of its vascular membranes, chiefly the yolk sac. Uterine milk is also an important source of nutrition to the embryo even in some placental mammals, where it contains leucocytes and the detritus of
disintegrated cells of various sorts in addition to glandular secretion. The placental mammals are so called because an organ named the placenta is developed, which is essentially composed of villi or vascular tufts developed on the surface of the chorion and supplied with blood vessels by the allantois. These chorionic villi come into intimate contact with the mucous membrane lining the uterus, which becomes greatly modified during pregnancy, and through their rich vascular supply the blood of the embryo is brought into close osmotic relation with that of the mother, thus permitting the diffusion into the embryonic circulation of soluble foods and oxygen from the maternal blood and at the same time removing carbon dioxide, so that the placenta serves the functions of embryonic nutrition and respiration. It is important to note that there is no admixture of maternal and embryonic blood, the two in all cases being separated by an amnic membrane. In some mammals the placental villi are minute and scattered over almost the entire chorion, forming what is known as a diffuse placenta, as in the horse and pig. In others they are aggregated into a number of brush-like tufts, the cotyledonary type, found in most of the ruminants, as the deer, ox, etc. In other cases the villi are limited to a broad girdle forming a zonary placenta, as in most carnivora and in the elephant. In insectivores, rodents and most of the primates, including man, a diffuse type or placenta is found in which the villi are limited to a single cake-like mass. In many cases, especially the diffuse and cotyledonary types, the villi fit into corresponding crypts of the uterine mucous membrane from which they are drawn at birth without injury. In other cases, the so-called deciduate placenta, the uterine lining becomes greatly altered and its union with the villi becomes so firm that at birth portions of the maternal tissue are torn away with the embryonic placenta. Recent investigation, however, favors the view that even in deciduate types the maternal portion is largely absorbed before full term, so that the placenta at birth is almost wholly of fetal origin. Though the eggs of mammals are very minute and undergo considerable cleavage, their development is remarkably like that of the large eggs of reptiles and birds in the mode of germ-layer formation, organogenesis and relations of extra-embryonic membranes, and strongly indicates the descent of mammalia from ancestors whose eggs had abundant yolk and underwent partial cleavage. This, indeed, is often cited as one of the classic examples of the persistence of ancestral developmental plan. In this particular case the evidence is confirmed by the occurrence of oviparous habit, large eggs and reptile-like mode of development in the primitive monotreme mammals.

**Fig. 1** Early cleavage. *Four-cell stage of monkey.* After Selenka.

**Fig. 2** Slightly later cleavage of mammalian egg. The "Embryonic mass" gives rise to the entire body.

**Fig. 3** Section of early blastocyst of mammalian embryo. The "Embryonic mass" gives rise to the entire body.

**Fig. 4** Section (slightly diagrammatic) of Peters' ovum, one of the youngest human embryos which has been carefully studied. 

**Fig. 5** Frontal section (diagrammatic) of human uterus and embryo about the end of the second month of pregnancy, to illustrate the relations of the embryonic membranes, and the vascular relations of embryo and mother in the placenta. The placenta is formed by the Decidua basalis and maternal blood vessels, together with the Chorion frondosum.
chemical interaction the embryonic vesicle undergoes implantation, sinking into the superficial layer of the decidua, which grows over and encloses it, thus separating it from the uterine cavity. Implantation is usually on the posterior wall of the uterus, though it may occur elsewhere, and in abnormal conditions the embryo may become attached in the oviduct, causing tubal (ectopic) pregnancy.

The earliest human embryos studied had already become implanted. In one of these (Peters' ovum) the entire blastocyst was about one millimeter in diameter, the embryo one-fifth millimeter, or about one hundred and twenty-fifth of an inch in length. This was estimated by Peters at three or four days, but it is now believed to be several days older. The three germ layers are distinguishable and the amnion and yolk-sac are already formed. The chorion is covered with villi which have invaded the capillaries of the uterine mucous, thus bringing the embryo even at this early stage into nutritive relation with the maternal blood by osmosis. (Fig. 4).

In a slightly older embryo (Graf Spee's embryo) measuring 1.54 millimeters in length, the nervous system and neurula are discernible, and a chord-like brain is formed. Blood-channels representing some of the chief veins and arteries are distinguishable, and also the two heart rudiments, not yet united in the median line. The chorionic villi already contain blood vessels. The yolk-sac has become quite empty of yolk and its size has greatly diminished, and the allantois has appeared. Several embryos of the third week have been described. At this age the spinal cord and brain form a closed canal, the heart is a twisted tube, and from comparison with other mammals there can be no doubt that the heartbeat is already established. By the 21st day the embryo is four or five millimeters in length, and head, tail, gill-slits and rudiments of eyes and inner ears are clearly distinguishable. By the end of the first month the hind parts, and legs appear as lateral buds and the rudiments of the face are formed. There is a well-marked tail, and head and tail are so flexed as nearly to meet. Measured from nose to rump the embryo is about one centimeter in length. The yolk-sac has become a small pedunculate vesicle. Practically all the great organs are indicated by the beginning of the fifth week. For example, from the alimentary canal the rudiments of thyroid, thymus, lungs, liver and pancreas have budded out. In general structural plan the embryo up to this stage is rather more like a fish than like the adult human. This is especially true of the blood-vascular and urinary systems.

During the second month growth is rapid, and by the end of this period the embryo is about 30 millimeters long. Even the layman could now identify it not merely as a mammal but as human, or at least as a primate. The face is now fairly well formed, even to mouth and nostrils, and the external ear is taking shape. The tail diminishes after the sixth week and has almost disappeared by the eighth. Elbows and knee flexures are well marked and hand and foot exhibit digits. The third month witnesses an increasing humanness in the appearance of the embryo—or fetus—as it is commonly called after the establishment of its external form. About the 11th or 12th week it becomes possible to distinguish the sex from the external genitalia. Before this time these organs were present but very indistinct in development, though sex is actually determined at fertilization and can be distinguished about the end of the first month by microscopic examination of the genital ridges, the structures which later give rise to ovary or testis. About the middle of pregnancy, toward the fifth month, muscular movements of the fetus become strong enough to be felt by the mother, a fact which has given rise to a vulgar belief that life begins at this period of quickenings as it is called. About this time the face and most parts of the body become covered by a dense growth of fine hair, the lanugo. This fetal hair increases for a month or two, but is shed to a great extent before birth. With the growth of the fetus great changes have taken place in the embryonic membranes, the later conditions of which and their relations to the decidua or uterine mucous membrane are illustrated in the diagram (Fig. 5). It may be stated in brief that the amnion enlarges greatly, becoming adherent to the chorion. The cord-like brain is at this time still visible but will gradually disappear. The chorionic villi disappear except on the portion of the surface directed toward the original site of attachment, where they persist, forming the chorion frondosum, which comes into close relation with the corresponding part of the decidua, and forms the placenta, the vascular organ by which the fetus, physiologically a parasite, derives its nourishment and its oxygen from the maternal blood.

Birth occurs approximately 280 days after fertilization, though a fetus born as early as the seventh month may survive. The average weight at birth is near seven pounds. The fetus is expelled by involuntary contraction of the uterus, aided by contraction of the abdominal muscles. Rapid movement of the amnion by muscular pressure precedes birth, and shortly after the child is born the placenta, torn loose by further uterine contraction, is expelled, together with the amniochorion. The entire mass is called the afterbirth. Tremendous physiological changes occur suddenly in the child at birth. Cessation of placental oxygenation of the blood stimulates the lung-breathing reflex. Dilation of the lungs at the first breath brings into service the pulmonary circulation, including the functioning of the left side of the heart, and also effects the closure of the foramen ovale, an opening between the two auricles. Certain arteries and veins, hitherto very important, suddenly become non-functional and undergo rapidatrophy. Thus, almost in an instant a fundamental alteration is effected in the respiratory, circulatory and nutritive mechanisms by which the physiologically passive fetus is transformed into the active breathing and feeding infant.

Bibliography.—Many excellent works on human embryology have been published. Among the best texts are: Brodhun's 'Development of the Human Body' (Philadelphia 1907); Bryce, T. H., 'Embryology' (Vol. I of Quain's 'Elements of Anatomy,' London and New York 1908); Keibel and Mall, 'Manual of Human Embryology' (Vols.
EMBRYOLOGY OF PLANTS

J. H. McGregor, Professor of Zoology, Columbia University.

EMBRYOLOGY OF PLANTS. That phase in the life history designated as the embryology begins within the fertilized egg, but its end is not marked by any such definite feature. In general, the embryo represents the early stages in the development of an individual from the egg. In the ferns and their allies, somewhat later stages, in which one or more leaves are visible to the naked eye, are called sporelings. There is no definite feature to mark a line between the sporeling and the adult plant. In the seed plants, the series is embryo, seedling, adult, with no features to mark the transitions. The difficulty is the same as that in defining baby, boy and man. The early stages in the development of the embryo are fairly well known in all groups from the liverworts to the highest flowering plants. In the liverworts and mosses, the development of the embryo from the fertilized egg up to the adult stage, and even to the death of the individual, is rather short. The embryo, and even the adult, are small, are parasitic upon the egg-bearing plant (gametophyte), and do not produce any leaves. In the lowest liverworts the egg divides into halves, then into quarters and continues dividing until a spherical mass becomes differentiated into an outer protective layer enclosing a large number of spores. In the higher liverworts and in the mosses, the embryo starts in the same way, but later becomes differentiated into three regions called the foot, stalk and capsule, the latter producing the spores. In the lower liverworts, the adult is a small spherical body not more than one-sixteenth of an inch in diameter; in the higher liverworts and in the mosses the diameter is not much greater, but there is considerable elongation. A couple of inches is rather long; but a few liverworts reach a length of five or six inches and one of the higher mosses is said to reach a length of 10 or 12 inches. (Figures of some of these features may be found under SPOROPHYTE, EVOLUTION OF.) In the ferns and their allies, the embryo begins to develop in the same way, forming a spherical mass of cells, but definite growing regions soon appear, marking the root, stem, leaf and foot. The embryo is parasitic upon the gametophyte until the root becomes developed and begins to get nutrition from the latter, and the leaf begins to secure materials from the air. When this stage has been reached, we no longer call the young plant an embryo, but a sporeling. In the seed plants, which include the Gymnosperms and Angiosperms, the development of the embryo presents great variation and complexity. In the cycads (q.v.) which represent the lower living Gymnosperms, the fertilized egg does not immediately give rise to a mass of cells, but nuclear divisions, without any separating walls, take place, until there may be as many as 1,000 nuclei lying free in the cytoplasm of the egg (Fig. 1, A). Cell walls then appear at the lower part of the egg (Fig. 1, B). The cells, thus formed, become differentiated into three regions, (1) a group of cells remaining within the limits of the egg, (2) a region of rapidly elongating cells called the suspensor and (3) at the tip of the suspensor some small cells with dense protoplasmic contents (Fig. 1, C). The root, stem, cotyledons and leaves of the embryo come from these small cells, the other two regions being temporary structures which function only during the early development. After the embryo breaks out from the seed and becomes independent, it is usually called a seedling. The eggs of the cycads are very large, reaching one-eighth of an inch or even one-fourth of an inch in length. In the higher Gymnosperms, the eggs are much smaller, in most Pines not more than one-one-hundredth of an inch in length. In these higher forms there is a constant tendency to reduce not only the size of the egg, but also the number of free nuclei. There are still the three regions mentioned above, but each consists of only a few cells. In a few Gymnosperms, the free nuclear period is entirely eliminated, a cell wall following the first division of the egg nucleus. In the Angiosperms the eggs are still smaller, all being microscopic in size, and in all the cases the first division of the nucleus of the fertilized egg is followed by a cell wall so that there is no free nuclear stage. Even under the microscope, the eggs of this group look so exactly alike that it hardly seems possible for one to develop into an herb, another into a shrub and another into a tree. We say the course of development is determined by heredity, and those who are satisfied with the mere naming of a phenomenon may be satisfied with this explanation. Although the eggs and embryos are very small, modern technic is so efficient that the embryology is well known from the willows and crowsfoot to the sunflowers and orchids. A simple and fairly typical type of embryology is illustrated by the Shepherd's Purse (Capsella), a familiar and widely-distributed weed (Fig. 2). The first division of the fertilized egg (A). Divisions then take place so that a filament consisting of a single row of cells is produced (B); the terminal cell of the row then divides vertically and from the two resulting cells the stem, cotyledons, leaves and nearly all the root

Fig. 1.
are produced (C). The cell in which the vertical division has appeared is generally called the embryo cell, and the rows of cells below it, the suspensor. A second vertical wall at right angles to the first one gives rise to four cells, each of which immediately divides transversely, so that eight cells, apparently just alike, are produced (D). Each of the eight cells now divides, forming a wall parallel to its outer surface (E). These outer cells (dotted in the illustration) continue to divide, but all walls are perpendicular to the surface, so that the result is an extensive layer of cells only one cell in thickness. Since this layer, at maturity, is the epidermis, it is called the dermatojen, which means the epidermis producer. In the lower half of the more or less spherical embryo, the four central cells, inside the dermatojen, divide longitudinally (F). The four inner cells resulting from this division (dotted in the illustration) constitute the plerome and give rise to the vascular system of the root; the outer four give rise to the periblem which gives rise to the cortex of the root. In the upper half of the embryo, which is to form the stem and leaves, the differentiation into cortex and vascular region takes place much later, after a large number of cells has been produced. Thus there are three embryonic regions, one producing epidermis, another producing the vascular system and the third producing cortex. These regions, established in the early development of the embryo, are also found in the adult plant.

There are other types of embryology in the flowering plants. Many have no filamentous stage; some have a single, very large suspensor cell, while some have a massive suspensor. In many the differentiation into the three embryonic regions takes place much later; some do not differentiate at all until the seed germinates; while in others, like the bean, the embryo, while still in the seed, has not only cotyledons but well-developed leaves. Some special features of embryology will be found under Plants, Recapitulation in, and Spermatheca, Evolution of.
Austrian emperor; 'The Fight Near Aldenhoven' (1859); 'The Square of the Battle of Acre' (1860); 'Bomber of Calpe the Mar Faun'; 'Armies of the Mar Faun'; 'Attack on the English by French Cuirassiers at Waterloo'; 'Battle of Wurzburg' (1867), his best work; 'The Archduke Charles at Battle of Neerwinden' (1872); 'Attack of the Bournemain Division Near Elsasshausen'; 'Battle of Maubeuge' (1874); 'Victory of Prince of Orange at Nijmegen' (1879); 'Cavalry Encounter near Langenbruck' gained first medal at the Vienna Exposition in 1873.

**EMERALD** (O. Fr. emeraude, Gr. ομαθία, a gem of pure green color, often very rich and beautiful. It is a variety of the mineral beryl and is, therefore, a silicate of aluminium and glucinum (q.v.), its green color being due to the presence of a little chromium. It is usually found in quartz nodules or in distinct six-sided prisms of the hexagonal system. It is a little harder than quartz and has a specific gravity of about 2.69. It is not acton by acids. Many of the most intensely colored and valuable emeralds are found and exported from Colombia, which is one of the most beautiful gem producing countries in the world. Colombian emeralds crystals up to nine inches in length and of rich color have been found in Alexander County, N. C., while extensive mining in Mitchell County, N. C., has yielded beautiful gems and much so-called "emerald matrix." The rarity, rich color, brilliance and hardness of emerald have made it one of the most prized of gems. "Oriental emerald" is green sapphire, "lithia emerald" is hiddenite (q.v.), "Uralian emerald" is demantoid, "Brazilian emerald" is tourmaline (q.v.). See also Beryl, and Precious Stones.

**EMERALD GREEN** known also as **SCHWARZBURTH or PARIS GREEN**, and by a great number of other names, is one of the most beautiful green pigments. It appears to contain copper, arsenic and acetic acid and is usually regarded as an aceto-arsenite of copper. It is a crystalline powder, which becomes pearly by grinding, is not affected by light and air and is insoluble in water, but is decomposed by alkalis. It is employed as a water and as an oil color and is used for tinting wall-papers, though with much less frequency since the danger of that practice has been discovered.

**EMERALD ISLE**, an epithet applied to Ireland, from the freshness and bright color of the verdure, produced by the abundant heat and moisture continually reaching it from the Atlantic. This epithet was first used by Dr. W. Drennan (1754-1820), in his poem entitled 'Erin.'

**EMERSON, Edward Waldo**, American physician, writer and lecturer: b. Concord, Mass., 10 July 1844; son of Ralph Waldo Emerson (q.v.). He was educated at Harvard, where he was graduated in 1866 and from the medical school in 1874. After retiring from practice he was instructor in art anatomy at the School of the Museum. First president of the Boston Naturalists' Journal, from 1868. First president of the Boston Naturalists' Journals, with W. E. Forbes (1890); joint author with M. Storey of 'The Life of E. R. Hoar' (1911) and many contributions to magazines.

**EMERSON, George Barrell, American educator:** b. Kennebunk, York County, Me., 12 Sept. 1797; d. Newton, Mass., 14 March 1881. He was graduated at Harvard College (1817), and was the tutor in mathematics and natural philosophy there (1819-21). In 1823 he opened a private school for girls in Boston, which he conducted until 1855, when he retired from professional life. He wrote the second part of the 'School and Schoolmaster,' of which the first part was written by Bishop Potter of Pennsylvania. He was appointed chairman of the commission for the geological and botanical survey of Massachusetts, in which capacity he collected many plants, trees and shrubs growing naturally in the forests of Massachusetts (1846); and was also the author of 'A Manual of Agriculture' (with C. Flint, 1861) and 'Reminiscences' (1878).

**EMERSON, Luther Orlando, American composer:** b. Parsonsfield, Me., 3 Aug. 1838; d. Hyde Park, Mass., 29 Sept. 1915. He studied music and later taught for eight years in Salem, Mass. He then served as organist and musical director in various churches in Massachusetts, and was the director of about 300 musical festivals and conventions. He published 'The Romberg Collection' (1853); 'The Golden Wreath' (1857); 'The Golden Harp' (1858); 'The Sabbath Harmony' (1860); 'The Heart of Judah' (1863); ' Jubilate' (1866), etc.

**EMERSON, Oliver Farrar, American educator:** b. Traer, Iowa, 24 May 1860. He studied at Iowa College, taking a post-graduate course at Cornell University, where he received the degree of D.Ph. in 1891. After serving as superintendent of schools in Grinnell, Iowa, he was principal of the Academy of Iowa College (1885-88); instructor in English (1889-91) Cornell University, and assistant professor of rhetoric and English philology in the same institution (1892-96), when he took the same chair in Western Reserve University. He is member of the Modern Language Association, American Dialect Society, Simplified Spelling Board, and is a regular contributor to philological papers. He has published 'History of the English Language' (1894); 'A Brief History of the English Language' (1896); first edition of 'Dr. Jonson's Rasselas' (1895); and 'Memoirs of the Life and Writings of Edward Gibbon' (1898); 'A Middle English Reader' (1905); 'Poems of Chaucer' (1911); 'Outline History of the English Language' (1916), and contributions to various philological journals and magazines.

**EMERSON, Ralph Waldo, American poet and philosopher:** b. Boston, 25 May 1803; d.
Concord, Mass., 27 April 1882. The celebration in 1903 of the 100th birthday of Ralph Waldo Emerson served as a meeting also of broad and deep thought and interest, which a single original thinker gifted with literary expression can exert at the end of his first century; for there was public recognition of his ethical and poetic genius in every quarter of the globe. Along with this appreciation went also the perception that a distinct Emersonian school of thought had arisen, modified in some degree by the circle of striking writers and thinkers — men and women of thought, fancy, imagination and eloquence — who gathered around Emerson early or late in his career and now constitute the group known as the "Concord Authors," or the Concord School of Philosophy. Most of these at one time or another lived in the rural village of Concord in Massachusetts, where Emerson spent a half century of his life. Such were Alcott, Hawthorne, Thoreau, Ellery Channing, Louisa Alcott, George William Curtis, Elizabeth Hoar, Elizabeth Peabody, Julian Hawthorne, J. W. Chadwick, W. T. Harris, John Abbott, and F. H. Munro, whom lived for longer or shorter times in Concord; and on the outside of the circle, yet not far away, Margaret Fuller, Theodore Parker, Dr. Bartol, David Wasson, Mrs. Ednah Cheney, Christopher Cranch and John S. Dwight. All these stood in relations more or less direct to Emerson, and were influenced in varying degrees by his fertilizing mind and gentle social attraction. Several of them, as Hawthorne, Thoreau, Channing, Margaret Fuller and Alcott, were as original as Emerson, though gifted with the qualities that form a school or coterie; and none of them could properly be styled satellites or Emersonidae although that term has been applied to several of them. Emerson was the eldest born of all these, except Alcott. He was the son of a Boston pastor, Rev. William Emerson of the First Church, which had become Unitarian instead of Calvinistic. Most of his male ancestors as far back as the English Reformation were clergy-men, and his house in Concord, Alcott, was said traditionally to come from one of those Waldenses who incurred the censure of the popes as heretics far away in the Middle Ages. His oldest American ancestor founded the Christian Church in 1635 (Rev. Rev. Peter Bulkeley) and by that line Emerson was related to the noble English family of Saint John, of which was Pope's brilliant friend Bolingbroke. From another clerical ancestor, Rev. William Thompson, through the Cogswells, he was related to Wendell Phillips, Phillips Brooks and other men famous for eloquence; and by another line he descended from a clerical family of Moodys, whose genius verged upon insanity. This last name was perpetuated in Emerson's aunt, Mary Moody Emerson, his father's sister, who had much to do with his intellectual and spiritual training more than any of his early instructors. With this strong clerical bent in his ancestry young Waldo Emerson was destined to the pulpit from his cradle, and was carefully educated in Boston and Exeter, and at Harvard College with that view. He entered college early and came under eminent teachers, Edward Everett in Greek, George Ticknor and Edward Channing in literature and Caleb Cushing in mathematics—but for the last-named study he had no inclination, and did not stand high in general scholarship at his graduation in 1821. He read widely, however, and the discipline of teaching in his elder brother William's school for young ladies at his mother's house in Franklin street, Boston, gave him exactness in Latin, French and Greek. He presently (1823) took up the study of divinity with Dr. Channing, and Prof. Andrews Norton, and began to preach sermons in 1827. He spent much time in youth at his grandmother's, who owned the Old Manse in Concord, and there he preached for some months in 1828, during the absence of her second husband, Rev. Dr. Ripley. His own grandfather, Rev. William Emerson of Concord, who built the Old Manse, died as a chaplain in the Revolutionary army in 1776.

The clerical life of Emerson was a distinct era, marked by independence and originality in the young divine. His uncle's early settlement was at the Second Church of Boston, which had been Cotton Mather's, and was Henry Ware's when Emerson was ordained as a colleague in 1829. He became sole pastor in 1830, and in the meantime cultivated a delicate young Bostonian, Ellen Louisa Tucker, who died in 1832. In 1833, upon a point of doctrine concerning the rite of the Lord's Supper, in which he found himself at variance with his deacons, he preached a sermon entitled, "Forth with his scruples and resigned his place, much against the wish of his people. But he had been ill and despondent since the death of his wife and the illness of his brother Edward; and a foreign tour was prescribed for him, which broke the continuity of his labors, as he continued to officiate in pulpits here and there for some six years after his first visit to Europe. Miss Elizabeth Peabody, who had often heard Emerson preach, said at the Concord School of Philosophy in 1883:

From 1834 never omitted an opportunity of hearing Emerson preach. I sought and planned to leave to read the sermons he had in manuscript. They were all as truly "transcendental" as any of his later writings in prose or verse. If a volume of them could be printed to-day in their form they would interpret his later revelations, of which they are but a varied expression. In the first to the pure shut in his vision of the living God to the limitations of his own or any other individual conception, and to him the reply of an unconsciously wise and pious woman of the Lexington congregation, when asked why they did not settle an eminent preacher (Dr. Hedge), "Why settle for a very simple people in East Lexington; we can hardly understand anybody but Mr. Emerson." He did not laugh; on the contrary, with an accent almost pathetic, he replied, "If I had not been cut off untimely in the pulpit, perhaps I might have done something of the weekly sermon."

No doubt he would have done much of it. But what he did was better; he turned the lecture desk into a pulpit, and for more than 30 years preached righteousness there. From 1835, the date of his second marriage, to Miss Lidian Jackson of Plymouth, lecturing was his chief occupation during half the year. His essays were first lectures and were generally given to many audiences before he thought them good enough to print. His first book, 'Nature,' published in a small edition in 1835, was not a course of lectures, but rather genuine essays, thought out for years, and mostly written down in their final form at the Old Manse, or finished in his own study at the home he made for himself in 1835 at the east end of Concord Village, and where he died, 27 April 1882. The book attracted little notice in America or England at first,
and a second edition was not issued until 1849, a dozen years having been required to sell 500 copies. But Carlyle, whom he had visited at Craigenputtock in 1833, and with whom he formed then a strict friendship and corresponded until Carlyle's death, saw its value, and so did Alcott, Hawthorne, Parker, Thoreau and a circle of high-minded men, who became his constant hearers. It now takes rank as the nearest approach to a system of philosophy which he put forth in successive chapters during his whole active life. He planned another and more elaborate work, which he called The Natural History of Intellect, and of which he wrote several chapters, intended to set forth the function and operation of the qualities of the human mind—memory, imagination, reason, volition, etc.—but he never brought it to such completion that it could be published as a whole, either by himself or by his successive editors, Mr. Cabot, Dr. Emerson, etc. When invited to lecture on philosophy at Harvard, as he was in 1870, he threw these chapters and copious notes and readings into 18 lectures, two a week, but the effort was too great for him at his age and in his failing strength, and he could never afterward bring the papers into form for printing. Several of the chapters appear separately; and perhaps some future scholar may combine them with Nature into a single work.

Emerson was actually introduced to noisy public notice by two of his early addresses, which are now printed in the same volume with Nature—his Phi Beta Kappa oration of 1837 and his Divinity School Address of 1838. The first attracted attention of which he was mingled with surprise; the second, from its bold appeal to preachers to revise their theology and meet their hearers with original truths, not with traditional forms of religion, aroused the native intolerance of New England to such protest and uncharitable malediction. His own college, of which he was the most illustrious graduate, drew back in timid aversion from thoughts alleged to be revolutionary, and it was not until 1867, 30 years after his first Phi Beta oration, that he was invited to address the student-body, or to receive any collegiate honor. About the same time (1837-38) he identified himself with the unpopular cause of negro emancipation, with the advanced ideas of Alcott in education, and with several schemes of social reform, which the commercialism of the period viewed with dislike or scornful indifference; and so he alienated another class in the New England and New York communities, who might otherwise have been charmed with his literary skill and his peculiar eloquence. Thus his Alcott's continued small and his writings had little general circulation, until the gradual education of people in his ideas and his phraseology gave him the hearing that his genius deserved.

Meanwhile Emerson was drawing about him in Concord and Boston, in Plymouth, Salem and other New England towns a circle of friends and a school of thought. The number of these persons was small at first, but their enthusiasm was fervent, and their intellectual and social force was considerable. Prominent among them was Margaret Fuller, a woman of genius who drew other women by her talent and her sympathies, and who had formed a circle of her own in Cambridge and Boston. Among men, the most prominent for a time was Bronson Alcott, an educational reformer, who had shown insight and eloquence in dealing with the young, but whose talent for conversation was not accompanied by any corresponding gift of expressing his thoughts in writing. Others of the circle were F. H. Hedge, an accomplished student of German literature, afterward distinguished in theology; Dr. Convers Francis, a learned pastor and professor at Cambridge; Theodore Parker, equally learned and more radical in his theology; and a young man like William Henry Channing, James Freeman Clarke, Henry Thoreau, Wentworth Higginson, Ellery Channing, S. G. Ward, Marston Watson of Plymouth, J. Elliot Cabot; and in his own immediate acquaintance, Mrs. Sarah Ripley, the most learned woman of New England, who had married Emerson's uncle, Rev. Samuel Ripley; her brother, George Bradford; Miss Elizabeth Hoar, an accomplished woman, betrothed to Emerson's brother Charles (who had died in 1836), effort was too great for him at his age and in his failing strength, and he could never afterward bring the papers into form for printing. Several of the chapters appear separately; and perhaps some future scholar may combine them with Nature into a single work.

Emerson was actually introduced to noisy public notice by two of his early addresses, which are now printed in the same volume with Nature—his Phi Beta Kappa oration of 1837 and his Divinity School Address of 1838. The first attracted attention of which he was mingled with surprise; the second, from its bold appeal to preachers to revise their theology and meet their hearers with original truths, not with traditional forms of religion, aroused the native intolerance of New England to such protest and uncharitable malediction. Meanwhile Emerson was drawing about him in Concord and Boston, in Plymouth, Salem and other New England towns a circle of friends and a school of thought. The number of these persons was small at first, but their enthusiasm was fervent, and their intellectual and social force was considerable. Prominent among them was Margaret Fuller, a woman of genius who drew other women by her
the first number of the Massachusetts Quarterly:

The aspect this country presents is a certain maniacal activity, an immense apparatus of cunning machinery, which turns out at last some Numberous toys. Has it got erated, as great interests do, any intellectual power? One would say there is nothing colossal in the country but its geography and its material activities; that the moral and the intellectual effects are not on the same scale with the trade and production. It is a poor consideration that the country wit is precocious, and, as we say, practical; that political interests on so broad a scale as ours are administered by little men with some saucy village talent; by deft partisans, good scribes, strict economists, quite empty of any genuine spirit. The state, like the individual, should rest on an ideal basis. As soon as men have tasted the enjoyment of learning, friendship, and virtue—for which the state exists—the pride of office appears polluted, and their followers outcasts.

The profound discontent so manifested, yet lightened by an ideal hope of better things, was working in the mass of the Northern people, as well as in this small nucleus of Platonists and agitators of New England, New York and Ohio. While The Dial had to perish for want of subscribers, the Tribune of New York rose up to more than fill its place; and Margaret Fuller, Thoreau, George Ripley and George William Curtis found Greeley ready to give them the hearing in his daily and weekly newspaper, which had readers everywhere. It reported Emerson's lectures, the sermons of Parker and printed the higher criticism of Ripley, Dana and Margaret Fuller. Political parties began to be formed on ideal issues and courageous minorities began to grow into triumphant majorities here and there.

In this escape out of the ideal into the practical Emerson rather unwillingly found himself involved. He began to be popular, and his books, which up to 1850 had scarcely paid for the cost of publishing them, became a source of moderate income. He had followed up the publication of essays in The Dial by the issue in 1841 of a volume selected from his earlier lectures and essays, a second series in 1843, a complete collection of 'Nature' in 1849, and in 1850 his most effective book for European recognition of his high quality, the 'Representative Men.' All these books had been lectures mainly, though much changed in publication, as may be seen by reading the omitted passages cited in the 'Notes' to Dr. Emerson's 'Centenary Edition' of his father's books, issued in 1904. And by 1850 Emerson had become a widely-sought lecturer and went as far west as Galena and Saint Louis, though practically shut out of the slave-holding States by his pronounced anti-slavery opinions which began to be made public by him in 1844. This wider hearing as lecturer was needful to him now pecuniarily, for his small fortune which had made him independent since 1832 had become involved in railroad speculations by the ambition of a classmate at college and yielded him little revenue for years. The way had been prepared for his extended reputation in England and on the continent by his visit there in 1847.89 when he lectured extensively in England and Scotland, and made for him by Alexander Irelan of the Manchester Guardian and by his friend Carlyle and others in London. He had even aroused the envy of Mrs. Carlyle by his welcome in England among the aristocratic circle to which he had access through his friends George Bancroft and Charles Sumner, as well as by the simple dignity of his own manners, which admitted him everywhere in the exclusive society of great cities. On this visit he saw something of the French Revolution and made acquaintance in England with Arthur Hugh Clough, Matthew Arnold, Froude and others of the rising young men in literature, as well as the older men of letters whom he met at the breakfasts of Rogers and in the circle to which Carlyle, long resident at Chelsea, belonged.

Emerson had ever been more forward to publish his friends' books than to hasten to the press with his own. The first edition of 'Sartor Resartus' in America was introduced by him in a preface, and he took charge later of American editions of the French Revolution and the earlier essays of Carlyle, by all of which the author received from sales in America before 1842 about $1,000, which he assured Emerson was more than he had then got from his books (not his review articles) in Great Britain. Emerson also edited the first edition of Jones Very in 1839, and promoted the earlier volumes of Ellery Channing and Thoreau from 1840 to 1854, when Thoreau issued the second of the only two volumes published in his lifetime. Altogether, for Carlyle, Margaret Fuller and his other friends, he had caused to be printed three times as many volumes as appeared of his own writing during the 20 years after his second marriage in 1835. In 1852, while in the midst of his lecturing popularity, he paused at Buffalo, N. Y., from one of his extended tours to urge on his friends at Plymouth to gratify the ambition of Ellery Channing, who would figure as a lecturer as well as a poet. Emerson wrote then to Maria W. Wister, the 'Plymouth Evelyn,' as Alcott styled him, thus (4 Jan. 1852):

Mr. Scherib is a very proper person to take a part in your series of Sunday lectures, and will gladly do so. One other person I should like well to have engaged, my friend Mr. Ellery Channing. But I dare not say he has any lecture for your purpose, until I hear his lecture on the 'Future.' Both the others of his three I have of his three I have of his three.

As a poet Emerson had been slightly known to his youthful associates in college and elsewhere, and in 1834 he had been invited to write the customary poem for the Phi Beta Kappa anniversary at Harvard and did so. But he was dissatisfied with it and for some years after did not publish verses. In 1837 he sent to his friend J. F. Clarke at Louisville, Ky., for printing in the Western Messenger of Louisville and Cincinnati three poems of his earlier composition, and he continued to print others in The Dial. In 1846 he collected these and others in a small volume, printed in Boston and London in 1847, and he issued another volume, largely made up from contributions to the Atlantic Monthly, in 1867. His son has added many poems and fragments to the edition of 1866 so that it is now possible to judge of Emerson as poet by a perusal of all that he wrote in metre. At first his verse attracted little attention, except by parodists, who viewed it as something comical and to be satirized; this he had expected, for it had happened with his
prose also. But even those who admired and quoted his poetical prose were rebuffed by his irregular and difficult verse, and only some 20 years after the volume of 1847 did it begin to be recognized that here was a philosopher putting his thought into oracular verse, some of which has become prophetic, as oracles are wont to be. Since 1884, when at the summer session of the Concord School of Philosophy this feature of his poetry was set forth, it has become a fashion to interpret it in readings; and the essence of his deeper philosophy is best given in his verse; a key to the whole Emersonian theory of the universe being found in the oracular 'Sphinx' of the first 'Poems,' where it stands at the beginning as befits a key. Besides this philosophic quality there is also much of the high literary character in single poems devoted to love, friendship, patriotism and the cause of liberty.

Had it been predicted in 1847, when Harvard professors were scoffing at Emerson's verse and declaring his philosophy unintelligible, that 60 years later Harvard would be teaching philosophy in a spacious hall named for Emerson and built in part by the contributions of his followers and friends, the prophecy would have been classed with almanac presages of the weather. Yet that very thing has happened and happened partly in consequence of the 160 years' continuance, from 1879 to 1888, of the summer school of philosophy and literature just mentioned. This school carried out an early dream of Emerson and Alcott, who both took part in it till Emerson's death in April 1882 and Alcott's stroke of paralysis in the following October. It brought together speculative men of different schools, all in their way idealists, and it raised into prominence Emerson's share in quickening and deepening philosophic ideas in America.

Emerson had published his 'English Traits,' a masterly summary of English history and character, in 1856; in 1857 he became a leading writer for the 'Atlantic'; in 1860 published the 'Conduct of Life'; in 1864, 'Society and Solitude,' in 1874 a selection of poems (omitting his own) called 'Parnassus'; and in 1876 'Letters and Social Aims,' edited by his subsequent biographer, Elliot Cabot. During the Civil War he was a frequent orator for the Union and emancipation, and his political speeches have been posthumously collected in a volume of 'Miscellanies,' published in 1883 and enlarged in the Centenary edition. A volume of 'Lectures and Biographical Sketches' (1883 and 1904) gives his posthumous lectures and personal tributes, and a final volume (1893 and 1904), 'Natural History of Intellect,' gives others, and a general index, long needed.

The classification of topics in these later books does not well agree with the titles, and there are still other volumes promised from Emerson's journals and letters, although these have been much drawn upon in notes to the 12 volumes already issued. It remains for some future editor to arrange the writings with a better regard to their chronological sequence, since the estimate of Emerson as a writer depends so much on the observed growth and decline of his powers as in the analogous cases of Plato and Goethe.

It is in the class with these two world-renowned authors that Emerson will stand hereafter. Less copious and less imaginative than either Plato or Goethe, he is not less original than they, and his expression of profound thought and ethical truth was guided by a taste often better than theirs. Much mannerism and many repetitions are found in his works, though many apparent inconsistencies also, as with them. But these last grew out of the development of his thought and his increasing perception of the complexity of the two worlds, Nature and Man. Of his many biographers and critics few have fully comprehended him — they furnish material for final judgment rather than a statement to satisfy future readers. The best, in this view, are Elliot Cabot and Dr. Emerson, to whom the world is indebted for much material drawn from the manuscripts and not found in type elsewhere.

Emerson's health and vigor failed after the partial burning of his house in 1872, and his last tour abroad, in 1872-73, did not restore him. He continued active for years, though withdrawing more and more from publicity by reason of his health and serenity of mind and serene nature remained unshaken by these accidents of mortality, and his final illness, though pathetic from his anxiety to avoid burdening others, was short and hardly afflactive. His wife and three of his four children survived him — Mrs. Emerson, the father of all, living in 1892 at the age of 90. His descendants are numerous, by various names; his friends are numberless, for he never had a personal enemy and he inspired affection almost as much as admiration. "EMERSON'S ESSAYS, TRANSCENDENTAL PHILOSOPHY,..."

Bibliography.—Memoirs of Emerson in various forms began to appear even before his death in 1882, the first good one being by G. W. Cooke (Boston 1881), 'RALPH WALDO EMERSON. HIS LIFE, WRITINGS AND PHILOSOPHY,' followed in 1882 by Alcott's last book, 'AN ESTIMATE OF EMERSON'S CHARACTER AND GENIUS IN PROSE AND VERSE.' In 1883, supplemented in 1885, appeared 'THE CORRESPONDENCE OF CARLYLE AND EMERSON,' edited by Prof. C. E. Norton, containing much not found in any biography of either. 'The Genius and Character of Emerson, Lectures at the Concord School of Philosophy' (Boston 1884) contains estimates by 12 or 15 literary and philosophic friends. The authentic biography is 'A MEMOIR OF RALPH WALDO EMERSON' by J. Elliot Cabot (Boston 1887); the best full biography is Dr. Richard Garnett's 'Life of Ralph Waldo Emerson' (London 1888). Dr. E. W. Emerson's 'Emerson in Concord, a Memoir' (Boston 1889), is a supplement to Cabot's memoir, dealing chiefly with Concord incidents. The latest recent addition to our knowledge of Emerson's life and writing is found, however, in Dr. Emerson's 12 volumes of the Centenary edition of 1904, containing at least 1,000 pages of new matter, with many dates and incidents not elsewhere recorded (Boston 1903-04). Consult also 'Letters from Ralph Emerson to a Friend,' edited by C. E. Norton (ib. 1899); Cooke, G. W., 'BIBLIOGRAPHY OF RALPH WALDO EMERSON' (ib., 1895); Howells, 'RALPH WALDO EMERSON' (New York 1900); Elliot, 'Emerson as a Seer' (Boston 1904); Morley, John, 'CRITICAL MISCELLANIES' (Vol. I. London 1892); Cary, 'Emerson, Poet and Thinker' (New York 1904);
EMERSON’S ESSAYS — EMERY

Sanborn, F. B., ‘Personality of Emerson’ (ib. 1904); Dugard, M., ‘Ralph Waldo Emerson; sa vie et son œuvre’ (Paris 1907); Harrison, J. S., ‘Teachers of Emerson’ (New York 1910), and ‘Ralph Waldo Emerson and other Essays’ (English trans., ib. 1912). An extensive literature concerning Emerson exists in French, German and Italian, and he is studied to some extent in Scandinavia, Russia, Greece, Persia and India. The autobiographies of M. D. Conwell and A. D. Herff (1904-05) contain information on these points.

F. B. SANBORN, Author of ‘Life of Emerson.’

EMERSON’S ESSAYS. In 1841 Emerson published a volume which he called simply ‘Essays.’ When he published another volume of the same kind he called it ‘Essays: Second Series.’ So these two books—the First and Second Series—may properly be called ‘Emerson’s Essays.’ The name, however, may also be taken to cover all of Emerson’s work, for although his later volumes, which were generally collected when he had lectures as well as essays, there was no very striking difference between the two forms. Emerson usually wrote as if he were speaking to some one, so that his essays always have the spoken tone; and in the actual lectures which he really delivered, he gave his thoughts much the same turn as if he were writing a book. The ‘Essays: First Series’ are, however, both in thought and expression the most characteristic things Emerson ever did. In the matter of style, Emerson’s Essays are like Bacon (q.v.) in one way; they are series of reflections and meditations rather than finished treatises. If Emerson writes on history or on art, we are not to expect a systematic account of the subject, complete within the range allowed by its length; we have something very different. While the course of thought is not rambling or disconnected, yet the essay makes its impression chiefly by the sense and meaning of each idea as we come to it, by the illustrations or the figures; by the interest of each element, in short, rather than by the round of completed thought which it presents. This kind of expression has one great advantage at least, for it gives us Emerson’s thought with the utmost sincerity and genuineness and permits him to say exactly what he wants to say and exactly as he wants to say it. His method of writing aided in this effort; he used to write down his thoughts day by day in a ‘Journal,’ and when he wrote an essay on any subject he would gather up whatever he had said on the subject at any other time and use it. His ‘Journals’ have relatively little as to his goings and comings about Concord or about the house, but they are very full of what he was thinking about. And his thoughts were very likely to be not about everyday things, but about larger questions and the philosophies of life. One finds in the ‘Essays,’ then, the real essence of Emerson’s thought—sincere, original, independent, undistorted, unadorned, unmingled. Here we have, not merely what he might think of in writing, but the sum and substance of his thinking on the matter, as it had for years simmered and distilled in his mind till it left the pure and concentrated essence. Thus his writing has a very personal quality, although there is none of the gossiply character which we often think of as belonging to the personality of the essayist. It is Emerson himself, so intent on his thought that we forget that it is Emerson and not the world. As to what the world is, that will be better found in the article on Emerson. It may be said here, however, that Emerson was interested in philosophy in its broad sense, namely as the knowledge of himself and the universe that enables a man to get the best out of life. Two methods may be quoted: one by Lowell from ‘My Study Windows’ who said of Emerson’s later lectures that even if the meaning were not always clear, one always felt that something beautiful had been that way; and the other by Matthew Arnold in ‘Discourses in America,’ that whatever Emerson might be as poet and philosopher, he was pre-eminent the guide and companion of those who wish to live by the spirit. The ‘Essays’ and ‘Journals’ may be compared with the recent authorized editions edited by Edward Waldo Emerson and Waldo Emerson Forbes.

Edward E. Hale.

EMERY, Henry Crosby, American economist: b. Ellsworth, Me., 21 Dec. 1872. In 1892 he was graduated at Bowdoin and studied at Harvard, Columbia and Berlin. From 1894 to 1900 he was instructor and professor of political economy at Bowdoin and from 1901 to 1909 was professor of political science at Yale. In 1909 he was made chairman of the United States Tariff Board. He returned to the chair at Yale in 1913. He has written ‘Speculations on the Stock and Produce Exchanges of the United States’ (in ‘Columbia University Studies’ (1896)); ‘The Tariff Board and its Work’ (1910); ‘The Work of the Tariff Board in Connection with the Cotton Industry’ (1911); ‘Politician, Party and People’ (1913); ‘Some Economic Aspects of War’ (1914).

EMERY — EMETINE

at Princeton in 1861 and at the Harvard Law School 1864. He was admitted to the New Jersey bar in 1865. He was vice-chancellor of New Jersey from 1895 to 1 Jan. 1916, when he retired under the provisions of his retirement act.

EMERY, Stephen Albert, American musician: b. Paris, 1841; d. 1891. He studied at Leipzig where among his masters were such lights as Hauptmann, Plaidy and Richter. He removed later to Dresden and continued his studies under Spindler. Shortly after his return to America he became instructor at the New England Conservatory in Boston. He was three years in this position when he became professor of harmony and counterpoint at the newly founded College of Music of Boston University. He wrote pianoforte pieces, songs, string quartets and textbooks on pianoforte playing and the elements of harmony.

EMERY, an impure variety of the mineral corundum (q.v.), reddish brown, black, blue black or gray in color and next to the diamond the hardest mineral known but is not crystalized. It consists of nearly pure alumina (65 to 75 per cent) and oxide of iron and a small amount of silica and water. Emery occurs in large boulder-like masses, closely resembles a fine-grained magnetic ore in texture and is often mistaken for it. In its native form its value as an abrasive has been known from the earliest times and many references are made to it in books by Greek authors. Then as now it was used in cutting and polishing jewels and intaglii in the sculpture of statuary from the harder rocks and in polishing marble. It was undoubtedly used by the Egyptians and there are many evidences of the use of it or as hard a substance in the manufacture of prehistoric stone implements.

As now used, in its pulverized form, it is one of the most useful substances known to the arts. The rock is broken in powerful crushers and stamps-mills and separated into powders of varying degrees of fineness by screens or by elutriation. These powders, varying from particles one-tenth of an inch in diameter to the finest flour, are sprinkled with water or oil upon the lead wheel of the lapidary, or spread upon wet cloth or cloth with which a thin layer of glue has been previously applied; or as has been found to be its most effective application, mixed with various adhesive substances and molded into solid wheels. Emery-stones of various shapes and sizes are also made in the same manner.

Emery-wheels are now made up to 36 inches in diameter and from four to six inches in thickness and in every variety of coarseness from rough shapers to fine polishers for brass and steel. The cementing material is usually a secret with the manufacturer and upon this and upon the quality of emery used depends the cost and the subsequent life and usefulness of the wheel. Properly mounted and turned at a proper speed it is our most effective cutting tool, tearing its way rapidly into chilled castings that have been cooled in a cold bath, the wheel will not cut, or taking the teeth instantly off the hardest file. Special points to be observed are uniformity of texture, that the wheel may wear away evenly under use; carefully fitted bearings, that there may be no vibration under the high speed at which it is run; the wheel must not be fitted closely to either mandrel or flanges, lest expansion by heat burst the wheel; and the cementing material of the wheel must be able to resist the tendencies to centrifugal visual disrupt that the heat generated by its friction with the object being cut. Its effective speed must have been determined and tested and the degree of pressure with which the work is to be applied must likewise be ascertained. Emery wheels that have become misshapen through use are turned true by various special contrivances, all of which must have a cutting edge of rough diamond. Wheels are often shaped for special work in the same manner.

The present supply of emery is chiefly from the island of Naxos and from near Smyrna, Turkey. A small amount is mined near Chester, Mass., and Peekskill, N. Y., and it is found in insignificant quantities elsewhere in the United States. Corundum and precious sapphire have been found in Georgia. Consult Merrill, 'Non-Metallic Minerals' (New York 1910) and Pratt, 'North Carolina Geological Survey' (1905).

EMERVILLE, Cal., city in Alameda County, on San Francisco Bay, near Oakland, on the Atchison, Topeka and Santa Fe Railroad. It has large stockyards, packing-houses, iron foundries, paint and rubber works, cracker factories and fertilizer plants. Shell Mound Park, so named from an Indian mound, is the most noteworthy feature. Pop. 2,613.

EMESA, an ancient town, now called Hems. See HEMS.

EMETIC, any agent used to induce vomiting. In medicine the emetics that are used are now few in number. The main object to be attained by their use is to empty the stomach of irritating or poisonous contents. As most emetics act strongly on the sympathetic nervous system, they also cause muscular relaxation, dilated arteries and a sense of weakness, amounting at times to collapse. Emetics are usually classified as local or as systemic — those acting directly on the stomach walls, such as lukewarm water, mustard, alum and the more violent corrosive metallic salts, or those, as copper sulphate, whose influence is exerted on the central nervous system, after first being absorbed into the blood. Of these tartar emetic, ipecacuanha and apomorphine are examples. Emetics should be given with caution. In children particularly the stronger emetics often cause great prostration and if a child be suffering from a disease that causes heart weakness, such as diphtheria, emetics are not advisable. In cases of poisoning emetics should be promptly given, but washing out the stomach by means of a flexible rubber tube is preferable. It is sometimes justifiable to give emetics when there seems to be danger of asphyxiation from retained mucus in the bronchial tubes. The relaxation following emesis is sometimes remarkable. See TOXICOLOGY.

EMETINE, an alkaloid occurring in ipecacuanha and constituting its chief active principle. It can be extracted from ipecacuanha by moistening the finely powdered root with ammonia and extracting with alcohol. From the total alkaloids so isolated, emetine is separated by extraction with ether in the presence
of alkali. Its chemical formula has not been established with certainty, but is considered to be \( \text{CaH}_{2}\text{ON}_2 \). Emetine is sparingly soluble in water and in ether, though it dissolves readily in alcohol, chloroform, carbon disulphide and various essential oils. It is colorless, but is turned to a yellow by the action of sunlight. When taken internally in considerable doses it acts as a powerful emetic, to which circumstance it owes its name.

EMEU. See EMU.

EMIGRATION, the removal of the population of a country or region for the purpose of settling elsewhere. Within the United States the movement of population from the Eastern States to the Western, or from the Northern to the Southern is properly termed emigration, but no statistics are kept as to such movements. The removals from the United States to foreign countries, however, are recorded by the Commissioner General of Immigration and embodied in his annual report to the Secretary of Labor.

In the United States two classes of emigration are recognised: first, the flow of the people of a country as the country as a whole shrinks by emigration back to their native lands; second, the emigration of United States citizens to other countries.

For the fiscal year ended 30 June 1917 the departing emigrants included in the first class numbered 68,277—a figure which must be compared with those of previous years to gain a fair estimate of emigration under normal conditions. In 1915-16 the number was 129,765; in 1914-15, 204,074; in 1913-14, 303,338; in 1912-13, 308,190; in 1911-12, 333,282—the largest record for any one year. The influence of the war is readily noticeable. Of the total alien emigration for the year 1916-17, 15,924 were women and children. The chief occupations of the 38,649 men who emigrated were as follows: laborers, 24,801; mechanics, 5,700; seamen, 4,003; professionals, 1,930; miners, 1,049. The destinations of the larger groups of these departing aliens were: British North America, 18,994; Italy, 12,542; Russia, 5,947; West Indies, 5,891; England, 2,798; Spain, 2,491; France, 2,054; Greece, 2,034; China, 1,871; Norway, 1,633; Portugal, 1,353; Ireland, 1,027; South America, 993; Sweden, 969; Mexico, 812.

The number comprised in the second class cannot be determined from the United States records, but as the only considerable emigration of United States citizens is into Canada, the figures must be obtained from the records of the Canadian Immigration Office. From these it appears that 61,389 former residents of the United States entered Canada as immigrants in the fiscal year ended 30 June 1912. It is a significant fact noted by Canadian officials that this immigration from the United States constituted 81 per cent of the total immigration for that year. In addition to this large number admitted, 17,988 residents of the United States entered Canada as tourists, 3,880 as students, 1,376 as seamen, and 2,000 as laborers. The total number of all persons admitted under these classes, with the exception of tourists, was 1,778,764 or 21,381 per cent over the total of 1911.

Up to the year 1916 the total of immigration of about 3,250,000 from all countries; and about 225,000 other residents of the United States have been refused admission in the same period because of their undesirable character or destitute circumstances. The earlier emigrants were chiefly former Canadians who had settled in the United States but returned to take advantage of improved conditions. Later there were added to this group numbers of European immigrants who did not become naturalized in the United States. The larger part of the more recent emigration from the United States into Canada has been of American-born citizens who have been attracted by the inducements of the Canadian Provincial land offices and by the great mining opportunities in Western Canada, made available by the completion of the Canadian transcontinental railroads. See United States—Immigration to.

EMIGRÉS, é-mé-grés, a French term for those who have been compelled to leave their country on account of religious persecutions, as did the Huguenot, for instance, in the 17th century, or for some other causes. The term, however, is now most commonly applied to those Frenchmen, many of them of noble family, who left France at the commencement of the first French Revolution. Princes, nobles and prelates crossed the frontier into Switzerland, Germany and Holland, and even penetrated as far as Italy. Their conduct made the position of Louis as a constitutional monarch untenantable, for they were constantly plotting with the enemies of France. Proscription followed: between October 1792 and the dissolution of the convention more than 150,000 were passed against the emigrés and their relatives. The relatives who remained behind were formed into an ostracised class, deprived of civil rights and obliged to live under police supervision, and exposed to all manner of special fines and exactions. In 1796 relatives were on the list of proscribed. Vast interests depended on the maintenance of the laws against them: their property formed part of the security on which the assignats had been issued, and the granting of an amnesty and reclamation would have made the assignats of no more value, and, by partially restored the social fabric to ruin. At the head of the emigrés stood the royal princes of Condé, Provence, and Artois, the first of whom collected a part of the fugitives to co-operate with the allied armies in Germany for the restoration of the monarchy. At Coblenz a particular court of justice was established to settle causes relating to the French emigrés. But the invasion of the Netherlands by Dumouriez drove them from these provinces in mid-winter in a deplorable condition, while their number was daily increased by the system of violence and terror carried on in France. The corps of Condé was finally taken into the Russian service, and was disbanded in the Russo-Austrian campaign in 1799. When Napoleon became emperor it was one of his first acts of grace in the spring of 1801 to admit a few of the emigrés to return to their country, but by the terms of the charter of 1814 they were precluded from regaining either their status or their ancient privileges. During the Restoration period they persistently petitioned Louis XVIII and subsequent Chifflet and Chabret for reinstatement and indemnification, but though
EMILE—EMINENT DOMAIN

a government grant was made for their compensation, the measure was rendered abortive by the July revolution. One of the largest settlements comprising several thousand acres near Towanda, Pa., was made at the place now called Russell and located on the Lehigh Valley Railroad in Bradford (and formerly in Luzerne) County. Here, from 1793 to 1800, was a centre of French refinement, to which luxury-loving parties from the coast cities came for the purchase of articles from dealers and agents for the language. The place was called Azilum, Asylum or Frenchtown. Consult Murray, 'The Story of Some French Refugees and their Asilum' (1903).

EMILE. After all deductions have been made Rousseau's 'Emile' or 'Emilius' (1762) remains our most important treatise on education. It is so, not necessarily because its principles are sound or its logic always convincing, but because it is a clear and unequivocal statement of a theory formulated by one, who whatever his weaknesses as philosopher, was uncontestedly one of the greatest artists of the 18th century.

Rousseau's artistic instinct led him to cast his work in the form of a romance, as is indicated by the title 'Emile' and it should be considered as such, the story of a lad's progress from infancy to manhood from helplessness and dependence to complete mastery of self and assurance in independent activity. It is unfair therefore to consider it as a practical manual or guide for teachers, the details of which can be transferred without change to the schoolroom. It was its character as romance, furthermore, that helped give it its astonishing popularity. Rousseau realized that the situation there assumed was most unusual and could not often, if ever, be duplicated in real life. He sought, therefore, to inculcate not so much a practical method as two cardinal principles on which any such method should be based. These principles attach themselves very closely to his general philosophy, and it is by them that his theory of education must stand or fall.

Underlying his treatise we find everywhere the two cardinal Rousseauistic assumptions which are the heart of his doctrine—man is by nature good, society and civilization corrupt his native goodness. For this reason a large part of the work of Emile's tutor is negative, consisting in preventing misleading contacts and the remainder lies in guiding and directing natural desires and tendencies rather than in inculcating aims, aspirations, or what is generally termed culture. His object is not to teach any traditional body of knowledge, but is entirely utilitarian, directed toward developing a healthy, vigorous, right-minded citizen. He insists everywhere on the natural, the normal and the favor which these words have since enjoyed in connection with education is sufficient testimony to his influence. As an instructor in this faculty, Rousseau's philosophy involves a criticism of his doctrine of education, we refer to the article on Rousseau where his theories are considered more at length.

CHRISTIAN GAUSS.

EMILIA, ē-mē'li-ā, division of Central Italy, comprising the provinces of Bologna, Ferrara, Forli, Moderna, Parma, Piacenza, Ravenna and Reggio nell'Emilia. The name is derived from the ancient Via Emilia and was built by the censor Emilius Lepidus in B.C. 186. It is a continuation of the Via Flaminia, which passed through these territories. Area 7,993 square miles; pop. 2,740,316. Prior to its inclusion in the kingdom of Italy, in 1860, it consisted of the former dukies of Parma and Modena and the papal Romagna.

EMIN PASHA, a'men pash'-a, or pash'a (EDUARD SCHNITZER), African army surgeon, governor and explorer: b. of Jewish parents at Appen, Prussia, 28 March 1840; d. October 1892. He was educated at Breslau, Berlin and Königsberg, going to Turkey in 1864 and being appointed surgeon in the Turkish army 1865. In 1875 he went to Egypt, becoming surgeon-general of the Egyptian army under General Gordon, who made him governor of the equatorial provinces in Sudan. He made several exploring expeditions, his route surveys extending to over 4,000 miles, and gave to the world much information in reference to the fauna and flora of that region, together with much geographical knowledge. He also showed himself an enlightened ruler, and was opposed to the slave trade. He was cut off from relations with the rest of the world by the insurrection of the dervishes under the Mahdi in 1883, although maintaining his position. The Egyptian government made him a pasha 1887. Rescued by Stanley in 1888 he entered the service of the German East Africa Company in 1890. He went with Dr. Stuhlman to East Africa upon an exploring expedition and was assassinated at the instigation of Arab slave raiders. Consult Schnitzler, G., 'Emin Pasha' (2 vols., London 1898).

EMINENCE, as a designation of cardinalitial dignity, is of comparatively recent introduction; it dates from the 17th century. Down to that time the cardinals were addressed by the titles Most Illustrious ('Illustissimus'), and Most Illustrious Lordship ('Illustissima Domitia'); but in 1630 Pope Urban VIII promulgated a decree, drawn up in accordance with a report of the Congregation of Rites, substituting for the previous formulas Most Eminent ('Eminentissimus'), and Eminence ('Eminencia'), respectively. No dignitary but a cardinal (or by exception the Grand Master of the Knights Hospitalers of the Order of Saint John of Jerusalem) was to be addressed in this form. Further, a cardinal was to ignore any communication addressed to him in any other form; and any prelate who assumed the title Eminence, or Most Eminent, was made liable to penalties. The title was also applied in the Roman Empire in its later days to the emperors and the highest officials.

EMINENT DOMAIN, the power of the State to appropriate private property for public use on payment of just compensation to the owner. A superior right of property subsists in a sovereignty, by which private property may, in certain cases, be taken, or its use controlled for the public benefit, without regard to the wishes of the owner. The highest and most exact right of property is immanent in the government, or in the aggregate body of the people in their capacity as a community, giving the power to resume the possession of the property, in the manner pointed out by the constitution and the laws of the various States, when the
public good requires it. There seems to be no objection to considering this right, theoretically at least, as so much of the original proprietorship retained by the sovereign power in granting lands or franchises to individuals or corporations, wherever the common-law theory of original proprietorship continues, and unforeseen occasions arise in cases of extreme necessity in time of war, or of immediate and impending danger, in which private property may be impressed into the public service, or may be seized and appropriated to the public use, or may even be destroyed, without the consent of the owner. The power exists only in cases where public exigency demands its exercise. It makes no difference whether corporeal property, as land, or incorporeal, as a franchise, is to be affected by the exercise of the right. It is part of the constitutional law of the United States that no person can be deprived of his property by eminent domain except it be taken for public use, by due process of law, and for just compensation. The first conversion of the courts to include not only public improvements carried on directly by the State, as the construction of docks, fortifications, etc., but also private or semi-public undertakings, as railroad bridges, etc. There exists some difference of opinion as to what constitutes the process of law. The usual method is by condemnation proceedings, determined by general law. These are instituted before a court of competent jurisdiction, or a referee appointed for the purpose, just as any equity suit. The final step is an order of condemnation and award. The legislature may, however, substitute any other process, provided the owner is given notice of the proceedings contemplated. Just compensation means payment of the full value of the property taken or of any interest therein, whether vested or contingent, present or future. (See Sovereignty; Taxation). Consult Cooley, 'Treatise on the Constitutional Limitations which Rest upon the Legislative Power of the State' (7th ed., Boston, 1903); Kent, 'Commentaries on American Law'; Dugas, 'Eminent Domain' (2d ed., Chicago 1900); Mills, 'Eminent Domain' (2d ed., Saint Louis 1888); Randolf, 'Eminent Domain' (Boston 1894).

EMINESCU, a-mèn-ès’koo, Michael, Rumanian lyric poet: b. Botuschani 1849; d. Bucharest, 27 June 1889. After receiving his education at Vienna and Berlin, he returned to Rumania and was appointed librarian at the University of Jassy. He was for a time editor of Timpul, a strong Conservative journal, and the fierce nature of political strife would seem to have spoiled his fine poetic genius. He died in a madhouse. His fame rests on his first volume of Poems (1st ed., 1884); they are mostly elegiacal, and touch questions political, social, religious and moral; all of his thought being pervaded by the philosophic pessimism of Schopenhauer, who influenced him profoundly.

EMIR, é’ mér, or AMEER, é’ mér (that is, noble, princely), a title of honor given in the East and in North Africa to those who claim descent from Mohammed and his daughter Fatima. As a title of honor, it makes her more rigidly holy; they are the chieftains of the Bedouins. Their origin, however, is doubtful. In Turkey they form a kind of hereditary nobility, and wear as a badge a green turban, as Mohammed is said to have done. They have certain privileges, but otherwise no higher claims to civil offices than other Mussulmans. The word emir is also applied to certain offices and employments, for example, emir had jär, commander of the guards and envoy to Mecca; emir-akhbar, commander of the Turkish horse; emir-bazar, overseer of the markets; emir-alem, the Turkish standard-bearer; emir al Umara, prince of princes. The title emir-al-a’muman, commander of the faithful, was borne by the caliphs. In earlier times the title emir was much more generally assumed by nobles and princes of high rank. It was borne, for instance, by the Thaferids and Samanids in Persia, by the Tuluids in Egypt and by the first seven Omoids of Cordova, Spain. There were also Christian emirs in the Lebanon region of Palestine, who represented Mohammedan clans converted to Christianity.

EMMA, Adelheid Wilhelmine Therese, queen dowager of Holland: b. Arolsen, Germany, 2 Aug. 1858. She was the second daughter of Prince George Victor of Saxe-Weimar and Pymont, and was married 7 Jan. 1879 to King William III of Holland. She is the mother of Queen Wilhelmina of Holland, and was queen regent of the Netherlands after the death of William III 23 Nov. 1890 until 6 Sept. 1898, when her daughter ascended the throne. She took an active interest in charities, especially hospitals for consumptives.

EMMA. From the time of its publication in 1816, this has been one of the most highly regarded of the novels that Jane Austen wrote. It is the fruit of matured artistry, meditated observation and ripened judgment. The plot involves rather more strands than is customary in her work, but the main line of action is simple. Emma Woodhouse, the youthful heroine, is much given to matchmaking. Having married off her governess before the opening of the story, she sets herself to bring about other marriages among her friends and acquaintances. But the men and women around her are not mere pawns; they act in unanticipated ways; unsuspected factors alter situations; and in the resulting complications Emma eventually awakens to the fact that she herself has fallen in love. Difficulties and misunderstandings are smoothed away and she is happily married. The easy, natural development of the action, by means of incidents and conversations so normal in aspect as to conceal the artistry of their conception, is especially noteworthy. Plot, however, is subsidiary to characterization. The book abounds in living personalities: the aggressive, vulgar Mrs. Elton; the valiant and father of Emma, with his taste for thin gruel; the immortally loquacious, tender-hearted Miss Bates; the admirable, thoroughly sensible Knightley; and Emma herself. It is one of the triumphs of Miss Austen’s art that, despite the writer’s fears—"I am going to take a horrid one but myself will much like," she had observed—Emma is one of her most fascinating creations; the girl is fundamentally generous, sincere and affectionate; her obvious faults but serve to make her more rationally human. In recounting the experiences of these delightfully normal but highly individualized char-
acters, the author has presented us with an account of English village life remarkable for vitality, wholesomeness and unassuming insight, related with amused tolerance and untrusive irony, in a style easy, limpid and absolutely adequate. The novel is not a complete picture of life. The awe and mystery of the world, the stormy passions of men, have no place here. But what is done is done supremely well. The ordinary occurrences of ordinary lives are transmuted into the pure gold of literature. Consult Howells, W. D., 'Heroines of Fiction'; Cornish, Francis Ware, 'Life of Jane Austen'; Smith, Goldwin, 'Life of Jane Austen'; Scott, Sir Walter, 'Review of Emma' (Quarterly Review, Vol. XIX, 188).

GEORGE B. DUTTON.

EMMANUEL COLLEGE, founded in connection with Cambridge University in 1854, by Sir Walter Mildmay as a Puritan institution. The chapel was designed by Wren. John Harvard, who gave so liberally to education in America, is remembered in this college by one of a master, 16 fellows and 36 scholars. In 1913-14 there were 74 undergraduates.

EMMANUEL MOVEMENT. The, so named after the Emmanuel Church, Back Bay, Boston, Mass. The movement was started by the rector of the church, Rev. Elwood Worcester, D.D., and his associate, Rev. Samuel McComb, D.D. Dr. Worcester had been residing in Philadelphia, where he enjoyed the friendship of Dr. S. Weir Mitchell, one of the great nerve specialists of the country. Neither of the leaders of the movement had studied medicine, but Dr. Worcester had not only studied psychology under Wundt at Leipzig but for several years had taught the subject at Lehigh University. Dr. McComb had studied the subject at Oxford University. In 1905 work was begun with a tuberculosis class and in 1906 a similar work was begun among the nervous and morally diseased. From the first, the movement had the co-operation of several leading physicians. Dr. Cabot of Boston, Dr. Barker of Johns Hopkins University, Dr. Putnam was known to have had a class such subjects as worry, anger, habit, suggestion, insomnia, nervousness, what the will can do, what prayer can do and similar topics. Patients were given mental treatment along with the reading of Scripture and prayer. For some time the movement attracted considerable attention and the Emmanuel Church had many imitators in nearly all denominations. At the present time it seems to have nearly passed away. Consult 'Religion and Medicine — The Moral Control of Nervous Disorders,' by Elwood Worcester, Samuel McComb and Isador H. Coriah, M.D. (1906); 'Faith and Health,' by Charles Reynolds Brown (1910).

EMMAUS, ē-mā'us or ēm-mā-'ūs, Palestine, (1) A village, about eight miles from Jerusalem, the place mentioned in Luke xxv., 13. The exact location of this village is not known; the modern El Kubebe, 60 furlongs northwest of Jerusalem, on the road to Lydda, has in its favor the tradition of Emmaus, its distance from Jerusalem and the fact that in 1099 A.D. the Crusaders found the name Castellum Emmaus given to the place. Recently the modern Kolonieh has been favored by expert opinion as the site of Emmaus. In its favor is cited the evidence of its name to the colonizing of the place and the statement by Josephus that Titus planted a colony of 800 veterans at a village called Emmaus, 30 stadia from Jerusalem. (2) Modern Amwas, the place mentioned in Macc. iii, iv and ix. In ancient times and down to the conquest of the Mohammedans, this Emmaus was a place of importance. Its position, about 16 miles northwest of Jerusalem and near the Roman road from Jerusalem to Jaffa, on the seacoast, made it prominent. It was the capital of one of the 10 toparchies into which Judea was for a time divided. It was known as Nicopolis after the 3d century. Consult Sanday, 'Sacred Sites of the Gospels' (Oxford 1903), and Schurer, 'History of the Jewish People' (Eng. trans., 5 vols., New York 1896).

EMMENAGOQUES, ē-mē-nā-go'gaz, are agents that stimulate the pelvic organs and are used to bring about a restoration or regulation of menstruation. Normally menstruation occurs at 28 days, but this is not always the case. Occasionally absence of menstruation is due to anemia or lack of iron in the blood, in which case taking iron internally, by overcoming the anemia, restores menstruation and may be thus termed "abnormal." More properly speaking, however, the term is applied to such drugs as ergot, quinine and hydrastis. These bring about direct stimulation of the unstripped muscles of the body and hence act most forcibly on the uterus, being the largest mass of unstripped muscular tissue in the body. Aloe, myrrh and the active cathartics act as emmenagogues by increasing the amount of blood in the large intestine and other pelvic organs, thereby increasing the nutrition of the uterus. Occasionally massage and electrical applications are used to bring about the restoration of the menstrual flow and hence may be included in this group.

EMMERAN, or EMMERAM, Sain't, martyr, bishop of Poitiers: b. the last of the 6th century; d. 653. His feast is kept on 22 September, but the exact date and place of his death is not known. He is venerated in France for his piety and learning. His biographer says of him: "For his great learning and sanctity he was chosen bishop of Poitiers in the 7th century; he preached the pure maxims of the gospel with indefatigable zeal, without respect of persons." After a time his zeal led him to ask permission to go to Bavaria to preach to the "infidels and idolators." After three years' work in Bavaria he began a journey to Rome. On the way he was assassinated by men who believed false accusations which a wicked woman had made. He is the patron saint of Ratisbon, where he was buried.

EMMERICH, ēm-mēr-ich, Germ. town in Rhenish Prussia, on the Rhine, five miles northeast of Cleves. It is enclosed by walls and ditches, contains several ancient and modern churches, a gymnasium, ecclesiastical seminary and orphanage, and has manufactures of woolen and linen cloth, hosiery, leather, machinery, oil, soap, cigars, tobacco, etc.; some shipping and a free port, at which an active trade is carried on, chiefly with Holland. Its history dates from the 7th century. In 1233 it came under the dominion of the counts of
Geldern, by whom it was raised to the rank of a city, but in 1402 it passed to Cleves. In 1407 it belonged to the Hanseatic League and is believed to have contained a population of 40,000. It subsequently shared the fortunes of the duchy of Cleves. Pop. 13,418.

EMMERSION, Henry Robert, Canadian lawyer and politician: b. Maugerville, N. B., 25 Sept. 1853. He entered the New Brunswick legislature in 1888 and was Premier of the province, 1896 to 1900, when he was elected to the Dominion House of Commons and was Minister of Railways and Canals in the Laurier administration, 1900-07.

EMMET, Robert, Irish patriot: b. Dublin 1778; d. 20 Sept. 1803. He intended to practise law and with that view studied at Trinity College, Dublin, from which, however, in 1798 he was expelled on the ground of exciting rebellion. Subsequently he became an object of suspicion to the government and accordingly quitted Ireland and traveled on the Continent. He interviewed Napoleon and Talleyrand, the former of whom promised aid to the Irish revolution. He returned to Ireland on the repeal of the suspension of the Habeas Corpus Act. He now became a member of the Society of United Irishmen, whose object was the establishing the independence of Ireland. In July 1803 he was the ringleader in the badly planned rising which had for its object the seizing of Dublin Castle, and in which Lord Kilwarden and several other persons were killed, but which was almost immediately suppressed. Emmet was arrested a few days afterward, tried and executed by the sentence of a special court. His fate excited considerable interest from the circumstance of his attachment to Sarah Curran, daughter of the celebrated barrister. Moore has immortalized his memory in 'O breathe not his name,' and that of Miss Curran in the poem beginning 'She is far from the land where her young hero sleeps.' Consult Madden, 'Life and Times of Robert Emmet' (Glasgow 1902); O'Donoghue, 'Life' (Dublin 1902); 'Robert Emmet: Causes of the Rebellion' (London 1871).

EMMET, Rosina. See Sherwood, Rosina.

EMMET, Thomas Addis, American lawyer: b. Cork, Ireland, 24 April 1764; d. New York, 14 Nov. 1827. He was a brother of Robert Emmet (q.v.), and being tried for the crime of treason was sentenced to be hanged. He came to the United States and became a noted lawyer in New York. In 1812 he was elected attorney-general of the State.

EMMET, Thomas Addis, American geologist: b. Charlottesville, Va., 29 May 1828. He is of a distinguished Irish family. His father was professor at the University of Virginia and his grandfather, after whom he was named, was a prominent leader of the Irish movement for independence in 1798 and after coming to America served as attorney-general of New York. He was brother of Robert Emmet (q.v.). He was graduated at Jefferson Medical College 1850. He served as physician at the Ward's Island Hospital for Immigrants and established his practice in New York in 1852. He was successively assistant surgeon, after 1852, chief surgeon after 1872, and visiting surgeon after 1890 at the Women's Hos-

EMMETSBURG, Iowa, city, county-seat of Palo Alto County, on the Des Moines River, the Burlington and M., the Chicago, Milwaukee and Saint Paul and the Cedar Rapids and other railroads, about 123 miles northeast of Sioux City. It is in an agricultural section of the State and it has several grain elevators. Some of the industries are the manufacturing of butter, cheese, flour, brick, cement and tile works. It contains a fine lake and a Carnegie library and owns its waterworks. Pop. 2,325.

EMMETT, Daniel Decatur, American song writer and negro minstrel: b. Mount Vernon, Ohio, 1815. He served in the army, joined a circus company 1835 and formed the first negro minstrel company 1842 with Frank Brown, William Whitlock and others, appearing at the old Chatham Theatre, New York, and later in Boston and in England, where Emmett remained till 1844. He was with Dan Bryant 1854-65, writing the famous song 'Dixie' in 1859. He became a manager 1865, returning to his native town 1878. He was the most prolific song writer and among his productions were 'Old Dan Tucker;' 'The Road to Richmond' and 'The Boatman's Dance.'

EMMITSBURG, Md., town in Frederick County, on a branch of the Western Maryland Railroad, about 45 miles northwest of Baltimore. The town is known for its large educational institutions, Mount Saint Mary's Theological Seminary (q.v.), just outside the town's limits, and Saint Joseph's Academy, within the town. It contains also the mother-house and seminary of the Sisters of Charity of Saint Vincent de Paul, from Paris. Emmitsburg was the scene of the labors of Mother Eliza Seton (q.v.) when establishing the Sisters of Charity in the United States. There are about 1,800 sisters working in different parts of the country who belong to this mother-house. The city contains a public library and a museum. Its industries include cattle raising and the manufacture of furniture, brooms and hosiery. Settled about 1757, Emmitsburg received its present name in 1785, was incorporated in 1824, and under a charter of 1911 is governed by a burgess and three commissioners. Pop. 1,054.

EMMONS, Ebenzer, American geologist: b. Middlefield, Mass., 1799; d. 1863. He was educated and afterward taught at Williams College, later becoming geologist-in-chief, second district, New York State Geological Survey. He introduced the new Taconic stratigraphic system, not now in vogue. He was made professor of chemistry in the medical college at Albany 1838, and had charge of the geological survey of North Carolina 1858. His works include 'Manus of Mineralogy and Geology' (1826); and 'American Geology' (1856), and the monographs published in the reports of the geological surveys of New York and North Carolina.

EMMONS—EMOTION

navy as midshipman in 1828; was promoted lieutenant in 1841; rear-admiral 1872; and was retired the next year. He was a member of the Spanish-American War exploring expedition under Captain Wilkes in 1838-42; took part in the Mexican War; and during the Civil War captured Cedar Keys, Fla., and Pass Christian, Miss., with 20 prizes, in 1862. He served as captain of the fleet under Dahlgren, off Charleston, 1863, and retired in the rank of rear-admiral on 12 March 1869. He published ‘The Navy of the United States, 1775–1853’ (1853).

EMMONS, Samuel Franklin, American geologist: b. Boston, Mass., 29 March 1841; d. 1911. He was graduated at Harvard, taking postgraduate courses at the Ecole Imperiale des Mines, Paris, and Freiberg, Saxony, Mining School, and was a member of several scientific societies, including the National Academy of Sciences and the Geological Society of America, of which he was president in 1896 and 1903. He was in the employ of the government almost uninterupted from 1867 and geologist upon the United States Geological Survey, Colorado division, after 1879. He made a survey in 1870 of Mount Rainier, the loftiest point in the State of Washington. Among his writings are ‘Descriptive Geology of the Fortieth Parallel Region’ (1877); ‘Statistics and Technology of the Precious Metals’ (1885); ‘Geology and Mining Industry of Leadville, Colorado’ (1886); ‘Geology of Lower California’ (1890); ‘Geological Distribution of the Useful Metals in the United States’ (1893); ‘Progress of the Precious Metal Industry of the United States’ (1893); ‘Geology of the Denver Basin in Colorado’ (1896); ‘Ten-mile District, Colorado’ (1898); ‘The Downtown District of Leadville, Colorado’ (1907); ‘Ore-Deposits’ (1913).

EMODIN, one of the active constituents in Cascara sagrada and in other species of the genus Rhamnus. Emolin acts as a cathartic.

EMORY COLLEGE, an educational institution at Oxford, Ga., founded in 1836 under the auspices of the Methodist Episcopal Church; reported at the close of 1915: Professors and instructors 17; students, 260; volumes in the library, 35,000.

EMOTION, a complex mental state intimately associated with our actions and with extensive and often sudden physiological changes. Among the more familiar emotions are fear, anger, hate, joy, love, pity, pride, shame, grief, awe, contempt and surprise. They almost invariably seem to involve all the following factors: (1) an experiencing subject; (2) an object toward which they are directed; (3) a set of coexisting actions and physiological changes on the part of the experiencing subject; (4) the mental representation of a future course of action, together with the intention to pursue or to avoid it; (5) a general pleasantness or unpleasantness. The best-known theory of the emotions is that of William James and C. Lange. These authorities regard emotion as entirely constituted by factor (3), the set of coexistent actions and more especially of physiological changes on the part of the experiencing subject. In their opinion, fear consists in a feeling . . . of quickened heart-beats . . . of alarmed breathing . . . of trembling lips . . . of weakened limbs . . . of gooseflesh . . . [and] of visceral stirrings. 

Rage is constituted by . . . ebulition in the chest . . . flushing of the face . . . dilatation of the nostrils . . . clinching of the teeth . . . [and an] impulsive to violent action. Each of our emotions is subject to a similar analysis and nothing is found beyond our awareness of an active response to some exciting object.

The consciousness of our own reactions is indeed a factor of the utmost importance in the generation of an emotional state. Whether it is the sole factor is a disputable point. Certain recent experiments as to the nature of the vascular and organic changes characteristic of emotional states appear to tell strongly against the James-Lange theory. As Prof. W. B. Cannon writes in his ‘Bodily Changes in Pain, Hunger, Fear and Rage’ (1910), ‘In terror and rage and intense elation, for example, the responses in the viscera seem too uniform to offer a satisfactory means of distinguishing states which, in man at least, are very different in subjective quality. For this reason I am inclined to urge that the visceral changes merely contribute to an emotional complex more or less indefinite, but still pertinent, feelings of disturbance in organs of which we are not conscious.’ The peculiar marks which separate emotion from emotion cannot always reside in the grosser concomitant actions, for these are by no means invariably present, while on the basis of what Professor Cannon has shown, the visceral aspect of the immediate emotional act is too generalized to serve as a principle of individuation. The main differences of the emotions are to be found in the courses of purposive conduct intended by the subject and the shadings of pleasantness or unpleasantness with which the emotional states are tinged. It is not the involuntary organic preparation for flight which makes fear distinct from rage, but the conscious intent to flee; while no state of excitement can be called elation unless it is distinctly and intensely a state of pleasure.

The intimate association between emotion and hedonic tinge demands a more thorough analysis, for it is closely connected with one of the most interesting features of an emotion—its directedness. Both pleasant and complex emotion may have an object. To be pleased or angry or afraid is usually to be pleased or angry at something, or in fear of something. The relation between the emotion and its object is not one of the simple coexistence of an awareness of the object and the emotion; it is possible, for example, to be conscious of many things and to be annoyed at but one of them. The object need not be the efficient cause of the emotional state—one’s annoyance may be caused by indigestion, but directed toward those whom one chances to meet. Furthermore, the object of an emotion does not gain its rank as object by virtue of a place in the focus of attention. One may be annoyed at the buzzing of a mosquito of which he is but dimly aware, while his annoyance is directed toward the book which he is reading. It is by no such extraneous means as these that the reference of mental states can be explained. The reference of one experience to another is due to the fact that the unity of the content of the mind is the unity of a system and not the unity of a mere fortuitous aggregate. The definite directions of
pleasure or emotion can only be explained on the basis of the existence at each stage of psychological analysis of some unanalyzed state with a definite reference. However, pleasure and emotion are not themselves directed in unanalyzed states. From what had already been shown of emotion, it is clear that it involves many undirected experiences of the nature of organic and kinesthetic sensations or images. Pleasure likewise appears to have the dual aspect of a mass of organic experiences, going to make up what may be called a sense of well-being and of an attribute of other mental states. Now, if we strip all sense of well-being from our pleasure, say, at a dinner, all that remains is an act of bare approval. This approval does not appear to be qualitatively distinct from that involved in an aesthetic judgment, an ethical judgment or a normative judgment of any kind. (See Norm). Similarly, active displeasure is apparently composed of a sense of ill-being, accompanied by, and possibly forming a part of, the object of, an act of disapproval. The hedonic tone of an emotional experience thus generally seems to involve: (a) a diffuse organic experience of well-being or ill-being; and (b) an act of approval or disapproval directed toward some definite object. It is almost, if not quite, impossible to think of a case where an emotion involves an act of approval or disapproval of this sort, but where the objects of the emotion and those of the act are distinct. There seems to be no valid objection to identifying the objective references of the emotion with the objective references of the act. On the basis of this and of what has been said previously concerning the emotions, it is easy to account for the coexistence of different emotions in the same individual: the physiological excitement characteristic of an emotion is present; but it is accompanied by a background of organic sensations conforming in its entirety neither to that of well-being nor to that of ill-being though sensations of both sorts are present; by the approval of certain objects and the disapproval of others; or by the intention of pursuing different courses of conduct with regard to the different emotional objects.

The emotions are clearly indispensable for the propagation of the species, the nurture of young, the protection of the individual in times of danger, and for many other essential needs of the race. They have undergone a strict process of natural selection. Among the emotions showing the deepest and most recent effects of this natural selection are those that form the basis of the moral conduct. In many ways our emotions and their modes of expression show traces of the needs of a more primitive existence — thus a sneer is a rudimentary unshelving of the teeth for combat. (See Aesthetics; Feeling). Consult Cannon, W. B., "Body Changes in Pain, Hunger, Fear and Rage" (New York 1915); Darwin, C., "Expression of the Emotions" (London 1873); James, W., "Principles of Psychology" (New York 1890); Mantegazza, "Physiognomy and Expression" (tr. London 1904); Ribot, "Psychologie des sentiments" (Paris 1896); Stout, "Manual of Psychology" (London 1899).

Norbert Wiener,
Editorial Staff of The American.

EMPALEMENT, a mode of executing criminals, mentioned by Juvenal, often inflicted in Rome, and still used in Turkey and Arabia. In England the dead bodies of murderers were sometimes staked in the same position, being buried; but the custom was abolished in 1823.

EMPÁRAN, Diego de, dé-á’gó dá ēm- pá-rán, Mexican writer: b. Puebla, 5 April 1718; d. Ravenna, Italy, about 1807. His book, "The Jesuits and the Pope" (1746), published soon after entering the priesthood, gained him five years' imprisonment. The year after his release he issued a bitter criticism of Church dignitaries, for which he was deposed from the priesthood and imprisoned in the Castle of Sant' Angelo, but released later. His work was burned by the executioner. His other works include "The Tombs of Mohammed and Christ"; "Voltaire and His School"; "Science and Superstition"; and "Religion and Hygiene."

EMPECINADO, ēm-pa-thē-nā’dō, Don Juan Martín Díazel, Spanish patriot: b. Cestillo de Duoso, Valladolid, 1775; d. 1825. He joined the army at 17, and for his activity in the war against the French in 1808, was appointed colonel and later made a field marshal. Losing favor with King Ferdinand VII on account of his action in petitioning him to restore the Cortes, he was thrown into prison, his imprisonment being followed by banishment to Valladolid. Taking part in the insurrection 1820 he saw much fighting, but was captured 1823, cruelly treated while a prisoner and after two years he was stabbed while resisting the executioner by whom he was about to be hanged.

EMPECINADO, El. See Díaz, Don Juan Martin.

EMPECÓLES, Greek philosopher: b. Agrigentum, Sicily, about 460 B.C. His fellow-citizens esteemed him so highly that they wished to make him king; but being an enemy to all political forms which elevate a few above their fellows, he refused their offer, and prevailed on them to abolish aristocracy and introduce a democratic form of government. Aristotle states that he died in obscurity at the age of 60 years, in the Peloponnesus, but there are various legends respecting the manner and place of his death. Empedocles presented his philosophy in a poetical form. His general point of view is determined by the influence of the Eleatic school upon the physical theories of the Ionic philosophers. He assumed four primitive independent substances — air, water, fire and earth, which he designates often by the mythical names Zeus, Hera, etc. These four elements, as they were called, kept their place till modern chemistry dislodged them. Along with material elements he affirmed the existence of two moving and operating powers, love and hate, or affinity and antipathy, the first as the uniting principle, the second as the separating. The contrast between matter and power, or force, is thus brought out more strongly by Empedocles than by previous philosophers. His theory of the universe seems to assume a gradual development of the perfect out of the imperfect and a periodical return of things to the elemental state, in order to be again separated and a new world of phenomena
formed. Of his opinions on special phenomena may be mentioned his doctrine of emanations, by which, in connection with the maxim that like is known only by like, he sought to explain the nature of perception by the senses. He attempted to give a moral application to the old doctrine of the transmigration of souls, his views of which resembled those of Pythagoras. The fragmentary works of Empedocles have been edited as Sturz (1805); Karsten (1838); and Stein (1852). Consult monographs by Lommatsch (1830); Raynaud (1848); and Gladisch (1858); also Windelband, 'Geschichte der griechischen Philosophie' (3d ed., Munich 1912).

EMPEDOCLÉS ON ETTNA is a dramatic poem by Matthew Arnold, based on legendary accounts of a Greek philosopher who lived in Agrigentum, Sicily, in the 5th century before Christ. The interest of the drama centres in the philosophical despair of Empedocles and his suicide, which he accomplishes by leaping into the crater of the volcano. Before his death he discourses at length on the consolations of philosophy for the benefit of his friend, the physician Pausanias, who accompanies him part way to the summit. Dramatic relief and contrast are provided by Callicles, a young harp-player, who on his lower hopes of the moulseman sings with unshaken faith in the traditional divinities and the eternal freshness and delightfulness of nature.

Arnold first published this drama in 1852, but which it was a selection which was withdrawn from circulation before 50 copies were sold. He reprinted fragments of it in 1853, '54, '55, '57, and in 1867 revived it in its entirety at the instigation of Robert Browning. In an interesting preface to a volume of verse published in 1853 he explained both why he wrote the poem and why he withdrew it. He had been attracted to the theme because Empedocles, like Arnold himself, was a troubled spirit wandering between two worlds, one dead, the other powerless to be born, the calm, the cheerful, the disinterested objectivity having disappeared; the dialogue of the mind with itself has commenced; modern problems have presented themselves; we hear already the doubts, we witness the discouragement, of Hamlet and of Faust. He had seized upon this parallelism between his position in the 19th century and that of the Greek philosopher in the 5th century B.C. to express with penetrating power the profound melancholy of religious disillusion which sorely afflicted his early manhood. As a critic, however, he felt bound to condemn as morbid, monotonous and painful the representation of a situation in which a continuous state of mental distress is prolonged, unrelieved by incident, hope, or resistance; in which there is everything endured, nothing to be done; and accordingly he suppressed the work. Its restoration was justified by its poetic beauty and power, by its importance to an understanding of Arnold's intellectual development and by its illustrative value in the history of Weil- schuss in the Roman Age. For periodical criticism consult T. B. Smart's 'Bibliography of Matthew Arnold' (1892); books on Arnold, by George Saintsbury (1889); H. W. Paul (1902); G. W. E. Russell (1904); W. H. Dawson (1911); J. M. Dixon (1906); S. P. Sherman (1917).

STUART P. SHERMAN.

EMPEROR, the title of the highest rank of sovereigns. The word imperator, from imperare, to command, had very different meanings among the Romans and Romans of different periods. It signified one who exercised imperium authority, whether in a civil or military capacity. In the time of the Roman consuls were called imperatores before they entered on their office. The soldiers afterwards saluted the man in general, after a victory, by hailing him imperator; the Senate also called a victorious general imperator until he had celebrated his triumph. After the overthrow of the republic imperator became the title of the rulers or emperors who assumed to themselves personally every department and privilege of civil and military imperium. Victorious generals were still, however, sometimes saluted with the title imperator, in its original sense. With the fall of Rome the title was lost in the West, but it was kept up in the Eastern or Byzantine empire for nearly 10 centuries. In 800 it was renewed in the West when Charlemaigne was crowned, by Leo III, as "Caro- lus Augustus, the God-sent and pious emperor of Rome," which title was borne by his successors until the dissolution of the Holy Roman Empire in 1806.

The Eastern Empire having been finally overthrown by the conquest of Constantinople in 1453, the imperial dignity in the East became extinct. The sultans, who succeeded the emperors, have never received, in official language, the title of emperor. This title was adopted in Russia by Peter I in 1721, but the right of the Russian sovereign to its possession was not acknowledged by the German Empire until 1747, by France in 1745, and by Spain in 1759. Napoleon adopted the old idea of an empire, as a general union of states under the protection, or at least political preponderance, of one powerful state. Napoleon crowned himself as emperor in 1804; the title fell into disuse at his deposition in 1815, but was revived by his nephew in 1852, and again ended on 5 Sept. 1870. In 1806 the first German Empire, 1,000 years old, became extinct and the German emperor, Francis II, adopted the title of Francis I, Emperor of Austria. In December 1870 the second German empire was formed, King William of Prussia having accepted the imperial office and title offered him at Versailles while engaged in the siege of Paris.

Great Britain is considered as an empire, the crown as imperial and the Parliament is styled the Imperial Parliament of Great Britain and Ireland; but the sovereign has not the imperial title in reference to the home dominions, though the king bears the title of emperor of India. The sovereigns of Japan and Morocco are often, though with little propriety, called emperors.

EMPEROR, or PURPLE EMPEROR, name of a butterfly of the genus Apatura. The antennae are rather long, the ground color of the wings is rust-coloured, black, decorated in the male with a purple lustre wanting in the female; seven white spots in the male; as the eye-spots in the female; on the four wings above a transverse white band; an ocellated spot and a darker marginal bar on the hinder ones.

EMPHYSEMA, ém-fi-se'ma, a disease of the lungs, in which there is a dilatation of the air vesicles with lack of elastic recoil. It is most frequently the result of persistent hype-roalveolar tension, acting upon weak lung
tissue. The most important symptoms are bronchitis, loss of breath with harsh and wheezy respirations, and a certain amount of cyanosis or purplish coloring of the face, due to insufficient oxidation in the lungs.

EMPHYSEUSIS, em-fiz-e-us-is (Gr. "implanting"), in Roman law, a perpetual right in a piece of land, for which a yearly sum was paid to the proprietor. It was secured by contract on condition of improvement, as well as payment of the annual sum, and much resembled a feudal holding in the features of perpetuity, etc. See FEUDAL SYSTEM.

EMPIRE STATE, a name given to New York State because of its predominant wealth and commerce. The expression "Empire," probably rendered more vivid by Berkeley's prophecy made at Newport, R. I., a generation previous. "Westward the course of empire takes its way" was quite common after the Revolutionary War. It was not necessarily of political significance, as relating to a form of government, but referred rather to the course of progress in civilization; or, as we say "expansion." As such, it was applied especially to New York. When the Free Quakers of Philadelphia, led by Colonel Eyre, built their first temple, at Fifth and Arch Streets, in Philadelphia, they dedicated it as the stone inscribed and set in the façade declared, "Erected in the year of our Lord, 1783, of the Empire."

EMPIRICISM. See EMPIRICISM.

EMPIRICISM (Greek, empeiria, trial, experience, from the adjective empereoros, which means expert, or experienced in). The philosophical view that experience is the source and the criterion of all knowledge; the theory that all knowledge is derived from material or data existing in the form of particular states of consciousness. As sense, outer and inner, is regarded as the source of this material, empiricism, as a theory of the origin of knowledge, is nearly synonymous with Sensationalism (q.v.). Moreover, since historically it has been customary for representatives of empiricism to explain the connections and relations of ideas by means of the primary phenomena, as a result of his theories, empiricism is closely connected with Associationism. Empiricism, however, is not alone in its appeal to experience; all modern systems profess to draw their conclusions from this source. But as a philosophical theory, it is distinguished by the particular way in which it envisages the mind and its content. For it, the mind is either merely the place or support of ideas (as for Locke), or (with later writers) simply a general name that is given to the stream of conscious processes; it is not itself a contributing factor in experience and has no power to supply ideas or principles which are not already furnished to it by the original data. At birth the mind is like a blank sheet of paper: it contains no innate ideas, and has no original capacity. In this respect, empiricism is closely connected with (q.v.), Transcendentalism (q.v.), and all theories which find in experience some expression of the nature of reason or intelligence.

As a theory of the origin of knowledge, empiricism has the task of explaining how the most complex and abstract of knowledge and of concrete experience have been derived from the simple psychological elements which it assumes as its data. As these elements are particular and isolated states of consciousness, the most difficult problem for empiricism has been to explain the connectedness of experience, and more especially the nature and validity of general propositions. How can experience, which is by hypothesis originally constituted of particular states, guarantee the truth of universal statements, such for example as are arrived at by science? Since for this theory the mind possesses no general principles in the form of innate truths from which it might deduce conclusions, it is evident that empiricism will emphasize induction as its method of reasoning and seek to explain universal propositions as derived in this way from particular experiences.

In regard to the validity of knowledge, empiricism holds that only those ideas are valid that have their source in and can be traced back to some original data which can be exhibited in the form of actual impressions or without consciousness. In Hume's statement, all ideas are derived from some original impression. If then it is impossible in any case to point to the impression from which our supposed idea is derived, we have to conclude that the idea is no proper idea at all, but only an illusion of the imagination. It is by means of this principle that Hume and the empiricists who have constantly followed his lead discredit the idea of the self and all universal principles and categories which cannot be traced back to some particular experience or group of experiences.

Empirical views regarding the origin and criterion of knowledge were maintained by the Greek Sophists, and more systematically by both Stoic and Epicurean schools. In the Middle Ages, the doctrine was maintained in the formula, "Nihil est in intellectu quo prius quam non fuerat in sensu." But it has been in the modern period that empiricism has been systematically developed and applied as a philosophical doctrine. The name is especially connected with the English school that begins with John Locke and includes as its chief representatives, George Berkeley, David Hume, David Hartley, Joseph Priestley, James Mill, J. S. Mill and A. Bain. The views of H. Spencer also are very largely associated with this school, though his application of the doctrine of evolution leads him to some new conclusions. It should be recognized, however, that the influence of empiricism has not been confined to any single group of thinkers, but that it has in a sense formed a general platform for the sciences of mind and society. By providing a set of conceptions through which the inner life can be readily ordered and made comprehensible, empiricism came to be accepted as a matter of course by writers on psychology, ethics, sociology and education, oftentimes without even being aware that their procedure had committed them to any philosophical position. During the past generation the empirical view of mind and experience has furnished the framework which has largely determined the course of investigations in these fields, even when, as in the case of Spencer, they have been accompanied by professions of allegiance to the principle of development. The truth is that the empirical way of representing knowledge, constituted out of atomic "states" or "elements" which unite in accordance with certain principles to form "complexes," is so convincing to "common sense" and at the same time so suc-
successful in rendering the mind picturable and describable in terms of science that it appears to be both natural and indispensable. It has accordingly happened that the demonstrations of the shortcomings of empiricism as a philosophical doctrine which have been furnished notably from the point of view of Kant and the idealistic school (cf. T. H. Green, ‘Introduction to Hume’) have failed to overthrow the influence and standing of this doctrine in popular favor. The rival view of experience put forward by Kant and his followers, being more difficult to understand and to envisage, did not so readily form the basis for investigation and discussion in this field, and so the dominance of empiricism remained almost unshaken. In recent years, however, there are signs that investigations into psychological and social phenomena are becoming more fully penetrated with historical and developmental conceptions, and are being carried beyond the atomic and mechanical logic of the older empiricism. This movement beyond empiricism is illustrated by the important contributions to studies of behavior and function at the present time, and especially by the tendency shown to interpret mind and its various types of experience in the light of the categories of historical development.

Radical Empiricism.—With the movements described in the last sentences there may be connected the position outlined by William James, to which he gave the name of "radical empiricism." James distinguishes his own empiricism from that of Hume and the English school by insisting that in addition to the substantive states of consciousness to which the latter had called attention, there are also certain "conjunctive relations" given directly through experience, and so to be accepted as equally real in a true empirical theory. Radical empiricism thus professes to give a more accurate description of experience than that of the earlier school; it recognizes the fact that experience presents itself as whole and continuous and not as a series of discrete substantive states; or, as James objects, to maintain the wholeness and continuity of experience, and at the same time to avoid any appeal to rational elements which cannot be themselves experienced as facts. "Radical empiricism," just by being "empiricist," implies that it itself is able to describe the thing just as it is experienced, without imposing upon it any conceptual form through logical interpretation.

Empiricism in Medicine.—The Empiric school of medicine arose in Alexandria in the 3rd century B.C., in opposition to Dogmatism. The latter supported itself by appeal to the theories of Plato and earlier philosophers, while the empirics took Aristotle as their leader. They avoided the one-sided theorizing tendencies of the dogmatists regarding the ultimate causes of disease, and emphasized the practical ends of medicine as an art of therapeutics. Though the influence of this school was in many respects beneficial in leading to the study of cases and to careful methods of observation, it tended in the end to resolve itself into charlatanism, and to occupy itself exclusively with a search for specifics. Consult Locke, J., "An Essay Concerning Human Understanding" (1660); Mill, J., "An Analysis of the Phenomena of the Human Mind" (1820); Hodgson, S. H., "Metaphysics of Experience" (1898); Green, T. H., "Introduction to Hume" (1874); James, W., "Essays in Radical Empiricism" (1912); Moon, R. O., "The Relation of Medicine to Philosophy" (1907). JAMES E. CREIGHTON, Professor of Logic and Metaphysics, Cornell University.

Empiricism, in medicine, refers to at least two different things. In the age of renovation, or the reform period in medicine, a special group of men, Phaimus and others, at their head, founded what was called the Empirical School. They were disciples of Hellenus and Erasistratus, and from 200 to 300 A.D. they formed one of the most important Alexandrian schools. Their followers were mostly opposed to the teaching of the Dogmatic School. Their chief point of view was that of practical observation, as opposed to the theoretical speculations of the Dogmatic School. Their chief alliances were with the skeptics. Anatomy, inasmuch as it could teach nothing of physiology, they believed was of secondary importance.

At the present day what is meant by empiricism is the following of accumulated experience independent of rational grounds. A physician uses a drug empirically because he, or others, believe it to be of service, although no reason can be given by him, nor by others, why it should be of service. Little by little, the real cause of the action of drugs that physicians have used from time immemorial has been revealed by students of medicine and the reproach that medicine is an empirical science has little weight at the present time. See Empiricism, in philosophy.

Employers' Associations, combinations of business establishments for the purpose of dealing with or fighting labor organizations. They are a special form of capitalist organization, exclusive of those general combinations (see combination, industrial) which have been formed to advance the political, social, or economic interests of employers. Their history follows the history of trade unions—their power have been weak or strong according to the strength of the unions. Two distinct types of employers' associations prevail (1) bargaining associations; (2) hostile associations. Employers recognize the unions while the latter are opposed to every form of collective bargaining.

The bargaining associations aim to check the abuses and excesses of organized labor by endeavoring through deliberation and discussion to work out some system of agreement with their employees. The employment of labor is treated as a simple business proposition. The first employers' association of national importance of this type was the United States Potters' Association formed in 1867. The Stove Founders' Association formed in 1886 stimulated similar organizations in all branches of that industry. By 1905 national employers' associations representing the stove and furnace making, foundry work, lake transportation, machine construction, publishing and printing, marble cutting and ready-made clothing industries were successful in making working agreements with employees. Employers' associations have been steadily on the increase. Their organization is essentially similar to that of the unions. They have local bodies with
national federations, and nearly all maintain employment agencies, secret service departments, and a proxy-acting delegate system; control the members who are forced to agree to measures adopted by the central organization; issue publications; and have a defense fund.

The class of hostile employers' associations is a comparatively recent development and represents the counteraction of the forces of aggressive industrial unionism. In many cases the associations were first formed for the purpose of negotiating joint agreements with the unions, but after the failure of negotiations or the breakdown of an agreement, they assumed their present form. In some cases associations which have been hostile have resumed relations with unions.

But there is a strong tendency for an organization of this type to develop exclusive principles and policies which make an agreement with the unions impossible. Their platform shows absolute disagreement with unionist principles. They insist that the conditions of employment shall be determined by the individual worker and the individual employer. This generally means that employers, either as an association, or, in many cases, as individuals, have the right to dictate the terms of employment. Discharge and discrimination is made either against all union workers, or else their number is so limited as to prove ineffective in agitation. Any indication of spread of unionist principles is watched for and instantly suppressed. They deny the privileges of arbitration and conciliation and, when called upon to serve on boards, etc., do not hesitate to seek redress in event of such crises by employing strike breakers and spies. This extreme form of hostility takes on a highly anti-social aspect. But the more enlightened employers of the hostile associations have begun to realize the vast psychological problems underlying unrest and opposition of laborers; and they attempt to change conditions where there is evidence of dissatisfaction. They endeavor to ameliorate affairs by profit-sharing and welfare systems, safety devices, offering opportunities for advancement. This minimizes the advantages of unionism and secures satisfactory results. A striking example of this type of reform was evinced by the voluntary introduction of the eight-hour law into the Western Union Telegraph Company in 1917. Among noteworthy hostile employers' associations may be mentioned the National Association of Manufacturers (q.v.) and the Citizens' Industrial Association of America.

The weakness of the first type of employers' associations lies in the fact that a considerable number of employers, though accepting results of collective bargaining, do not belong to the associations and thus lessen the force of bargaining power. The United States government through its Board of Mediation and Conciliation recognizes the fact that agreements made between employers' associations and trade unions form a basis for settling trade problems which is equitable, elastic and intrinsically democratic. Consult Hollander and Barnett, 'Studies in American Trade Unions' (Chap. 12, 1912); M'Culloch, 'The History and Growth of Trade Unions' (2d ed., 1939); Gilman, N. P., 'Methods of Industrial Peace' (Chap. 3, 1904). The 'Reports of the United States Industrial Commission' contain valuable studies in mediation and conciliation which are pertinent to the working of these associations. Consult especially 'Senate Documents' (Vol. XIX, Washington 1916).

EMPLOYERS' LIABILITY, a term generally used to denote the liability of employers for injuries inflicted upon workmen in their employ. In many States workmen injured in the course of their employment can recover damages from their employers only if the employers be proved guilty of negligence and if such negligence resulted in the injury. Employers are not liable for injuries resulting from the obvious occupational risks or for accidents that are inevitable or for which blame cannot be fixed. Since an employer is responsible for injuries due to his own negligence or that of his servants, an employee thus injured supposedly would be entitled to recover damages from the employer. But under the common-law relation of master and servant, as interpreted in formerly civilized countries until recently, and since discarded in nearly all civilized countries save the United States, an employee, on entering service, agrees to run all the ordinary risks of the service, including injuries that might befall him through the negligence on the part of fellow-servants. The so-called absolute duties of the employer are to furnish a reasonably safe and proper place in which employees may engage in their work, suitable appliances, reasonably competent employees, such as superintendents, foremen and other servants, and rules and regulations when they are reasonably necessary. The employer is liable for gross negligence, for risks of an extraordinary nature involved in the service, and for all acts of negligence, whether committed by himself or by employees, occurring outside the regular servicer. Modern industrial conditions necessitated a modification of these common-law rules, especially in England, where the liabilities of employers has been greatly extended by such acts as the Employers' Liability Act of 1880 (43 and 44 Vict. c. 42) and the Workmen's Compensation Acts of 1897, 1900 and 1906 (60 and 61 Vict. c. 37; 63 and 64 Vict. c. 22; and 6 Edw. VII c. 58). Under this legislation employees are virtually insured by the employer against injury while in his employ, the employer being compelled to pay a limited sum to the injured or to the families of employees killed by such accidents, whether or not due to the negligence of the employer or to that of fellow-employees.

In the United States the employee must prove that in a given instance the master has failed to fulfill one of the above-mentioned absolute duties. In contesting such an action the employer, in general, may rely on three defenses: (1) that the injury sustained by the employee was among the ordinary occupational risks which he assumed when entering the employ of the master, or was caused by a danger of which the employee either was or should have been cognizant, but in spite of which he continued to work; (2) that the injury inflicted upon the employee was not due to negligence on the employer's part but was the fault of a fellow-servant of the plaintiff, wherefore the employer is not liable since the employee assumed this risk, too; (3) that the injured employee failed to use reasonable precautions.
against accident and that this contributory negligence had resulted in his injury. During the past few years several of the United States have enacted laws of a very diverse character which differ widely from the general principles of the American system as above set forth and considerably extend the liability of the employer. Attempts have been made to offset the liability laws by compelling employees to sign contracts waiving the benefits of such legislation, but subsequent enactments have overcome this evasion of the law by forbidding such contracts. The courts have sustained such contentions the tendency has been to amend the constitutions so as to permit such legislation, and acts passed under such amendments have been upheld in the court of last resort. The rapid advancement of the movement to compel compensation to injured workmen led to the extension of the field of insurance, some companies now issuing employers' liability policies, under which, for a stipulated premium, the employer is insured against liability for injuries to employees, and any damages for which the employer may be legally liable being paid by the insurance company. The most recent laws make such insurance compulsory, while State insurance funds, placed on a sound actuarial basis, have been created in some States, since, as the New Jersey commission on employers' liability reported in 1915, previous laws have not ensured the payment of compensation in case the employer should become insolvent. Most of the States have compensation laws which apply to public as well as to private employees, while the Canal Zone order and the Federal statute apply to public employees and to persons engaged in interstate commerce. In general either compensation or insurance is provided and either type of law may be elective or compulsory. Alaska, Colorado, Connecticut, Illinois, Indiana, Iowa, Kansas, Louisiana, Maine, Michigan, Minnesota, Montana, Nebraska, New Hampshire, New Jersey, Pennsylvania, Rhode Island, Vermont and Wisconsin provide elective compensation; while in Arizona, California, Canal Zone, Hawaii, Maryland, New York and Oklahoma the compensation is compulsory as it is under the Federal statute. Massachusetts, Nevada, Oregon, Texas and West Virginia have elective insurance laws, while Ohio, Washington and Wisconsin have compulsory insurance. See ACCIDENTS; WORKMEN'S COMPENSATION; LABOR; FAMILY LAW; FACTORIES AND FACTORY INSPECTION; DISEASES, OCCUPATIONAL.

EMPLOYMENT BUREAUS, establishments, whether private or public, at which those wishing to work are introduced to those concerned with their employment, and who are offering it. Private employment bureaus are found in every large city, but they are often conducted without judgment, sometimes have been accused of dishonesty, in many cases are mercenary, and their usefulness is at least problematical. In order to combat the evils arising from the practice of these bureaus, much remedial legislation has been passed. No agency is now allowed to charge a fee before informing an applicant of a situation that is actually open to him, and should such position, through no fault of the applicant, be found not open to him as understood when the fee was paid, such fee is required to be returned promptly. All employment bureaus are under the supervision of some State bureau, while some cities impose these fees and bonds of varying amounts and limit the amounts of the fees to be charged for registration, also requiring the return of fees should applicants fail to secure positions within a prescribed time. Public bureaus, opened by the national or city government, are now numerous, and the motive that has prompted their establishment is a sound humanitarian and political motive. Such bureaus have two practical objects. They are a means of communication between employer
and employee—labor exchanges, as they are called in France. In the second place they do something toward settling the wage question, by giving quotations of the amount offered and asked. The only country that has set up a system for free public employment offices in the United States, instituting hers in 1890, and the movement has spread so that 19 States now have more or less effective systems of public employment offices in about 60 different cities, the offices usually under the supervision of a superintendent of free employment offices, or some other State official, such as the commissioner of labor or the chief of the bureau of statistics. These offices find employment annually for about 300,000 wage-earners at exceedingly low cost, ranging from four cents for unskilled workers in Seattle to $2 or more in some small offices. With two exceptions the various laws stipulate that there shall be no charge to employer or employee for the service rendered. Municipal bureaus are operated independently in seven States. In 1914 the United States Department of Labor, through a bureau called the Federal Employment Bureau, began the establishment of 38 branch offices in various parts of the country. The employment service was extended to the scope of the work so as to include a woman's division. The country is divided into 18 zones of distribution, each with headquarters in a large city; besides the station headquarters there are 80 sub-branches.

The public governmental employment bureau originated in France. In 1848 one such bureau was established in each of the mairies of Paris. The institution languished and in 1851 a measure submitted to the legislative assembly for the establishment of a comprehensive system of employment bureaus throughout the country failed to be adopted and nothing of importance was accomplished until 1888 when the Bourse de Travail was opened at Paris, which institution received a subsidy of 150,000 francs from the government. In 1892 a law was passed which enlarged the scope of the work so as to include a woman's division. The country is divided into 18 zones of distribution, each with headquarters in a large city; besides the station headquarters there are 80 sub-branches.

Germany's first municipal bureau grew out of a private bureau established at Freiburg in 1892, and the movement has been taken up enthusiastically by almost every city of importance. Ordinary commercial bureaus in Germany concern themselves chiefly with securing positions for domestic servants. The trade unions have their own bureaus. The Berlin public employment bureau is under the charge of various united societies but it is a distinct bureau of the city government and is also strictly supervised. A nominal fee is charged to workers who register but it is free to all employees. The management is equally divided between employers and employees and prominent citizens are in charge of the important committees. The best system that of Munich. The Bavarian communes are held legally responsible for the conduct of the employment bureaus; the separate municipal bureaus are federated into a complete system with central bureaus in the largest Bavarian cities. No charge is made for services, the municipality defraying the entire cost with the aid of appropriations by the Bavarian government. In almost every German city of 50,000 or more inhabitants a municipal bureau will be found, and such bureaus are particularly successful in southern Germany, but in the northern part of the country the work of the municipal bureau is performed, to a great extent, by voluntary associations, aided by the municipalities. See LABOR LEGISLATION IN GERMANY.

EMPLOYMENT MANAGER. The new profession of employment manager has within the past few years come to be recognized as one of the most vital factors in industry. Ten years ago, workmen were hired by foremen or clerks simply because they happened to apply for jobs that were vacant but without regard for any particular fitness for the work to be performed. Naturally, there was general dissatisfaction, both on the part of employer and employee, and as this greatly increased the labor turnover and reduced production, a closer study of the question of the human element in the industrial organization was made, with the result that many manufacturing concerns have placed their employment work in the hands of a trained executive, with the power to hire, place and handle the working force with a view to more efficient labor management.

The employment manager occupies the position of the representative of his company in the labor market. He must be familiar with all surrounding policies of supply and be capable of selecting the men and women needed for the different positions in his plant in accordance with their fitness for the jobs, for the duties of the employment manager are not only to keep the machines running but to see that they are operated by the workmen who are able to maintain a high standard of efficiency in the quality and quantity of the goods produced.

As the connecting link between the management and the worker, the employment manager is entrusted with all matters of personnel connected with the company. The hiring of the help, their assignment to tasks that they are fitted to perform, their change of jobs or transfer from one department to another, and, when necessary, their discharge, are matters that rest in his hands. He is the "friend at court" to whom all requests for assistance are made and it is he who must sit as a judge upon all grievances that are brought to his attention, separating the imaginary from the real.

The employment manager must not only enforce the policies of his company and see that all rules for the management of the help are understood and obeyed, but he must also see that there is effective co-operation between his office and the heads of other departments, for his duties require that he keep as fully in accord with the various foremen as with the workers. The successful maintenance of these varied relations requires both intelligence and executive ability of a high type.

This plan of delegating all personnel problems to a skilled employment manager has proved so successful, both in improving production and in promoting an esprit de corps, that it has been adopted in nearly all important industrial concerns and in many financial and mercantile establishments.

Employment Managers' Associations.—

The development of the profession of employment manager has resulted in the organization of associations, or clubs, where the employment managers could meet to discuss the problems arising in their work, exchange experiences and otherwise fit themselves to handle more efficiently the human element so vital to the success of an industrial enterprise. The first employment management society was organized in Boston, about five years ago, and soon proved so helpful to its members that similar employment executives' organizations have since been formed in nearly all of the industrial centres of the country. Three conventions have been held, Minneapolis, Minn., 1916; Philadelphia, Pa., in 1917, and Rochester, N. Y., in 1918. At the latter, on 11 May 1918, the several organizations formed a permanent union to be known as the National Association of Employment Managers.

Employment Manager's Course.—The success of the employment manager in promoting production and standardizing industrial employment came to be so generally recognized that in 1918, as one of its war measures, the United States government established an intensive course in employment management, under the direction of the employment management division of the War Industries Board. The first course was inaugurated at the University of Rochester, where the first class graduated on 9 May 1918, and courses have since been established at Harvard, in connection with the Massachusetts Institute of Technology, Boston; Columbia University, New York; Carnegie Institute of Technology and the University of Pittsburgh, Pittsburgh; the Case School, Cleveland; the University of Washington, Seattle, and the University of California, at Berkeley. The courses of instruction occupy from six weeks to two months, and the classes, which are conducted by the foremost employment executives and industrial authorities in the country, devote themselves to such subjects of study as the following:

Functions and organization of an employment department; labor turnover, its causes and how to reduce it; character analysis; science of hiring, transfer and promotion; discharge; following employees' progress in the plant; educational work for employees; recreational work for employees; safety and sanitary engineering; method of wage payment; bonuses and profit sharing; hours of labor and fatique; industrial organization; sources of labor supply; public employment offices and methods of cooperation with them; labor statistics; causes of labor unrest; employers' liability and compensation; history of the labor movement, etc.

In outlining this course of study, the War Industries Board stated that the introduction of the employment manager into industry and the standardization of the services of an employment department is one of the greatest movements taking place in the manufacturing industry in this country, and employers of labor, particularly those having war contracts, were urged to suggest men or women from their organizations as candidates for the government courses.

JOHN R. MEADER.

EMPLOYMENT MANAGEMENT. Employment management embraces the work of recruiting, placing, retaining, and discharging the working force. This modern method of handling personnel problems was inaugurated by one or two employers of labor a comparatively few years ago, but the plan quickly demonstrated its value so clearly that it has now come to be quite generally adopted, not only in important industrial plants but by many large mercantile establishments and financial institutions as well.

The development of the present system of employment management began when large em-
mployers commenced to realize the fact that the greatest labor problem confronting industry was that of the proper handling of the working organization. The studies of the efficiency engineer and the science man to take over the plant, to operate effectively, must have something more than the number of hands required to run the machinery. If the highest possibilities of production were to be reached it was necessary to obtain and retain the good will and active co-operation of the men. The shop was similar to that in the family, but with the growth of industry came the development of the impersonal corporation and the loss of the human touch that had been so largely the source of the loyalty and friendship that existed between the "boss" and the worker. The great industries, therefore, found themselves face to face with the necessity of finding a substitute for the human relations which they had sacrificed and employment management, under a trained director of personnel, is their solution of this problem.

The primary purpose of employment management is to stabilize the working organization by reducing the number of men employed to maintain the necessary average working force, or, in other words, by reducing the labor turnover. To accomplish this end, employment management includes many and varied functions, ranging from the preliminary work of securing the help to the larger social problems involved in guiding and protecting them.

The functions of the department devoted to employment management begin with the selection of the right type of person for the "job" to be performed and this naturally includes an analysis and classification of the various tasks, as it is necessary that all prospective employees shall conform as closely as possible to the specifications of the "job-analysis." Once employed, the new operative, if he is a "learner," may be placed under competent instruction, preferably in a segregated school under a specially trained teacher. Close watch must be kept upon his progress, not only during this period of instruction, but during the length of his stay with the concern, in order that he may find no occasion for discontent or discouragement in the fact that he does not profit in proportion to the degree of efficiency which he attains. The performance of these functions, as well as those of a so-called "welfare" character (which are just as close allied to the work of employment management), require close personal contact with the workers, the ability to inspire confidence in the genuineness of the firm's intentions to deal justly with its individual employees and the careful maintenance of a system of records through which thorough supervision may be kept over the development of the plant personnel.

Broadly stated, these are the functions of an employment department. Described in detail, the scope of employment management embraces:

1. Maintaining a Constant Survey of the Labor Market and a List of Available Applicants for Positions.—Both are necessary if the organization is to be maintained at its normal standard. It is assumed that an employment department will receive advance notice from foremen of places to be filled and the job will be given to the men that can best do it. The employment department is provided with the names of two sources of supply: the outside labor market or prospect files built up from information obtained from voluntary applicants or from inside the organization, through personal recommendations by operatives already employed. To accomplish this purpose, however, the data must be easily available, which means that the information must be secured and properly filed in anticipation of every possible demand.

2. Hiring the Right Type of Employees.—To meet this demand, the employment department must not only be familiar with the character of every operation to be performed but must employ new operatives in conformity with technically correct "job specifications" for all classes of help required. To assure the best results in hiring, all applicants should be carefully interviewed as to domestic relations and individual responsibilities as well as to records of previous employment. While employment managers differ in their opinions regarding the value of references, the data supplied in a statement of previous employment usually affords an illuminative record of the man's accomplishments and most authorities are agreed that knowledge regarding an applicant's personal responsibilities is important in preventing the possible hiring of men for the minimum wage, that is, for a smaller wage than that on which they are accustomed to live, as men employed at less than they have previously earned are likely to regard the place as a make-shift rather than a permanent position. The opinions of employment men also differ regarding the value of character analysis based upon personal appearance or psychological tests, although there is a general agreement that tests are advantageous in the case of operatives who are to perform tasks requiring certain well-established qualifications.

3. Examination of Applicants.—Many important concerns now require a physical examination of applicants before actual employment, not only as a safeguard against conditions for which the firm might be held responsible under the compensation laws (such as hernia, etc.), but also as a protection for other employees against possible infection.

4. Introduction of New Employees.—The introduction of the newly employed worker also devolves upon the employment department. If the employee is a "learner," he is introduced both to the instructor and to other members of the "school"; if a skilled, or semi-skilled, operative, to the foreman and the operatives working near him. An "introduction" must also include an explanation of the policies and regulations of the concern, a description of its welfare activities and full information regarding the location of such important points as the emergency hospital, lunchroom, lockers, washrooms and toilets, stockroom, etc. Lasting impressions of a plant are frequently gained during the first days of employment, and the frequency of production which shows a personal interest in the welfare of a new employee is of incalculable value.
5. Following up Employees' Performances. — The work of following up the performances of new employees is one of the most important functions of employment management. In the schools, it assumes the responsibility of determining when the "learner" has attained a sufficient degree of fitness to graduate as a skilled operative; with all operatives, the "follow-up" covers such tangible evidences of efficiency as: (a) General conduct; (b) Earning capacity from week to week; (c) Absences and tardiness; (d) General health and accident rates; (e) Regular ratings as to efficiency in: (1) Workmanship, covering both quantity and quality of product as well as record of waste; (2) Reliability and industry; (3) Attitude toward work. A record of this character is of great value to the employment director in many ways. It enables him to see that "learners" are transferred to regular "jobs" as soon as they are capable of assuming greater responsibilities; it suggests a program from which a careful study of the average earnings of the employees can be made, both as a check upon possible decreases in productive ability of the individual worker and as an indication of rate-changes, transfers or promotions that may have become desirable. From this record may be secured the facts regarding tendencies toward absences and tardiness that require further investigation.

6. Investigations.— Much of the success in employment management depends upon the thoroughness of the department's investigations. All instances of chronic tardiness should be investigated and, if possible, a means should be found to remedy this defect. Absences must also be investigated and in each case a record should be made of the causes. In cases where the absence is due to illness, injury or personal troubles, advice can often be given and material assistance afforded, and where the failure to report is the effect of a misunderstanding that has inspired the desire to "quit," a personal interview at this early stage in the withdrawal from the firm, fully as much depends upon the character of the employment management, as it is essential that both applicants for "jobs" and those actually working in the plant shall be pleased and impressed by the treatment they receive at the hands of the employment department. This means (1) All applicants must be handled promptly and treated courteously, applications being taken and filed for future reference where there are no positions to be filled; (2) Employees shall invariably be treated courteously and justly and shall be advised and assisted in every way practicable; (3) Even those who are discharged, or who are leaving the concern because of dissatisfaction, shall be treated so fairly and courteously that they will go away with as agreeable an impression of the firm as possible.

7. Arrangement of Transfers.— Transfers in an industrial plant usually are made for one of two reasons: (1) Because the individual worker has been found, in cases under assuming greater responsibilities, and (2) because an operative has failed to "make good" in one "job" but is to be given a chance to perform a different task for which he seems to be better fitted. The practice of filling the higher positions by promotion has proved so valuable in developing an espirit de corps that this rule should never be violated except in cases where there is no material available within the plant, while the plan of transferring the more inefficient operatives, instead of discharging them has been proved to be a valuable change in practice by many important concerns. It is one of the vital functions of employment management to see that promotions are given to those deserving them and that an operative is not considered worse than a round peg in a square hole, is put where he may perform effective service.

8. Power of Discharge.— In plants where the hiring and placing of workers is delegated to an employment department, the final discharge of an operative becomes one of the functions of employment management. In concerns where this rule is in force the authority to discharge unconditionally does not rest with the foreman. A foreman usually is given the privilege of seeing when a man shall not continue to work in his department but the authority to decide that an operative shall not be permitted to work in any other part of the plant is delegated to the employment manager, subject, of course, to the approval of the plant manager. To perform these duties successfully and without weakening departmental discipline requires that the health and accident records, as handled diplomatically and each case upon its own merits. In fact, where these methods are pursued, the employment manager becomes a man who sits in judgment upon all questions of differences between the employees and their superiors, who is entrusted with the important duty of seeing that the foreman is protected in the exercise of all just methods of directing his help and that every employee is assured a square deal.

9. Maintaining the Reputation of the Firm. — If a plant is prosperous and obtains and retains its workers, it is essential to the character of the employment management, as it is essential that both applicants for "jobs" and those actually working in the plant shall be pleased and impressed by the treatment they receive at the hands of the employment department. This means (1) All applicants must be handled promptly and treated courteously, applications being taken and filed for future reference where there are no positions to be filled; (2) Employees shall invariably be treated courteously and justly and shall be advised and assisted in every way practicable; (3) Even those who are discharged, or who are leaving the concern because of dissatisfaction, shall be treated so fairly and courteously that they will go away with as agreeable an impression of the firm as possible.

10. Management of Welfare Activities.— The various welfare activities of the firm, including those of a social character, must be handled prompt and treated courteously, applications being taken and filed for future reference where there are no positions to be filled; (2) Employees shall invariably be treated courteously and justly and shall be advised and assisted in every way practicable; (3) Even those who are discharged, or who are leaving the concern because of dissatisfaction, shall be treated so fairly and courteously that they will go away with as agreeable an impression of the firm as possible.

11. Keeping Labor Records.— In order that these various functions may be performed effectively, it is necessary that a system of department records shall be adopted and carefully kept. These include records of (1) Applications for employment and data regarding condition of labor-market. (2) Employment cards, containing such information as: Name and address, date of application, place and date of birth, date of arrival of foreign-born immigrant, degree of education, language spoken, domestic condition and record of previous employment. (3) Physical examination. (4) Daily report of those tardy and absent, with causes. (5) Labor turnover sheet, detailing the number of "quitting" or discharged both by departments and "jobs," with such facts as (a) reason for withdrawal, (b) length of service, etc. See Labor turnover sheet.

In plants where these methods have been...
EMPORIA—EMS DISPATCH

EMPORIA, Kan., city and county-seat of Lyon County; on the Neosho River near its junction with the Cottonwood, in the central part of the State, and on the Missouri, Kansas and Texas, and a division point of the Atchison, Topeka and Santa Fe and other railroads; 60 miles southwest of Topeka. It is the commercial centre for a large section of country devoted to farming and dairying and to the fattening of western range cattle for the eastern market. Emporia has a thriving jobbing and enveloping trade, the enveloping industry manufactures, including marble and iron works, carriage and canning factories, woolen mills, corrugated metal works, and flour and gist mills. It has three banks, with a combined capital of over $250,000 and doing a large annual business and daily and weekly newspapers. It has a business college, railroad and public libraries, nine school buildings, 11 churches, and many handsome business buildings and private residences. It is the largest town in Kansas that ever has permitted a saloon to open within its limits since the passage of the prohibitory law in 1880. The city adopted the commission form of government in 1910. Emporia was founded in 1856 by P. B. Plumb, afterward United States Senator, and a group of pioneers from the Middle States; it was incorporated in 1870. Pop. 12,329.

EMPYEMA, ēm-pē-ě'ma, a collection of pus consequent on pleurisy. True empyema is pus secreted from the pleura; the false, when an abscess of the lung bursts into the cavity of the chest. When the quantity of fluid is so large as to cause great dyspnea and endanger life, it must be let out by tapping the chest.

EMPYREAN, a word used by the ancient Greek philosophers to designate the highest region of the heavens, where the purest and most rarefied elements of fire and light exist; and by mediæval poets to indicate the ninth heaven, the home of the blessed. In modern poetry the empyrean is merely the over-arching dome of the heavens.

EMPYREUMA, ēm-pē-roo'ma (Gr. ἐξ ἀθάνατος, ék athenátoς), the smell acquired by organic matter when subjected to the action of fire, but not enough to carbonize it entirely. The products of imperfect combustion, as from wood heated in heaps or distilled in close vessels, are frequently distinguished as empyreumatic.

EMS, ēmz, Germany, a celebrated watering place in the Prussian province of Hesse-Nassau; on the river Lahn. The environs are beautiful. As early as 1584, it was a town of resort. As a watering-place. The mineral waters at Ems are warm—from 70° to 133° F.; they are of the saline class, containing large quantities of carbonic acid gas, and are used with much effect in chronic catarrhs, pulmonary complaints and some other diseases. The history of the town dates back to the 9th century, and the lead and silver mines have been worked a number of years. Since 1865 the fall of the springs has overshadowed its industrial and trade advantages. It was here that the memorable interview between the king of Prussia and the French ambassador, Benedetti, took place which formed the prologue to the Franco-Prussian war of 1870-71.

EMS, river of Germany, which rises at the southeast extremity of the Teutoburger-Wald, in Lippe-Detmold, flows northwest through Rheinish-Prussia and Hanover, and into the Dollart, near Emde; length about 210 miles. It drains an area of about 4,600 square miles. Its chief affluents are the Aa, the Haase, the Hessel, and the Leda, all from the east. It is navigable as far as Papenburg for light vessels, but it supplies water to numerous canals, which are used for both irrigation and navigation. In 1818 it was connected by a canal with the Lippe, and thus with the Rhine, and its importance has been greatly increased by the opening of the Dortmund-Emms and other canals.

EMS DISPATCH. The historical designation of the communication which precipitated the Franco-German War of 1870-71. The history of the famous Ems telegram, with the texts of the original dispatch, is as follows:

Isabella, Queen of Spain, deposed in 1868, formally abdicated 25 June 1870, and the Spanish throne was thus left vacant. On 5 July the foreign governments were notified, and the fact was generally made known that Prince Leopold of Hohenzollern, evidently with the approval of the King of Prussia, had consented to become a candidate for the vacant throne. The announcement created intense excitement in France. Seven days later the withdrawal of Prince Leopold's candidacy was made public.

The next day, 13 July, the French ambassador, Count Benedetti, forced himself upon the presence of the King of Prussia at Ems and insisted that the king make a formal and specific declaration that no Hohenzollern prince would be permitted to accept the throne of Spain. The king declined to listen to such demands and broke off the interview. When the account of what happened was sent to Bismarck, it was with permission to "use" it. Bismarck used it by giving to the press abridged features of the French demand, with the result that the Germans were inflamed against France, France declared the nation insulted, and war was declared. The details are shown in the texts, which follow:

This is Abeken's telegram of 13 July 1870 to Bismarck:

*His Majesty the King writes to me: Count Benedetti caught me on the Promenade and inopportune requested me to authorize him to send a telegram at once saying I bound myself not to consent to the Hohenzollern candidature should they recur to it at any future time; this I declined, and rather sternly at last. One cannot enter à tout jamais into such an engagement. I, of course, told him that I had no news, but as he got his from Paris and Madrid sooner than I did, he must understand that my government was taking no part in the matter."
“Since then his Majesty has received a letter from Prince Karl Anton. His Majesty had informed Count Benedetti that he was expecting news from the Prince, but, having regard to the above mentioned clauses of his Majesty’s resolution, on the advice of Count Eulenburg and myself, not to receive Count Benedetti again, but merely to send him a message by an adjutant to the effect that his Majesty had now received from the Prince the confirmation of the news which Benedetti had brought him, added, that his Majesty had nothing further to say to the ambassador. His Majesty leaves it to the decision of your excellency whether this new demand of Benedetti and our refusal to comply therewith should not be forthwith communicated to our ambassadors and to the press.”

As issued by Bismarck, the telegram read as follows:

“Afater the news of the renunciation of the Prince of Hohenzollern had been officially communicated to the Spanish government to the French government, the French ambassador in Ems nevertheless demanded that his Majesty should authorize him to telegraph to Paris that his Majesty pledged himself for all future time never again to give his consent to the Hohenzollerns resuming their candidature. His Majesty has therefore declined to receive the ambassador again and has informed him through the adjutant that he has nothing further to communicate to the ambassador.”

Consult Barrett-Lennard (Mrs.) and Hoper (Mrs.), Bismarck’s Pen: ‘The Life of Heinrich Albarch’ (London, 1911).

EMSER, Ėmˈzər, Hieronymus, German Roman Catholic theologian; b. Ulm, 26 March 1472; d. Dresden, 8 Nov. 1527. In 1502 he became professor at the University of Erfurt, where Luther is said by him to have been among his pupils. In 1534 he established himself at Leipzig, where he also lectured at the university. He served as secretary to Duke George of Saxony, who sent him on a mission to Rome, in order to obtain the canonization of Bishop Benno of Meissen. With Luther and the other pastors of Wittenberg he was on good terms until the disputation of Leipzig in 1519, from which time he made, in union with Dr. Eck, incessant endeavors to oppose the increasing influence of Luther and the progress of Protestantism. The German translation of the Bible by Luther was attacked by him as erroneous, on account of it being in forbidden in Saxony by Duke George. Emser then himself published a translation of the New Testament into German, made from the Vulgate (1527). He also wrote ‘Regia S. Benonis,’ as he ascribed to Saint Benno his recovery from a severe sickness.

EMU, the only representative of the family Dromaiidae, and with the cassowaries the Australian representatives of the order Struthiones. In size the emu ranks between the African ostrich and the rhea of South America, the African bird being seven feet in height and the emu five. In general appearance and form it is more bird-like than either of the others. Like the cassowary of northern Australia, its head and neck are feathered, and the back is gracefully arched. Its body is covered with a rich brown plumage; and its tail has a rich ruff, it has three toes on the foot, while the African ostrich has but two. The emu is a bird of the plains, where it feeds upon fruits, herbs, and roots. The nest is scooped in the sand, and the number of eggs is six or seven, of an attractive green, each measuring five inches in length. It is esteemed for its plumes and feathers, and the flesh is eaten only by the natives. Coursing the emu has been carried to such an extent that the birds of New Holland, once spread throughout the whole continent, are now in many parts exterminated. It is valued by the natives chiefly for the fat beneath the skin which contains great quantities of oil. The emu utters a faint booming noise and sometimes a shrill piping note. In confinement it is found to be tractable, and is readily tamed.

EMUCKFAW AND ENOTACHOPCO, Battles of, in the War of 1812. After the battle of Talladega (q.v.), the volunteers mutinied and on 10 Dec. 1813 demanded their discharge, but on 14 Jan. 1814 Jackson was reinforced by 900 sixty-day militia and therefore decided to co-operate with Gen. John Floyd (q.v.) who had marched from the Tennessee to ATNCESS, aiming at Emuckfaw, a town 40 miles north of Tuckabatchee (q.v.). On 20 January with 930 militia and about 200 Creeks and Cherokee, he camped on Enotachopco Creek, 12 miles from Emuckfaw, where on the morning of the 21st he was attacked by the Indians but repulsed them with great slaughter and drove them nearly two miles from the field. On the 23d Jackson began the return journey to Fort Strother but the next day, while crossing Enotachopco Creek, the Indians attacked and threw his force into disorder, many of the troops fleeing. But Colonel Carroll with 25 men maintained their ground and, rallying the fugitives, Jackson soon turned defeat into victory. His loss in the two fights was 24 killed and 71 wounded, and that of the Indians 200 dead and many wounded. On 27 January he returned to Fort Strother where he remained until the battle of Horseshoe Bend (q.v.). Floyd in the meanwhile having fought the battle of Tuckabatchee (q.v.). Consult Adams, Henry, ‘United States?’ (Vol. VII, pp. 247-249); Fay, General, ‘His Memoir’ (pp. 170-178); Lossing, ‘War of 1812’ (pp. 773-777); Wiley and Rines, ‘The United States’ (Vol. V, pp. 452-453); biographies of Jackson by Parton (Vol. I, pp. 487-494), Buell (Vol. I, pp. 318-321). Frost: (pp. 205-223)

EMULSIN (β-glucose), a mixture of closely related enzymes which hydrolyze the β-glucosides. It contains a β-glucose proper, a cyanase, an amygdalase and a lactase. It is found in many seeds and especially in the bitter almond, but also in the sweet almond and the kernel of the cherry pit. The addition of a small amount of water to this seed develops the characteristic reaction and the formation of the oil of bitter almonds, containing the deadly poison prussic acid in solution. Emulsin is exceptionally wide in its action, owing probably to its compound nature. But it is commonly considered as a unit, and a special enzyme for β-alkyl glucosides; and all glucosides which are hydrolyzed by it are regarded as derivatives of β-glucose. Some of its properties are erratic: it hydrolyzes isomaltose, but synthesizes glucose to maltose the rhea and cassowary, it has three toes on the foot, while the African ostrich has but two. The emu is a bird
EMUS (emu goose), a mixture of elongated ovals which hydroxylates products. It contains a paraffinic component, an anhydride and a ketone, found in many seeds and especially in the Emu food. But also in the water-soluble fraction of the emu. The additional amount of water to this solid describes the reaction and the formation of oil of bitter almonds, containing the disaccharide, and is not found in the Emu food. For this reason, using paraffins is essential. But this mixture, it is considered as a unit, and a specific enzyme catalyzes hydrolyses and all the reactions of it are considered as direct, basic processes. Some of its properties are quite different than those of fat, but some are close to those of fat, which hydroxy substes oil and sometimes close to those of a bird.
EMU (Hippalectry Uniappendiculatus)
ferin, daphnin, dhurrin, gentiopecin, helicin, incarnatin, indican, mandelonitrile glucoside, melatian, oleropein, picein, praluraarm, salicin, sambunigrin, syringin, taxicatin and veratinalin, and the synthetic β-glucosides.

Emulsion is prepared by digesting the oil-free pulp of ground sweet almonds with a little toulene or oil of cloves, and keeping it in an overnight. The whole is then put into a cloth bag and the liquid pressed out. This is treated with acetic acid, drop by drop, until the protein has been all precipitated. The clear liquid is treated with alcohol in repeated small quantities until no more precipitate falls. Pouring off the liquid the precipitate is hurriedly washed with absolute alcohol and ether to remove all moisture. It is then thoroughly dried in a vacuum to a soft white powder. Consult Armstrong, E. F., "Lactose, Maltase and Emulsion" (London 1912).

EMULSION, the term applied to those preparations in pharmacy in which oily substances are suspended in water by means of gum, sugar, carrageen, etc., called emulsifiers. In general it will be found that the bulk of the emulsifier must be first be taken, while the oil should only be added little by little, rubbing together in a mortar, and taking care that it is completely absorbed or emulsified before further additions. Should too much be added, the effect is to throw out most of what has already been incorporated; it is then practically impossible to remedy the error. The emulsion of cod-liver oil is familiarly known. Milk and the yolk of eggs are natural emulsions. The name is also given to suspensions in water of certain insoluble substances, such as resins. These being reduced to impalpable form are mixed with a syrup of gum or sugar, or other viscid fluid thick enough to prevent their settling. A familiar instance of this form of emulsion is common coal tar, which appears black because of the particles of free carbon suspended in the colorless pitch.

ENAMBUC, ə-nəm-búk, or ESNAMBUC, Pierre, French navigator: b. Dieppe about 1570; d. Saint Christopher, W. I., December 1636. Being of an adventurous spirit, he sailed from Dieppe in 1625 in a brigantine of eight guns, for the Antilles. He landed in the island of Saint Christopher on the same day with a party of English colonists, with whom he divided the island, and, until his death, held the French half of the colony with extraordinary tenacity. In 1635 he took possession of Martinique, in the name of the king of France, and founded the town of Saint Pierre (q.v.).

ENAMELS AND ENAMELING. The term enamel is used for certain siliceous compounds employed for coating metals. They are, in every sense of the word, glass, either transparent, opaque, white or colored. The art is a very ancient one, some claiming it originated with the Scythians, who are said to have introduced it into China during the reign of a certain Emperor Thawonti, but India was acquinanced with the Chinese manner. Extant evidence exists that the ancient Egyptians, Phoenicians and Assyrians used enamel coating in the decoration of jewelry, and of the clay beads and scarabs of the Nile-dwellers in our museums many are covered with colored glass. The subject of enamel work on the precious metals is discussed in another article (see Art ENAMELS), so we will confine this article to the technical side of enamel production and the industrial utilization of enamel.

Raw Materials.—The ingredients used in the production of the different kinds of enamels are felspar, quartz, fluor spar, borax, boric acid, soda, potash, salt petre, cryolite, clays, ammonium carbonate, stannic oxide and water. The coloring agents used are cobalt oxide, limonite, iron oxides, chromic oxide, cupric oxide, etc. The felspar composition most desirable consists of siliceous earth 85 per cent, per cent, alkalis 16 per cent. For the creation of white enamels it is essential that the felspar shall be as free from iron oxide especially, as possible. Quartz must be pure but it is frequently replaced beneficially with a fine white river sand, which is pure quartz. Fluorspar or calcium fluoride of the purest quality only can be used, for white enamels especially. The borax needed for enamels is of the monoclinic system of crystallization (containing 10 molecules water of crystallization) and forms the regular system, which contain only five molecules water. It is used as a flux or accelerator of fusion. Boric acid functions the same as borax but the former is more frequently used than the latter. Soda and potash have identical action in enamels and their presence heightens the lustre if it is not used too freely. The soda of commerce, being cheaper, is mostly employed; it is first calcined to obtain its anhydrous condition, then finely powdered. Salt petre (nitre) used is the sodium variety, being cheaper than the potassium salt. It is used chiefly to decolorize; little or none at all is needed in the blue enamels. Cryolite used in the enamel industry may be either the natural or the artificial. This sodium-aluminum-fluoride is utilized for its double reaction of acting as flux and creating opalescence. Ammonium carbonate is supposed by some to be a valuable ingredient to inhibit cracking or crazing of the enamel in firing on account of its making the substance more uniform. Some authorities, however, declare its use a waste of money and useless. Stannic oxide is expensive with the present prices of tin but its use continues as a necessity after many attempts with substitues. Care must be taken in maintaining the purity of the metal while in the oxidizing process so that small black spots will appear in the baked enamel from impurities or may occur from particles of metal not having become oxidized. This chemical produces perfect opacity, which antimony substitutes do not; unless sufficient be used to cause other defects. The poisonous character of antimony has also caused its use to be forbidden in many countries. Lead oxide lends a wonderful brilliancy to enamels; it acts also as a flux of great power. The lead oxides were formerly used considerably on earthenware utensils to assist the glaze, but long since they have been eliminated by law on account of their poisonous nature, their solubility rendering them extremely injurious when used on vessels for cooking. Extant evidence exists that the ancient Egyptians, Phoenicians and Assyrians used enamel coating in the decoration of jewelry, and of the clay beads and scarabs of the Nile-dwellers in our museums many are covered with colored glass. The subject of enamel work on the precious
Aside from its use in pigment cobalt oxide has the physical value of adhesiveness to sheet iron through its coefficient of expansion being the same as that of iron. Hence, it is an ideal ingredient for the enamels used in cooking utensils. Perhaps it is here necessary to the uninstructed to state that one of the first requirements in an efficient enamel body is that it shall adhere to the metal under the stress of changes of temperature. On account of this the cobalt nickel oxide is much used, through its considerably lower price. Limonite is a peroxide of manganese (called also pyrolusite) and is used in enamels to bleach out any impurity of tone in the white enamels. Additional proportions will produce dark violet (the noted manganese violet of the ceramist) and mixing a proportion of iron oxide with the limonite gives beautiful brown to black effects. Limonite in small proportions is sometimes blended with the French maroon (marron de Paris) to give a very rich blue of much brilliancy. Ferric oxide may be prepared to produce either a bright red or a reddish violet pigment according to the amount of heat applied in its manufacture. Chromic oxide produces a green tone; cupric oxide gives a dark-green and a bluish-green; again a bluish-green can be obtained by a combination of copper and cobalt salts or chromium and copper salts, varying from bluish-green to greenish-blue according to their equivalents in the mixture. The salts of chromium, cadmium, uranium and titanium can each be used in obtaining yellow enamels. Ferrous chromate produces a lovely brown; it is called Bronsgiart's brown, after the great French ceramic chemist. Nickel is used in obtaining a gray enamel. The salts of gold produce a beautiful rose enamel as well as the loveliest pink. But a far less expensive pink is produced by chalk, quartz, stannic oxide, borax and bichromate of potash mixed and heated to a frit, the pigment being dissolved in water to separate it from the solids. Antimony produces several yellows including the noted Naples yellow (lead antimonate) of the art porcelainists; they are, however, poisonous and forbidden in food utensils. The secrets of the manufacture of enamel are locked in the knowledge of those who have made the art a science. Operations only absolutely trustworthy operators are employed. The working formulas are kept strictly secret from all but the highest officials. From this point our description will be devoted to practices applied in the sheet iron and steel enamel industry. Every ingredient has to be dry and the degree of pulverization cannot be too fine to obtain a homogeneous enamel. The same care and time has to be given to the process of mixing the different ingredients. The French machine (mollettes) is employed for this. The various chemicals are kept in separate bins, and, in order to maintain secrecy, each ingredient is known only under a letter or number. Taking the raw material from the bins it is loaded into small cars termed "dolies," which are loaded to a height approximating the quantity, then run on to a scale and weighed and the excess shoveled back or fresh added. The precaution is taken to have the scale beam and its graduation marks invisible to all but the person who works it. With the completion of loading all the different materials in correct proportions in their individual "dolies" the material is mixed on a hard maple floor of the machine. First comes the coarser material at bottom, the finest on top. The mixture made, it is hoisted by an electric elevator and run to its bin and the process is renewed before, forms an ideal cream, again to be stowed in its special bin. By means of a traveling bucket holding the correct amount for a melt the mixed raw material (about 1,200 pounds) is carried to the blast furnace (rarely a crucible furnace). The kind of furnace commonly in American use is the same that is used in the manufacture of glass and is heated with natural gas or crude oil as the most economical fuel, though coal is used in the older factories. The furnace temperature has to be very carefully regulated as insufficient heat produces a slow melt liable to create a decomposition, whereas too high a degree may create combustion or some chemical reaction injurious to the outcome. Some authorities place 1,300° C. for a glaze heat and about 1,300° C. for deglaze, or in smelting, when the heat is permitted by the installation of pyrometers. A furnace can afford from seven to eight melts in 24 hours. As the ingredients fuse separately according to their different melting points, and as the melted mass is kept stirred lest they separate. The length of time needed for the smelt differs according to the enamels, a white fusing well at two hours while ground enamels and blues take from two-and-a-half to three hours, and so forth. The enamel is now a liquid glass, in which state it is drawn off by releasing a fire-clay plug located in the front of the furnace. The molten body flows into a tank of cold water and, with noisy reaction, the vitreous liquid is torn into shreds and small pieces with explosive violence, leaving minute fissures throughout the substance. Besides toughening the enamel body this so-called "quenching" assists in easing the next process, which is grinding. This grinding cannot be too fine, in fact the finer the resulting insinuatable powder the brighter the resulting lustre of the enamel. The suddenly quenched glassy mass is known as a "frit." During the grinding other materials are added, such as stannic acid for creating an opaque effect in the mixing operations of enamels in various colors. About 30 hours is required for grinding in the large ball mills. The latter are cylindrical, about five feet in length and have a diameter of about six feet, and are lined with porcelain bricks. To the frit, which should contain about 50 per cent of water, is added a small percentage of white ball-clay. About 2 per cent zinc oxide improves a white. The clay addition is made to help hold the other ingredients in suspension, hindering them from sub-siding or escaping gravities; it also creates opacity, increasing at the same time, the needed quality of elasticity of the enamel. Other additions are added in proportions in accord with the secret formulae, such as sal-ammoniac, ammonium-carbonate, magnesium-chloride, burnt magnesia, chloride of sodium (table salt), borax, soda, etc. The ground mass should reach the consistency of a rich cream, when it is poured into tanks and left to mature for a week or more.

Formule—A German formula for a white enamel is (in kilogram equivalents) borax, 132; quartz, 152; felspar, 130; soda, 25; salt petre, 6; cryolite, 78; fluorspar, 3; magnesia, 6. An acid-resisting enamel white is borax, 74;
felspar, 100; quartz, 115; cryolite, 47; stannic oxide, 40; fluor spar, 6; soda, 20; saltpetre, 10; magnesium carbonate, 1; pure fused glass, 4; lead fluorspar, 53; clay, 12; calcspars, 5; A blue enameling formula is borax, 600; alumina, 36; felspar, 101.0; soda, 62; natural cryolite, 24.0; saltpetre, 3.0; fused enamel fragmentary, 400.0; cobalt oxide, 4.0; limonite, 3.0; ferric oxide, 0.3; uraniferous black, 9.0; alluvial, 3; feldspar, 101.0; soda, 62; ferric oxide, 8.0; cobalt oxide, 2.0; smalt, 16; limonite, 16.

The Metal and Treatment.—In the production of steel enamelled kitchen utensils the metal should be as free as possible from sulphur, carbon, silicon or phosphorus and with a general manganese content of about 0.2 per cent. The sheets (oblong or square) run from 27 to 20 gauge. Applying as little heat as possible, they are circled, stamped and spun, using a lubricant that is easily eliminated. A pickling process must, of course, cleanse the metal from impurities before the shaping is done. The additional trimmings (ears, handles, etc.) should be weldod on because the enameling of riveted parts is a difficult process.

The Process.—The operation as carried on in American factories is clearly described by R. D. Landrum, an expert. This work starts in the "dipping room," where the liquid enamel is placed in tanks of dish-pan form sunk into tables. The operator, the "slusher," dips the stamped steel vessel (which has been previously cleansed of all grease and impurities) into the enamel. Coming out of the immersion the vessel is covered with a film of the wet enamel, any drip or excess is eliminated by the slusher gently swinging the object, when it is placed, bottom down, on three metal points that project from a board. After several vessels are placed on the board it is set in a rack, and, when dry and the rack full, they are conveyed to the furnace room, where a bank of fuel set fires them. The temperature (about 1,000° C.) here fuses the minute powdered particles of enamel together into a glass coating covering the entire vessel, a process requiring but three to five minutes. Other colors are used, over this ground coat. In a three-coat piece we wish, perhaps, three coats of white on the inside and turquoise-blue outside. The ground coat enamel having dried and been passed through the oven comes out almost black, from the cobalt and nickel oxides, and the piece is left to cool. The slushing room operator now gives the vessel an immersion in white enamel and adds a black "bead" or edge on the rim. This second coat still shows up grayish as the first coat penetrates through the glaze firing, so it is subjected to another dip at the hands of the slusher in the white enamel. A spray of blue-green enamel is applied to the outside, before drying, with the aid of a wire brush, or the more up-to-date machine which acts as an atomizer. The vessel is next dried and fired again in the oven, leaving turquoise blue spots outside on the white background. The next process is the assorting of the finished wares into "firsts," "seconds" and "thirds" or job lots, according to their perfection or defects. Imperfections in enameling of the original vessel may have caused minute spots to appear on the surface, due to rust or dirt. This defect can sometimes be remedied by filing the spots off, or subjecting them to a sand-blast, and giving the vessel another coat of enamel. The discovery, or invention, of applying enamel coatings to metal ware such as kitchen utensils, bathtubs, etc., in a small way, in the 18th century, and the use of tin plates and earthen utensils which had been used by our fathers was indeed opportune, for the rising price of the metal had made the process of tinning so exorbitant that the industry was in real distress, with the certain prospect of the price of tin advancing to much higher proportions. The iron-enamel industry has extended its lines into sanitary ware, hygienic implements, chemical apparatus and numerous other branches. The growth of the industry, starting principally in France and Germany on a large scale, has extended to the United States, all in the course of about 25 years. The German output, by 1909 already, was 90,000,000 kilos, employing a capital of near $15,000,000. In 1914 the industry in Germany and Austria-Hungary employed in the neighborhood of 60,000 wage earners. In the United States the Census of Manufactures (1914), gives us the following interesting statistics of the sheet iron and steel enamel industry (in percent of total), employing 28,731 operators. They produced goods valued at $68,979,005, and had a payroll of $15,242,586. Consult Gruenwald, J., 'The Theory and Practice of Enameling on Iron and Steel' (translation by H. H. Hodgson, London 1900); id., 'The Raw Materials for the Enamel Industry and their Chemical Technology' (London 1914); Landrum, R. D., 'Enamels' (Cleveland 1918); Millenct, L. E., 'Manuel pratique de l'émaillerie sur métaux' (Paris 1917).

Clement W. Combe.

ENARA, a-ná'rá, or ENARE, a-ná'rá, a lake in Finland; area, about 145 square miles. The outlet is Patsjoki River, which flows into the Arctic Ocean. A town of the same name, at the southwest extremity, is inhabited chiefly by fishermen.

ENAREA, é-ná'ré-á, a country of the Gallias, south from Abyssinia, between lat. 7° and 8° N., and long. 35° and 37° E. In the valley of the Gibbii, immediately beyond Sakha, the chief town of the country, are extensive plantations of coffee, which, along with ivory, is largely exported. The inhabitants are of the most civilized of the Gallas, and show much skill in manufactures. Pop. about 40,000.

ENARGITE, en-ar'jit, a native sulpharsenate of copper, of which it contains 48.3 per cent. It constitutes an important ore of copper and is found in cavelable-granular masses, also in orthorhombic crystals. It has eminent prismatic cleavage, a brilliant metallic lustre, and grayish-black color and streak. Its hardness is 3 and specific gravity 4.44. It is common in Chile, Peru, Mexico, South Carolina, Colorado, Utah, California and Montana.

ENAUUL, é nó, Louis, French novelist: b. Isigny, Calvados, 1824; d. Paris 1900. He used the pen-name "Louis Vermond." He wrote many novels and books of travel, including among them, 'Promenade en Belgique et sur les bords du Rhin' (1852); 'La terre sainte' (1854); 'Considérations sur la Terre' (1855); 'Voyage en Pologne et en Norvège' (1857); 'La Méditerranée, ses éles et ses bords' (1862); 'L'Amérique centrale et meridionale' (1866); 'Paris brulé par la Commune' (1871);
ENCENIA, én-sé'ní-a, or ENCENIA, a name given to the feast in commemoration of the dedication or consecration of Christian churches. In early times it was applied to the feast in honor of the founding of a city as well as in honor of the founding, or taking possession, by dedication or consecration, of churches. The custom of observing the anniversary of the consecration of a church or cathedral dates from the time of Constantine, when Christians were permitted more freedom of worship in the Roman territory; but the Jews before the coming of Christ solemnly dedicated their tabernacles; and in a certain sense, consecrated their houses of worship. The Christian ceremonies became very elaborate on these occasions and were disapproved and finally modified. The name is applied also to commemorating festivals in honor of the founders and benefactors of Oxford and Cambridge universities. At Oxford University "Consecration," or "Encenia," usually takes place the third Wednesday after Trinity Sunday. The oration in honor of the founders and benefactors is given in Latin.

ENCALADA, én-sá-lá'dá, Manuel Blanco, Chilean soldier and statesman: b. Buenos Aires, Argentina, 1790; d. Santiago, Chile, 5 Sept. 1876. He studied at Madrid, and in the Naval Academy at Leén, and after deserting from the Spanish ranks joined the Chilean revolutionary party, and served with distinction both in the artillery and in the navy. He became rear-admiral in 1819, and major-general of infantry in 1820; and in 1825 was appointed head of the army of Chile. He was for two months President of the republic in 1826, governor of Valparaíso 1847-52, and Minister to France 1853-58.

ENCAMPMENT, the military camp in its more comprehensive sense, including the occupants of the camp proper, as well as the physical objects created and arranged to shelter and provide for them. In military parlance the shorter term "camp" is used to embrace the whole significance of the term encampment — which therefore has hapsed to a greater or less degree into disuse, except among the romantic writers. See CAMP.

ENCAUSTIC. See MURAL PAINTING.

ENCAUSTIC PAINTING. See PAINTING, TECHNIQUE OF.

ENCAUSTIC TILES, a species of ornamental tiles made of a finer kind of clay than the ordinary tiles, but not so fine as porcelain. These are of two sorts: plain and figured. The plain tiles are sometimes square, but more frequently triangular or oblong. The latter shape renders possible a greater number of designs when the tiles are employed in a sort of mosaic work for the paving of churches, halls, etc. They are made by putting the colored clay into strong steel molds and subjecting it to a moderate degree of heat. The printed tiles are usually fitted accurately into the mold. The under surface of the tile is usually ribbed in order to afford a better hold for mortar. The clay for figured tiles is pressed into an iron mold, the bottom of which is formed of a plaster of Paris pattern, bearing the desired design. The pattern being removed, the depressions on the surface of the tiles are filled with colored clays, and the surface is then shaved to remove all superfluousities and ruggedness, leaving the pattern intact. The tile is then dried for two or three weeks and finally fired by being exposed to an intense heat for 60 hours.

ENCENTHE, én-sä'nt, in military engineering and in fortification, the continuous line of works which forms the main enclosure of a town or fortress. The term is also applied to the area within this line.

ENCELADUS, son of Tartarus and Gea, in Greek mythology, one of the hundred-handed Titans who made war against the gods. Jupiter slew him with a thunderbolt and burned him under Mount Ætna. The name Enceladus was given to the second satellite of Saturn, discovered by Herschel 28 Aug. 1789.

ENCEPHALITIS, an inflammation of the brain proper which may be acute, chronic, or latent, may be confused, and results from coexistent intoxications, or following any acute affection such as ulcerative endocarditis, rheumatism, mumps, etc. It is quite probable that many cases of acute encephalitis occur in children, resulting in the well-known picture of infantile hemiplegia. The symptoms are very indefinite. There is headache, vomiting, somnolence. There may be coma or delirium, the symptoms all pointing to acute inflammation of the brain. Acute encephalitis is usually fatal. In many of the insancies, as acute mania, delirium, dementia paralytica, there is a form of encephalitis usually present. Localized encephalitis usually results in abscess. See BRAIN, DISEASES OF THE.

ENCEPHALOCELE, én-sé'l-á-ló'sél, a hernia or a protrusion of a portion of the contents of the cavity of the brain through an opening in the skull beneath the skin. At least three different forms are described: Meningocele, when the dura mater alone protrudes from the cavity, forced out by the pressure of the cerebrospinal fluid; hydroencephalocele, in which the tumor consists of an encephalus; and encephalocoele, which is made up of true brain-tissue with more or less fluid surrounding it. Most of these tumors are of congenital origin, due to insufficient union of the bones of the skull; a few are acquired later in life. Surgical procedure is the only efficient mode of treatment.

ENCEPHALON, the contents of the skull. See BRAIN.

ENCHANTER'S NIGHTSHADE, a name common to plants of the genus Circaea, belonging to the family Onagraceae, of which there are three American species, C. lutetiana, C. pacifica, and C. alpina. The first is about a foot and a half high, and has delicate ovate leaves, small white flowers tinged with pink, and small roundish seed-vessels covered with hooked bristles. It abounds in woods from Nova Scotia to western Ontario, south to Georgia, and west to Utah. The second, C. alpina, is a low plant of the high mountains of the Pacific coast, and is a commonly found wildflower of the forests of Nova Scotia to western Ontario. The third, C. alpina, is a smaller and more delicate, is found in cold, moist shady woods throughout the north-
ern hemisphere. Both plants are common in Europe and Asia. Neither has any affinity with the true nightshades.

**ENCASING**, or CHASING, the art of enriching, beautifying and finishing ornamental designs in raised work upon metal surfaces, especially gold and silver. When these designs have received their general form by casting or hammering they are ready for the skilled hand of the artisan and his chasing tools. These are of a great variety of shapes and sizes, fitted to correspond with the minute details of the most complex work. Some are grooved or checkered at the ends, and some of the gravers and burnins are curved and blunt, while others taper to a needlepoint. The worker possesses a set of hammers, big and little, graded in size to suit any kind of tool. To offset his alternating task of punching and carving he employs sand bags upon which to rest his work. In order that the form of hollow articles may not suffer injury during the operations they are filled with a composition of melted pitch and brick dust or resin. Articles in copper and brass are sometimes filled with lead to give them firm support within. Fine steel blocks are often used to the same end. Excellent specimens of chased work are seen in pieces of ancient armor, and in vases and other ornaments in gold and silver-plate. Among the most beautiful are those executed by Venenuto Cellini (q.v.) in the 16th century. Bronze, richly wrought, has taken its place beside gold and silver work.

**ENCINA**, ën-thë'éñä, Juan del, Spanish dramatist: b. La Encina, Spain, 1469; d. there 1534. Little is known of his life; the probable facts are that he was educated at Salamanca, and in 1492 became a member of the household of the Duke of Alba, under whose patronage he began to write his plays. He was appointed mestro di cappella to Leo X at Rome, took orders and was ordained priest at Leon. His first volume of poems, 'The Song-Book' contains also a dissertation on 'The Art of Castillian Poesy.' His lyrics are full of charm and lively wit. He wrote 14 dramas, eight of which are shepherd-plays or eclogues; the rest are pieces for church holy seasons. It is to the former that he owes his fame. His plays are 'Tribadia;' or, the Sacred Way of Jerusalem' (1521). He has been styled 'The father of the Spanish drama.' His dramatic works were edited by Asenjo Barbieri, in 'Teatro Completo' (Madrid 1893); his lyrics by Francisco Asenjo Barbieri in 'Cancionero musical de los siglos XV y XVI' (Madrid 1894). Consult Diaz Jiménez y Molleda 'Juan del Encina en Leon' (Madrid 1909).

**ENCISO**, ën-thë'éñó, Martin Fernandez de, Spanish geographer: b. Seville, about 1470; d. after 1528. He came to America in 1500; practised law in Santo Domingo and supplied funds to Alonso de Ojeda for the colonization of Tierra Firme, the region about the Isthmus 1501. He received a grant in 1510 and founded the city Santa Maria la Antigua del Darien. His soldiers revolting, he was arrested by Vasco Nuñez de Balboa, and went to Spain, returning to Darien 1514 as alcalde, and opposing Balboa till the latter's unjust execution by Pedrorias Davila at Darien 1517. He was the author of 'Suma de Geographia, que trata de todas las partidas del mundo,' the first Spanish description of America which touched upon the difference in level of the two oceans.

**ENCKE**, ënké, Erdmann, German sculptor: b. Berlin, 21 Jan. 1843; d. 1896. He was a pupil of the Berlin Academy and of Albert Wolff, his first piece being a group entitled 'A German Struggling With Two Gauls.' He took a prize for the statue of Jahn in 1872, and was made professor at the Berlin Academy in 1883. His art was related to the school of Rauch, his temperament being at the same time realistic and poetical. Among his prominent works are a statue of the Great Elector, Frederick I of Brandenburg (Town Hall, Berlin); a colossal statue of Queen Louise of Prussia (Thieergartn, Berlin); and the sarcophagi of Emperor William I and Empress Augusta in the mausoleum at Charlottburg.

**ENCKE, Johann Franz, German astronomer:** b. Hamburg 23 Sept. 1791; d. Spandau, 26 Aug. 1865. He studied under the astronomer Gauss, at Gottingen; during the war of liberation (1813-15) served as a volunteer in the German army, and on the conclusion of peace was appointed assistant in the observatory of Seeberg, near Gotha. Here he calculated the orbit of the comet observed by Mechain, in 1786, by Miss Herschel in 1787, and by Plass in 1805–18. He predicted its return in 1822–25–28, and with each reappearance more data were afforded for computing its exact orbit, which, it was calculated, required three and a quarter years to complete. By comparison of the times of its earlier and later appearances, Encke was subsequently led to detect a gradual acceleration of its movement, amounting to about two and a half hours on each revolution. This acceleration he ascribed to a resisting medium, which sensibly affects the body of the extreme rarsity of this comet, which is transparent to its centre. The fame of his two publications 'Die Entfernung der Sonne' (1822), and 'Der Venusdurchgang von 1769' (1824), led to his appointment as director of the observatory of Berlin (1825) for four years, and till his death. Many of his works are contained in the 'Astronomische Jahrbücher' (1830–66), a publication during these years issued under his direction. His various scientific publications were collected and published as 'Gesammelte mathematische und astronomische Abhandlungen' (3 vols., Berlin 1889); and 'Astronomische Abhandlungen' (3 vols., Berlin 1886).

**ENCLOSURE**, or conventional seclusion of nuns who have taken solemn lifetime vows, is guarded very strictly by the laws of the Roman Catholic Church. The conventional seclusion of monks is less strict, the prohibition of converse with the outer world being in their case limited to the exclusion of women from the interior of the monasteries and rigid rules on the observance of silence. The Council of Trent forbids the convenant to continue for a short time on any account whatever save for a legitimate cause—a cause specified in the law—with the approval of the local bishop. And no person from outside, male or female,
ENCATITES, or old, high or low, lay or clerical, is to be admitted within the cloisters of a nunnery unless with leave in writing from the bishop or superior. By violation of this rule excommunication is incurred ipso facto. These rules, however, apply to regularly cloistered nuns who take solemn life-vows of detachment from the world: they do not apply to the houses or convents of religious who live in contact with the outside world, such as Sisters of Charity, of Mercy, Little Sisters of the Poor and the like. In such religious institutes the spirit of the Tridentine law governs, not the letter.

ENCATITES, en-krē-töt's, a division of fossil crinoids or so-called "stone-lilies" distinguished from the more common forms with angular stems (pentacrinites) by having stems whose cross section was circular or oval. The Derbyshire "birdseye" marble is noted for the vast numbers of encrinular remains it contains, the silicon skeletons appearing in the polished stone as if in relief. See CYNOD.

ENCYCLES, or letters encyclical, a circular letter. The word used in an ecclesiastical sense means a letter addressed by the Pope to all the bishops in the world who are in communion with him, in which he condemns errors prevalent in the world, or explains the line of conduct which Christians ought to take in reference to practical questions pertaining to faith and morals. Pius IX was the author of a renowned encyclical which noted 80 prime errors in current thought. Leo XIII issued a large number of encyclicals on such questions as, rights of labor, education, marriage, Bible study, and Papal infallibility. Certain trends of modern thought and actions. An encyclical differs from a bull or brief, in that the encyclical is to the bishops of the whole world, treats of matter of universal interest and is of concern to the entire Church. A bull or brief is determined by circumstances, is of a special nature and may be of particular value only to some locality. There is a difference in the form of an encyclical from that of a bull or brief, that is, in the seals used, the signatures and the introductory words.

ENCYCLOPEDIA, CYCLOPEDIA, or CYCLOPEDIA. This word, formed from the Greek en, in, kuklos, a circle, and pediein, instruction, but not a native Greek compound, originally denoted the whole circle of the various branches of knowledge which were comprehended in the seven liberal arts (the arsliberales of the Romans). The distinction between the words encyclopedia and cyclopedia is almost too trifling to be comprehended. At a later period the word was applied to every systematic view, either of the whole extent of human knowledge or of particular departments of it. The want of such general surveys was early felt; and as knowledge increased they became still more desirable, partly for the purpose of having a systematic arrangement of the sciences in their mutual relations, partly for the ready finding of particular subjects; and, for these two reasons, such works were sometimes philosophically, sometimes alphabetically, arranged. The spirit of compiling, if not of having a systematic arrangement, was soon led to attempts remotely allied to this; and Varro and Pliny the Elder, among the Romans, composed works of a similar kind.

The honor of undertaking encyclopedias on a regular plan belongs to the Middle Ages, which produced not only a large number of encyclopedias of particular sciences, called Summae or Specula (for example, the Summa Theologiae of Thomas Aquinas), but also a Universal Encyclopedia, such as had never been seen before. The indefatigable Dominican, Vincent of Beauvais, about the middle of the 13th century, exhibited the whole sum of the knowledge of the Middle Ages in a work—or rather three works—of considerable size—a real treasure to the inquirer into the literary history of the Middle Ages. One of the very popular works was the De Proprietatibus Rerum of Bartholomeus de Glanvill, an English Franciscan friar, which maintained its reputation from the year 1350 to the middle of the 16th century. In the 17th century various encyclopedic works were compiled, of which the Latin one of John Henry Alsted, Encyclopaedia vet Tomis distincta (Herborn 1620), a work in which the subjects are divided into 7 classes, and treated in 35 books. In 1674 appeared the first edition of Moret's Le Grand Dictionnaire Historique. In 1677 John Jacob Hoffman published at Basel his Lexicon Universale, the first work of the kind in which a summary of art and science was presented in dictionary form. In 1697 appeared Bayle's famous Dictionary Historique et Critique (Rotterdam, 4 vols.), a work which is still of great value. Among the greatest works of earlier date would have been reckoned the Bibliotheca Universale of Cornovoli, and it had been completed according to the original plan. It was to have appeared in 45 folio volumes, of which only 27 were published (Venice 1701-06). More successful, especially in being brought to a completion, was the Grosses vollständiges Universallexicon aller Wissenschaften und Künste (Grand Universal Lexicon of all the Arts and Sciences), commonly called Zedler's, from the person, a bookseller, who conducted it (Halle and Leipzig 1732-50, 64 vols.; Supplement 1751-54, 4 vols. folio). It has, on the whole, much merit. Lives of living men were included after volume XVIII.

The transition from the ancient type to the modern occurred about the middle of the 17th century and originated in the desire to make books of this kind more easy of consultation. This changed the arrangement of the material by classified liberal education by key words, names or special topics. The encyclopedia thus approached and was assimilated to the dictionary. The change was not confined to the form, for the alphabetical arrangement inevitably led to a change in the purpose and character of encyclopedic compilation, viz., that from the exposition of the system
of human knowledge to the mechanical arrangement of its contents. In this line of its development the *encyclopédia* became a work of reference in the strict sense of that word—a work for occasional use in which any particular topic or item of information desired can be found under the proper word in an alphabetical vocabulary. This practical aim and this method have, however, been adopted by modern encyclopedists. On the one hand, there has been a tendency to approach more and more closely to the dictionary type by increasing the number and variety of the vocabulary words, and correspondingly subdividing the material contained in the book; and, on the other, a tendency (traceable to the ancient systematic type) to restrict the vocabulary and combine the material as much as possible under comprehensive titles. In its extreme form the former tendency has given rise to the modern "encyclopedia dictionary," and the latter to encyclopedias which are little or nothing but aggregations of monographs.

In practice, however, encyclopedia makers incline more and more toward the adoption of the dictionary type, as better suited to the practice of the learned and literary worker. As such and as, in fact, essential to the adequate presentation of the vast accumulations of modern science, history and biography. An important characteristic of modern methods is the employment of a large corps of specialists as compilers and as editors. In general it may be said that no good general encyclopedia is now possible which does not include in its editorial staff a small army of men of science, historians, theologians, lawyers, and so on. The aim is to collect at first hand the special knowledge of the time and to present it in a manner that is acceptable to specialists. Lastly, the use of pictorial illustrations—plates and diagrams and pictures in the text, which found a place in encyclopedias at an early date—has been extended in quality improved.

The first encyclopedia written in English and with the articles alphabetically arranged was the "Lexicon Technicum," or a "Universal Dictionary of Arts and Sciences" (London 1717, 1 vol. folio), by John Hadley. This was a useful and popular work, though it omitted from its scope theology, biography, antiquity and poetry. It was reprinted in 1708 and a second volume was added in 1710. Among other important encyclopedic works in English the following may be mentioned: Ephraim Chamber's "Cyclopaedia;" or a "Universal Dictionary of Arts and Sciences"—a work published in 1728, in two volumes folio. A second and improved edition came out in 1738. Latterly it was revised and enlarged by Abraham Rees, in which form it was several times reprinted, being finally known as "Rees' Cyclopaedia," and published in a number of volumes. Then was published the "Encyclopaedia Britannica." Of this there have been 11 editions. The first edition was completed in 1771, in three volumes and the 11th edition was completed in 1910-11 in 29 volumes and an index volume. The "Edinburgh Encyclopaedia" (1810-30, 18 vols.) was devoted particularly to the sciences and technology and was conducted by Sir David Brewster. The "Cyclopaedia Metropolitana" (London, begun 1815, completed 1845, in 25 vols., was published in four divisions, according to a plan devised by the poet Coleridge). The "London Encyclopaedia," by Thomas Curtis (22 vols.) and the "Penny Cyclopaedia" (29 vols.), appeared in 1833-46. Chambers' "Cyclopaedia" (in 10 vols.) was published in 1800 and a new edition appeared in 1902.

During the 19th century, the various branches of science and technology, history, biography, theology, commerce, publishing, law, the fine arts, etc., are all admirably represented in their works; the growth of the special encyclopedia having kept pace with the advance of knowledge and of industry. Among the most important are the encyclopedias of biography. Some excellent examples of the special encyclopedia date from the 17th and 18th centuries; but those produced in the 19th century are much more numerous and, in several cases, far more comprehensive. The most notable of these later biographical works are the "Biographie universelle ancienne et moderne" (85 vols., 1811-62, including supplement; 2d ed., 45 vols., 1842-65) of Joseph and Louis Gabriel Michaud; and the "Dictionary of National Biography" (66 vols., 1st supplement, 3 vols., 1885-1901; 2d supplement, 3 vols., 1901-11; republished in 22 vols., 1913).

In the United States an early work in the general field was the "Encyclopaedia Americana," edited by Francis Lieber and published 1st ed., 13 vols., 1829. "The American Cyclopaedia," edited by George Ripley and Charles A. Dana, appeared in 1858-76 in 16 volumes. The publishers of this work have since 1861 published the "American Annual Cyclopaedia," designed to record the progress of science and the arts, and the world's history from year to year, and to serve as supplements to the "American Cyclopaedia." It is in the same form as that work, octavo, and comprises about 800 pages per volume. "Johnson's New Universal Cyclopaedia" first appeared in 1874-77, in four imperial octavo volumes. It was especially strong in the departments of natural science—physics, chemistry, mechanics, etc.—and American gazetteer matter. In its later form "Johnson's Universal Cyclopaedia" (1893-95, 8 vols.), with a change of publishers, was thoroughly revised, by a corps of 36 editors, under the direction of Charles Kendall Adams. Then followed "The International Cyclopaedia" (New York 1884), which was succeeded by "The New International Encyclopaedia" in 20 volumes (1902; 2d ed., 24 vols., 1914), and later by the "Encyclopaedia Americana" (1st ed., 16 vols., 1903; 2d ed., 20 vols., 1906; 3d ed., 22 vols., 1910; new and enlarged edition, revised throughout, 30 vols., 1918).

Of the French encyclopedias the most famous is the great "Encyclopédie, ou Dictionnaire Raisonné des Sciences, des Arts, et des Métiers," by Diderot and D'Alembert. This was published in 35 volumes 1751-80. Not only information was given in these volumes, but opinions of the most radical character—opinions to the Church, subversive of religion, intensely antagonistic toward everything in the old order of things. The clergy and the court had fought the work, had even broken into it with alterations secretly made at the printers', and left not stone unturned to prevent its circulation. Yet Europe was filled with it and shaken with the effects of it. It was an immense burst of every-
thing which journalism to-day means; a fierce prophecy of change, which are still pending; a vivid prediction of the problems of human aspiration and desire. Not only were the sciences pushed to the utmost by Diderot, but he made industry, labor, human toil in the shop, an interest uneceasingly cherished. It was an expected heralding of the Revolution a quarter of a century later. Still more comprehensive is the 'Encyclopédie Méthodique, ou par Ordre des Matières' (Paris 1781–1832, in 1665 vols.), an aggregate of dictionaries rather than a single work. The French have also the 'Encyclopédie Moderne,' begun in 1824, finished in 1832, 26 volumes, and subsequently republished; the 'Encyclopédie des Gens du Monde' (1835–44), 22 volumes; Larousse's more recent and valuable 'Grand Dictionnaire Universel du XIXe Siècle,' 16 volumes folio (with two supplementary volumes); 'La Grande Encyclopédie,' an extensive and excellent work which was completed in 1903, and 'Dictionnaire encyclopédique universel, illustré de 20,000 figures,' etc. by E. J. Souchon and begun in 1835. Of works published in Germany the most famous is 'Brockhaus' Conversations-Lexikon,' now in its 14th edition. It is equalled, if not surpassed, by the similar work of Meyer. The huge 'Allgemeine Encyclopädie der Wissenschaften und Künste,' originally edited by Profs. J. S. Ersch and J. G. Gruber, begun 1818, is not yet completed. To 1916 168 volumes have been issued. Three sections of the alphabet are carried on simultaneously. Other German encyclopedias deserving mention are those of Pierer and Spamer.

In Italian, the 'Nuova Enciclopedia popolare' (14 vols., Turin, 1841–51); the 'Dizionario universale di scienze, lettere ed arti' (Milan 1874), by Lessona and Valle; the 'Enciclopedia popolare italiana' (ib. 1872), edited by Giovanni Berri, and the 'Nuova enciclopedia italiana' (25 vols., Turin 1875–88), are the principal. In Spanish Meliano published the 'Enciclopedia moderna' (34 vols., with an atlas) at Madrid in 1848–51. Another Spanish work of note is Montaner y Simon, 'Diccionario enciclopédico Hispano-Americano de literatura, ciencias, y artes' (25 vols., Barcelona 1887–99); the greatest of all such works in Spanish is 'Enciclopédie des Arts,' begun at Barcelona in 1907 and of which nine volumes had appeared up to 1916. The 'Dizionario popular historico, geographico, mythologico, etc.' (16 vols., Lisbon 1876–90), by Chaga; 'Diccionario universal português ilustrado,' by Zeforina, are the standard works in Portuguese. Other works deserving of notice are Salomonson's 'Store illustrerede Konversationsleksikon' (19 vols., Copenhagen 1891–1911) in Danish; the 'Geillustreerde encyclopedie: woordenboek for wetenschap en kunst' (2d ed., 16 vols., Rotterdam 1884–88); 'Nordisk Famil eybok' (Stockholm 1904–15, vols. to 1911); 'Entisiklopediachesky Slovar' (41 vols., Petrograd 1890–1904) and 'Encyclopedya Powszechna, etc.' (16 vols., Warsaw 1898–1904).

The rapid advancement of the sciences and arts and the present communication between all civilized nations, have made a general acquaintance with many different branches of knowledge more necessary than ever before. This is one of the chief causes which have produced in our time so many encyclopedias of various kinds, some very learned and others more adapted for the general reader; some embracing all the sciences and arts, others only single branches.

END-BRAIN, a name given to the front part of the brain, which corresponds to the fore-brain or telencephalon. See Brain.

END-ORGANS, important nerve-structures specially designed for particular purposes. Thus the taste-buds in the mouth and tongue, the touch-bulbs in the fingers and the muscle-plates in the muscles are special forms of nervous end-organs. There is a vast variety of nervous end-organs found in the special glands, such as the secretory glands of the skin, of the mucous membranes, in the liver, the spleen, the kidneys, etc.

ENDEZ, én' dé. Hermann, German architect: b. Landsberg 1830; d. 1907. He studied at the Academy of Architecture at Berlin; made a tour of Europe, during which he studied all the great models. At Berlin, with Böckmann, he erected the Red Palace, Royal York Lodge, the Bank of Commerce, the Ethnological Museum and the buildings of the Zoological Gardens. In 1866 he designed several public buildings for the city of Tokio, Japan, at the behest of the Japanese government. From 1885 to 1901 he was chief professor in the High School for Technical Arts at Berlin. He was a member of the Berlin Academy of Arts and honorary member of those of Vienna and Saint Petersburg.

ENDEMAN, én'dé män. Wilhelm, German jurist: b. Marburg, Hesse, 24 April 1825. He studied at Heidelberg and was professor of law at Jena 1862–66 and at Bonn in 1867. He was a member of the Reichstag 1871–73. His writings on German commercial law are highly esteemed. Among his works are 'Die Beweislehre des Civilprozesses' (1860); 'Der deutsche Civilprozess' (1878–79); 'Die Entwicklung des Beweisverfahrens im deutschen Civilprozess' (1895).

ENDEMIE (Gr. "prevailing among the people"), a name often applied to diseases which attack the inhabitants of a particular district or country, and have their origin in some local cause, as the physical condition of the soil or water where they prevail, or in the employments, habits and mode of living of the people. Every part of the world, every climate and every country has its peculiar endemics. Thus the tropical and warm climates are subject to peculiar cutaneous disorders, eruptions of various kinds, because the constant heat keeps up a strong action of the skin. In northern climates eruptions of the skin occur, but they are of a different kind. Thus in all the north polar countries, especially in Norway, a kind of leprosy, the rodeurige, is prevalent, arising from the coldness and humidity of the climate, which dispose the skin to such disorders. Hot and moist countries generate the most violent typhoid and putrid fevers; the West Indies and some of the South American coasts, for instance, produce fever by paradox. In different races and communities among the United States intermittent fevers, arising from local malarial conditions, are common, as they are in countries generally in places that are damp and not warm, on marshes and large rivers, etc. Places in a more dry and elevated situation, northern coun-
tries particularly, are peculiarly subject to inflammatory disorders. In countries and districts where much exposed to current of wind, especially in mountainous places, we find at all seasons of the year rheumatism, catarrh and the whole train of complaints which have their origin in a sudden stoppage of the functions of the skin. In large and populous towns we meet with numerous instances of pulmonary consumption. In cold and damp countries like England, Sweden and Holland the most frequent cases of croup occur.

Diseases which are endemic in one country may also appear in others and become epidemic if the weather and other physical influences resemble those which are the causes of the endemic in the former place; the climate being for a time transferred, as it were, from one to the other. Endemic disorders in some circumstances become contagious, and thereby spread to other persons, and may be transplanted to other places, the situation and circumstances of which predispose them to receive these disorders. This is known by the migrations of diseases, the spreading of leprosy from Oriental countries to Europe, and the like.

It is favorable to the cure of obstinate disorders for the invalid to remove to a climate where his particular complaint is rare. Thus it is customary for people attacked with pulmonary complaints to remove to localities where the air is pure and dry and sunshine abundant. So it is of advantage to the consumptive to exchange unhealthy city air for pure air in the country. Modern sanitation is learning to deal with conditions which, alike in populous and sparsely peopled places, have hitherto bred diseases so that immunity from fatal disorders may be said to show the good results of sanitary science, as do also the improved statistics of longevity.

**ENDER, Eduard.** Austrian painter: b. Vienna 1824. He is the son of Johann Ender (q.v.) and is noted alike for his historical and genre works, among which are 'Francis I in the Studio of Cellini'; 'Shakespeare Reading Macbeth' before the Court of Elizabeth'; 'La Corbeille de Mariage'; and 'A Game of Chess.'

**ENDER, Johann.** Austrian artist: b. Vienna; d. 16 Nov. 1854. As a portrait painter he was successful at an early age. In 1818–19 he made a tour of Italy, Turkey and Greece, remaining in Rome 1820–26. Upon his return to Venice he devoted his attention to miniature and historical paintings, being professor at the Academy from 1829 to 1850. Among his works are 'Madonna with Slumbering Christ-Child' (Vienna Museum); 'Marcus Aurelius on His Death Bed' (1814, Estesfazy Gallery); his masterpiece, 'The Crucifixion' (a fresco in the Vienna Cathedral); 'Orestes Pursued by the Furies' (1815); 'Minerva Showing Ithaca to Ulysses' (1816); 'Assumption'; 'Sleeping at Christ's Sepulchre' (1817); 'Judith'; 'Bacchus Finding Ariadne'; and many portraits.

**ENDER, Thomas.** Austrian artist: b. Vienna, 4 Nov. 1793; d. there, 28 Sept. 1875. He was twin brother of Johann Ender (q.v.). He also studied at the Vienna Academy, becoming a noted landscape painter. He won the grand prize at the Vienna Academy 1816. Going to Brazil in 1817, he brought back nearly a thou-

sand drawings and water colors. He visited Italy, Palestine, Greece and Paris. In 1836 he became corrector and later professor at the Vienna Academy, filling that chair until 1849. Among his works are 'View of Grossglockner'; 'Castle Tyrol'; 'Coast of Sorento'; 'View of Rio de Janeiro' (Vienna Academy); Chapel in the Woods (Nationale Gallery, Berlin).

**ENDERBY LAND, a region in lat. 65° 57' S., long. 47° 20' E., named by John Briscoe in 1831, when on a whaling voyage, in honor of his employer, Samuel Enderby. Briscoe could not approach within 20 or 30 miles, and was unable to say whether it was an island or a strip of continental coast. It was surveyed by Dirk Gerritz, in 1599, and named for him.

**ENDERMIC, a term designating a form of medication once much in vogue, but now almost abandoned, consisting in raising a blister upon the affected part and applying to the raw surface the remedy to be absorbed. It has been superseded by the hypodermic method. See HYPODERMIC INJECTION.

**ENDICOTT, John.** American colonial governor: b. Dorchester, England, 1589; d. Boston, Mass., 15 March 1665. He was sent out to this country by the 'Massachusetts Company' to carry on the plantation at New London, or Salem, where he arrived 6 Sept. 1628. In April 1629 he was chosen governor of 'London's plantation'; but in August it was determined to transfer the charter of the colony to New England, and Winthrop was appointed governor. Endicott was deputy-governor of the Massachusetts colony 1641–44, in 1650 and 1654; and was governor in 1644 and 1649, 1651–54 and 1665–65. He was bold and energetic, a sincere and zealous Puritan, rigid in his principles and severe in the execution of the laws which he differed from the religion of the colony. So averse was he to everything like popery that he cut out the cross from the military standard. He was opposed to long hair, insisted that the women should wear veils in public assemblies and did all in his power to establish what he deemed a pure Church. In 1659, during his administration, four Quakers were put to death in Boston. Consult Endicott, C. M., 'Memoir of John Endicott' (Salem 1847).

**ENDICOTT, Mordecai Thomas.** American naval officer: b. May's Landing, N. J., 22 Nov. 1844. He was graduated at the Rensselaer Polytechnic Institute in 1868; practised as civil engineer from 1868 until appointed civil engineer in the United States navy in 1874. He served as consulting engineer at various navy yards and in the Navy Department at Washington. In 1895 he was appointed member of the New York Canal Commission, of the United States navy armor factory board in 1897 and in 1898 became chief of the Bureau of Yards and Docks with rank of commodore. Later he was advanced to the rank of rear-admiral, and reappointed in
1902 and 1906. In 1905 he became a member of the Isthmian Canal Commission, retired in 1906, but continued to work on active duties until 30 June 1909. He is a member of the American Society of Civil Engineers and was its president in 1911.

ENDICOTT, William Crowninshield, American lawyer: b. Salem, Mass., 19 Nov. 1825; d. Boston, 6 May 1900; was a descendant of John Endecott (q.v.), the Puritan governor of Massachusetts. He was graduated at Harvard College in 1847; served as justice of the State Supreme Court (1873–82); was an unsuccessful candidate for governor of Massachusetts, on the Democratic ticket, in 1884; and was appointed Secretary of War in President Cleveland's Cabinet in 1885.

ENDIVE, en'div (Cichorium endivia), an annual or biennial herb of the natural order Composita. It is an East-Indian annual or biennial, with a rosette of smooth radical leaves, more or less lobed or cut, blue axillary sessile florets, and globular seeds. It has long been cultivated as a salad, for which use it probably ranks in Europe next to lettuce, but not quite so high in America. It is as easily cultivated as lettuce, but must be blanched, either by loosely tying the outer leaves up over the inner ones or by covering the plants with large drain-tiles or similar tubes. Of the numerous varieties, those that naturally are most curly-leaved, and that ordinarily develop a white centre without blanching, are the most esteemed. The leaves are also used as a pot-herb and as an ingredient in soups, stews, etc.

ENDLESS or PERPETUAL SCREW, a mechanical contrivance consisting of a screw thread of which gears into a toothed wheel at an oblique angle corresponding to the pitch of the screw. It derives its name from the endless recurring effect its thread produces when in motion. It is in general use as a means of producing slow motion in the adjustment of machines rather than as a transmitter of great power.

ENDLICH, Gustav Adolf, American jurist: b. Alsace Township, Berks County, Pa., 2 Jan. 1832; was educated in Germany and at Princeton; studying law and being admitted to the bar in 1877. He was elected judge of the 23d judicial district, Pennsylvania, 1879, and re-elected 1889. He was member of the United States assay Commission in 1897, and from 1906 to 1910 was president of the board of trustees of Muhlenberg College. He edited the Criminal Law Magazine and Reporter 1890–94. He has published 'The Law of Building Associations' (1882); 'The Law of Affidavits of Defense in Pennsylvania' (1884); Woodward's Decisions (1885); 'Commentaries on the Interpretation of Statutes' (1888): 'Rights and Liabilities of Married Women in Pennsylvania' (1889); and numerous articles on legal subjects for periodicals.

ENDLICHER, end'lîkh-ér, Stephen Ladis-las, Hungarian botanist: b. Hungary, 24 June 1825; was ordained a priest in 1849, and began botanical and linguistic studies. He became curator of the manuscript department of the Imperial Library at Vienna in 1828; and in 1836 of the botanical department of the Royal Natural History Museum there, and in 1840 became professor of botany in Vienna and director of the Botanical Garden. Much disturbed by the events of 1848, he fell ill into melancholy, and in 1849 put an end to his own life. His 'Genera Plantarum' (1836–40) has had great influence on succeeding botanists. His studies in Oriental philology are also important. Among them may be mentioned 'Anfangsgründe der chinesischen Syntax' (1845); 'Geschichte der chinesischen Poesie' (1849) with Eichenfeld, 'Analecta Grammatica' (1837).

ENDOCARDITIS, inflammation of the endocardium or serous membrane lining the valves and internal surface of the heart.

ENDOCRERAS, en-dôs'e rãs, genus of fossil cephalopods, found in the Orдовician rocks of the United States, Russia and Scandinavia. Many species have been uncovered; the conch is long, slender and either annulated or smooth. Specimens have been found in the Trenton rocks of New York, having a length of over 10 feet. See CEPHALOPDA.

ENDOCHROME, the characteristic pigment mixture of diatoms. It is apparently a mixture of a green constituent and a golden-brown constituent (diatomin). See DIATOMACEOUS EARTH.

ENDOCRINOPATHIES. Diseases or disorders of growth or adjustment due to disturbances of the endocrine glands, or glands of internal secretion. The early mechanistic conceptions concerning the push that lies behind the metabolism of the organism have slowly and gradually undergone modification until the importance of a number of overlooked structures has forced itself, almost with a whir, upon the medical horizon. These structures are the endocrine glands. The study of their anatomy and functional importance now constitutes an enormous specialty.

As early as 1828 Parry called attention to the relationship between enlarged thyroid and increased frequency of the heart beat (tachycardia), since which time the works of Johannes Müller, Addison, Gull, Brown-Séquard, Marie and many others have served as starting points for the building up of a rich structure which is amply recorded in a score of monographs. The chief of these are Besold, 'Internal Secretions' (bibliography of 4,000 titles, 1913); Falta, 'Ductless Glands' (1915); Parhon et Golstein, 'Les Secrétions Internes' (1909); Levy and Rothschild, 'Endocrinologie' (1913); Gley, 'Les Secrétions Internes' (1914); Sajous, 'Internal Secretions'; special articles in Lewandowsky's 'Handbuch der Neurologie' (1913), and Jelliffe and White, 'Diseases of the Nervous System' (2d ed., 1917).

Out of this prodigious development to be found in the works just cited and in current medical literature, much of which is fragmentary and hastily constructed, a large amount of solid substance remains and a number of permanent acquisitions have been made. The net result has been to show much more essentially than ever before the fundamental physicochemical foundation of biological metabolic processes as they are utilized in the upkeep of the animal machine. The viewpoint has been attained that a marked degree of chemical interrelationship takes place between the different organs of the body. That this is automatically regulated
through the vegetative nervous system (the old sympathetic) chiefly, apparently in some cases, though this is by no means clear, solely through chemical regulation. The disorders of this adjustment and deficiency of vegetative neurology, and are most conveniently grouped under the terms endocrinology, or the endocrinopathies.

In the earlier period of the study of these endocrinopathies individual disease groups, uniglandular syndromes, were isolated. Among these most accentuated of these were Addison's disease, diabetes mellitus, myxedema, cretinism and acromegaly; but of recent years it has been increasingly emphasized that whereas a certain group of symptoms, which may be linked to plus or minus activities of one or another gland may be most prominent, nevertheless other glandular modifications are bound up in them and are not to be neglected. Hence has arisen the viewpoint that most of the endocrinopathies are, strictly speaking, poly- or pluriglandular syndromes, that is, that disease or maladjustment in one gland usually induces compensatory changes in other glands.

For many years, even back to the earliest date, the doctrine has been held that every living tissue yields a chemical product which will act upon other tissues. The early alchemic studies, those of Paracelsus, to the later work of Hahnemann, and the isotherapists, are all attempts to co-ordinate a host of empirically observed facts. They are all worth rereading if the reader will put himself in sympathy with them through a comprehension of the now strange symbols then used.

Endocrine glands for the present purposes are those structures which yield products termed hormones, which may have some definite or specific action related to, yet different from, enzyme activities. These structures are developed from different embryological formations. The hypophysis (posterior lobe) and chromaffin tissues (suprarenal cortex) are nervous; the thyroid and pituitary (anterior lobe) come from the buccal cavity; the pancreas and mucosa of the small intestine from the intestine, the parathyroids and thymus from the branchial arches (old glory sits of fishes); the sex organs from the genital bodies from the genital riddings. Some of these, in humans, merge into one structure, as thyroid and parathyroid, as chromaffin and interrenal cells in the suprarenals, as hypophysis (posterior lobe) and pituitary (anterior lobe).

The present résumé, largely following the author's summary in Stedman's 'Reference Handbook of the Medical Sciences,' will attempt to sketch only the general outlines of the various uniglandular and pluriglandular disease pictures which school is followed, but at the same time attention should be called to the fact that the French school presentations contain gross fallacies, and should be read cum grano salis. Still the clinical suggestions of these writers are so rich it is felt to be a better course to call the attention of the intelligent layman to possible relationships rather than to take the more conservative attitude of directing attention only to that which can indubitably be proved. This whole subject is still so essentially critical that the principle of putting the hypotheses to a test will be found to be more advantageous than that of recording only the obvious. The former attitude may result in gaining useful therapeutic truths, the latter becomes monotonous and frequently encourages stupidity.

The more recent individual and extreme summaries of Biedl, Falta, Laignel-Lavastine, Levi and Rothschild are therefore here summarized.

Uniglandular Syndromes. Thyroid.—Myxedema.—The chief symptoms are arrest of development, dwarfism, infantilism, infiltration of skin and mucous membranes, central nervousness, slow ideation, defective memory, apathy, laziness, sluggishness, sleepiness, taciturn, awkwardness. The pulse is usually small, rapid and irregular, at times increased tension. There are constipation, diminished urination, hypothermia and chilliness of the skin. Reflexes diminished. The voice is frequently nasal, slow, monotonous and raucous. Headache is frequent and at times epileptic attacks occur. These are all symptoms of diminished secretion.

Exophthalmic Goiter.—A more or less complete catalogue of findings for a lot of cases will include tachycardia, arrhythmia, anxiety, insomnia, tension, thickening of the skin, exophthalmos, epiphora, v. Graef's, Stellwag's, Moll's symptoms, factitious paresis, cramps, tremors, neuralgias, chiefly frontal and ocular, colic, hot flashes, profuse sweating, thermophobia, engorgement of the skin, dermographism, transitory edemas, pigmentation, urticaria, alopecia, diminution of electrical resistance, albuminuria, polyuria or glycosuria, anorexia, bulimia, vomiting, asthenia, hyperchlorhydria, diarrhoea, dyspnoea, amenorrhoea, atrophy of mamma, loss of flesh, agitation, emotional instability, volubility, insomnia, anxiety, excessive anger or reverse, maniacal excitement, marked depression, cyclothymic variations, confusion, epileptic attacks. Epinger and Hess have endeavored to separate a vagotonic and sympathicotonic type.

In the vagotonic type the more prominent signs are decreased lacrimation, less exophthalmos, with enlargement of the palpebral fissures, v. Graef's sign, abundant sweating, diarrhoea, mild tachycardia, no alimentary glycosuria, pilocarpine and oculocardiac reflexes positive. In the sympathicotonic type the changes are in the thalmus, dryness of eyes, violent tachycardia, glycosuria, oculocardiac reflex reversed or absent, increased reaction to adrenalin. Most cases are mixed in type. In all save infections the terms psychatical influences are striking and psychotherapy is extremely valuable in the early stages, less so in chronic cases. Money worries are of great importance in the causation of the psychogenic cases.

Thyroid insufficiencies, other than those of myxedema, are infantilism, obesity, Dercum's syndromes, pseudolipomata, alopecia, precocious loss of hair, scleroderma, urticaria, puritus, recurring herpes, transitory edemas, migraine, asthma, constipation, mucous enterocolitis, acrocyanosis, Raymond's syndrome, localized erythemas, rhinorrhoea, glucose tolerance, genital instability, chilliness, mammary hypertrophy.

Thyroid Instability (Levi and Rothschild).—From dyshypothyroidism: chilliness, baldness, headaches, depression, crying, giddiness, passing edemas, neuralgic pains, suffocations, shivering hot flashes at menstrual period. With predominant dyshyperthyroidism: thinness, in
crease of eyebrow development, hot flashes, palpitations, intestinal spasms, irritability, emotionalism, phobias, inquietudes, asthma, hyperhidrosis, dysidrosis, tremors. Mixed cases: chilliness, shivering, migraine, frequent urination, neuralgic pains, distractable reddening of eyebrows, catamenia; neuralgias, anxiety, dilatation of palpebral fissures, swelling of feet, variations in volume of the feet, tremors, nervous crises, hysterical attacks.

Parathyroids.—Tetany.—This syndrome is unquestionably related to parathryoid loss or deficient Parkinson's syndrome (?). The viewpoint of Lundborg and of Gauthier is that this syndrome belongs here, and is a hyperfunction disorder but it rests on very unstable foundations.

Thymus.—Vagotonic Symptoms of Base- dow Syndrome (?): Profuse sweating, palitation, lymphocytosis, eosinophilia, sensation of weakness.

Myasthenia of Erb-Goldfliam (?): Headache, ptosis, external ophthalmoplegia, fixed or transitory palsies principally of the face, the neck, myasthenic electrical reaction.

Thymus Loss: Idiocy of Klose and Vogt.

Tetany (?): Basch.

Suprarenals.—Addison's Syndrome and Suprarenal Insufficiency: Asthenia, arterial hypotension, morning nausea and vomiting, lumbar pains, melanoderma, white lines on the skin, amyotrophy, aboilia, depression. At times myoclonus, epileptic attacks, tetany, periodic palsies, delirium, mental confusion, sudden death.

Suprarenal-genital Syndrome: External feminine pseudo-hermaphroditism with virile secondary sexual characters; suprarenal virilism; amenorrhea, gynecomastia, adipsis with easy bruising, all signs of feminine maturity; hypertrophy of the clitoris, hypertrichosis of masculine type, masculine voice, muscular and nervous hyperasthenia, active and violent sexual inyersion; arterial hypertension, arteriosclerosis; glycosuria.

Sympathetic Paragonailia.—Chromaffin cells of the solar plexus, aortic paraganglion of Zuckerkandl, cardiac paraganglion of Wiesel and Weisgr, Luschka's carotid and coccygeal glands, tympanic paraganglia. The syndrome of the affections of these glands is entirely obscure.

Pancreas.—Diabetes Mellitus: Glycosuria, polyuria, polyphagia, polydipsia; neuralgias, pruritus, impotency, constipation, dry mouth, dry skin, diminished perspiration, atrophy of the testicles, abolition of the tendon reflexes, arterial hypertension, asthenia, headache, susceptibility to cold, perforating ulcer of the foot, syncope, comatose or apoplecticiform attacks, paralyses, vertigos, asthmatic dyspnoeas, pseudoanina, narcoplepsy, depression, apathy, hypochondria and coma.

Hypophysis.—Froehlich's Genital Adiposity Syndrome: Adiposity, arrest of development or regression of the genital glands of the genital organs and the corresponding secondary sexual characters; somnolence.

Syndrome of Hypophyseal Insufficiency of Rénon (?): Tachycardia, instability of the pulse, arterial hypotension, insomnia, anorexia, distressing sensation of heat, exaggregation of sweat secretion.

Acromegaly: A simple hypertrophy, not congenital, of the upper and lower extremities and also cephalic, headache, amenorrhea, tendon reflexes increased, arrhythmia, syncope, perspiration, polyuria, glycosuria, sensitiveness to cold, neuralgias, acroparesthesia, cramps, lancinating pains, lassitude, irritability, depression.

Giantism: “Acromegaly of the subjects in the epiphyseal cartilages which have not yet ossified,” impotency, amenorrhea, idolence, infantilism, aboilia, asthenia, glycosuria, polyuria.

Finea.—Genital Macrosmosis: Abnormal increase in height, premature genital and sexual development with secondary sexual characters, hypertrichosis, exaggerated mental precocity.

Finea Adiposity: Diffuse obesity.

Choroid Plexus.—Hydrocephalus: Hypertension of the cerebrospinal fluid, rapid development, nervous and mental syndrome of ventricular hypertension, obnubilation, idiocy.

Ovaries.—Infantilism: Amenorrhea, absence of secondary feminine characters, obesity, deficiency of hair, childishness.

Acquired ovarian insufficiency. (a) Peripheral vasodilatation, subjective symptoms of heat, sweating, continuous or paroxysmal tachycardia, palpitations, arterial hypertension, insomnia, severe headache, facial neuralgia, lumbago, neuromuscular asthenia, memory instability, irritability, enervation, hysterical crises; exaggeration of the sexual instincts, more often absent or inverted; obesity, restlessness, anxiety, phobias, impulsions, gastrospasm, constipation, vomitting, vertigo, syncope.

(b) "Vagotonic crises" before the menses and at the beginning of pregnancy, pallor, tendency to syncope, nausea, vomitting, constipation, diminished arterial tension, pulse rather slow, ocuulocardiac reflex positive, Samogus's sign, psychic depression particularly connected with the development of the corpus luteum. These crises occurring before menstruation or at the beginning of pregnancy must not be confused with the reactionary dyshypothyroidism of the menopause marked by flashes of heat, sweating, hypertension, paroxysmal tachycardia, palpitations, anxiety.

"Hyperovaria" (Dalchê).—Precocious puberty, copious menstruation, pain before and during the first days of the period, intermenstrual leucorrhea, developed sexual instinct, well-marked eyebrows, thinness, pallor, small breasts, large pelvis, rounded lower limbs contrasted in size with the upper ones, arterial hypertension, craving for movement and action, enervation, tendency to loquacity, erotic crises.

Testicles.—Infantilism: Defective development of the male genital organs, absence of secondary sexual characters, obesity, deficiency of hair length of the lower limbs, small cranium, childishness.

Acquired Testicular Insufficiency: Increase in height, diminution of the pilous system, glabrous state of the body, tendency to obesity, gynecomastia, frigidity, impotency, sensuality, arterial hypertension (?), asthenia.

The types of testicular insufficiency according to Rebattus and Granger are: (a) The sterile. (b) Eunuchoid gigantism, because the internal secretion of the testicle is established late. In this case there is a prolonged infantilism. (c) Eunuchism by castration character-
ized by gigantism and infantile appearance. The secondary sexual characters do not appear.

(d) The reversible infantilism of Gandy, where simply a sort of a sexual condition is maintained, without growth of secondary sexual characters and a certain degree of obesity, with late testicular difficulty in the adult.

Dyshydribdastematia: Lower limbs short and cranium very large, pilous system well developed, especially the mustache, thinness, persistence of youth, a degree of arterial hypertension, virile character, activity, moral and physical energy.

Prostate.—Prostatic Insufficiency: Asthenia, diminution of potency, neuroasthenia, at times suicide.

Hypertrophy of Prostate: Arterial hypertension, retardation of the heart, cerebral hemorrhages, genital excitation.

Pluri glandular Syndromes.—Basedow’s disease with thymic hypertrophy and vagotonic symptoms, edema, and letany, amenorrhea, Addison’s syndrome; acromegaly, etc.

Myxedematous with Thymic Hypertrophy: Tetany, acromegaly, Addison’s syncopal, amenorrhea, infantilism, mammary hypertrophy, etc.

Acromegalics or ovarian insufficiencies with various disturbances, psychic, nervous, vasomotor, trophic, etc., connected at one time with the myxedematous, at another with the basalowian series.

Ovarian Predominance.—Thyroid Reaction to Ovarian Insufficiency: Tachycardia, palpitations, perspiration, nervous irritability, vertigo, scanty urination, trembling, anxiety, etc.

The differences between these nervous manifestations and the picture of the attenuated forms of exophthalmic goitre are very slight says Laignel-Lavistine. This pathogenic conception permits of important therapeutic results; one may ask, for example, whether the anti-basalowian therapy with hematothyroidin would not be of advantage in the nervous and psychic disturbances of the normal menopause which repeat one feature after another of the basalowian series.

Dyshyperovaria of the Hypothyroid: Anticipation, propagation and copiousness of the menses, menorrhagia, metrorrhagia.

Thyro-ovarian Disturbances of the Same Significance.—Either ovarian insufficiency in the myxedematous series, or the dyshyperovarian in the basalowian series; in either case the nervous disturbances of the dysthyroid are modified by all factors of the ovarian rhythm, whatever they may be.

Hypophyseal Predominance.—Infantile giants, with their clinical varieties: feminism, enchinism, eutropherism, feminine pseudo-hermaphroditism, mental infantilism.

Acromegalics with deficiency syndromes, myxedema, infantilism, amenorrhea, obesity, asthenia.

Acromegalics with syndromes of hyperactivity, more or less vicious, synergetic or substitutive: simple or exophthalmic goitre, arterial hypertension and atheroma, lactic secretion.

Suprarenal Predominance.—Addisonian with amenorrhea, impotence, chilliness, tetany or, on the other hand, exophthalmic goitre.

Very often basalowians, acromegalics, giants, with spontaneous glycosuria, alimentary or merely adrenal, the latter making it possible in certain cases to suppose a certain degree of suprarenal hyperactivity.

Without Marked Predominance.—The case of Claude and Gougerot is an example: Loss of sexual characters, countenance old-looking, skin thickened, wrinkled, pigmented; chilliness, absence of perspiration, asthenia, arterial hypertension, tetany; testicular, prostatic, suprarenal, thyroidal and perhaps parathyroidal atrophy.

Consult Jelliffe and White, "The Nervous System" (Chapter III, "The Endocrine Pathies"); Empinger and Hess, "Vagotonia, Nervous, Mental and Mental Disease" (Monograph Series, No. 20, New York).

S M I T H E L Y J E L L I F F E .

ENDODERM, or ENDODERM (also called entoblast or hypoblast), the innermost layer of cells in the developing embryo. In man it subsequently develops into the epithelium that lines the digestive canal and its appendages, the pancreas, liver, lungs, etc. See EMBRYOLOGY.

ENDODERMIS, in plants, the layer of cortical cells which surrounds the vascular region and generally called the bundle sheath. In many cases there is but a single sheath surrounding a single vascular region; in others there are several vascular regions each protected by its own sheath or endodermis. See MORPHOLOGY.

ENDOGAMY, a custom among some savage peoples of marrying only within their own tribe. Opposed to exogamy.

ENDOGENS, ęn’dō-jēnz, a name for monocotyledonous plants, referring to the mode of growth of the stem. See BOTANY; MONOCOTYLEDONS.

ENDOR, ęn’dér, a village of Palestine, four miles south of Tabor, now a poor mud hamlet.

It was the place which Saul visited (1 Sam. xxviii, 7) to consult the "woman with a familiar spirit." The word is in common use in the writings of the Philistines.

ENDORSE, in heraldry, a subsidiary equivalent to one-eighth or one-fourth of a pale.

ENDOSCOPE, in surgery, a general term for an instrument for the examination of internal parts. It consists of a tube and an apparatus for lighting. The most serviceable is that devised by Nitze and Leiter.

ENDOSMOSIS. See OSMOSIS.

ENDOTHELIA, ęn-dō-thē-li-o’ma. See TUMOR.

ENDOTHELIA, a modified form of the cells lining certain internal organs. Such are the internal lining membranes of the heart and blood vessels, the joints and other closed cavities. Endothelium is a modification of epithelium (q.v.).

ENDOTHYRA, genus of fossil. Foraminifera, the shells of one species of which (E. baileyi) form a large part of the oolitic limestone of the Lower Carboniferous and known as Bedford limestone. See FORAMINIFERA.

ENDROMIS (1) a kind of boot which was first generally worn by Cretan huntsmen and then by athletes in general. It was close-fitting, reached above the ankle, with the top turned down. (2) a woolen rug or covering worn by Roman athletes, gladiators, etc., after violent exercise. It was made in Spain or in Tyre.

ENDYMION, in classical mythology, according to some a huntsman; according to others a shepherd; and according to a third account a king of Elis. One tradition is that he asked of Zeus eternal youth and eternal sleep, and that Selene (the moon) saw him sleeping and became enamored of him. Others relate that Selene herself, charmed by his beauty, conveyed him to Mount Letmus in Caria and threw him into a perpetual sleep in order that she might kiss him whenever she pleased. The legend is the subject of Keats' "Endymion."

ENEMY. Keats was 23 when, in April 1818, he published his first long poem, "Endymion." The young poet, in love no less with the beauty of his native England than with the beautiful mythology of Greece, incarnated in the poem his own passionate seeking for the soul of beauty in the world. We may trace this theme through the "uncertain path" of a story which is almost lost in the luxuriant tangles and by-paths of incident and description. Endymion, smitten with strange trance at the feast of Pan, confesses to his sister the vision of an immortal loved one that has turned waking life to despair. Led on to "woe-worn wanderings" by a mysterious command, he descends "into the silent mysteries of earth." He is succored by Diana, urged on by Venus, who foretells his happiness, and is moved to pity by the vain loves of Alpheus and Arethusa. And when at length his "fated way" leads him through the sea-depths to the rescue of spell-bound Glaucus, Endymion's awakened sympathy with suffering gives him power not only to restore "all lovers tempest-tost" to eternal love and youth, but to win Cynthia and immortal bliss. So at last his mortal love, the Indian damsel, reveals herself as the goddess; and through earthly loveliness he attains immortal beauty. And so this story of Endymion's love for the moon-goddess is the symbol not only of Keats' intense susceptibility to the loveliness of moonlight but of his life-long passion for "the principle of beauty in all things."

The form of the poem is, like its spirit, wavering, but shot through with imaginative glory. Structure is lacking — the poet does not master his story, but is swept on by it, like Endymion on his celestial steed. Metre and diction are treated with a freedom not only Eliotian but revolutionary. And in such lyric ecstasies as the "Hymn to Pan" and "O Sorrow," in such perfect images as the "dancing poppies," "tip-toe Night," "panting light," "rain-scented eglandine," there speaks Keats, the magician of English poetry. Consult article "Keats" in "Cambridge History of English Literature" (Vol. XII) and Colvin, Sidney, "John Keats" (New York 1917).
ENEMY ALIEN PROBLEMS

In early times it was the practice of belligerent governments upon the outbreak of war to arrest the citizens or subjects of the enemy power residing within their jurisdiction, to confiscate their property, and sometimes to expel them summarily from the country. In the course of time, however, relaxations from this harsh practice began to be made and many treaties were concluded providing that such persons should either be allowed to remain in the country, or, if they were expelled, they should be allowed a specified period within which to dispose of their property and wind up their business affairs. The policy of confiscating their property also ceased and wholesale expulsions became rare. During most of the wars of the 19th century the treatment accorded to enemy aliens was uniformly liberal and humane. During the Spanish-American War of 1898, for example, neither belligerent molested the citizens or subjects of the other, so long as they demeaned themselves peaceably and their property was not interfered with in the slightest degree. When the present European War broke out the rights of enemy aliens had not been regulated by any of the great international conventions; the treatment to which they were subjected, therefore, depended upon the customary law of nations and upon particular treaty stipulations between the opposing belligerents.

The enemy alien problem of the present war has been somewhat different from that of any previous war. The first reason for this was that the unprecedented number of enemy aliens which were found in most of the belligerent states at the outbreak of the conflict, and partly because of the enormous amount of property held by such persons in the countries where they resided. In England, for example, there were more than 50,000 German subjects; in France the number was still larger; and in the United States the number of such persons probably exceeded a million. In consequence of the German policy of universal compulsory military service large numbers of them were reservists; when they had been allowed to depart would have returned to Germany and joined the army. Many of them were of course spies, for the German historian Treitschke tells us that "in the national wars of the present day every honest subject is a spy." The presence of such persons in so large a number in England and France, because of the close geographical proximity of those countries to Germany naturally constituted a grave danger to both countries. It was impossible in view of these circumstances to allow aliens of military age to leave the country and it was equally impossible to leave them to remain in complete freedom.

The treatment which was accorded to every alien by the various belligerent governments might be summarized under the following points: (1) the in respect to their personal freedom; (2) measures in respect to their property and business undertakings; and (3) their right of access to the courts. At the outset Great Britain accorded to German subjects a period of seven days during which they might leave, but it does not appear that any considerable number succeeded in getting away. France allowed them to leave before the end of the first day of mobilization, but few were able to return to their home countries. Germany and the United States did not allow any days of grace for this purpose and Germany even went to the length of arresting all Japanese subjects found in the country at the outbreak of the war between that country and Japan. British and French nationals were summarily expelled from any German towns and cities and without being allowed to take their effects with them. On the day of the outbreak of war between France and Germany the French government precaution required all enemy subjects to evacuate the region of the northwest, and also the cities of Paris and Lyons and to retire to other regions in the west. They were not, however, expelled. Portugal appears to have been the only belligerent country which went to the length of expelling all enemy persons between certain ages. In every belligerent country measures were early taken to restrict the liberty of movement of enemy aliens. In England they were required to reside in certain designated regions or to change their places of residence or travel more than five miles without a permit; they were forbidden to have within their possession any firearms and various other articles such as signaling apparatus, military maps, motor cars, etc.; they were forbidden to frequent clubs; to see any but English newspapers, etc. In every belligerent country they were required to register and were placed under strict surveillance by the authorities. In the United States they were forbidden to reside within a certain distance of any fort, arsenal, armory or similar place; they were excluded from residing near to or from approaching water fronts or wharves, and they were prohibited from remaining or residing within the District of Columbia. All enemy aliens including women were required to register, and in general they were subjected to other restrictions similar to those adopted by the British government. On account of the close geographical proximity of France to Germany, the French government at the outset ordered a general internment of the enemy population. They were therefore removed to concentration camps located in various parts of France, mainly in the west, behind a line extending roughly from Dunkirk toNice. For some eight months after the outbreak of the war the British government did not go to such lengths, although considerable numbers of suspicious and dangerous characters were interned as a precautionary measure. In consequence, however, of various acts of the Germans, such as the bombardment of undefended coast towns, Zeppelin raids upon England, the use of asphyxiating gases as a means of combat, the ill-treatment of English prisoners, and the like, public opinion in England came to demand that the whole enemy population of England should be interned, and the sinking of the Lusitania in May 1915 greatly intensified the popular demand. This last act led to serious mob outbreaks against the Germans in England and the dominions, during the course of which many German houses and shops were burned and a considerable number of lives were lost. Partly,
therefore, in the interest of the national defense and partly in the interest of the Germans themselves, whom it was difficult for the public authorities to protect so long as they were scattered throughout the United Kingdom, the British government in May 1915 ordered the internment in camps of practically all enemy persons then left in England, although exemptions were granted in particular cases where internment would have worked a serious hardship without subserving any purpose of national defense. The order for internment may be added, applied not only to enemy subjects but also to British subjects (of which there were some 8,000), of enemy origin. So far as possible work was provided in the camps for such persons; classes for instruction were organized, libraries were established, and instructors in the handicrafts were furnished. Long before the British policy of internment had been decided upon, the German government, in consequence of reports that large numbers of Germans were being arbitrarily arrested and imprisoned in England, had issued an order (November 1914) for the general internment of all British males between the ages of 17 and 55. Most of them were interned in the buildings of a race course at Ruheleben near Berlin. The United States was almost the only great power which did not resort to the policy of general internment; for there the presence of enemy aliens at large did not, by reason of the remoteness of the country from Germany, constitute the same danger as it did in England and France. Large numbers of individual German citizens were, however, arrested and confined in internment camps in various parts of the country. The members of the crews of German merchant vessels in American ports as well as the crews of German warships which took refuge in American ports were likewise interned. Other enemy persons who conformed to the regulations in regard to residence, movement and registration and who demeaned themselves honestly were left large, although they were subjected to close surveillance and were frequently warned against the consequences of misbehavior and disloyalty.

Subsequent to the inauguration of the policy of wholesale internment, special conventions were concluded between a number of the belligerent governments providing for the reciprocal exchange and release of women and males except those of military age. Thus in January 1917 an arrangement was concluded between the British and German governments under which all males over 45 years of age and under 17 held in either country as interned prisoners were released and allowed to return to their own countries. In pursuance of this arrangement some 7,000 Germans in England and some 600 or 700 British subjects in Germany were repatriated. Similar arrangements were concluded between the German and French governments and between the German and Austro-Hungarian governments.

The presence in many of the belligerent countries of enormous property holdings and businesses created willy-nilly or in part by, or under the control of, enemy persons raised a difficult problem for belligerent governments. Obviously considerations affecting the national defense made it necessary to deprive the enemy of the use and control of such property or business; otherwise his power would have been employed to increase its own strength and resources. Steps were therefore taken in every belligerent country for placing enemy-owned property and enemy business undertakings under the control or supervision of the public authorities. In England and the United States all such property was placed in the hands of a public custodian who was empowered to hold and administer it and in general to exercise over it all the powers of a common-law trustee throughout the period of the war. At first the American custodian was given only a limited right to dispose of such property by sale, as for example, when it was necessary to prevent waste or protect the rights of the United States therein, but later he was given a general power of sale and numerous German holdings aggregating many millions of dollars worth of property were sold. The proceeds were used to increase the national resources of the United States and it is understood that the eventual disposition of it will be determined by the treaty of peace at the close of the war. The proceeds in some cases were used to purchase war bonds. It should be remarked, however, that this somewhat rigorous policy was not enforced against the property owned by enemy persons residing or domiciled in the United States, but only against property of those living in the enemy country and who were presumably engaged in making war upon the United States. The property holdings of the former, except those interned, have not been molested. The property of American citizens residing in Germany, however, was treated as enemy property on the theory that the test of enemy character is domicile rather than nationality.

In France enemy property was put under the control of sequestrators appointed by the courts and their power over such property was substantially the same as that of the English and American custodians, except that they were not given a general power of sale. Again and again it was emphasized in France that sequestrators were mainly conservators with no general power to dispose of the property placed in their custody. They were authorized to sell enemy property only when it was perishable or when it was necessary to protect it from waste or loss. Germany began by placing enemy property under supervision, but later on adopted the policy of other countries and put it in the hands of administrators who had the power to manage it and in some cases to dispose of it by sale. There was widespread complaint in France of the conduct of the German government in respect to its treatment of French property, especially in Alsace-Lorraine where large quantities were held and the proceeds of which in some cases were employed for the purchase of war bonds. As regards enemy business enterprises and undertakings, all belligerents adopted a somewhat similar policy. In England an official known as the controller was appointed to manage and carry on any enemy business undertakings the continuance of which was demanded by
the public interest. Other businesses were prohibited and liquidated and the Board of Trade. In the United States this power was exercised by the alien enemy cus-todian. Certain enemy businesses such as insurance were prohibited; in the case of other businesses under the ownership or control of enemy persons residing in the United States, action was taken by the Board of directors were reorganized by the appoint-ment of new directors by the custodian, and the business was continued by the reorganized di-rectorate. In Germany all enemy business enter-prises were put under a régime of com-pletely managing and liquidating companies appointed and government appointed agents. Some of them were continued; many were wound up by and liquidated. Likewise, in France administrators were appointed by the courts to operate and manage any enemy enterprise, the carrying on of which was required by the public interest; others were wound up by a liquidator, likewise appointed by the courts. In the case of that particular species of property in the form of patents, trademarks, copyrights, etc., the policy of the French government was more liberal than it was in respect to other property. In general, the policy of all of them was to suspend such rights but without confiscating them. Citizens who held patents in enemy countries were allowed to transmit money thereto in or-der to pay the necessary fees for the renewal of their patents or copyrights. In most of the belligerent countries enemy patents for the manufacture and sale of articles which the public interest required to be manufactured were assigned to local firms or persons, the licensees in whose possession the product was required to pay the fees and royalties due the enemy patentee into the public treasury the same to be held for the benefit of the enemy patentee until the end of the war or to be otherwise disposed of as might then be determined, presumably by the treaty of peace.

As to the right of enemy subjects to enforce their rights by suits in the courts or to appear in court and defend actions brought against them the policy of most of the belligerent govern-ments has been fairly liberal. Under the English common law no enemy alien was allowed such a right unless he remained in England by permission of the Crown and was under the special protection of the king. During the present war, however, the English courts have not only held that an enemy alien residing in England may defend an action brought against him in the courts but that an enemy subject who is interned may bring an action as a plain-tiff. Since practically the entire enemy popula-tion has been interned the effect of the decision is to enable the courts generally to all enemy aliens in the country. This privilege, however, does not extend to persons residing or domiciled in enemy territory. Germany allowed enemy aliens domiciled in the empire the right of access to German courts but denied it to those residing or domiciled outside the empire. In France the French government would not allow enemy aliens to bring actions but others less liberal refused it. The Court of Appeals of Paris in April 1916, however, rendered a notable decision upholding this right. In the United States the policy of the courts has been some-what divided but in general enemy aliens re-
siding here have been allowed access to the courts on a footing of equality with citizens. Those residing in enemy country, however, are not allowed the privilege.

JAMES W. GARNER,
Professor of Political Science, University of Illinois.

ENERGETICS. In physics, mechanics and chemistry, Energetics is the science that treats of energy and its transformations — energy being defined as that attribute of a body, or of a material system, by virtue of which the body or system can do mechanical work; and work being simultaneously defined as the overcoming of resistance through distance. Any such body or system, that can do mechanical work by changing its shape, position or configuration, or its physical or chemical state, is said to possess energy — that is, power to do work.

The mechanical work is often performed directly and immediately by the body possessing the energy, without the intervention of any other agency. This is by no means essential, however, because the conception of energy has been extended so as to include all systems and processes, however complicated or indirect the development of the work may be. Thus a hot body is said to possess energy, because its heat can be used to actuate a heat engine; and a galvanic battery is similarly said to possess energy, because it can generate electricity and thereby operate an electric motor. We even speak of food as possessing energy, because when eaten, digested, assimilated and oxidized in the muscles it enables human beings or ani-mals to perform mechanical work.

In view of the varied kinds of bodies and systems that exist, and the varied ways in which they may perform work, we speak of 'heat energy,' 'electrical energy,' 'chemical energy,' and energy of other types; but in using such expressions we merely indicate, in a rough way, the kind of source that we are dealing with and the general nature of the processes to which we may have to resort, if we attempt to utilize the energy. The energy is the same thing in every case — namely, it is the capacity of the body or system under consideration to do mechanical work. In many cases, in fact, it is hard to say in what condition the energy exists in a body. For example, a mass of hot, compressed gas certainly possesses energy, but in view of the fact that we can obtain work from it either by direct adia-batic expansion, or by keeping the volume constant and using the heat (for example) to op-erate a thermo-electric battery and a motor, it is scarcely logical to say that the energy of the original mass existed either in the form of heat or in the form of mechanical compres-sion. If we try to solve this difficulty by re-placing that it existed in both forms, we are quickly made aware of the superficial nature
of the answer, if we attempt to determine how much is present as heat, and how much is present as mechanical compression. When we increase the energy of a body or system, we say that we "add energy" to it; and when we decrease its energy, we say that we "subtract energy" from it. We can always tell what form the energy has that we add or subtract, but it is often impossible to tell what form it has, while it actually resides within the body or system, with which it is associated.

For purposes of measurement and computation it is necessary to have a satisfactory unit, in terms of which we can make definite quantitative statements with regard to energy; and in view of the definition of energy, it is evident that this unit must necessarily be either the same as the one that is used for measuring work or else a mere multiple or submultiple of it. The unit that is adopted in the measurement of work depends upon the nature of the problem that is under consideration. In modern scientific investigations the unit of work is commonly the erg, which is defined as the work done in overcoming a resistance of one dyne, through a distance of one centimeter. In engineering operations, the unit of work commonly employed at least in the United States (and in England) is the foot-pound, which is defined as the amount of work done in overcoming, through a distance of one foot, a resistance equal to the weight of one pound of matter. In countries using the metric system, the unit of work in engineering operations is the kilogram-meter. The foot-pound is not as precise and definite a unit as the erg, because the attraction that the earth exerts upon a pound of matter varies with the latitude and with the elevation above the sea and hence the foot-pound varies in the same manner. The variation is not great enough, however, to destroy the usefulness of the foot-pound as a unit of work or energy for engineering purposes, and hence the familiar unit is not likely to be discarded for ordinary, rough purposes.

To avoid the indefiniteness of the foot-pound, we might adopt the far more scientific (but exceedingly uncommon) unit known as the "foot-poundal," which is defined as the quantity of energy that must be applied in order to overcome a resistance of one poundal through a distance of one foot—a poundal being the force which, when applied for one second to a body having a mass of one pound, subject to no other forces and initially stationary, will produce in that body a velocity of one foot per second.

A moving body possesses energy in virtue of its motion and work must be done by it before it will stop. Thus a railroad train, moving at high speed, cannot be brought to rest at once, because the energy of motion that it possesses must first be expended in overcoming the resistance of the brakes, or the natural frictional resistance of its axles in their journals and its wheels upon the tracks. The mechanical energy of a body in virtue of its motion of translation or rotation is called "kinetic energy"; and that which it possesses in virtue of its position or its state of elastic strain is called "potential energy." The body must do, in order to come to rest. If the mass of the body is M and the velocity is V, it can easily be shown, from the principles of theoretical mechanics, that the work thus performed is $\frac{1}{2} MV^2$. This is therefore the numerical expression for the kinetic energy of the body. If V is given in feet per second and M is given in pounds, this formula gives the kinetic energy in foot-pounds; and hence if it is desired to state the result in foot-pounds, it is necessary to divide by the acceleration of gravity, as expressed in the same fundamental units — namely, by 32.2, in a locality in which the speed of a body falling freely in a vacuum increases, each second, by 32.2 feet per second.

It is not only impossible, in many cases, to state what form the energy has, within a given body or system, but it is also usually (and perhaps universally) impossible to say how much energy the body or system contains in the aggregate. In other words, there is usually no absolute and natural zero from which the energy can be reckoned; and hence we have to assume an arbitrary zero point, or else confine our attention to the quantities of energy added to the body or system (or subtracted from it), without attempting to estimate the total amount present. In the case of ordinary kinetic energy, there is apparently a natural zero, corresponding to absolute rest; but it will be evident that this zero is only conventional, inasmuch as "rest" is a relative term and a body that is seemingly quite devoid of motion is nevertheless rushing through space, with the earth, at a considerable speed. The case is even plainer in connection with the potential energy of a raised body. The body can do work by falling, but it evidently can do an indefinite amount of work by falling through an indefinite distance. In applying the principles of energetics to falling weights it is therefore conventional to assume some arbitrary level (at least as low as the lowest point to which the weight can go) as the level of zero potential energy. In the case of a pendulum, for example, we say that the bob has no potential energy when it is at the lowest point of its swing, for the simple reason that it cannot do more work by falling in order to fall to that point. It is already at the lowest point to which the construction and mounting of the pendulum will allow it to go; yet we know very well that it could do more work if the supports were removed and the pendulum as a whole were allowed to fall still further.

Transformation of Energy.—It often happens that energy of some one given and distinctly recognizable type may be transformed into energy of some other easily recognizable and definite type. The simplest example of the transformation of this kind is afforded by the case of a freely-falling body. The potential energy that the body possesses in virtue of its elevated position grows less as the body descends, and the kinetic energy that it possesses increases at the same time. If it is a simple matter to show, by the aid of elementary mechanical principles, that the gain in kinetic energy is precisely equal to the loss in potential energy. In the same way, an electric current flowing through a wire causes the wire to become hot. It has been proved that the heat-energy thus produced is precisely equivalent to the electrical energy.
that disappears and which is not otherwise accounted for.

When energy is thus converted, it is found that there is always an exact relation between the quantity of heat which wholly converted into that of the other type that appears and the quantity of energy of the other type that appears. In fact, these two quantities are precisely equal, if they are both expressed in work-units—that is, in ergs or foot-pounds. As a matter of practical convenience, however, energy of a given special type is often measured in some special unit that lends itself, more readily than the erg or foot-poundal, to the particular measurements and approximate calculations that are associated with this species of energy. Heat is a familiar case in point, as it is commonly measured in terms of either the "British thermal unit," or the "calorie"—the British thermal unit being defined as the quantity of heat required to raise the temperature of one pound of water by one Fahrenheit degree, at a certain specified point on the thermometric scale, and the calorie being defined as the quantity of heat required to raise the temperature of one kilogram of water by one Centigrade degree. Some units and others analogous to them, which are based upon obvious, directly-observable properties of substances and which do not involve any physical theories whatever might with propriety be called "natural units." Owing to the fact that energy of one type may be transformed into energy of another type, it becomes exceedingly important to know the numerical relation between the "natural" units in which different forms of energy are measured; for until we possess this knowledge, we cannot compare amounts of energy of different types—become we cannot express these quantities in terms of the erg, or foot-poundal, or any other common or fundamental unit. We should, in fact, be in the same position as a man who had measured one liquid with a gallon measure and another one with a pint mug, but who had no idea of the relation of the pint to the gallon.

It is especially important to be able to compare the "natural" unit of heat accurately with the erg or the foot-poundal, and many elaborate experimental researches have been conducted for the purpose of improving our knowledge of this relation. For full particulars with regard to this topic the reader should refer to the "HEAT AND THERMODYNAMICS," but it may be said, in this place, that Rowland found that one British thermal unit of heat is the equivalent of about 778 foot-pounds of mechanical work—the "foot-pound" here being understood to signify the attraction of the earth for one pound of matter, at sea-level in the latitude of Baltimore.

Efficiency of Conversion.—It is not always possible to convert a given quantity of energy of one type wholly into energy of some other given type, or wholly into mechanical work. Heat, for example, at any temperature, is analogous to intensity, in the sense that they do not depend in any way upon the mass or volume of the body, but only upon its physical state; and for this reason they are called the "intensity-factors." At the same time the infinitesimals of energy, since the dimensions of every one of the added quantities are the same as the dimensions of energy, will be proportional to the volume of the body, or to
its mass, or to some other quality or attribute that would necessarily vary if the size of the body should vary, without any change in $X$, $Y$, $Z$. The terms $\Delta x$, $\Delta y$, $\Delta z$, are therefore called the "capacity factors" of the terms on the right of the equation. Furthermore, the interpenetration of the body will be shown to have an effect that is dependent on its value within the body, as compared with its value in the environment immediately external to the body, determines whether the energy represented by $X \Delta x$ will enter the body or leave it.

By way of elucidation, let us consider the case of a perfect gas subject to variations such that any two of the three variables pressure, temperature and volume, will suffice to define its condition at any given moment; and let us assume that the only forms of energy to be considered are heat-energy and the energy of elastic compression. Then the foregoing equation takes the form

$$\Delta E = T \Delta \phi - \Phi \Delta v,$$

where $T$ is the absolute temperature, $\phi$ is the entropy, $\nu$ is the volume of the gas, and $\Phi$ is the pressure to which it is subjected, per unit of its bounding surface. (See Thermodynamics.) The first term on the right is then the quantity of heat-energy absorbed, and the second is the quantity of compression-energy absorbed. (The negative sign is affixed to the last term because we are considering the energy added to the system, and the internal energy due to compression increases when $\nu$ decreases).

If the body or system undergoes any kind of a cyclic change, such that its final state in all respects identical with its initial state, then the algebraic sum of all the changes of $E$ (the internal or intrinsic energy), summed up for the entire cycle, will be zero; for if this were not the case, then by causing the body to pass around the cycle repeatedly, in one certain direction, we could obtain an indefinite supply of energy from it; and this would violate the principle of the conservation of energy. (See below.) Suppose, now, that in the special case we are considering, the body undergoes the following cycle: (1) With its temperature constantly equal to $T_1$ it passes from the state in which $\phi = \phi_1$ to the state in which $\phi = \phi_2$; (2) with $\phi$ constantly equal to $\phi_1$ it passes from the state in which $T = T_1$ to the state in which $T = T_2$; (3) with $\phi$ constantly equal to $\phi_2$ it passes from the state in which $\phi = \phi_2$ to the state in which $\phi = \phi_1$; and (4) with $\phi$ constantly equal to $\phi_1$ it returns to its initial state, so that $T$ changes from $T_1$ to $T_2$. In each stage the heat absorbed will be obtained by integrating along the path that is followed. Thus in the first stage $T_1(\phi_1 - \phi_2)$ units of heat will be absorbed. In the second stage there will be no heat absorbed, because $\phi$ does not change. In the third stage $T_1(\phi_2 - \phi_1)$ units of heat will be absorbed; and in the final stage no heat will be absorbed. But as $T$, the absolute temperature, is essentially positive, it follows that $T_1(\phi_2 - \phi_1) = -T_1(\phi_1 - \phi_2)$ is negative, hence heat cannot be absorbed. Hence if heat enters the body during the first stage of the cycle, heat is rejected by the body during the third stage. The amount of heat that is absorbed in the course of the whole cycle is $T_1(\phi_2 - \phi_1) - T_2(\phi_1 - \phi_2) = (T_1 - T_2)(\phi_1 - \phi_2)$, and in view of the principle of the conservation of energy, this must have been converted into some other form of energy. But it is not represented by any increase in the internal energy of the body, because a complete cycle has been described, and the body has returned to its original state. Hence it has been converted into mechanical energy.

The only heat that has entered the body (in the positive direction) is the quantity taken in during the first stage of the cycle. Hence the efficiency of the conversion of heat-energy into mechanical-energy is

$$\frac{(T_1 - T_2)(\phi_1 - \phi_2)}{T_1(\phi_1 - \phi_2)} = \frac{T_1 - T_2}{T_1}.$$
cannon-ball is accompanied by the generation of enormous quantities of heat, and the wood-work on battleships is often set afire in consequence of the mere impact of projectiles. The water at the bottom of a waterfall is measurably warmer than that at the top; and the rise in temperature that results from a large mass of lead is suddenly arrested was used by Himmel with remarkable success for the determination of the mechanical equivalent of heat.

The idea that energy cannot be created appears to have been familiar to Galileo, whose contemporaries, for example, are much more easily discussed by the aid of the principle of conservation of energy than they could be without it. The extension of that principle so as to cover all the cases in which it had previously appeared to be violated could not be made until the fact was recognized that heat is not a substance; for, obviously, it was impossible that a substance could be converted into mechanical energy. It was not until about 1840, however, that the great steps were taken that led to the establishment of our present views. Several eminent names are connected with these beginnings of the modern theory of heat. The most familiar is that of Joule, who seems to have carried the idea to its logical conclusion. But at the same time the credit among them justly. Prominent among these names are those of Séguin, Mayer, Colding and Joule; but it is undoubtedly to Mayer and Joule that we are chiefly indebted for the new ideas, and the controversies that were rife at one time concerning the credit that should be given to different investigators for their work along this line were mainly confined to a discussion of the priority and the relative importance of the contributions of these two men.

Dr. Julius Robert Mayer, an obscure physician of Heilbronn, Germany, who had had some professional experience in the island of Java, had observed that the venous blood of the Javanese often exhibits the brilliant red color that is characteristic of the highly oxygenated blood of the arterial circulation; and after much reflection he came to the conclusion that this is because a lesser amount of oxidation suffices to maintain the temperature of the acceptance it now holds required in a cooler one. These observations were made in the summer of 1840. In May 1842 he published, in Liebig's Annalen, a paper entitled 'Remarks on the Forces of Inorganic Nature,' in which he gave a preliminary account of his discovery. Here he presents the general outline of the new theory very clearly, and the grasp of the subject that he displays at this early date is truly wonderful. The locomotive itself was then a great novelty, but he uses it to illustrate the transformation of heat into mechanical energy and back again in the following sentence, which would be a credit to the most advanced physicists of to-day: "The locomotives may be compared to distilling apparatus; the heat beneath the boiler passes into the motion of the train, and is again deposited as heat in the axles and wheels."

In 1845 he published a second and much more remarkable paper entitled 'Organic Motion in its Connection with Nutrition,' in which he gives a detailed calculation of the mechanical equivalent of heat, from the known specific heats of air. The contributions of James Prescott Joule, of Manchester, England, to the mechanical theory of heat and the conservation of energy were the natural outcome of investigations that he had been making upon the heating effects of electric currents. His first paper that distinctly enunciated the new conception of a form of energy was read at Cork, in 1843, before the British Association, and was entitled "On the Caloric Effects of Magneto-Electricity, and on the Mechanical Value of Heat." As first written it was very involved, and Faraday, who appears to have failed to grasp its exceeding importance, advised Joule not to submit it. He did submit it, however, and in it he gave a number of estimates of the mechanical equivalent of heat. The paper apparently did not greatly impress either the British Association or the outside world; for when Joule brought the subject up again before the same association in 1847 he had an experience that is best described in his own words: "The chairman suggested that, as the business of the section pressed, I should not read my paper, but confine myself to a short verbal description of my experiments. This I endeavored to do, and discussion not being invited, the communication would have passed without comment if a young man had not risen to protest. As a result of the intelligent observations created a lively interest in the new theory." The young man was Lord Kelvin, then simply William Thomson, two years out of college. In later years Joule obtained far better values for the mechanical equivalent of heat, and spent much of his time devising and executing new methods for its determination.

In England and the United States Joule is commonly credited with the discovery of the true nature of heat; but in Europe the honor is frequently given to Mayer. Tyndall compares the two very fairly. "Withdrawn from mechanical appliances," he says, "Mayer fell back upon reflection, selecting with marvellous sagacity, from existing physical data, the single result of which could be founded as an expression of the mechanical equivalent of heat. In the midst of mechanical appliances, Joule resorted to experiment, and laid the broad and firm foundation which has secured for the mechanical theory the acceptance it now holds."

In May of Joule's time was occupied in actual manipulation; freed from this, Mayer had time to
follow the theory into its most abstruse and impressive applications. With their places reversed, however, Joule might have become Mayer, and analyse become Joulization.

In 1847 Helmholtz published his remarkable paper entitled 'On the Conservation of Energy,' in which the subject was presented with great generality and clearness, and which had a profound influence in spreading the new doctrine which had been so fruitfully discussed by Mayer. But we must not annihilate, but that we have to do merely with endless transformations of it from one form into another. Attempts have been made to deduce the principle of the conservation of energy from the general laws of mechanics, and in many special cases these attempts have been successful, though they cannot be in all cases, because systems are easily imagined in which the law is not fulfilled. The point is, however, that these imaginary, non-conservative systems appear to de are not based in direction. In allusion to the twofold nature of the subject (that is, the mathematical and physical aspects), it has been humorously said that everybody believes firmly in the conservation of energy, because the facts of scientific observation, while the physicists believe it to be a theorem in mathematics. It is now generally admitted, however, to be a fact of observation, the truth or falsity of which is to be established by experiment. Helmholtz proved that in any system composed of particles moving about in paths or orbits, and subject only to "central forces" (that is, to forces that act always toward fixed centres or foci, or which act, between every pair of particles, along the line adjoining their centres), the energy must be conserved, if the ordinary laws of theoretical mechanics hold true for the motions of the particles of which the system consists. Hence, if it be admitted that all matter consists of atoms that act upon one another only by forces that are central, a long step has been taken toward proving the law for all material systems. Unfortunately, however, we are not sure that central forces are the only ones that act upon the atom. It is an interesting fact that it was the study of the properties of energy that gave Mayer his first inspiration concerning the true nature of heat, and yet it is precisely here that the only doubt as to the entire generality of the law of conservation now exists. The most general test that can be applied to a system to enable us to judge from theoretical considerations whether it is conservative or not is this: Let the system be protected from external influences, and then, at a given instant, conceive the motion of every one of its particles to be stopped, and then, without being modified in any other way. If, when left to itself, the system would then retrace its previous history so that the events of that history would recur in reverse order, the conservation of energy is rigorously fulfilled in it. If, on the other hand, the system would not so retrace its history, we cannot affirm that it is conservative, but must test the point by a direct appeal to experiment. Now, although this crucial condition is frequently fulfilled in inorganic nature, we certainly cannot assert it to be true in connection with living matter, even with respect to the meanest fungus. Hence we cannot, from reasoning based on the inorganic world alone, draw any sound conclusion whatever about the conservation of energy in the organic changes that occur in living tissues. To reach such conclusions for the living animal, we must weigh and analyze both the energy that is excreted or excreta given off; we must determine the oxygen absorbed and the carbon dioxide and other products exhaled; and we must measure the heat given out and the external work performed. When these things have been weighed, measured and analyzed for a scientific system and with the necessary precision, then, and then only, shall we be competent to affirm or deny the truth of the conservation of energy in the animal machine. Such data are difficult to obtain, but much has been done in this direction, and while we are not yet prepared to establish it as a fact, beyond controversy, that energy is conserved in the animal body, all the data that we have point to this conclusion and it is now commonly admitted to be true.

The fact that energy cannot be either created or destroyed has led physicists to speak of it as though it were a real thing, having an objective existence. It is useful to think of it in this way, and convenient to speak of "conversions" from one form of energy to another. In reality, however, it is no more a real thing than is momentum, or "action" (which figures prominently in modern theoretical mechanics). In pure mathematics the theory of transformations makes us familiar with the idea of "invariant" functions and configurations, which retain their forms or values when subjected to the given transformations. It is more logical to think of energy as being a similar invariant under the physical transformations that the existing universe and its contents can undergo. If this be admitted, then the discussions that are now often encountered, in which the possibility of energy having a molecular structure is considered, must be taken in a figurative sense only. It is quite possible that it is given out discontinuously in connection with radiation phenomena, just as the water handled by a "bucket brigade," at a fire, is delivered discontinuously; but the question as to whether or not energy has a molecular structure, or of organic nature that gave Mayer his first inspiration concerning the true nature of heat, and yet it is precisely here that the only doubt as to the entire generality of the law of conservation now exists. The most general test that can be applied to a system to enable us to judge from theoretical considerations whether it is conservative or not is this: Let the system be protected from external influences, and then, at a given instant, conceive the motion of every one of its particles to be stopped, and then, without being modified in any other way. If, when left to itself, the system would then retrace its previous history so that the events of that history would recur in reverse order, the conservation of energy is rigorously fulfilled in it. If, on the other hand, the system would not so retrace its history, we cannot affirm that it is conservative, but must test the point by a direct appeal to experiment. Now, although this crucial condition is frequently fulfilled in inorganic nature, we certainly cannot assert it to be true in connection with living matter, even with respect to the meanest fungus. Hence we cannot, from reasoning based on the inorganic world alone, draw any sound conclusion whatever about the conservation of energy in the organic changes that occur in living tissues. ENERGISM — ENFIELD

potentiel thermodynamique; Gibbs, 'On the Equilibrium of Heterogeneous Substances'; Helmholtz, 'Die Energetik'; Helmholtz, 'Über die Erntee und die Kraft'; Joule, 'Scientific Papers'; Nernst, 'Theoretical Chemistry,' and 'Thermodynamics and Chemistry'; Stewart, 'The Conservation of Energy'; van't Hoff, 'Lois de l'équilibre chimique.' See also MECHANICS; PERPETUAL MOTION; RADIATION; RADIATION THEORY; THERMODYNAMICS.

ALLAN D. RISTEEN,

ENERGISM, the name given by many philosophical writers to the neo-Aristotelian view concerning the chief ultimate goal of human life. It is summed up in the dictum, "the goal at which the will of every living creature aims is the normal exercise of the vital functions which constitute its nature." Energism is opposed to Egoism, which puts pleasure as the chief goal of human life. Consult Paulsen, 'System der Ethik' (Berlin 1894; English trans., 1899).

ENERGUMEN, én-ér-gú-mén, a person controlled or "worked up" (ἐνεργούμενος) by evil spirits. The word is in common use in the writings of the Greek and Latin fathers; it is equivalent to the δακτυλικός (daktulikós) (possessed by a devil) of the New Testament. In the 3rd century the churches kept registers of their energumens and dealt with them much as they were lepers; they were supported by the alms of the faithful and lodged in dwellings near the churches. The treatment of energumens and their relationship to the Church was discussed at and regulated by a number of synods, especially that held at Orange in 441 and usually known as Concilium Arusianum. See EXORCISM. Consult Hefele K. J., 'A History of the Councils of the Church' (translated by W. R. Clark and others, Vol. III, Edinburgh 1883).

ENERGY, Conservation of. See ENERGETICS.

ENEURESIS, a symptom of many diseases of the bladder, resulting in incontinence or involuntary passing of urine. It is a prevalent malady of childhood and only becomes of importance after the period of infancy, when the child should have learned to control the bladder. The control of the bladder is in part a matter of conscious effort, and has its representation in the higher brain-centres. Bladder-control is also exercised by that portion of the sympathetic nervous system found in the solar and sacral plexuses, and likewise in a number of cells in the spinal cord situated in the lumbar region. Interference with the action of any or all of these centres may result in enuresis. Disease of the spinal cord may cause excessive irritation of the sympathetic nervous system and may result in nocturnal enuresis, and the cutting off of the cerebral control may also bring about this condition. During deep sleep the cerebral control is usually cut off, accounting for the prevalence of enuresis in deep sleep in children. Very frequently the immediate cause of enuresis is some form of local irritation. This is particularly prevalent in young girls, and should always be removed, if possible, in the treatment. Drug medication is extremely unsatisfactory for this condition. The most efficient measures consist in building up the general nervous system of the patient by tonics, cold baths and exercise in the open air.

ENFANTIN, ὀν-φάν-τάν, Barthélemy Prosper, French socialist of the Saint-Simon school: b. Paris, 8 Feb. 1796; d. there, 31 May 1844. He was the son of a Paris banker, and after studying for some years at the École Polytechnique went into business. After traveling extensively for a number of years he settled in Paris in 1823. In 1825 he first met Saint-Simon (q.v.) and became strongly interested in his political and economic theories. After the July revolution of 1830 Enfantin associated himself with Bazard for the active propagation of Saint-Simonism. They became the supreme heads of the sect. Bazard exploded it in its relations to philosophy and politics; Enfantin mainly in its relations to the social state. They established a paper, called Globe, in which they expressed their views. Soon, however, a schism broke out between the two on the question of marriage and the relation of the sexes, for his views on which Enfantin was, in 1832, sentenced to one year's imprisonment and to pay a fine of 100 francs. This broke up a model community, which, together with 40 of his disciples, he had founded at Ménilmontant after the break with Bazard and where he was known as 'Le père.' Being released from prison at the expiration of a few months he went to Egypt. He was subsequently appointed a member of the scientific commission for Algeria, and on his return from Africa published 'Colonization of Algeria' (Paris 1843). At this time he became again actively interested in business and in 1845 was made director of the Paris-Lyon Railway. After the revolution of 1848 he founded and edited the Journal Le Crédit, which stopped publication in 1850. He was then made administrator of the Lyon Railway, in which position he was quite successful and which he occupied until his death. His library of 1,018 volumes and 63 manuscripts he left to the Library of the Arsenal at Paris. His various writings, all on economic and political subjects, have been published together with those of Saint-Simon as 'Œuvres de Saint-Simon et d'Enfantin' (47 vols., Paris 1865-78). Consult Housse, E. S., 'Enfantin and Saint-Simon' (in Theological Review, Vol. IX, p. 50, London 1872).

ENFANTS DE DIEU, ὀν-φάν-δε-δύ, a name of the French Camisards (q.v.).

ENFANTS PERDUS, per-dú ('lost children'), in military parlance the men appointed to perform some exceedingly hazardous duty from which their chances of returning safely are practically nil. Our English equivalent phrase is "a forlorn hope."

ENFEOFFMENT, én-éf-mént, (1) the act of bestowing or investing with a freehold estate; (2) the instrument or deed by which such estate is conveyed; (3) the estate so conveyed. See FREEHOLD.

ENFIELD, Conn., town in Hartford County, on the Connecticut River and the New York, New Haven and Hartford Railroad, 15 miles north of Hartford. Its chief manufactures are carnets, shoddy, powder, filter
presses, supplies for undertakers and bicycles, and it has large brick works. A large amount of the now celebrated Connecticut tobacco is here prepared for use and shipped to different parts of the world. Shaker Station is a part of the town (see SHAKERS). It contains a Great Forest, and the government is administered by town meetings. Pop. 11,006.

ENFIELD, England, a market town in the county of Middlesex on New River, nine miles northeast of London. Enfield is the seat of the well-known government manufactory of rifles and small-arms, and the standard rifle used in the British army is made here. At Cuffley, three miles north of Enfield, the first Zeppelin to be brought down on English soil was shot down on 3 Sept. 1916 by Flight-Lieutenant Robinson, who was awarded the Victoria Cross for the daring deed. The airship fell headlong, sinking to the ground in flames, and the members of the crew burned to death. Some noted people have lived in Enfield. See BEACONSFIELD; LAMET; KEATS. Pop. 56,388.

ENFIELD RIFLE, a muzzle-loading rifle used in the British army prior to the introduction of the breech-loading system. It was also used in the United States during the Civil War by the Northern army, when Springfields could not be obtained, and by the Confederate army. In England large numbers of these rifles were converted into breech-loaders on the Snider principle and were known as the Snider-Enfield or simply Snider. The Enfield rifle must not be confused with the recent British Lee-Enfield, which is a modified Mauser.

ENFILADE, ēn-flī-lād' (from the Fr. en-fier), in the military art, is to rake by fire the enemy's trenches or positions along the whole length. In conducting the approaches at a siege care must be taken that the trenches be not enfiladed from any part of the place besieged. To avoid this they are generally cut in a zigzag. The same principle holds true of trench warfare, where the boyaux or communicating trenches are zigzagged and the firing trenches are protected by trench art.

ENFLEURAGE, ōn-flē-rāzh, in perfumemaking, the method of extracting by contact and absorption the scents of flowers used for perfumery. For this purpose wooden frames containing glass smeared with pure grease are filled with flowers, which are allowed to remain from one to six days. The grease gradually absorbs the scent, the flowers being renewed from time to time. The scent is afterward separated from the grease by soaking the latter in strong spirits of wine. Sometimes wire frames covered with cotton cloths, saturated with fine olive-oil, are used instead of glass. In this manner the most delicate odors are extracted from flowers which would be lost in the process of distillation. This process is employed especially in the south of France. It is rather complicated, and has the disadvantage of permitting the flowers to come into direct touch with the grease and imparting to it possibly some impurities. In modern perfume factories the process of enfleurage, therefore, is frequently accomplished by placing flowers and grease in separate containers, the odor is created by means of an exhaust fan in such a manner that it passes first over the flowers and later over the grease, which latter rapidly absorbs the odors originated by the flowers. Another method consists of passing a current of carbonic acid gas through a tin box containing fresh flowers and then into a glass jar of strong alcohol cooled by water. The carbonic acid absorbs the odors of the flowers, which, in turn, is absorbed by the alcohol. Consult Askinson, G. W., 'Perfumes and Cosmetics, their Preparation and Manufacture' (translated from the German by W. L. Dudley and others, New York 1915); Rolet, A. V., 'Les Essences et les Parfums' (Paris 1907); Pissier, G. W. S., 'Chimie des Parfums et Fabrication des Essences' (Paris 1917).

ENG AND CHANG. See SIAMESE TWINS.

ENGADINE, ēn-gā-dĕn', a beautiful valley in Switzerland, in the Grisons, on the banks of the Inn, bordering on the Tyrol. The extent of the valley is 60 miles and it has an area of 653 square miles. The language generally spoken is the Ladin, a branch of the Romanic tongue. Several towns and villages are situated in the valley, which is visited by numbers of strangers on account of its picturesque beauty and its mineral springs as well as its invigorating climate. Pop. 12,193.

ENGAGEMENT. See BETROTHMENT.

ENGAGEMENT, Military, a minor battle or encounter in which all the parts or divisions of the contending armies do not have a part. Engagements or skirmishes usually occur when major forces are being manoeuvred for position to secure the advantage in a pitched battle. See MILITARY SCIENCE; TACTICS, MILITARY.

ENGANO, ēn-gā'lo, an island of the Malay Archipelago, 60 miles south of Sumatra. It is covered with forests and surrounded by coral reefs; area, including several small adjacent islands, 300 square miles. The natives are Malays.

ENGEDI, ēn-gē'dē or ēn-gē'di (Heb. "Fountain of the Goat"), on the western shore of the Dead Sea, about 30 miles southeast of Jerusalem. The modern Arab name is Jidy. The ancient name was applied also to the eastern part of the wilderness of Judah. The city in the time of Abraham was called Hazazon-tamar (Gen. xiv, 7), the tamar meaning palm tree. In 1 Samuel xxvii mention is made of David fleeing into the wilderness of Engedi to escape from Saul. There are numerous other references to the place in the Old Testament. In modern times nothing remains except the never-changing effectiveness of the scenery arising from the combination of steep cliffs, the Dead Sea, strange vegetables, balmy air and almost excessive quietness. Consult Robinson, E., 'Biblical Researches in Palestine, etc.' (Vol. II, Boston 1841); Wilson, Sir C. W., 'Picturesque Palestine' (Vol. I, London 1884).

ENGEL, Ernst, German statistician: b. Dresden, 1821; d. Berlin, 1896. After a preliminary education he took up the study of mining engineering at Freiberg and Paris. For a time he was a member of the commission investigating industrial and labor conditions in Saxony, and in 1850 was appointed chief of the Royal Bureau of Statistics at Dresden. He resigned in 1858 and was made chief of the Saxon
Mortgage Insurance Company, but two years later became director of the Prussian Bureau of Statistics, from which he retired in 1882. He was one of the most efficient of modern statisticians and his investigations into the social condition of the working classes have proved invaluable. He wrote 'Die Methoden der Volkszählung' (1861); 'Land und Leute des Preussischen Staates' (1863); 'Das Zeitalter des Dampfes' (1881).

ENGEL, Franz, German explorer: b. Röbel, Mecklenburg-Schwerin, 1834. He traveled extensively in South America in the years 1857–63 and published the results of his explorations in several valuable volumes, including 'Studien unter den Tropen Amerikas' (2d ed., 1879); 'Aus dem Pflanzerstaate Zulia' (1881). From 1872 to 1896 he published the 'Landwirtschaftliche Jahrbücher.'

ENGEL, Johann Christian von, Hungarian historian: b. Teutschau, Hungary, 1793; d. 1849. He received his education at the University of Göttingen, where Heyne and Schlözer were among his teachers. He wrote several historical works which in their day were treasure-houses of knowledge and scholarship. He was the first to put the history of Hungary on a sound scholarly basis. In 1812 he was ennobled. His greatest works are 'Geschichte des ungarischen Reiches und seine Nebenländer' (5 vols., 1797–1804); and 'Geschichte des Königreichs Ungarn' (5 vols., 1814).

ENGEL, Johann Jakob, German prose writer: b. Parchim, 11 Sept. 1741; d. there, 28 June 1802. On the accession of King Frederick William III of Prussia, whose tutor he had been, he was invited by his former pupil to Berlin, where he made himself exceedingly useful in the Academy of Sciences by his writings. Among his philosophical works may be mentioned his 'Der Philosoph für die Welt,' distinguished for acute observations on men and manners, enlivened by elegant illustrations. Of a similar character is his 'Mirror for Princes' (1789), 'The Principles of the Administration of Justice,' &c. They are full of taste, acuteness and knowledge of human nature, may be regarded as a kind of manual for actors. Anxious to make the German theatre the mirror of the national life, he wrote several plays, but they were of little merit — 'Der dankbare Sohn'; 'Edelknaben,' etc. His 'Lorenz Stark,' a novel, is a masterly picture of life and manners. A complete edition of his works appeared at Berlin (1801–06).

ENGEL, Joseph, Austrian anatomist: b. Vienna, 1816; d. 1889. He was appointed professor of anatomy at Zürich in 1844 and later the chair of physiology fell to him also. Five years afterward he was appointed to the chair of pathological anatomy at the University of Prague. In 1854 he became professor of anatomy at the Josephakademie, Vienna, in which position he remained until 1874. He made many important contributions to the systematization of anatomical science and its study. His principal works are 'Lehrbuch der pathologischen Anatomie,' and 'Kompendium der topographischen Anatomie.'

ENGEL, Karl Dietrich Leonhard, German musician and writer: b. grand duchy of Oldenburg, 21 Feb. 1824. He went to Russia as a violin virtuoso at the age of 18, becoming a member of the Imperial Orchestra at Saint Petersburg at 22, and later its concert-master. He went to Dresden in 1869 and took up his residence there. Among his works are 'Deutsche Puppen Komödien' (1874–93); 'Das Volksschauspiel Doktor Johann Faust' (2d ed., 1882); 'Zusammenstellung der Faustschriften vom 16. Jahrhundert bis Mitte 1884' (2d ed., 1884); 'Die Don Juan Sage auf der Bühne' (1887). His musical compositions include a concerto in B minor and the humorous fantasy entitled 'Jüdischer Carneval.'

ENGELBERG, Switzerland, a noted health resort, situated in Unterwalden Canton, in the Engelberg Valley, about 3,500 feet above sea-level, and 15 miles south of Lucerne. It is the seat of a Benedictine monastery, dating from the 12th century, with a library of 20,000 volumes, including incunabula and manuscripts of great value. Connected with the monastery is a gymnasium which was founded in the 11th century. Cheese-making is the main industry. Pop. 2,500.

ENGELBERT, Bohemian monastic author: b. Völkendorf, Styria, about 1250; d. 1331. He received his education at Prague and Padua, entered the order of the Benedictines and in 1297–1298 was abbot of Admont, Styria. He is best known to scholars through his Roman history; entitled 'De Ortu, Progressu et Fine Imperii Romani,' which has gone through numerous editions. For other works of this author consult 'Thesaurus Anecdotorum Novissimius' (1721) and 'Bibliotheca Ascetica Antiquo-nova' (1723–25).

ENGELBERT, Saint, archbishop of Cologne: b. Berg, 1185; d. 1225. In 1186 he was excommunicated, but was restored to friendly relations with the Church and reinstated two years later. In 1216 he was appointed archbishop of Cologne. He was one of the most progressive men of his age; he greatly improved the administration of his see; patronized agriculture, the industries and art, and opposed the repressive and cruel methods of the feudal barons. He reformed the electorate and after 1220 was administrator of the empire. In 1217 he crowned Henry VII. He was assassinated by hirelings of his nephew whom he had accused of maladministration. He is commemorated as a martyr on 7 November, although he has never been formally canonized. Consult Stoffel, 'Engelbert der Reichsverweser' (Elberfeld 1893).

ENGELBRECHT, Theodor Heinrich, German geographer: b. Obendeich, Schleswig-Holstein, 1853. He acquired his education at the universities of Leipzig and Strassburg, and in 1911 received the honorary degree of doctor from the University of Breslau. In 1895 he became a member of the Free Conservative party in the House of Deputies. His works include 'Die Landbauzonen der aussertropischen Länder' (3 vols., 1899), a valuable work on the study of agriculture in Europe; 'Die geographische Verteilung der Getreidepreise' (2 vols., 1908), the first volume dealing with the United States, the second with India; 'Boden-
ENGELBRECHTZEN — ENGELMANN

baut und Viehstand in Schleswig-Holstein (1905).

ENGELBRECHTZEN, eng'el-brett-zen, Cornelis, Dutch painter: b. Leyden, 1468; d. there, 1533. He was the son of the wood-engraver Engelbert, and the teacher of Lucas, being the earliest known painter in Leyden and the first of his nation to use oil colors. Many of his works were destroyed during the Reformation, and the only two properly authenticated pictures of large size are altarpieces with 'Crucifixion' and altarpiece with 'Pieta,' Town Hall, Leyden. Doubtfully attributed to him are 'St. Leonard,' Antwerp Museum; 'Crucifixion,' old Pinakothek, Munich; 'Deposition,' Moritz Chapel, Nuremberg; 'Madonna and Child,' National Gallery, London; 'Crucifixion,' Venice Academy. The Van Leydens were his pupils.

ENGELHARD, Friedrich Wilhelm, fréd'-rih vil'helm eng'el-hart, German sculptor and painter: b. Grünhagen, Frussia, 19 Sept. 1813; d. 22 Jan. 1902. He studied at Hanover, at Copenhagen with Thorwaldsen and at Munich with Schwanthaler. He executed many groups, single figures and genre pieces. Among his creations are 'Love on a Swan;' 'Dancing Spaniards;' 'Slayer with Dog;' 'Bacchus Conquering a Panther;' 'Cupid and Psyche;' the frieze of the 'Edda,' his chief work; 'A Child Fishing;' 'A Child Threading a Needle;' statue of 'St. Michael;' portrait medallion of Bismarck for the monument of Canossa, near Hanover; 'Christ Blessing Little Children;' and the legendary characters of Germany, 'Odin,' 'Thor' and the Valkyries.

ENGELHARDT, Georg von, Russian statesman: b. Riga, 1775; d. 1862. He went to Saint Petersburg in 1790 and six years later secured a post in the Department of Foreign Affairs. He became Undersecretary of State in 1801 under Alexander I. He was made director of the Pedagogical Institute in 1811 and of the Lyceum at Tsarkoe-Selo in 1816. His liberalism, however, led to his removal in 1823. From 1838 to 1852 he edited the Russische Zeitung. He published 'Russische Miscellen zur Kenntnis Russlands und seiner Bewohner' (4 vols., 1828-32) and edited the manuscript journals of the explorer, Wrangel, which he issued in 'Reise längs der Nordküste von Sibirien und auf dem Eismeer' (1839).

ENGELHARDT, Johann Georg Veit, German theologian: b. Neustadt-an-der-Aisch, Bavaria, 1791; d. Erlangen, 13 Sept. 1855. In 1822 he became professor of theology at Erlangen; during the years 1845, 1847 and 1848 was the representative of his university in the diet at Munich. His most celebrated works are a translation of the writings ascribed to Dionysius the Areopagite; 'Handbuch der Kirchengeschichte' (1834); 'Richard von St. Victor und Johannes Ruybroeck' (1836); 'Dogenmenschen' (1839).

ENGELHARDT, Moritz von, Russian naturalist: b. Esthonia, 1779; d. 1842. He received his education at Leipzig and Göttingen and the Freiberg mining school. He made a tour of Europe with Karl von Raumer and in 1811 visited the Crimea and Caucasus with von Parrot, and seven years later he traveled through Finland. He taught mineralogy at Dorpat in 1820-30, and thereafter traveled and explored Russia, discovering vast deposits of gold, platinum, etc., detailed in his reports, which were issued at Riga in 1830. His principal works are 'Geognostischer Umriß von Finnland' (1821); and, with von Raumer, 'Geognostische Versuche' (1816) and 'Geognostische Umrisse' (1817).

ENGELHARDT, Vassili Pavlovič, Baron, Russian astronomer: b. Kustovitchi, Grodno, 1828. He received his education in Saint Petersburg, entered the government employ in 1847 and remained in its service for six years. He built an astronomical observatory in Dresden in 1872. He also gave valuable astronomical instruments to the University of Kazan and erected buildings there to house them. His published works include 'Observations astronomiques faites à Dresde' (3 vols., 1886, 1890, 1895).

ENGELHARDT, Zephrynn (Charles Anthony), American writer and missionary: b. Bilshausen, Hanover, Germany, 13 Nov. 1851. He came to the United States in 1852, was educated in the parish schools and Saint Francis Seraph College, Cincinnati. From 1855 to 1857 he entered the Franciscan order, was ordained to the priesthood in 1878 and in 1878-80 was teacher at Saint Joseph's College, Cleveland, Ohio. From 1880 to 1885 he was missionary to the Menominee Indians in Wisconsin and from 1885 to 1887 was stationed at Superior, City, Wis. He was vice-commissary for the Holy Land and editor of the 'Weekly Pilgrim of Palestine' at New York in 1887-88 and for the ensuing two years was missionary in Mendocino County, Calif. In 1889 he was stationed at Saint Joseph's Monastery, Cleveland, and from 1894 to 1900 was superior of the missions of his order in northern Michigan and of the Indian Boarding School, Harborsprings, Mich. In 1901 he was stationed in California. In 1895 he founded and for five years edited the 'Anishinhwa Enamiid, a periodical in the Ottawa-Chippewa language. He is a member of the Texas Historical Association and of the National Geographical Society and has published 'Kachkenoman on ene' (1882); 'Kateshin' (1883); 'The Franciscans in California' (1897); 'Missions and Missionsaries of California' (5 vols., 1908-16); 'The Holy Man of Santa Clara, or Life of Father Magin Catala' (1909). He is a contributor to the 'Katholische Missionen, California Volksfreund, Sankt Josephsblatt.' He writes in German under the nom-de-plume of 'Der Bergmann' and in English of 'Esperanza.'

ENGELMANN, George, American botanist: b. Frankfort-on-the-Main, 2 Feb. 1809; d. Saint Louis, Mo. 4 Feb. 1884. He studied medicine at the universities of Heidelberg, Berlin and Würzburg, receiving the degree of M.D. from the last-named institution in 1831. The first half of 1832 he spent in study at Paris where he met Braun and Agassiz. In September 1832 he sailed for the United States where relatives of his had bought some land in the Mississippi Valley. In 1835 he began the practice of medicine at Saint Louis, Mo. Although he was highly successful in the practice of his profession, he had, even during his student days, become deeply interested in botany. This in
terest grew gradually until almost all his leisure hours were occupied with scientific investigations, chiefly in relation to botany, although some of them were devoted to meteorology. As his success in his profession increased he found it possible at times to take protracted vacations, some of which he spent abroad and all of which he devoted to botanical investigations. The results of these were some 100 papers published at various times in different scientific journals, especially in the transactions of the Saint Louis Agricultural Society which were examples of the most painstaking and thoroughgoing scholarship. He soon was recognized as an authority on the botany of the North American continent. The most important of his papers were on Cuscutina, Cactae, Coniferæ, American oaks and grape vines. They together with all his other writings, hardly less important, have been collected and published, illustrated by many plates, as 'The Botanical Works of the Late George Engelmann' (ed. by W. Trelease and Asa Gray, Cambridge, Mass., 1889). This publication also contains an exhaustive biographical sketch. He was the first president of the Saint Louis Academy of Science and an active or corresponding member of many learned societies. His extensive botanical collection is in the Shaw Botanical Garden, Saint Louis, Mo.

**ENGELMANN, Johannes**, Russian jurist: b. Mütter, Courland, 7 July 1832. Educated at the University of Saint Petersburg he became professor of Russian law at Dorpat 1860, retaining the chair for 39 years, and delivering his lectures in Russian instead of German after 1887. These lectures covered a wide field and contributed greatly to the advancement of the science of jurisprudence in Russia. Among his works are 'Die Verjährung nach russischem Privatrecht' (1867); in Russian, 'Der Zwangsvollstreckung; auswärtiger richterlicher Urteile in Russland' (1884); and 'Das Staatsrecht Russlands' (1888).

**ENGELS, Friedrich**, German Socialist: b. Barmen, Prussia, 28 Nov. 1820; d. London, 5 Aug. 1895. The son of a German manufacturer he spent two years in Manchester, England, 1842-44, and took part in the revolutionary movement in Baden in 1848. He returned to Manchester in 1850, and was partner in a manufacturing business from 1860-69, after which he lived mainly in London. He was an intimate friend of Karl Marx (q.v.), and his most efficient helper in the work of organizing the International Socialist movement. In 1870 Engels was corresponding secretary of the International Workingmen's Society for Belgium, Italy and Spain. With Marx he wrote the 'Communist Manifesto' (1847); he also wrote 'The Working Class in England in 1844' (new ed. 1892); 'The Origin of the Family'; 'The Development of Socialism from Utopia to Science' (1845), a part of a large work left unfinished; and edited Marx's 'Capital.' Consul Simons, 'Friedrich Engel: his Life, his Work, his Writings' (1885), a translation from Tauskky's German text; Sombart's biography (1893); and Dawson, 'German Socialism' (1889).

**ENGERTH, eng'ert**, Eduard von, Austrian painter: b. Pless, Silesia, 13 May 1818; d. 1897. He was a pupil of the Vienna Academy, taking the gold medal there in 1845. He became director of the Prague Academy 1854 and in 1855 professor at the Vienna Academy. He was appointed director of the Belvedere Gallery 1871 and director of the Academy 1874. He was made commander of the order of Francis Joseph 1867. Among his works are 'Ham and Esau'; 'Ladislaus and Albrecht'; 'Coronation of Rudolph I'; 'Joseph Explaining the Dream' (1845); 'Seizure of King Manfred's Family' (1853), a masterpiece in the Vienna Museum; 'Victory of Prince Eugene at Zenta' (1863); 'Marriage of Figaro'; 'Fable of Orpheus' (1868); 'Coronation of Francis Joseph as King of Hungary' (1870); 'Death of Eurydice' (1877). Engelser frescoed the church at Alt Lerenfeld after the cartoons of Führich, painted numerous portraits and decorated the new Vienna Opera House.

**ENGERTH, Wilhelm, Baron**, Austrian engineer: b. Pless, Prussian Silesia, 1814; d. 1884. He received his education in architecture at the Polytechnic Institute and the Academy of Arts, Vienna. He became professor of mechanical engineering at Graz in 1844. He is known internationally as the inventor of the system for freight locomotives, which was generally adopted throughout Europe. He also designed and constructed a river gate near Nussdorf to prevent ice from entering the Danube Canal, which previously had been a barrier of annual inundations. In 1873 he was supervising architect of the Vienna Exposition buildings and had complete charge of the engineering department at the exposition.

**ENGHEN, än-gahn, Louis Antoine Henri de Bourbon, Duke of**, French prince: b. Chan- tiley, 2 Aug. 1772; d. Vincennes, France, 21 March 1804. He was the only son of Louis Henri Joseph Condé, Duke of Bourbon. From 1796 to 1799 he commanded with distinguished merit the vanguard of Condé's army, which was disbanded at the Peace of Lunéville (1801). He then married and took up his residence at Ettenheim, in Baden. He was generally looked upon as the leader of the émigrés, and was suspected by the Bonapartists of being privy to the attempt of Cadoudal to assassinate the First Consul in 1804. The spies of Napoleon reported that Enggien was often absent for 10 or 12 days together from Ettenheim, and it was believed that on some of these occasions he had secretly visited Paris. Napoleon therefore invaded the neutral duchy of Baden and the Duke of Enggien was seized 15 March 1804, conducted to Strasbourg, and thence to the fortress of Vincennes, where he arrived on the evening of the 20th. That same night a court-martial was assembled; his innocence being established, the ground of accusation was changed into that of compassing a new coalition against France, of which he was adjudged guilty. He requested an interview with Bonaparte, which was refused, and he was immediately led out to execution. He was shot between four and five o'clock in the morning in the ditch outside the walls, and his body was thrown, dressed as it was, into a grave dug, it is said, the day before. His execution was followed by an indignant protest and the rupture of diplomatic relations with Russia; but of the deed Napoleon never disavowed; he was the last representative of the house of Condé. Consult Dupin, 'Pièces judiciaires' (Paris 1823), and 'Mémoires historiques sur la
ENGINE

A motor or prime mover which is capable of utilizing natural forces, such as the pressure of steam or the expansion of a gas, and converting those forces into mechanical energy in the form of motion, which may be employed for doing mechanical work, thus distinguishing it from a "machine," which can receive motion only from a motor or engine external to itself.

The term engine was originally used in the sense of a machine, a usage which survives in steam-engines and cotton-gin (gin being simply a short form for engine). The first textile machines were called engines, and we still speak of engines of war. But when steam engine became familiarly shortened to engine, the term was confusing, and gradually machine was substituted for the word engine in nearly all uses except generation of power.

All heat engines act through the medium of a working substance which absorbs heat, converts a portion of that heat into mechanical energy, which is represented by the work performed by the engine, and rejects the remaining portion of the heat, still in the form of heat. The working substance may be a gas, a liquid or a solid. The various successful forms of heat engines may be conveniently grouped into three general classes—steam engines, gas and oil engines, turbines and rotary engines.

Steam Engines.—In ordinary forms of steam engines the working substance is saturated steam, a fluid consisting of a mixture of water and steam in varying proportions, the expansive energy of which is utilized to drive or impart motion to a piston working within a cylinder.

Miscellaneous Engines.—Many engines are named from some distinctive feature of their mechanism or a peculiarity of construction. Hence there is the automatic engine, one that is self-regulating, requiring little attention. In a stationary engine this would mean one that regulated its own speed or point of cut-off; in an automobile engine it would mean one that would run without attention, as long as the gasoline feed, carburetor, spark-plug, etc., were in order. A cut-off engine is one in which the steam or motive fluid is cut off before the end of the stroke. A quadrant engine is one having a piston that moves in a quadrangular chamber. A reciprocating engine is the most ordinary type, in which the piston moves back and forth. A direct-connected engine is one that has the crank-shaft extended to form the main shaft of a dynamo. A multi-cylinder engine is one having several cylinders operating on the same shaft, as a 6- or 8-cylinder automobile engine. A self-contained engine is one in which the engine and boiler are both housed in one framework. A screw or propeller engine is one in which the engine is coupled to the screw or propeller. A series-expansion engine is one having several cylinders in which the steam or motive fluid is successively expanded. A twin cylinder engine is one having two cylinders formed in one casting or "en bloc."* 

High-Speed Engine.—One in which the piston speed is rapid, according to some authorities exceeding 900 feet per minute. It possesses the advantages of small dimensions and small weight for a given power, and on account of the frequency of its strokes is capable of making variations in load more quickly than a low-speed engine. Its disadvantages consist in the greater waste of steam, the greater wear, increased danger of heating and higher cost of construction and operation.

Low-Speed Engine.—One in which the piston speed is slow, according to some authorities, less than 100 feet per minute.

Single-Acting Engine.—One in which the pressure of the steam is exerted only on one side of the piston, which is forced back again by the pressure of the atmosphere on the other side against the vacuum produced by the condensation of the spent steam. They were formerly used chiefly for pumping purposes, and in connection with steam hammers, but are now practically out of date.

Double-Acting Engine.—One in which the steam in the cylinder is exhausted into the piston, either against the pressure of the air, or against the vacuum of the condenser. Originally, all engines were made single-acting, but nearly all modern steam engines are double-acting.

Direct-Acting Engine.—One in which the action of the piston is transmitted directly to the crank-shaft. Nearly all engines are of this type.

Indirect-Acting Engine.—One in which the motion of the piston is communicated to the crank-shaft by means of intermediate levers. In the beam-engine, the connection between the piston and the connecting rods consists of a beam, the oscillating point of which is placed midway between the two rods. They are chiefly employed for pumping purposes and for driving paddle-wheel steamers. Other than in this limited field, they are becoming obsolete.

Expansive Working Engine.—An engine is worked expansively when the steam, instead of being admitted at full pressure into the cylinder until the termination of the stroke, is cut off at some fractional part of the stroke and thus caused to do work simply by its own pressure. The steam may be expanded in one or more cylinders. The amount of steam consumed is low as compared to the amount of work done. It is universally used where circumstances will permit, on account of its greater economy as compared with the engines of the non-expansive working type.

Non-expansive Working Engine.—An engine in which the steam is allowed to enter the cylinder at boiler pressure and is maintained at that pressure behind the piston during the whole of the stroke. The amount of steam consumed is disproportionately high as compared to the work done.

Condensing Engine (called also low-pressure or vacuum engine).—One in which the spent steam in the cylinder is exhausted into a condenser and the condensate is returned into the boiler, again operating the back pressure of the atmosphere and consequently effecting a gain of pressure equivalent to 14.7 pounds per square inch in the effective working pressure of the steam.

Non-condensing Engine (called also high-
Oscillating Engine.—A marine engine of the direct-acting type, in which the cylinders are suspended upon hollow trunnions and oscillate thereon, thus allowing the motion of the piston rods to accommodate itself to that of the crank at all parts of the revolution. It occupies but little space and is peculiarly adapted for paddle-wheel steamers. It survives mainly in toy engines because of its simple construction.

Trunk Engine.—An engine having a large hollow piston open at one end and called a trunk. The connecting rod goes right into the open end of this trunk-piston and is attached directly to the piston-head, so that there is no piston rod. It is used in some forms of gas engines and toy engines.

Corliss Engine.—A very economical type of engine, in which the valves are controlled automatically from the governor and the steam supply proportioned to the requirements of the engine at each moment during its working stroke. The valve forms a segment of a circle and turns through an arc of a circle and alternately covers and uncovers the steam port. It is operated by a rod from a wrist plate that is disconnected at every stroke of the engine and the supply valve closed instantaneously by means of a dash-pot.

Cornish Engine.—A standard type of pumping engine, originally of the single-acting type. At the present time it appears in two forms—the beam engine and the direct-acting engine. The valves of a Cornish engine are operated by a special device called a cataract, consisting of a weighted piston which works in a cylinder provided with a large inlet valve and a small discharge valve. The working stroke of the pump lifts the weighted piston and draws the water into the cylinder through the former, and the return stroke discharges it through the latter and at the same time actuates the valves of the steam cylinder of the pump so as to cause another working stroke.

Marine Engine.—Any form of engine used for propelling a vessel. They are usually of the compound or multiple-expansion type.

Stationary Engine.—An engine on fixed foundations, as distinguished from the locomotive, portable and marine engine.

Locomotive Engine.—A high pressure steam engine and multitubular boiler complete, mounted on a carriage and provided with suitable wheels to enable it to draw loaded cars upon a permanent way or railway track. See Locomotive.

Portable Engine.—A small engine of the locomotive type, mounted on a carriage which permits of its being moved from place to place for use in connection with work of a temporary character. Portable engines are extensively used for agricultural purposes and for general traction purposes on ordinary highways.

Gas and Oil Engines.—These classes of heat engines are commonly designated as internal-combustion engines. See Internal Combustion Engine and Diesel Engine.

The Slide-Valve.—The introduction of the slide-valve for operating the ports of a steam engine marked a distinct advance in economy, because it can be made at exactly the right time and also because it admits the hot steam to the cylinder through a port which has just been
cooled by the exhaust. As ordinarily constructed the slide-valve is a sliding D-shaped piece in the steam-chest, moving back and forth over the three ports — the two end-ports of the cylinder and the exhaust port in the centre — and permitting the steam to pass alternately to either end of the cylinder to push the piston and opening the exhaust for the release of the used steam. There are "laps" at the end of the D whose length determines the instant at which the ports shall begin to open. These laps are known as outside or steam-lap, and inside or exhaust-lap. The slide-valve has also been developed for automobile use in the Knight type of engine.

Superheating.—Originally, saturated steam was the only sort employed in steam engines, but as multiple-expansion developed and higher pressures were carried in boilers the use of superheated or dry steam at as high as 500° C. was tried, and it was demonstrated that the hotter the steam the more it expanded and the greater the power to be got out of it. Superheating began experimentally about 1895 and was operated in connection with an economizer. This is a mechanism for utilizing the waste heat and turning it into the feed-water, so that it can be closer to the boiling point, can be supplied to the boiler. Engines using superheated steam have been operated with as little as 1.3 pounds of coal per indicated horse power. See Locomotive.

Steam Turbines comprise a class of heat engines in which the kinetic energy of expanding steam is utilized to drive a wheel and thus convert the natural heat energy of steam directly into mechanical energy in the form of rotary motion. The principal forms are the Parsons, De Laval, Seger and Curtis turbines, and their first field of application and development was in the marine service. Noteworthy examples of their application are the Lusitania and Mauretania ocean steamships and many of the modern "dreadnought" type of battleships. They are now coming into use in large lighting stations and mammoth manufacturing plants. See Turbine.

Hydraulic Engines.—Mechanical power is obtained from flowing water by its weight, pressure or impact, utilizing its forms of water-wheels, turbines, hydraulic rams and water-pressure engines. In the water-pressure engine the pressure of the water only is utilized to drive a piston in a cylinder. In some forms the action of the piston is reciprocating and in others rotary. In all of them the actual amount of pressure expended is only that which is needed to impart motion to the fluid to follow the piston and escape from the cylinder, and, therefore, the greatest efficiency is obtained by making the piston as small as practicable and the forms of hydraulic lifts, for operating the opening machinery of various forms of swing, draw and lifting or rolling bridges, and in connection with cranes and various forms of hydraulic lifts.

For further detailed information relative to the construction, operation and application of the various forms of engines, consult the articles under the titles Automobile; Aeroplane; Internal Combustion Engine; Locomotives; Motor; Pumps and Pumping Machinery; Rotary Steam Engine; Tracttion Engines; Turbine; Water Motor; Water Wheel.

Charles H. Cochrane, Author of Modern Industrial Progress.

ENGINE, Testing of. Engines are tested in order to determine their economy with which they produce a given amount of power. The economy of steam engines, as usually determined, relates to the weight of steam consumed, or to the quantity of coal used in making the steam, or to the number of heat units supplied; while in the case of an internal combustion engine, it relates to the amount of gas, gasoline, oil, alcohol or other fuel burned. Also, if the latter operate on producer gas, the determination of economy involves the amount of coal burned in the gas producer.

Factory tests are generally limited to the performance of individual engines, to determine the set of the governor relative to the proper speed and to ascertain if the valves are set and operate properly. In the case of gas engines, the factory test is extended to cover the correct timing of the igniter and to determine the correct compression.

In its broadest sense, however, testing is a form of scientific investigation conducted for the purpose of securing practical results which are very important not only to the manufacturer, but also to the owner of the engine who has to pay the expense of its operation and to those who require information showing the capabilities of the machines for the purpose of advertising and trade.

As an engine test involves the determination of two elementary quantities — (1) the amount of fuel consumed, and (2) the amount of power developed — it is necessary that these two factors should be represented by units of measurement which are susceptible of universal application.

Standard Unit of Fuel.—The most satisfactory unit for expressions of economy based on the amount of fuel consumed is the British Thermal Unit (B.T.U.), which is the quantity of heat required to raise one pound of water 1 ° F. at or about 39.1 ° F. According to Joule, it is equivalent to 778 foot-pounds of mechanical energy.

A convenient and useful subsidiary standard is that in various forms of water-wheels, turbines, hydraulic rams and water-pressure engines. In the water-pressure engine the pressure of the water only is utilized to drive a piston in a cylinder. In some forms the action of the piston is reciprocating and in others rotary. In all of them the actual amount of pressure expended is only that which is needed to impart motion to the fluid to follow the piston and escape from the cylinder, and, therefore, the greatest efficiency is obtained by making the piston as small as practicable and the forms of hydraulic lifts, for operating the opening machinery of various forms of swing, draw and lifting or rolling bridges, and in connection with cranes and various forms of hydraulic lifts.

For further detailed information relative to the construction, operation and application of the various forms of engines, consult the articles under the titles Automobile; Aeroplane; Internal Combustion Engine; Locomotives; Motor; Pumps and Pumping Machinery; Rotary Steam Engine; Traction Engines; Turbine; Water Motor; Water Wheel.
ENGINE, TESTING OF

Rules for Conducting a Test.—All tests should be conducted systematically under a set of standard rules, clearly defining the character of the data to be obtained and the methods which should be employed for their determination. A set of such rules may be briefly defined as follows:

1. Object of the test.—At the beginning, the specific object of the test should be ascertained. It may relate to the determination of highest economy obtained, or the quantity of oil, or the cubic feet of gas supplied, by the total heat energy of fuel as determined by a calorimeter, or from the results of a chemical analysis. In determining the total heat of combustion, usually no deduction is made for the latent heat of the vapor of water in the products of combustion, therefore, for purposes of comparison, it should be taken into account whether the higher or the lower value has been used in the determination.

2. Condition of the Engine.—The engine should be carefully examined and its general condition noted, especially any points of design, construction or operation which bear upon the object of the test. Special examination should be made of all valves, by inspecting their seats and blowing over them, and care taken to ascertain, in the case of a gas engine, that the piston rings work freely in their grooves and are perfectly gas-tight.

3. Dimensions.—The cylinder dimensions should be taken whether they are already known or not, the measurements being made when they are hot and in working order. When practicable, the clearance volume or compression space of the cylinder should be measured by filling it with water previously measured, the proper correction being made for temperature.

4. Fuel.—When the test involves the complete plant—in the case of a steam engine including the boilers, and in the case of a gas engine including the gas producer plant—the class, name of coal mine, size, moisture, should be stated in the report—and the quality of the coal used should be of some recognized standard. This is desirable for purposes of comparison. In the case of an internal combustion engine, if the test is made to determine the maximum efficiency of the engine, it is desirable that the conditions should be as near as possible to those of the best obtainable, or one that possesses the highest calorific value.

5. Measurement of Fuel.—The methods of determining the amount of fuel consumed depend upon the character of the fuel used. If it be coal furnished to the furnace of a boiler, or to a gas producer, the amount consumed during a period not less than 24 hours should be carefully measured by weight. If it be oil, gasoline, distillate, alcohol, etc., it can be drawn from a tank, which can be refilled to the original level at the end of the test, and the amount required for this purpose weighed; or in the case of a small engine, it can be drawn from a properly calibrated vertical pipe. When gas is used, it should be measured by a suitable gas meter and gas bags should be placed between the metre and the engine to keep the pressure as constant as possible. The pressure and temperature of the gas and the barometric pressure and temperature of the air should be measured and in determining the quantity of the gas supplied, as given by the reading of the metre, the temperature and pressure of the gas should be taken into account.

6. Measurement of Heat Units Consumed.—The number of heat units consumed by the engine can be found by multiplying the number of pounds of coal or oil, or the cubic feet of gas supplied, by the total heat energy of fuel as determined by a calorimeter, or from the results of a chemical analysis. In determining the total heat of combustion, usually no deduction is made for the latent heat of the vapor of water in the products of combustion, therefore, for purposes of comparison, it should be taken into account whether the higher or the lower value has been used in the determination.

The Mahler calorimeter is a type much used for determining the heat of combustion of solid fuels and oils and the Junker calorimeter for gases.

7. Instruments and Their Calibration.—All instruments and apparatus used in the tests should be calibrated and their accuracy verified by comparison with recognized standards. All such as are liable to undergo changes, or become broken during the progress of a test, especially gauges, indicator springs and thermometers, should be calibrated both before and after the test.

Gauges.—For measuring pressures above that of the atmosphere, the most convenient and reliable standard is the dead-weight testing apparatus, consisting of a cylinder having a close-fitting vertical piston working in oil or glycerine, by the medium of which the pressure is transmitted to the gauge. The piston is surrounded by a circular stand on which weights may be placed so as to secure any desired pressure. The total weight, in pounds, on the piston, divided by the area of the piston, in square inches, gives the pressure in pounds per square inch.

The mercury column is another reliable standard of comparison for pressures, but when it is used care should be taken to see that it is properly graduated with reference to the ever varying zero point; that the mercury is pure and that the proper correction is made for any difference of temperature that may exist at the time of using and the temperature at which the instrument was graduated. This is essential to be the best obtainable, or one that possesses the highest calorific value.

8. Measurement of Heat Units Produced.—In determining the heat units produced, the conditions should be as near as possible to those of the best obtainable, or one that possesses the highest calorific value.

9. Measurements of Efficiency.—To determine the efficiency of the engine, the temperature and pressure of the gas and the barometric pressure and temperature of the air should be measured and in determining the quantity of the gas supplied, as given by the reading of the metre, the temperature and pressure of the gas should be taken into account.
exceed 2,000° F., some form of pyrometer or calorimeter should be used. That of Le Chatelier, which makes use of the thermocouple, has been successfully used for accurately measuring temperatures over 2,500° F.

**Indicator Springs.**—For gas-engine indicating, the indicator springs used should be much stiffer and stronger than that used for steam-engine work, so as to enable them to withstand the higher and more suddenly developed pressure. When indicator springs are calibrated, the temperature of the indicator should be as nearly as possible the same as that which exists during the test. An indicator may be conveniently heated by subjecting it to steam pressure immediately before calibration and the actual work of calibration then performed by the use of compressed air or compressed carbonic acid gas. The calibration may be made under a constant pressure, or more satisfactorily by covering the whole range of pressures through which the indicator acts, by gradually increasing the pressure from the lowest to the highest point, and then by gradually reducing it from the highest to the lowest point, and a mean of the results taken for at least five points—two for the pressures corresponding to the maximum and minimum pressures and three for equally distant intermediate points. These values should be compared with a dead-weight testing apparatus, or a steam gauge, or with one of the two first-named standards, and the correct scale of the spring used for calculating the mean effective pressure from the indicator diagrams taken during the test, should be the average based on this calibration.

**Gas Meters.**—A meter used for measuring the gas supplied to a gas engine should be calibrated by comparing its readings with the displacement of a gasometer of known volume; with a standard gas meter of known error; or preferably, through the meter from a tank containing air under pressure. In the latter case, the pressure and temperature of the air in the tank, both at the tank and the meter, should be observed at uniform intervals of time during the tests of calibration, and a mean of the air passing through the meter calculated from the volume of the tank and the observed temperatures and pressures.

The volume of the gas thus ascertained should be reduced to the equivalent volume at a given temperature and atmospheric pressure, corrected for the effect of moisture in the gas, which is usually at or near the point of saturation. For gas-engine work, a convenient standard is the equivalent volume of the gas when saturated with moisture at normal atmospheric pressure at a temperature of 60° F. A volume of moist gas at any other temperature may be reduced to this standard by being multiplied by the factor

\[
\frac{459.44}{b-29.92-\theta} \times \frac{294}{274}
\]

in which \(b\) represents the reading of the barometer in inches at 32° F.; \(t\), the temperature of the gas at the meter in degrees F.; and \(s\), the vacuum in inches of mercury corresponding to the temperature of \(t\) given in the steam tables.

**8. Duration of a Test.**—The length of time devoted to a test will depend largely upon its character and the purpose for which it is made. For determining the working economy, the time allowed should be equal to the number of hours per day during which the engine is really operated. In the case of a gas engine using producer gas, the time should be sufficient to determine the amount of coal used in the gas producer. It should never be less than 24 hours, and usually should extend over several days.

**9. Commencement of a Test.**—If the test is to determine the performance of an engine under working conditions, it should begin at the time the engine is started, and the observations continued until it shuts down for the day. If the test is for determining the maximum economy of the engine, at first it should be run a sufficient length of time to make all conditions normal and constant, then the observations may be commenced and continued for the allotted time.

**10. Measurement of Water.**—In the case of a steam engine this relates to the feed water or steam consumption. The usual method is to measure all the feed water supplied to the boilers, and deduct therefrom the quantity of water discharged by the separator and drip, and the water and steam lost by leakage from the boiler and its main and branch pipe connections with the engine. Where the engine exhausts into a surface condenser, the steam consumption can be measured by measuring the quantity of water discharged by the air pump and adding thereto the steam used by jackets, reheaters and auxiliaries as determined independently. In measuring the water, it should be carried through a tank resting on the platform of a suitably arranged and weighing scales, all the water subsequently emptied into a reservoir beneath, from which the pump is supplied.

For measuring small quantities of water, about 6,000 pounds per hour, the most convenient apparatus consists of a small hoghead connected to the suction pipe of the pump or injector and an ordinary oil barrel placed on a platform scale. The barrel is filled by means of a cold-water pipe leading from the source of supply. For pressure not less than 25 pounds per square, and the amount of water of internal diameter of one and one-half inches. The outlet valve of the barrel is attached to the side near the bottom and should be at least two and one-half inches in diameter, so as to permit of quick emptying.

Where larger quantities of water have to be measured, the barrel can be replaced by a hoghead and two hogheads can be joined together for the lower reservoir. With this arrangement, when the weighing hoghead is supplied through a two and one-half inch valve under 25 pounds of pressure and emptied through a five-inch valve, the capacity attained is 15,000 pounds of water per hour.

For the measurement of very large quantities, or in some cases, very small quantities, the orifice method gives the most satisfactory results, and when applied, the volume of water on the orifice must be ascertained and the discharge of the orifice should be calibrated under the conditions of use.

In the case of an internal combustion engine, the measurements of water relate to that supplied to the water-jacket provided for cooling the temperature of the cylinder. The measure-
ments may be made by the methods already described, but care should be taken, in cases where the temperature exceeds 212°, first to cool the charge by dipping it into a tank of cold water previously weighed, or by passing it through a coil of pipe immersed in running cold water, so as to prevent the loss of evaporation which takes place when hot water is discharged into the open air.

11. Determination of Speed.—The speed of the engine, or the number of revolutions of the crank shaft per minute, can be determined by counting the number of revolutions in one minute with the eye fixed on the second hand of a timepiece, or by the use of some form of mechanical counter such as a tachometer, or continuous recording engine register. The use of such instruments is imperative when the speed exceeds 250 revolutions per minute.

In the case of internal combustion engines governed by the hit-or-miss method, the number of explosions per minute should be ascertained, when the engine is running under nearly maximum load, by counting the number of times the action of the governor causes a miss in the explosions.

The determination of variation of speed during a single revolution on the effect of fluctuations due to sudden changes of load should be made especially in the case of engines employed to drive electric generators used for lighting purposes.

12. Indicator Diagrams.—From the indicator diagrams taken during the test for the computation of the mean effective pressure, etc., sample diagrams nearest to the mean should be appended to the report.

The mean effective pressure (M.E.P.) is obtained as follows: Measure the diagram with a planimeter and divide the area, in square inches, thus obtained by the length of the diagram in inches to obtain the mean height or mean ordinate of the diagram. Multiply the mean ordinate by the scale of the indicator spring and the product will be the mean effective pressure desired. In the absence of a planimeter, the diagram of a be divided by 10 ordinates and their mean length taken for that of the mean ordinate. If the indicator is specially designed for indicating internal combustion engines, the mean ordinate should be multiplied by twice the scale of the spring, unless the scale has been expressly marked for the reduced piston.

In the case of internal combustion engines, when indicator diagrams are not obtainable and the compression pressure is known, the mean effective pressure may be determined approximately as follows: For example, in gas engines the compression pressure ranges from 70 to 90 pounds per square inch, and the maximum pressure developed by the explosions is about 3.5 times the compression pressure. Therefore, if \( p \) represents the compression pressure, then for compressions of 100 pounds per square inch or less, \( \text{M.E.P.} = 2p - 0.01p \); thus, if \( p = 70 \) pounds per square inch, \( \text{M.E.P.} = 140 - 49 = 91 \) pounds per square inch.

For a steam engine, the steam accounted for by the indicator diagram may be calculated by means of the formula

\[
M = M.E.P. \times (C+E) \times We - (H+E) \times Wh,
\]

which will give the weight in pounds per indicated horse power per hour. M.E.P. represents the mean effective pressure, which in the case of a multiple-expansion engine is the combined mean effective pressure disregarded by the indicator in question. For example: In the case of a compound engine, the combined mean effective pressure for the high pressure cylinder consists of two items: (1) the mean effective pressure of the high pressure cylinder multiplied by the ratio of the piston displacement of the low pressure cylinder to that of the high pressure cylinder. The sum of these two items is the combined mean effective pressure for the high pressure cylinder.

Similarly the combined mean effective pressure for the low pressure cylinder consists of (1) the mean effective pressure of the low pressure cylinder, and (2) the mean effective pressure of the high pressure cylinder divided by the ratio already stated. The sum of the two items is the combined mean effective pressure of the low pressure cylinder.

In the given formula, \( C \) represents the proportion of the piston stroke completed at points on the expansion line of the diagram near the actual cut-off or release; \( H \) the proportion of compression; and \( E \) the proportion of clearance; all of which are determinable from the indicator diagram. \( W \) represents the weight of one cubic foot of steam at the cut-off or release pressure; and \( W_h \) the weight of one cubic foot of steam at the compression pressure.

13. Standards of Economy and Efficiency.—The standard expression for engine economy, as already stated, is the hourly consumption of heat units divided by the indicated horse power or the brake horse power. The standard expression for efficiency is the thermal efficiency ratio, or the proportion which the heat equivalent of the power developed bears to the total amount of heat actually consumed, as determined by test. One horse-power-hour represents the consumption of 2.545 B.T.U.'s per hour, therefore,

\[
2.545 \text{ B.T.U.'s per horse power per hour}
\]

expresses the thermal efficiency ratio.

In comparing the standard for internal combustion engines with that for steam engines, it must be noted that the former usually covers the losses due to combustion, but the latter does not, and therefore, in order to make a direct comparison between the two classes of engines as complete horse-power plants, the losses in generating the working agent must be considered in both cases not only on the basis of fuel used, but on the basis of equivalent fuel used in each case. In comparing a gas engine plant using producer gas, with a steam plant, the producer should be included in the former, and then the fuel consumption, represented by the weight of coal in both cases, may be directly compared.

14. Heat Analysis.—For scientific purposes, a heat analysis of the indicator diagram, in the case of a steam engine, and a heat balance in the case of an internal combustion engine, should be made, showing the manner in which the total heat of combustion is expended in working the engine.

In the case of a steam engine, the analysis shows the interchange of heat from steam to
cylinder walls, etc. For example: the amount of heat supplied to the engine in a given time is represented by the number of pounds of steam supplied multiplied by the total heat of one pound of steam. A portion of this heat is used in the jacket, if one be employed, and the remainder passes through the cylinder. The heat entering the jacket is lost largely by radiation from the outside surface, and the remainder enters the walls of the cylinder and is absorbed by the steam within it. The cycle of operations within the cylinder consists of the following phases: (1) A portion of the entering heat is transferred by its contact with a small portion of the thickness of the cylinder walls, and heats them to the temperature of the entering steam. This transfer of heat is more active during the period of admission and up to the point of cut-off than during any other part of the cycle. (2) Beyond the point of cut-off, the transfer of heat continues until the lower pressure due to expansion causes the temperature of the steam to fall below that of the interior surfaces of the cylinder last uncovered. At this point the interchange of heat is reversed, the metal giving up heat to the steam, and causing the re-evaporation of the particles of water condensed on the surface of the cylinder walls and piston. The radiation of heat from the small thicknesses of the interior walls, which were heated during admission to the temperature of the entering steam, commences after cut-off or after the pressure begins to lower by expansion, and continues to the end of the stroke.
