protected in most families, and which is indicative of the peculiar method of reproduction characteristic of the order, and for the support of which two bones (the epipubic bones), not present in higher mammals, project forward from the pelvis. The internal organs of reproduction are double, the two oviducts not uniting into a single uterine tube, so that the separation of the two parts is often imperfect; hence the term Didelphia (q.v.). The testes of the male are suspended in a scrotum in front of the penis, the gians of which is often double. As a rule no Allanotic placenta is present, but there is reason to suppose that the primitive marsupials were placental, and rudiments of this structure persist in the existing Australian bandicoots—a fact which invalidates the former prime distinction made between the marsupials and higher Eutheria.

The young are dropped from the mother’s womb as minute, undeveloped foetuses, those of the largest kangaroos being not half as large as mice when born. These larvae (for they are that) are then taken by the lips of the mother and placed, one within her ventral pouch, where each is attached to one of her teats, where it clings by means of its temporary sucking-mouth and is nourished by the milk which oozes or is pressed down its throat. They remain there a length of time varying with the size of the species, until they have grown to an advanced stage of development, when they gradually emerge; but for a long time afterward return to the mother’s pouch for refreshment, rest or safety when alarmed. The pouch varies in its capacity and completeness, in some families being quite absent, so that the young are shielded only by the long hair upon the mother’s belly.

While this strange method of reproduction is the most prominent peculiarity of the marsupials, they differ from other orders of mammals in several anatomical features, such as the simplicity of the brain, in which the cerebellum is completely exposed, and the tendency to separation of bones of the skeleton, usually solidly anchored in other mammals.

The early Tertiary times marsupials have been confined to South America and the Australasian region, with the single exception of the few North American opossum (q.v.). This family (Didelphidae) is restricted to the western hemisphere and alone remains of the large number of Tertiary forms once prevalent in South America, save a single Patagonian diprotodont, the opossum-rat (q.v.). The home of the group, then, is Australia, Tasmania and the Papuan group, where about 125 species are known; and the race seems to have survived in that insular region owing to the absence of destructive enemies, for most of them are almost defenseless vegetable feeders. They have, however, developed into a great variety of forms under the influence of varying conditions and long competitions, and present a most curious and interesting state of things among the higher and more widely diffused mammals. Some have large size, go in herds and occupy grassy plains; others are smaller, more agile and confined to mountainous districts. Others are still smaller, burrow and feed upon resemble little terrestrial rodents in appearance and habits; while many forms dwell altogether in trees and often simulate squirrels of various kinds. In another direction have been evolved a variety of predatory marsupials, whose needs have developed bodies, teeth and powers resembling those of wolves or bears, and which are wholly flesh-eaters. There is, in fact, hardly a group of mammals which does not find a counterpart among the marsupials, even the moles and shrews.

The classification of the order divides it into 10 or 12 well-defined families, some of which are wholly extinct, as follows:

**Polyprotodontia:**
- Doubtful primitive forms—Triconodon, Amphitherium, etc.
- Didelphyidae—Opossum (q.v.).
- Dasyuridae—Dasyures, Thylacines, etc.

**Didelphidae:**
- Peramelidae—Bandicoots (q.v.).
- Notoryctidae—Marsupial mole (q.v.).
- Diprotodontia:
  - Epanorthidae: Abderitidae, etc.—Fossil in the Miocene strata of Patagonia; but surviving in Canoletes.
  - Phalangeridae—Phalangers (q.v.).
  - Diprotodontidae—Extinct gigantic phalangers.
- Phascolomyidae—Wombats (q.v.).
- Macroodidae—Kangaroos (q.v.).

Consult Beddard, ‘Mammalia’ (1901); Thomas, ‘British Museum Catalogue of Marsupialia,’ etc. (1888); Gould, ‘Mammals of Australia’ (1865); and scientific works on Australia, especially those of Waterhouse, Attalo and Lydekker.

MARSYSAS, már'sÍ-æs, mythological son of Hyagnis and one of the Sileni of Asia Minor. Athena, having seen the reflection of herself in water, had thrown away the flute which she had invented, displeased because it disfigured the countenance in playing, and had pronounced the severest malefactions against any one who should take it up. Marsyas accidentally found this instrument, on which he soon acquired such skill that he dared to challenge Apollo to a contest, the conditions of which were that the victor should do what he pleased with the vanquished. The Muses, or according to others the Nysæans, were invited to be the umpires. The Muses decided in favor of Apollo, who put to death his rash competitor by binding him to a tree and slaying him alive. In this way was the curse of Athena accomplished. Marsyas’ statue was erected in several Roman cities as a symbol of liberty and other statues have been found illustrating his experiences, one by Praxitéles, which has been preserved in the Athens Museum.

MART, Tex., city in McLennan County, situated on the International and Great Northern Railroad, 20 miles east of Waco. The surrounding region is devoted to cotton-growing in which the city has extensive interests. It contains cotton gins, compresses and cotton-seed-oil mills, railroad repair shops and a high school. The commission form of government is in operation. The water supply system is owned by the municipality. Pop. 2,939.

MARTA OF THE LOWLANDS (Terra baixa), the foremost achievement of the Catalan theatre, was written in Catalan by Angel Guimerà for Fernando Díaz de Mendoza and
Maria Guerrero and performed for the first time by these actors in the Spanish translation by Jose Escario. It is the first Coral to work to obtain general currency beyond the limit of the provincial tongue. During the present century no play has been more popular in the Spanish or Hispano-American countries, where it has maintained itself upon the stage with the immemorial vigour of the ancient, the most celebrated talents of all the leading actors. 'Terra baixa' is predominantly social and human in appeal. This is its fundamental quality; but in equal degree it possesses high theatrical effectiveness, which is not inferior to the best work of its period in this vein, whether produced in Spain or elsewhere. Simple feeling and torrential passion, in conjunction with sensitive insight and unusual grasp of significant situation, convey an impression of elemental forces operating behind the broad effects of a carefully elaborated theatrical art, happily employed strictly in subservience to the theme. More than any other play, 'Terra baixa' has contributed to fix the general conception of Iberian peasant drama which prevails in Europe and America. Above all it should be noted in regard to the rural characters, a reminiscence of the author's apprenticeship in the poetic drama. In objective realistic detail Guimerá is an unequivocal master. 'Terra baixa' has been translated into more than 20 languages. The English version by Wallace Gilpatrick (New York 1914) is acted successfully in England and the United States previous to publication. As 'Tiefland, the play is favorably known in operatic form, with music by Eugène d'Albert.

JOHN GARRITT UNDERHILL.

MARTEL, Charles. See Charles Martel.

MARTEL DE JANVILLE, Gabrielle, Comtesse de ("Gyp"). French author: b. Coët-sal, Morbihan, 1856. She is a great grandniece of Mirabeau and at the age of 19 was married to Jeanne Martel de Janville. Her writings deal with types of Parisian life, of which Petit Bob, Loulou and Paulette have become famous. Over 135 volumes in all have issued from her pen. These include: 'Petit Bob' (1882); 'Au tour du miroir, 1883'; 'Un homme délicat' (1886); 'Elle et lui' (1885); 'Au tour du divorce' (1886); 'Pour ne pas l'être?' (1887); 'Pauvres petit femmes' (1888); 'Bob au salon' (1888); 'Mademoiselle Eve' (1889); 'Bob à l'exposition' (1889); 'L'Education d'un prince' (1890); 'Monseigneur Fred' (1891); 'Mariage civil' (1892); 'Du haut en bas' (1893); 'Mariage de chiffon' (1894); 'Le coeur d'Ariane' (1895); 'Le bonheur de Ginette' (1896); 'Totote' (1897); 'Isabel' (1898); 'L'Entrevue' (1899); 'La pays des champs' (1900); 'Le friquet' (1901); 'Sourrette' (1902); '2d ed., 1910'; 'Un ménage dernier cri' (1903); 'Maman' (1904; 2d ed., 1910); 'Le coeur de Pierreette' (1905); 'Ces bons Normands' (1907); 'La paix des champs' (1908); 'Jolies d'amour' (1910); 'L'Amoureux de l'eau' (1910); 'La gourmande' (1911); 'Le grand coup' (1912); 'Napoléonnette' (21st ed., 1913).

MARTELLO TOWERS, so called by corruption from 'Mortella', in Corsica, where a strong tower maintained a determined resistance to a superior English force in 1794. In consequence of the great strength exhibited by this fort the British government erected a number of similar towers round the coast of Great Britain, in the first Coral to a defense against the threatened invasion from France. They are circular, with walls of great thickness, and roofs bomb-proof, there are two stories, the lower for the reception of stores and the upper for the casement of troops. One traversing rifle can fire en masse, working which the men were secured by the lofty parapet. The ordinary guard was from 6 to 12 men. With improved modern artillery Martello towers are useless, and in many places were dismantled, but they have received a new and more powerful armament, or have been adapted to the use of the coast guard, or revenue officers. In some instances they are rented to private individuals. Martello towers are still to be found in New Brunswick and Nova Scotia. There are also several on the Gulf of Mexico and one still remains at Kingston, Canada.

MARTEN, the name of several fur-bearing animals of the weasel family (Mustelidae) that are mainly arboreal in habits, and do not change their other habits for the more cooler parts of the Northern Hemisphere. The beech or stone marten (Mustela foina) is to be found in Europe generally south of the Baltic, although not now a native of Britain. It is about 17 inches long in body, and its tail adds nine inches more. Its breast is white. It is tractable, and is believed by some to be the animal domesticated by the ancient Greeks as a mouser. The pine, or sweet, marten (M. martes) is rather smaller, but with a much longer tail, proportionally, and is more northerly in its distribution, occurring from the British Isles and Norway eastward to Siberia. It has a finer, more valuable fur than the other, and a yellow throat. Very nearly allied to it in size, form and color is the Siberian sable-marten (M. sibellina), noted for furnishings in its coat the finest, and most expensive of the furs from animals of this group. The demand for this fur can be met only by the most difficult, and often dangerous, exertion in trapping and hunting in remote Asiatic forests; and this has resulted in a steady diminution of the supply and very high prices for the pelts. There is also a native marten in India and another in Japan. North America has two species of the genus — the American pine-marten, or Canadian sable (M. americana), and the pekan (M. pennantii). The former is hardly distinguishable from the sable of the Old World, and its fur, although regarded as somewhat inferior, is largely used as a substitute for genuine Siberian sable. (See FUR-TRADE). The pekan is very distinct by its greater size (length, 24 inches, plus tail, 13 inches), its long and very dark coat and its dog-like head. Its fur is of great value. The body in all these martens is elongated and supple, with a long and somewhat bushy tail; the legs short and the toes separate and flexible, with long sharp claws adapted to the life in trees that most of them follow. They are fierce and cunning hunters, pouncing successfully on all sorts of small animals and birds, destroying birds' nests, catching frogs, and in winter pursuing and killing animals as large as hares and porcupines. The pekan, or fisher, is especially bold and voracious, but does not eat fishes in spite of its name. Both the
American species were formerly common in the mountainous parts of the eastern United States, but are now extinct in the remote woods of Canada. They make their dens, bedded with leaves and grass, in some high hollow of a tree-trunk, as a rule, but frequently choose a crevice among rocks, and there produce an average litter of four to ten young. The period of gestation is about three months, and the young begin to leave the nest when two months old.

Breeding for Fur.—These bloodthirsty little carnivores are the very type of savagery, and even the kittens are almost untractable. The high value of their fur (about 75,000 pelts of the sable, and 100,000 of the Canadian marten represented the market-supply just before the Great War) has caused much effort to be expended, especially in Canada, to breed them in confinement, but, as yet, the results have been small, although encouraging. The general treatment and food seem to be like that for minks. A large pen made of inch-mesh wire and floored with this, or in some way so prepared that the animal cannot dig out, should contain stumps and brush to get the marten accustomed to exercise. Two males cannot be put together. When the female is ready for a mate she is placed in his cage, or vice versa, and the mating will take place at night, so that the pair must usually be left together several days. Mating occurs naturally in January or February. When the young are about two months old they may be removed from the mother, and should be brought up by hand, if possible, so as to become more gentle. These general directions apply to the pekan, but his quarters should be larger than for the sable.

Consult, besides general natural histories, Cates, 'Fur-bearing Animals' (Washington 1877); Ingersoll, 'Life of Mammals' (New York 1909); Seton, 'Northern Mammals' (New York 1909); Jones, 'Fur-Farming in Canada' (Montreal 1913).

MARTENSITE, a constituent of steel, existing at a high temperature, and which being retained by sudden cooling, confers hardness upon the steel.

MARTHA'S VINEYARD, Mass., an island off the southern coast, in the county of Dukes, about 25 miles southeast of New Bedford. It is separated from the mainland by Nantucket and Vineyard sounds, from Nantucket Island by Hukeget Channel, and from Elizabeth Islands by Vineyard Sound. It is about 21 miles long and 10 miles across the widest part. The northern coast is high and rocky, Prospect Peak being 308 feet. The coast line has few indentations, the largest of which is Vineyard Haven. The southern coast is low and irregular, with sand bars and shallow lagoons. On the southwest is Gay Head, 200 feet above the water. A lighthouse is on Gay Head Point, Edgartown, the county-seat, is the principal town on the island. Bartholomew Gosnold discovered and named the island in 1602. The Indians, who then occupied the place, were quiet and friendly, and all became Christians. They remained loyal to the whites even during King Philip's War. The island is a favorite summer resort; annual camp-meetings and summer schools have been held here for a number of years. Pop. of county 4,504.

MARTI, José Julián, ho-sa' hoo-le-án' már'té, Cuban author and patriot; b. Havana, 28 Jan. 1853; d. Dos Ríos, Cuba, 19 May 1895. He studied in Havana, was sent to the quarries while only a boy as a political suspect, then went to Spain, where in Madrid and Saragossa he studied for the bar and made himself famous for his liberal views, and on his return to America was professor in the University of Guatemala, whence he came to New York City as consul for Uruguay, Paraguay and Argentina. In 1894 he attempted to land armed men in Cuba, but was intercepted in Florida; in the next year he succeeded in landing, joined Gomez and was killed in a skirmish with the Spanish at Dos Ríos. Marti founded the Cuban organ of independence in New York City, La Patria. He was a poet, and wrote a Spanish translation of Helen Hunt Jackson's 'Ramona' (1888).

MARTIAL, már-ch' l-ji (Marcus Valerius Martialis), the world's greatest early writer of epigrammatic poetry, was born in Bilbilis, Spain, 1 March of one of the years 39 to 41 A.D., and died probably between 102 and 104 A.D. Like his literary friends, the Senecas, Lucan and Quintilian, who also were of Spanish birth, Martial in his writings was thoroughly Roman, and indeed has left us our most valuable picture of contemporary Rome. A Fronto and Flaccilla, whom he mentions, may have been his parents, but we know nothing of their origin or station. The grammatical and rhetorical training which his parents secured for him perhaps at Tarraco or Corduba, he half-seriously disparaged as being of no financial advantage, but it was really to his pen that he owed, at least indirectly, his support through life. For, although he was apparently fully equipped for practice at the bar, the profession of an advocate was too exacting to be attractive. On his arrival in Rome, perhaps in 64 A.D., powerful friends launched him on a literary career which rapidly carried his fame even to the limits of the empire. But success as a poet brought him no contentment, since in return for the money, food, clothing, etc., which by flattery and bounties he gave imperial courtiers and other men and women of wealth, he had daily to perform social duties that were highly irksome to his indolent nature. From the patron's reception at dawn to the end of the latest dinner, he had to dance attendance with wit that should never fail. We find him living at first in humble lodgings on the Quirinal, later in a house of his own on the same hill. A barren farm near Nomentum was his usual refuge from the cares and noises of the capital, but he sometimes made long journeys in Italy, often visiting the country homes of his friends. To his poetical and social talents he also owed political favors from Titus and Domitian. A tribuneship gave him membership in the equestrian order, but probably not the fortune of a knight. He likewise received the coveted privileges to which a father of three children was entitled, the ius trium liberorum, though unearned; for the references that have given rise to the theories that he was married from one to three times are not of personal application. It is probable that even Maffarelli was no more than a pupil. When disgruntled at the client's life in Rome led him in 98 to return to Bilbilis, this Spanish lady gave him a fine estate. A longing soon seized
him, however, to be back in Rome with all its inspirations, a longing never to be granted; Pliny the Younger, who had helped Martial with a gift of money on his departure from Rome, records the poet’s death in Spain. Before those already named, Juvenal and Silius Italicus should be mentioned as Martial’s friends. Noteworthy among contemporaries whose names do not appear in his poems are Tacitus and Stalius. The former could have had no sympathy with his master, and the latter was no doubt his rival in literary mendacity. We have 1,575 of Martial’s poems. More than half of these are of four lines or less. His earliest book published in 80 contains epigrams describing shows given by the emperor. Then followed books XIII and XIV made up of two-line inscriptions for presents at the Saturnalia. The other books (I-XII), containing many poems which we should not call epigrams at all, appeared at varying intervals in the period 85-101. Martial’s influence in his chosen field has never ceased. A remarkable number of the best epigrams in modern languages are merely adaptations or translations of his poems. His personal character has received general condemnation. Obscenity and servile flattery are the charges brought against him in the lapses of the service language that he uses in speaking of the tyrant Domitian we must remember that it went only a step beyond the requirements of formal court etiquette. Kindly critics find in Martial some good points, his modest valuation of his own work, his freedom from envy, his scorn of all hypocrisy, his steady resistance to all temptations to use his powerful weapon of satire in either an unjust or unkind spirit, his tender love of children, humane treatment of slaves and above all his deeply affectionate attachment to his friends. See Epigram.

Bibliography.—The best text edition of his poems is that of W. M. Lindsay, Oxford, Clarendon Press. The German annotated edition of Friedlaender is invaluable. The only complete translation in English, is in the Bohn series.

Walton Brooks McDaniel, Professor of Latin, University of Pennsylvania.

Martial Law, government by arbitrary military power; that supersedes municipal law, or State law, yet is not a military law. When in time of war the powers are exercised from without or from within, the general safety cannot be trusted to the ordinary administration, or the public welfare demands the adoption and execution of extraordinary measures, it may become necessary to declare the existence of martial law. This is, indeed, no law at all in its ordinary sense; it is in fact the abrogation of it. That which is done under martial law has not an immediate constitutional or legislative sanction, as the military or the statute law, for example, has. Yet remembrance of the very nature of martial law expresses the will of the people. The Supreme Court of the United States has held that a State legislature may proclaim its existence whenever the public safety demands it; and the Constitution, by inaction at least, also permits its proclamation by that clause which provides that the privileges of the writ of habeas corpus shall not be suspended, unless when, in cases of rebellion or invasion, their suspension is essential to the general welfare. See also Law, Military; Military Courts and Court-Martial.

Martial’s Epigrams. Marcus Valerius Martialis, the epigrammatist, was born about 40 A.D. in Bilbilis, Spain, 20 miles west of the present Aragonese city of Saragossa. He went to Rome at the age of 23, and after nearly two score years, together with Leucianus, returned to his native town, where he died about 104. At the age of 40 he celebrated the dedication of the Coliseum and won the favor of the Emperor Titus by composing the “Book Of Spectacles.” A collection of epigrams on the incidents of the day’s sport. Several years later he published two collections of epigrams to be used with dinner favors and with presents at the Saturnalia, which afterward took their places in his works as books XIII and XIV. Books 1 to XII, his really characteristic work, were published at intervals more or less regular from 86 to 102, the last one having been sent from Spain after his return. The total number of pieces in the 15 books is about 1,550, of which three-fourths are in the elegiac couplet, like the verse of Ovid and the great part of Greek epigram.

Though at first glance Martial seems to continue the tradition of the epigram, which had already had long life and great fame in the Greek world, he is not even the heir of the original and creative, and is of the greatest importance in literary history as being the founder of the epigram as it has been popularly conceived ever since; that is, as a short, highly concentrated poem with a point that is made to appear suddenly or with a surprise.

“Chloé weeps with one eye. Do you ask how it’s done? The answer is easy: she has only one.”

(Dimsdale.)

Whether his influence has been the best is sometimes questioned. Those who are familiar with the calm, sunny, contemplative, tripping genius of the Greek Anthology, which, though its epigrams are always neat and concise, and sometimes stinging, has not as a whole the satiric character, will be likely to think Martial rather hard and metallic in both form and content. Those who enjoy “verbal exactness and mechanical ingenuity” (Dimsdale), and look to the epigram for the character of sting- ing, satiric pointedness usually associated with it, will set the Greek era as the world’s greatest epigrammatist, and understand his appeal to Dryden, Pope and Johnson.

Martial is not all pungency. A not inconsiderable number of his pieces are epigrammatic rather than epigrams; a few of them might be classed as short poems without reference to epigram. They are nevertheless homogeneous. Even more than perfection of form, the characteristic that gives them all a unity, is their quality as a human document. Martial was right when he said, “My page smacks of human life.” Province and simply bred, pursuing the existence of a free lance in a great capital in an intense age, gifted with a keen understanding, a quick eye, and a responsive pen, he converted into clear, carefree-like literary pictures for the amusement of his own time, and for the amusement and instruction of all time, innumerable vivid impressions from the fascinating realities among which he moved. To read his epigrams in quantity is like sitting before a cinematograph of the Flavian era. There flash before us lively scenes
of men and things: numerous faces of the
known and the nameless, types of men and
women from every sphere, the bawling school-
master with fusty sweetness, the poetical bore
reciting his verses to unwilling ears, the stinging
host, the snowstorm in the amphitheatre,
the routine of the Roman day, the patron who is
never at home, the guest who comes too early,
the transparent hypocrite, the slow barber,
the waste slopes of Mount Vesuvius, the incident
of the circus or theatre or the dinner of the
street. In an age of ennui, the world is
fresh and interesting to Martial. Not only men,
but things, find him attentive. Thinking of this
and of his facility of expression, Verrall says
(‘Literary Essays, Classical and Modern,’ p. 13)
that he is "perhaps the only writer in whom
plate and tapestry, earthenware and hardware,
beds and sofas, become truly poetic." Dims-
dale (‘Latin Lit.’ p. 472), commenting on his
method of attaining vividness by the use of
realistic detail, says that "he uses nothing in
expression without humor and poor, but speaks in
terms of jewelry, scents, linen, cloaks and
boots." Martial is a satirist, but only by accident.
He has no moral indignation such as a few
years afterward glows from the pages of Juven.
"A certain intolerance of hypocrisy," says
Mackall (‘Latin Lit.’ p. 194), is the nearest ap-
proach Martial ever makes to moral feeling.
He does not scold; he does not even preach.
He manifests no moral enthusiasm, and almost
no malice for anything. He is a satirist rather
than a humorist, though he is by no means without
humor. He merely records, and his quality as a
satirist is the outgrowth and accomplishment
of epigrammatic expression rather than the result
of conscious purpose. To portray freely and
realistically was in itself the aim.

The reader's enjoyment of Martial unex-
purgated is interfered with by coarseness in
about one in 10 of his pieces. This is hardly
higher or lower than the modern European
average, though his coarseness is not on this
account the more welcome. He is also charged
with servility in his attitude toward the em-
peror and other patrons. It should be said
in extenuation that literary patronage has until
not long ago been a regular and a recognized
relation and has always carried with it a certain
amount of purely conventional flattery, and that
Martial's servility perhaps did not seem so
offensive in his own day as it does now, when
the servility of the literary art finds expression
in other ways. So clean-hearted and clean-
lipped a man as the younger Pliny, in express-
ing regret at the poet's death, has left the
word condor as descriptive of him: "he was a
man of talent, penetrating, keen, with exceed-
ing wit and satire as a writer, and with no less
condor." This is probably a reference to the
sincerity and frank straightforwardness of
Martial the realist, who saw clearly and took no
pains to cover up either other men's failings or
his own. Of himself he says, "My page is
free, my life upright." Of his work he says:

"Good, fair, and bad
May here be had.
That's no surprise
There was vain to look
For any book
That's otherwise."

(Kirby Smith.)

Lovers of Spanish art in general, and of the
present day novel in particular, will find them-
selves wondering whether Martial is not to be
explained as merely a revival of the poetically
true and direct with a truthfulness and directness which so strongly
colorize the Spanish genius. Paul Nixon, in
"A Roman Wit," gives a spirited rendering, in-
evitably lacking in finish, of about 200 epigrams.
The Bohn Library Martial contains a greater
number of translations in both verse and prose.
Kirby Smith, in the "Seuence Review," Vol. 26,
No. 1, may be consulted for appreciation.

GRANT SHOWERMAN.

MARTIN, Saint, of Tours: b. about 316; d.
about 400. He attended the catechetical
school at Pavia. His father was a military
tribune, and, as is customary with Roman
patrons, he took up arms. He is said to have
early escaped from his father and received instruction in
Christian church. He served under Constantius and Julian, and went to Gaul, where he
appeared as the model of all virtue. Among
other acts he divided his cloak with a poor man
whom he met at the gates of Amiens (Ambi-
num). The legend says that Christ appeared
to him in the following night covered with the
half of this cloak. Soon after this vision
Martial was baptized, in 337. After living many
years in retirement he made a visit to his native
place, during which he converted his mother,
and opposed with zeal the Arians who prevailed in
Illyria. For this he was scourged from the
country, on which occasion he manifested the
firmness of a martyr. He now established a
monastery in Milan, but when he found himself
again exposed to persecution took refuge on the
island of Gallinaria, in the Ligurian Sea. He
next settled at Poitiers, where he assembled a
number of monks, and is said to have wrought
many miracles. In the year 375 (according to
others 371 or 374) the bishopric of Tours
was conferred on him against his will. In order to
withdraw himself from the world he built the
famous convent of Marmonier, between the
river Loire and a steep rock. This is regarded
as the oldest abbey of France.

MARTIN, the name of five popes of the
Catholic Church, as follows:

MARTIN I, Saint: b. Todi, Tuscany; d.
Chersan, Crimea, 16 Sept. 655. He was elected
Pope in 649, succeeding Theodore I. He sum-
moned the first Lateran Council at which he
caused the doctrine of two wills and operations
in Christ to be affirmed. The Emperor Con-
stans II upholding the doctrine which the
Council had condemned, took the Pope prisoner
and brought him to Constantinople on a charge
of treason and then banished him to the Cri-
mea. On account of his sufferings he is num-
bered among the saints. His day is 12 Novem-
ber.

MARTIN II, or MARINUS I: b. Monte-
fiasonce; d. Rome, 14 Feb. 884. He was elected
Pope in 882 after the death of John VIII.
While bishop of Caere he had been legate for
three popes in their negotiations with the East.
To English King Alfred he sent a piece of
the wood of the cross.

MARTIN III, or MARINUS II: b. Rome;
d. 946. He succeeded Stephen VII in 942 and
was greatly esteemed for his learning and
nobility of character.
MARTIN IV (Simon de Brion, sē-mōn də brō-ôn): b. France; d. Perugia, 28 March 1285. He succeeded Nicholas III in 1281, having previously been canon of Tours, and cardinal-nephew of his predecessor. He was much in favor of the pope, and his envoys in this respect, were named to the influence of Charles of Anjou, whom he supported them after, and did all in his power to enable that monarch to retain possession of Sicily. In his pontificate occurred the massacre known as "The Sicilian Vespers."  

MARTIN V (Oddone Colonna, ɒd-tōn-kə-lə-nə): b. Rome, 1368; d. there, 20 Feb. 1431. He was elected pope in 1417, after the abdication of Gregory XII, and the deposition of John XXIII and Benedict XIII, during the Council of Constance. His first act was to promulgate a bull against the Hussites, remarkable from the circumstance that in it he pope seems to recognize the supreme authority of the councils. He was one of the ablest of the popes, and through his efforts unity was finally secured to the Church and peace to Italy. In 1418 he dissolved the Council of Constance, though a number of difficulties were not then adjusted, and dispensations continued in the Church. Benedict XIII still lived; and at his death, in 1424, a new anti-pope was elected in Clement VIII, who renounced his pretensions in 1429, when he received the bishopric of Minorca as an indemnification.  

MARTIN, Alexander Carson, American missionary and educator: b. Livonia, Ind., 10 April 1849; d. Walworth, Iowa, 18 Dec. 1906. He was educated at the University of Indiana, from which he was graduated in 1866. He later studied at the New Albany Theological Seminary (now the McCormick Theological Seminary), at Chicago, from which he was graduated in 1847. The New York University conferred the degrees of D.D. and LL.D. upon him. He was appointed a Presbyterian missionary to China in 1849 and left here on 23 November of that year for Canton. For 67 years he worked among the Chinese. It was said of him that probably he knew China and the Chinese language as did no other American. Dr. Martin retired from active missionary work in 1888 to enter the Chinese government service. He was named by the Board of Foreign Missions here as an honorary missionary. He acted as interpreter for the United States Minister to China in the negotiations between the Washington government and the Imperial Government, at Peking, in connection with the United States-Chinese treaty of 1853. He was the organizer and president of the International Law and Language School in Peking which was destroyed in the Boxer rebellion in 1900. He was said to have been the first Western teacher to open the door of English learning to the youth of the Far East. After 30 years as adviser to the Chinese government, Dr. Martin became president of the new Imperial University of China. This movement for the establishment of a great institution of learning there was blighted by the Boxer uprising. Later Dr. Martin took the leadership of the Wu Chany University for a period of three years. He retired from this work about 78 years of age, but was so strong and vigorous that he was able to travel to Europe. At 78 years old, he gave up teaching, but remained in the capacity of adviser for both the government and the Presbyterian mission.  

MARTIN, Bradley, American banker, brother of Frederick Townsend Martin: b. Albany, N. Y., 1841; d. 1913. In 1863 he was graduated at Union University, Schenectady, N. Y. He served as a member of the National Guard during the Civil War, attaining the rank of lieutenant. Subsequently he was admitted to the bar. He managed his vast interests in banks, trust companies and the industries, and was one of the most prominent figures in the social life of the East. In 1893 he went abroad and thereafter lived in England and Scotland.  

MARTIN, Charles Cyril, American civil engineer: b. Springfield, Pa., 30 Aug. 1831; d. Far Rockaway, N. Y., 11 July 1903. He was educated at Rensselaer Polytechnic, Troy. He was engineer in the Brooklyn navy yard during the Civil War; and afterward chief engineer of Prospect Park, Brooklyn; and was appointed John A. Roebling's second assistant in building the Brooklyn Bridge, of which he became chief engineer after Roebling's retirement.  

MARTIN, Edward Sanford, American author: b. Owasso, N. Y., 2 Jan. 1856. In 1877 he was graduated at Harvard University and in 1884 was admitted to the bar at Rochester, N. Y. He is a writer of editorials in Life and for other weeklies and magazines. His published works are 'Sly Ballads and Jokes in China' (1882); 'A Little Brother of the Rich' (1890); 'Pirates of the Swede (1902); 'The Luxury of Children, and Other Luxuries' (1904); 'The Courtship of a Careful Man' (1905); 'In a New Century' (1908); 'Reflections of a Jerusalem Night' (1913); 'Unrest of Women' (1913); 'The War Week by Week' (1914); 'The Diaries of a Nation' (1917).  

MARTIN, Félix, French-Canadian clergyman and author: b. Auray, Brittany, 1804; d. 1886. He emigrated to Canada in 1842, having previously entered the Society of Jesus. His task in Canada was to aid in re-establishing the Jesuit mission at St. Sauveur's College, which had been destroyed by the British, was founded by him. Père Martin made diligent search in French and Canadian archives seeking out information regarding the early Jesuit missionaries in Canada. His principal works are 'Manuel du périn de Notre Dame de Bon Secours' (1846); 'Relação dos Jesuítas,' an enlarged edition of O'Callaghan (1850); 'Mission du Canada, relations indigètes' (1861); 'De Montcalm et Canada' (1867); 'Le reverend Père Isaac Jogues' (1873).  

MARTIN, François Xavier, American jurist: b. Marseilles, France, 17 March 1764; d. New Orleans, 11 Dec. 1846. He emigrated to Martinique when 18; later removed to New Berne, N. C.; taught French there, and became a printer; studied law, being admitted to the bar about 1789; and in 1792 was requested by the State legislature to compile the British statutes in force before the Revolution. He was himself a member of the assembly in 1806-07; was judge of the Mississippi Territory in 1809; went to Louisiana in the same capacity in 1810; and in 1813 became attorney-general of the new State of Lousiana, which position he filled until his death. Martin was a member of the Supreme Court of the State. Although blind for the last 10 of those 31 years, his ability was
not impaired, and it is due to him that the law of the State was in some measure evolved from the tangle of French and Spanish statutes in which it found it. He wrote a 'History of North Carolina' (1829); 'History of Louisiana' (1827); and a version of Pothier on Obligations.

MARTIN, Frederick Townsend, American author, brother of Bradley Martin; b. Albany, N. Y., 1849; d. London, 1914. In 1872 he was graduated at the Albany Law School. He became a member of the New York National Guard, in which he was commissioned colonel and served a period as judge-advocate. For many years previous to his death he had lived in Europe. He was prominent in charitably enterprises and a lavish benefactor of the poor. His writings deal with the doings of the wealthy and the so-called social-elect, of which class Martin was well qualified to speak. His works include 'The Passing of the Idle Rich' (1911); 'My Personal Experiences of Meeting Some Prominent Socialists' (1911); 'Reminiscences of My Life' (1911); 'The Worth I Remember' (1913).

MARTIN, George Madden (Mrs Attwood R. Martin), American author; b. Louisville, Ky., 3 May 1866. She was educated in the public schools of Louisville, finishing at home on account of her health. In 1892 she was married to Attwood R. Martin. She became a frequent contributor of short stories to magazines and periodicals and is author of 'Emmy Lou—Her Book and Heart' (1902); 'The House of Fulfilment' (1907); 'Abbie Ann' (1907); 'Leititia—Nursery Corps, U. S. A.' (1907); 'Selma,' (1914); 'Emmy Lou's Road to Grace' (1916); 'Warwickshire Lad' (1916).

MARTIN, Gregory, English translator of the Bible; b. Manchester, date unknown; d. Rheims, France, 26 Oct. 1382. Martin received his education at Saint John's College, Oxford, where he took the degree of B.A. in 1501 and that of M.A. in 1505. He was very well versed in Hebrew, Greek and Latin and was made a papal chaplain by the Pope. He was not a scholar, but possessed the Established Church: remained a staunch Roman Catholic and exerted a powerful influence on the Huguenots to remain true to the ancient faith. In 1570 his continued opposition to the new ecclesiastical order of things in England obliged him to seek refuge at Douai, Flanders, where he became professor of Hebrew in the newly-founded English College. He went to Rome in 1577 to aid in founding the English College there. In 1578 Martin went to Rheims, to which city the English College was moved from Douai, and there spent his remaining years in writing the production of the English version known as the Douai Bible. It is the official Bible for English Catholics, was made from the Vulgate of Saint Jerome and collated with the Greek and Hebrew versions. In 1882 the New Testament was issued but not until 1609-10 did the Old Testament appear. English Protestants criticized Martin's version, yet the commission of Forty-Seven made extensive use of it in preparing the Authorized Version in the reign of James I. 

MARTIN, Helen Faucht, LADY. See FAUCHT, HELEN.

MARTIN, Helen Reimensnyder, American author; b. Lancaster, Pa., 18 Oct. 1868. She made a special study of English subjects at Swarthmore College, Pennsylvania, and Radcliffe College, Cambridge, Mass. In 1889 she married Frederic C. Martin. Mrs. Martin is a contributor of short stories of Pennsylvania Dutch life to McClure's, Leslie's, the Century, Cosmopolitan, and the Home Journal. She has published 'Tillie,' a Mennonite Maid' (1904); 'Cabina, a Story of the Amish' (1905); 'The Betrothal of Elphelote' (1907); 'Revol of Anne Royle' (1908); 'The Crossways' (1910); 'When Half-Gods Go' (1911); 'The Fighting Doctor' (1912); 'The Parasite' (1913); 'Bar- nabella' (1914); 'Martha of the Mennonite Country' (1915); 'For a Mess of Pottage' (1915).

MARTIN, Henry Austin, American surgeon; b. London, 23 July 1824; d. Boston, 7 Dec. 1884. He came to the United States at an early age and was graduated from the medical school at Harvard in 1845, when he established a practice in Boston. He served as a surgeon until nearly the close of the Civil War, when he resigned and was brevetted lieutenant-colonel for gallant service. He devoted his attention principally to surgery and to the treatment of smallpox, upon which subject he was a generally recognized authority. He was the originator of many important innovations in the field of surgery and published valuable professional articles in periodicals.

MARTIN, Henry Newell, American biologist; b. Newry, Ireland, 1848; d. 1886. He received his education at University College, London, and at Christ's College, Cambridge. He was appointed to the chair of biology at Johns Hopkins University in 1876 and was also made director of the biological laboratory. Dr. Martin carried out important experiments on respiration. He was chosen president of the American Society of Naturalists in 1880. He published 'The Human Body' (1881); 'Observations in Regard to the Supposed Suction-Pump Action of the Lungs' (1887). Professor Martin assisted Huxley in the latter's 'Practical Biology' (1876) and edited 'Studies from the Biological Laboratory of Johns Hopkins' and the Journal of Physiology.

MARTIN, Homer Dodge, American painter; b. Albany, N. Y., 28 Oct. 1836; d. Saint Paul, Minn., 12 Feb. 1897. He was elected a member of the National Academy of Design in 1875, and resided in France in 1882-86. While he was influenced somewhat by the Barbizon School of painters, he developed a style entirely his own, which placed him among the best known of American landscape painters. His works include 'Landscape on the Seine'; 'An Equinocital Day'; 'Brook in the Woods'; 'In the Adirondacks'; 'Sand Dunes on Lake Ontario'; and 'White Mountains, from Randolph Hill.' Consult for reproductions Carroll, D. H., "Fifty-Eight Paintings by Homer D. Martin" (1913).

MARTIN, Joseph, Canadian statesman; b. Milton, Ontario, 24 Sept. 1852. He was educated in Canadian and Michigan public schools and at the University of Toronto. He was admitted to the bar in 1882 and from 1882 to 1892...
was a member of the Manitoba legislature. From 1888 to 1891 he was attorney-general and minister of education of Manitoba. In the latter capacity he introduced the bill abolishing the separate school system in Manitoba and thus precipitated a memorable crisis in Manitoba and Dominion politics. Martin failed of election to the House of Commons in 1891, but sat for Winnipeg in 1893-96. He removed to British Columbia in 1897 and in the following year became a member of the legislature of that province, sitting until 1903. In 1898-99 he was provincial attorney-general and minister of education and in 1900 was premier of British Columbia. In 1907 Martin was editor and publisher of the Vancouver Guardian. In 1908 he removed to England, contested Southwest Warwickshire in the Liberal interest in 1909. In Canada he took an active part against the Canadian Pacific Railway monopoly, in the abolition of French as official language and advocated the introduction of the Torrens system of land registry. He is a strong freetrader and advocate of reciprocity between the United States and Canada.

MARTIN, Josiah, English colonial governor in America: b. probably in Antigua, West Indies, Apr. 11, 1737; d. London, England, June 7, 1786. He rose to the rank of lieutenant-colonel in the British army in 1771, and in the same year was appointed to the royal governorship of North Carolina. He was successful in pacifying the "regulators," many of whom remained restless. In 1777, he was appointed to the post of adjutant general of the army of the United States. He was successful in securing the safety of the colonies from the British forces. In 1781, he was appointed a member of the board of war for the American colonies, and in 1782, he was appointed to the post of adjutant general of the army of the United States. He was successful in securing the safety of the colonies from the British forces. In 1781, he was appointed a member of the board of war for the American colonies, and in 1782, he was appointed to the post of adjutant general of the army of the United States. He was successful in securing the safety of the colonies from the British forces.

MARTIN, Luther, American lawyer: b. New Brunswick, N. J., Feb. 1748; d. New York, 10 July 1826. He graduated from the College of New Jersey (Princeton) in 1766; studied law at Queen's College, N. J.; was admitted to the Maryland bar in 1771; in 1774 was one of the commissioners appointed to oppose the claims of Great Britain; in 1778 became attorney-general of Maryland; and in 1787 was a delegate from Maryland to the convention that framed the Constitution of the United States. His opposition to the instrument was so strong that, rather than sign it, he left the convention, thus earning from Jefferson the sobriquet of "the Federal bull-dog." In 1804 he defended Samuel Chase (q.v.) in the latter's impeachment trial before the Senate, and in 1805 resigned his attorney-generalship and resumed private practice. He was counselor for Burr in Burr's trial at Richmond in 1807, in 1814-16 was chief judge of the Baltimore Court of Oyer and Terminer, and in 1818-20 was again attorney-general of Maryland. Among his writings was the series of pamphlets, "Modern Gratitude" (1801-02). Consult Goddard, "Luther Martin" (1887).

MARTIN, Percy F., English author and journalist: b. March 30, 1861. He received his education at University College, London, served as correspondent in Mexico of the Times, the Tribune and the Glasgow Herald, and in India of the Times (Engineering Supplement) and the Evening Standard. He also served as special correspondent of the Financial Times and The Engineer in Central and South America and as contributor to the Times Trade Supplement. He has published "Through Five Republics of South America" (1906); "Mexico of the Twentieth Century" (1907); "Salvador of the Twentieth Century" (1911); "Peru of the Twentieth Century" (1911); "Greece of the Twentieth Century" (1912); "Maximilian in Mexico" (1913); "The Sudan in Evolution" (1916). He is a contributor to the Quarterly, Edinburgh, Fortnightly and British Reviews, and other periodicals.

MARTIN, Sir Theodore, English lawyer and author: b. Edinburgh, 16 Sept. 1816; d. 16 Sept. 1906. He was educated at the University of Edinburgh and became a solicitor in Edinburgh in 1840. In 1846 he became a parliamentary solicitor in London, carried on an important and extensive business and varied professional cares with literary work. With Aytoun he published the once famous "Bon Gaultier's Ballads" (1845), "Life of Lord Lyndhurst" (1844), "Life of the Prince Consort" (1875-80), "Helena Faucit, Lady Martin" (1900). He was created K.C.B. in 1881.

MARTIN, Thomas Commerford, American electrical engineer and author: b. London, England, 22 July 1856. He was educated in an academy at Gravesend, England, by a private tutor and subsequently studied divinity. He was associated with Thomas A. Edison in laboratory work and electrical development in 1877-79 since when he has been engaged in editorial work. From 1893 to 1909 he was editor of the Electrical World and since 1909 has been executive secretary of the National Electric Light Association. In 1900-15 Mr. Martin was engaged as special expert of the Census office of the United States. He has lectured at the Royal Institute of Engineers, La Sagesse Internationale des Electrictades, Paris, the University of Nebraska, Columbia and Lehigh universities, Delaware College and for the New York Board of Education. He was a member of the conference committee organized by engineering societies to expend the $1,500,000 given by Andrew Carnegie for a united engineering building and the Engineers' Club of New York. Mr. Martin is a member of many scientific societies and has published "The Electric Motor and Its Applications" (1883); "Invention, Searches and Writings of Nikola Tesla" (1893) for Edison, "His Life and Inventions," with F. L. Dyer (1910), and contributions to reference books, magazines and journals on electrical topics.

MARTIN, Thomas F., Democratic leader in New Jersey: b. in New England, about 1808. He came to Hudson County and worked as a reporter on the Hudson Dispatch. Later he became business manager, and when the publishing company failed bought in the property at auction, re-established the paper and made it a political power. Entering politics, he
was chosen to represent North Hudson in the State legislature. For several terms he was the Democratic leader in the House of Representatives, including the years of Woodrow Wilson’s governorship. Since 1916 he has been secretary of state of New Jersey.

MARTIN, Thomas Mower, Canadian artist: b. London, England, 1838. He studied art at the Second High School; removed to Canada in 1852 and settled in Toronto, Ontario. His best-known pictures are ‘The Untamed Wilderness’; ‘A Summer Idyl’; ‘Sunrise, Muskoka.’ He was one of the founders of the Royal Canadian Academy, the Ontario Society of Artists, the Art Union of Ontario and the Ontario School of Art. His publications are ‘An Artist’s Letters from the Rockies’ (1889) and ‘Canada from an Artist’s Point of View’ (1895).

MARTIN, Thomas Staples, American legislator: b. Scottsville, Va., 29 July 1847. Since 1853 he has resided on a farm not far from his birthplace. In 1864-65 he was a cadet at the Virginia Military Institute and for much of that period was actually connected with the army of the Confederate States. In 1865-67 he studied in the Universities of Virginia and in 1869 was admitted to the practice of law. Since 1895 he has been United States senator from Virginia.

MARTIN, Victoria Claflin Woodhull, Anglo-American financier and reformer: b. Homer, Ohio, 25 Sept. 1818. In 1832 she married Canning Woodhull, from whom she later separated. Her second marriage was to John Biddulph Martin who died in 1897. With her sister, in 1870, Mrs. Woodhull founded a stock brokerage house in New York, from which there was issued Woodhull and Claflin’s Weekly. For many years she has edited the Humanitarian Magazine. In 1870 Mrs. Woodhull memorialized Congress for women’s suffrage, and lectured throughout the United States on finance, women’s suffrage, religious and scientific implications. In 1852 she was nominated for the Presidency of the United States by the Equal Rights party. She has organized conventions for the discussion of social reform, carried on a continuous propaganda in the interests of the working classes both in America and Europe for over 30 years. Mrs. Martin’s publications include ‘The Origin, Tendencies, and Principles of Government;’ ‘Social Freedom;’ ‘Garden of Eden: Horticulture;’ ‘Rapid Multiplication of the Unit;’ ‘The Human Body the Temple of God;’ ‘Argument for Woman’s Electoral Rights,’ etc.

MARTIN, William Alexander Parsons, American educator: b. Livonia, Ind., 10 April 1827; d. 18 Dec. 1916. He was graduated from the Indiana State University and studied theology. He went to China as a missionary in 1850 and has spent the greater share of his life there engaged in educational and missionary work. He assisted in making the treaty between the United States and China in 1858, and was an authority in China on questions of international law. He was professor and president of Tung Wen College 1868–98, and then president of the New Imperial University until 1900, when it was destroyed in the siege of Peking, in which city he was imprisoned with the American legation. In 1902 he was appointed president of the University of Wuchung. He has edited in Chinese the Peking Scientific Monthly, and the Science Monthly, and has published ‘Siege of Peking’ (1900); ‘Chinese Legends,’ ‘The Lore of Cathay’ (1901), etc.

MARTIN, Winfred Robert, American librarian: b. Ningpo, China, 22 March 1852; d. 1915. In 1872 he was graduated at Princeton University and three years later received the degree of M.A. at the same institution. In 1878 he was graduated at the law school of New York University. For several years subsequently he studied in Germany, receiving the degree of D.Ph. at Tübingen in 1887. He held the chair of Oriental languages and literatures at Trinity College, Hartford, from 1888 to 1907 and from 1902 to 1907 also taught Sanskrit at the Hartford Theological Seminary. In 1907 Dr. Martin was appointed librarian of the Hispanic Society of America. He received the honorary degree of LL.D. from Trinity College in 1907 and four years later King Alfonso of Spain created him knight of Isabella the Catholic.

MARTIN DE MOUSSEY, Jean Antoine Victor, French physician: b. Moussey-le-Vieux, 1810; d. 1869. His medical education was obtained in Paris, where he practised in the military hospitals. He removed to Montevideo, Uruguay, in 1841 and in 1843–52 directed the medical service of the French and Italians engaged in the siege of the city. In 1852 Dr. Martin was engaged by the Uruguayan government to prepare a work on the geography of Uruguay. In order to prepare himself for the task he traveled up and down the country in the years 1855–59. The work appeared in three volumes under the title ‘Description géographique et statistique de la confédération argentine’ (1860–64). Another volume was his ‘Mémoire historique sur la décadence et la ruine des missions des jésuites dans le bassin de la Plata’ (1865). Dr. Martin presented this morphological observatory to the city of Montevideo.

MARTIN, a swallow (q.v.). In the United States the name is restricted to the purple martin (q.v.), several other species of which (genus Progne) are familiar garden birds in South America. The bank-swallow (q.v.) is sometimes called sand-martin, especially in England, where the term is more generally used as a synonym of “swallow” than in America.

MARTINE, James Edgar, American legislator: b. New York, N. Y., 25 Aug. 1850. He received a public school education. He engaged in farming near Plainfield, N. J., and also acquired large real estate and building interests. At various times he was caucused into the New Jersey house of representatives, the senate and other offices. When Woodrow Wilson was governor of New Jersey Martine was one of his most ardent supporters and became United States senator for the term 1911–17. In the Senate of the United States he warmly championed the cause of labor in the discussions in regard to working conditions, wages, etc., in the coal mines of West Virginia and Colorado.

MARTINEAU, Mārt′i-nō, Harriet, English author: b. Norwich, 12 June 1802; d. Ambleside, 27 June 1876. She was a sister of James
Martineau (q.v.). Her first work, 'Devotional Exercises for the Use of Young Persons,' appeared in 1823; and in 1830-31 she won three prizes offered by the Central Unitarian Association for as many essays designed to convert respectively the Catholics, the Jews and the Mohammedians. The essays, 'probably converted nobody, but brought in 45 guineas.' Next came several stories, mostly intended to inculcate some useful lesson, such as those having the title, 'Illustrations of Practical Christianity,' which were followed by 'Illustrations of Taxation' (1834), and gained an immediate recognition. After a sojourn in the United States (19 Sept. 1834 - 1 Aug. 1836), she published 'Society in America' (1837), intended as a comparison of the existing state of society in America with the principles on which it is supposedly founded, and 'A Retrospect of Western Travels' (1838), including some criticisms of slavery that were not well received in this country. Up to about 1851 Miss Martineau had been known as a Unitarian, but she later showed a decided leaning toward Positivism, and in 1853 published a condensation of Comte's 'Positive Philosophy.' Among her other works of importance may be mentioned her 'History of England during the Thirty Years' Peace' (1849). During the last 20 years of her life her writings consisted mainly of pamphlets and contributions to newspapers and periodicals. A remarkably candid autobiography, which had been written for many years, was published after her death (1877). Consult also Miller, 'Harriet Martineau' (1884).

MARTINEAU, James, English Unitarian clergyman and philosopher: b. Norwich, 21 April 1805; d. London, 11 Jan. 1900. His father, Thomas Martineau, the great-grandson of a Huguenot surgeon who left France after the revocation of the Edict of Nantes, was a manufacturer of bombazines. Harriet Martineau (q.v.) was an elder sister. He was sent to Derby in 1821 to study civil engineering, but in the following year became a student of Manchester College. In 1827 he took charge for a year of Dr. Lant Carpenter's school in Brighthelmstone, and in 1828 he accepted a call to the copastorate of Eustace Street Presbyterian Church, Dublin. In 1831 he published 'Hymns for Christian Worship,' and next year resigned his pastorate, but shortly afterward accepted the copastorate of Paradise Street Chapel, Liverpool, of which in 1835 he became sole pastor. In 1836 appeared his first separate original work, 'The Rationale of Religious Inquiry,' which attracted considerable attention. In 1839 he was associated with J. H. Thring and Henry Giles in the defense of Unitarianism against attacks by orthodox clergymen, and of 13 addresses published in 'Unitarianism Defended' (1839), five were by Martineau. In 1840 he published his collection of 'Hymns for the Christian Church and Home,' a work written by a professor of mental and moral philosophy and of political economy in his old college, now named Manchester New College. On the removal of the college to London in 1853 he retained his professorship, but did not settle in London until 1857. In 1848-49 he spent 15 months on the Continent, mostly in Germany, during which his philosophical opinions were profoundly influenced by the study of Greek and German philosophy under Trendelenburg. The remaining publications of his first Liverpool period are an essay on 'The Five Points of Christian Faith' (1841), and the well-known collection of sermons entitled 'Endeavors after the Christian Life' (1843-47). During the period 1849-57, when he was pastor of Hope Street Church, Liverpool, he published many articles in reviews, among them that on 'Mesmerism and Astronomy,' which finally completed his sister Harriet's estrangement from him. In 1859, being now in London, he and J. J. Taylor, principal of Manchester New College, were chosen joint ministers of Little Portland Street Chapel, but from 1860 till his resignation in 1872 Martineau alone supplied the pulpit. On Taylor's death in 1869 he became principal of the college, a post which he held till his resignation in 1885. In 1866 he was a candidate for the chair of logic and mental philosophy in University College, London, but the united opposition of orthodoxy and secularism led by George Grote managed to defeat him by a single vote. His publications include 'Studies of Christianity' (1861), a volume of sermons on Sacred Things' (1876-80); 'Ideal Substitutes for God Considered' (1880), a criticism of Moral Idealism; 'A Study of Spinoza' (1883), his first great philosophical work; and 'Types of Ethical Theory' (1885), the earlier of his two masterpieces. During the last years of his life he published his great defense of the essential principles of religion entitled 'A Study of Religion: Its Source and Contents' (1888); and his freely critical 'Seat of Authority in Religion' (1890). The first academic degree ever conferred upon him was that of LL.D. by Harvard in 1872, but he received later the degrees of S.T.D. from Leyden (1879), D.D. from Edinburgh (1884), D.C.L. from Oxford (1888), and D.Litt. from Cambridge (1889). Martineau was one of the most eminent preachers of his time, but his greatest work was done in the fields of ethics and philosophical theology. At first a necessary and utilitarian, he was latterly the great modern champion of free-will and intuition. In the development of his Christology from a sort of Arianism to complete Humanitarianism, and in his ever-increasing insistence upon the continuity of revelation and the purely internal character of ultimate religious authority, he summed up more than any other the history of Unitarianism, and indeed of liberal theology generally during the 19th century. He was a powerful and eloquent champion of Theism against scientific agnosticism and materialism. All his works are written in a was appointed by a prose and happy use of figurative language. Consult Jackson, 'James Martineau: A Biography and a Study' (1900); Sidgwick, 'Lectures on the Ethics of Green, Spencer and Martineau' (1902); Drummond, 'Letters of James Martineau'; and Upton, 'A Survey of Philosophical Work' (1902).
MARTINELLI, már-té-né'tlê, Sebastiano, Italian prelate: b. Lucca, Tuscany, 20 Aug. 1848; d. 5 July 1918. He was educated at the College of Saint Augustine in Rome, entered the Augustinian Order and was ordained to the priesthood. He was the provost-general of the Augustinian Order throughout the world in 1889 and in 1894 was sent to America to visit the monks of that order and shortly afterward was designated apostolic delegate to the United States. At this time he was consecrated titular bishop of Ephesus. He returned to Rome as delegate of the statesmanlike solution of several important questions. In 1901 he was made a cardinal, returned to Rome soon afterward and became prefect of the Sacred Congregation of Rites.

MARTINEZ, Enriquez, én-rêkêth mão-té-'néth, or Enrico, Mexican engineer: b. about 1570; d. in Mexico, 1632. His birthplace is variously given as Germany, Holland, Spain (in Ayamonte, Andalusia) or Mexico. He studied engineering in Spain; went to Mexico as treasurer and surveyor and held the title of cosmographer royal; and in 1607 undertook to drain the valley of Mexico, threatened by lakes Zumpango and San Cristobal. His canal was fairly successful but inadequate, and after various experiments on the part of the other engineers, with whose work Martinez was accused of tampering, he was broken in his tunnel and canal. He died before the work was much more than started. Martinez established a printing-press in the City of Mexico and wrote on the natural history of Mexico, on astronomy and on trigonometry. His works are 'Discurso sobre la magnifica conjuncion de los planetas Jupiter y Saturno, acaecida en 24 Diciembre 1603 en Sagitario' (Mexico 1604); 'Repertorio de los tiempos, é historia natural de Nueva España' (Mexico 1606); 'Tratado de Trigonometria.'

MARTINEZ DE CAMPOS, Arsenio. See CAMPOS, ARSENIO MARTINEZ DE.

MARTINEZ DE ROZAS, Juan, hoo-an' mão-té-neth dá rô'zâs, Chilean statesman: b. Mendoza, Argentina, 1759; d. there, 3 March 1813. He was educated at Cordova; studied law at Saavedra, Spain, and in 1779 was made assistant intendant of the province of Concepcion; and in 1796 had risen to the second command in the presidency. He took a prominent part in planning the revolution of 1810; was a member of the governing junta until 1811, when he became its president; and showed himself an able administrator and a brave soldier. Carrera quarreled with him, got the upper hand and banished him to his birthplace, only a few months before his death.

MARTINEZ, már-té-'néth, Cal., town, county-seat of Contra Costa County, on the Strait of Carquines, and on the Southern Pacific Railroad, about 30 miles northeast of San Francisco and 85 miles southwest of Sacramento. It is near valuable mines and also rich farmland, the crops which large quantities of wheat, grapes, pears, etc., are raised. A novitiate of the Christian Brothers is here and the Brothers maintain a library which has about 6,000 volumes. It has a high school, city hall and courthouse, oil refineries, copper smelters and fertilizer works. Pop. 2,115.

MARTINI, már-té-'néth, Simone, Italian painter, sometimes mistakenly called Simone Memmi: b. Siena, about 1284; d. Avignon, 1344. He was the founder of the Sienese school of painting and executed frescoes in the churches of Siena, Assisi, Napoli in Italy, and at the invitation of Pope Benedict XII he went to Avignon and in collaboration with his brother, Donato, decorated the papal palace. He seems to have aimed at flat decorative effect rather than artistic boldness and originality in his wall painting and his color is harmonious and fresh, though his faces are conventional. The large painting of the Madonna on the walls of the Palazzo Pubblico is his most important work at Siena (1315); at Florence is to be seen an 'Annunciation' of his in the Uffizi, and fragments of his work also survive at Avignon. His other more important pictures are 'The Way to Golgotha' (1333) in the Louvre; 'The Blessing of Christ' in the Vatican; 'Christ as a Child with His Parents' in the Royal Institution, Liverpool; 'Saint Anthony of Padua' in San Lorenzo, Naples; fragments at Pisa, Arvieto. Fenway Court, Boston, contains some examples of his work. Consult Berenson, Bernhard, 'Central Italian Painters of the Renaissance' (New York 1897).

MARTINIQUE, már-ti-nék', West Indies, an island of the Lesser Antilles and, except Guadeloupe, the largest in the Caribbean chain. Area, 381 square miles. It is very mountainous (Mount Pelée, in the northwest, 4,900 feet; Mount Carbet but a little lower, while a peak near the southern coast rises to the height of 3,950 feet. The thermometer ranges between 76° and 88° F., the summers being hot and dry, autumn and a part of winter hot and rainy, and spring comparatively cool. The inhabitants number about 185,000. About 3 per cent are Caucasians, who reside chiefly in Saint Pierre; the balance of the population—those who, in the main, suffered least from the disaster of 1902—are described as negroes, mulattoes, *copre, chabin and matel*—that is, blends of the African, Carib Indian (q.v.), Mongolian and French races. A large part of the surface is covered with forests of silk-cotton, species of mahogany, etc. The flora is closely related to that of South America; the fauna abound in minor reptiles and insects. Of the snake kind the most dreaded is the fer-de-lance, whose bite is fatal. The mongoose has practically exterminated this serpent within recent years. Sugar and cocoa are the chief productions, followed by coffee, tobacco and cotton. There are over 40,000 acres under cultivation and tobacco-growing is subject to special regulation. There are 45 sugar mills and many distilleries. In 1910 sugar to the value of $5,900,000, rum to the value of $5,600,000 and cocoa to the value of $1,500,000 were exported. In the same year the total of all imports was $6,770,000 and of exports $12,195,000. There entered that year 537 vessels of 465,502 tons. Martinique is a colony of France, sending one senator and one deputy (two deputies until 1903) to the French legislature. Its affairs are administered by a governor, general council and elective municipal councils. Educational institutions are a law school at Fort-de-France, with 56 students; several secondary or normal schools and about 100 primary schools with
18,000 pupils. The island was acquired by the French in 1635. Toward the close of the 18th century and beginning of the 19th century it was temporarily held by the British. In May 1902 volcanic eruptions from Mount Pelée destroyed Saint Pierre, which was the largest city on the island, with a population of 26,011, and the ruins of that city continued to be visible for almost without exception; but the statement commonly made, that "a great part of the island was overwhelmed," is incorrect. The scope of Pelée's work was limited. (See PELEE, MONT.) About 10,000 persons besides those in Saint Pierre lost their lives (in all, 20 per cent of the total population); the best agricultural regions, however, in the south and along the eastern coast were uninjured. The capital, Fort-de-France (pop. 26,399), is situated in the southwest and is important as being the military and naval headquarters and rendezvous of the French Antilles; the terminus of the French transatlantic steamers and West Indian cable system. For local traffic there are mail coaches and motor-cars, which receive a subsidy from the government. Modernized steamers ply on the coast. The Bank of Martinique, situated at Fort-de-France, has a capital of $600,000. A statue of the Empress Josephine, who was born in Martinique, is one of the ornaments of the public gardens of Fort-de-France. In 1816 the military force consisted of 39 officers and 2,255 men. The capital has had its share of misfortunes in the past: it was nearly consumed by fire in 1890 and partially destroyed by an earthquake in 1839.

MARTIN'S FERRY, Ohio, city, in Belmont County, on the Ohio River and on the Pennsylvania, the Baltimore and Ohio and the Wheeling and Lake Erie railroads, almost opposite Wheeling, W. Va. The first settlement was made in 1769 and in 1865, nearly a century later, it was incorporated as a village. The charters were lost, and it is not now governed. It was granted in 1885. It is situated in a region noted for its abundance of bituminous coal, iron and limestone. The chief manufactures are iron, steel, stoves, shovels, nails, glass, tin, machine-shop products, lumber, barrels and boxes. The city owns and operates the light plant and the waterworks. Pop. 9,178.

MARTINSBURG, mär’tinz-bärk, W. Va., city, county-seat of Berkeley County, on the Cumberland Valley and the Baltimore and Ohio railroads, about 65 miles northwest of Washington, D. C. It is in the vicinity of valuable stone quarries and forests which furnish timber for many mills. The chief manufactures are hosiery, woolen goods, lime, wagons, lumber and canned goods. The repair shops of the Baltimore and Ohio Railroad and slate and limestone quarries furnish employment for a number of people. The chief buildings are the government building, the Berkeley Female Seminary, the Berkeley Female Institute and the King's Daughters' Hospital. The waterworks are owned and operated by the municipality. The government is vested in a mayor and city council, elected every three years. It was incorporated in 1778. Pop. 12,032. Martinsburg, as the chief city of the lower Shenandoah Valley, on the main road leading across the Potomac, the converging point of several roads, with the Baltimore and Ohio Railroad running through it, was an important point in the military operations of the valley. Early in July 1861, General Patterson, after a slight skirmish at the place, the Confederates falling back to Winchester. Patterson soon abandoned it, and it was reoccupied by the Confederates. Early in March 1862 it was again occupied by the Union forces under Banks. On 25 May 1862, after Banks' defeat at Winchester, but soon reoccupied by Banks. On 8 Sept. 1862 Gen. Julius White was in command of the place with about 2,500 men of all arms. At this time General Lee had crossed the Potomac and was at Frederick, Md. On the 10th Jackson led a column from Frederick, crossed the Potomac at Williamsport and moved on Martinsburg. White retreated during the night of the 11th to Harper's Ferry. In June 1863, Smithfield's cavalry moved down the valley in the Gettysburg campaign the place was held by Col. B. F. Smith with 1,200 infantry and a battery. On 13 June, Ewell, at Cedarville, detached Jenkins' cavalry brigade and Rodes' infantry division to assist the Union forces at Berryville and Martinsburg. Both garrisons escaped, Smith, with the greater part of his infantry, crossed the Potomac at Shepherdstown and making his way to Maryland Heights. The battery retreated by the Williamsport road and lost five of its six guns, with 200 infantry accompanying it. On 1 July 1864 the place was held by General Sigel with about 3,200 infantry and dismounted cavalry and a battery. On the 2d, Early arrived at Winchester to menace Washington and under General Lee's instructions, to clear out the lower valley and wreck the Baltimore and Ohio Railroad. Parties were sent north and west against the railroad, and on the 3d Bradley T. Johnson, with a cavalry brigade, was ordered to move through Smithfield and Lee Town, cross the railroad at Kearneysville, east of Martinsburg, and, pushing north, unite with McCausland at Hainesville beyond Martinsburg. Johnson arrived at Lee Town early in the morning, where he was met by Col. J. A. Mulligan with about 2,000 men and rifles the electric light and Federal fight was driven back on the divisions of Rodes and Ramsour, which were supporting him. Breckinridge's division, which marched on the main road to Martinsburg, drove before it Stahl's cavalry, an outpost at Darkeville. Sigel, warned of approaching danger, burned his stores, collected his command, and, leaving Martinsburg on the night of the 3d, crossed the Potomac at Shepherdstown and occupied Maryland Heights. Early cleared the valley and advanced on Washington, and on the 11th Martinsburg was occupied by Sullivan's division of Hunter's command, and remained in Union occupation until the 25th, when Crook, being defeated by Early at Kernstown, was driven through Winchester, made a short stand at Martinsburg and recrossed the Potomac at Williamsport, and continued on the railroad and destroying the railroad on either side of it, and continuing in possession until 10 August, when, upon Sheridan's advance to Hattstown, he abandoned Martinsburg and Winchester and fell back to Strasburg. He advanced from Strasburg on the 17th and reoccupied Martinsburg
on the 19th with his cavalry. From this time until 17 September the place was held alternately by Union and Confederate cavalry, on the 17th by Averell's Union division. On that day Early left Winchester with a heavy force of infantry, cavalry and artillery, and on the 18th attacked and drove Averell from Martinsburg across the Opequon. Sheridan defeated Early on the Opequon on the 19th, and drove him up the valley, and Martinsburg was again occupied by Union troops, to remain in their possession until the close of the war.

MARTINSVILLE, Ind., city, of Morgan County, situated on White River, the Cleveland, Cincinnati, Chicago and Saint Louis and the Vandalia railroads, 30 miles southwest of Indianapolis. It enjoys considerable reputation as a health resort, having several artesian mineral wells and modern sanatoria. It contains flour mills, planing and saw mills, brick yards, chair works and a woodenware factory. The city owns the electric-lighting plant and the water-supply system. Pop. 4,529.

MARTINSVILLE, Va., town and county-seat of Henry County, situated on the Danville and Western and the Norfolk and Western railroads, 40 miles northwest of Danville. It contains several fine public buildings, including the town-hall, courthouse, post office and high school. Its industrial establishments include cotton mills, tobacco warehouses, furniture and spoke factories. It has large farming interests, and the Roundabout stock farm is a show place. The electric-lighting, telephonic and water-supply plants are the property of the municipality. Pop. 3,368.

MARTIN, Philip, American sculptor: b. Alsace, 19 May 1838. His boyhood was spent in France working in various studios. Early in the 80's he came to America and made further studies under the direction of Saint-Gaudens. Martin's efforts in decorative sculpture have been conspicuously successful and his work has improved this branch of art in the United States. Among his best-known works are the sculpture on the grand staircase of the Congregational Library, Washington; the Carnegie Library, Washington; the New York Hall of Records; Chamber of Commerce groups, New York; bronze doors of St. Bartholomew's, New York; a fountain and figures in the Clark residence, New York; Soldiers' and Sailors' Monument, Jersey City; McKinley Monument, Springfield, Mass.; statue of Vice-President Hobart at Paterson, N. J., and the d e Gernay Monument at Newport, R. I.

MARTYR, Martin, Roman Catholic bishop: b. Schwyz, Switzerland, 12 Jan. 1834; d. Saint Cloud, Minn. 19 Sept. 1896. He received a collegiate education in Switzerland and Austria, was ordained to the priesthood in 1856 and in 1860 came to the United States. He assisted in the founding of a priory at Saint Meinrad's, Ind., and was its first superior; through his efforts the priory became an abbey in 1870 and Martin was its abbot. He resigned his office several years later in order to perform mission work among the Indians of Dakota, over whom he gained a wide influence. He mastered their language and wrote a Sioux grammar and dictionary. In 1880 he became the first bishop of Sioux Falls, and in 1894 was transferred to Saint Cloud, Minn.

MARTYN, mär'tin, Henry, English missionary to India: b. Truro, Cornwall, 18 Feb. 1781; d. Tokat, Asia Minor, 16 Oct. 1812. He was graduated from Saint John's College, Cambridge, in 1801; became a Fellow of the same college in the next year, and a member of the law, took orders, and landed in India in 1806. After three years at Dinapore he was transferred to Cawnpore, where he opened a church in 1810, in spite of violent opposition, and where he completed a Hindustani version of the New Testament. To perfect a translation of the New Testament into Persian and to recover his health in 1811 he traveled into Persia. In Tabriz he was taken ill with a fever, and on his hurried journey home was compelled to stop at the plague-stricken town of Tokat, where he died. In 1856 a monument to his memory was erected there. He was the great missionary hero of the Church of England up to the early part of the 19th century. Martyn's works include 'Controversial Tracts on Christianity and Mohammedanism' (1824), and versions of various parts of the Bible into Hindustani, Persian and Judeo-Persian. Consult Bell, C. D., 'Henry Martyn' (New York 1881); Smith, George, Henry Martyn, Saint and Scholar, First Modern Missionary to the Mohammedans, 1781-1812 (London 1892); Wilberforce, Samuel (ed.), 'Journals and Letters of the Reverend Henry Martyn' (2 vols., London 1837).

MARTYN, William Carlos, American Presbyterian clergyman, historical writer and lecturer: b. New York City, 15 Dec. 1841; d. 4 Aug. 1917. He studied law at Columbia under Prof. Theodore Dwight, 1860-62, and was graduated from Union Theological Seminary in 1869 and ordained to the Congregational ministry. He held important charges in Saint Louis, Chicago and New York; 1887-1902 was literary director in a New York publishing house, and has contributed largely to magazines and periodicals. His historical and biographical works cover a wide circle and include 'Martin Luther' (1866); 'John Milton' (1866); 'Pilgrim Fathers of New England' (1870); 'The Puritans' (1867); 'The Huguenots' (1867); 'The Dutch Reformation' (1868); 'John B. Gough' (1893); 'William E. Dodge' (1891), and 'Wendell Phillips' (1890), this last having an enormous circulation. In other veins were a work on 'Christian Citizenship' (1896), and a novel, 'Sour Saints and Sweet Sinners' (1898). Since 1905 Dr. Martyn has resided in Noroton, Conn., and has served the Presbyterian church there. At various times and places literary honors and dignities have come to him.

MARTYRIA, a genus of annual and perennial herb of the family Martyniaceae. The 10 species have thick sub-erect stems, opposite or alternate heart-shaped leaves, showy catalpa-like flowers in short terminal racemes, and horned capsules which suggest the names un- corn plant and proscis-cus-flowers. When ripe the capsules split and expose numerous wrinkled seeds. The stems and foliage are clammy and maldorous, but the flowers of some species are not unpleasantly perfumed. The species are all natives of warm parts of America. They are often planted for ornaments, as curiosities and for their capsules, which white
young and tender are used as material for pickles. M. *louisiana*, to which the popular names are generally applied, is the most commonly grown.

**MARTYR** (Greek for "witness"), a designation applied by the Christian Church to those persons in particular who, in the early ages of Christianity, suffered death rather than renounce their faith, and thus testified their confidence in the truth of the new doctrines. Martyrs are sometimes classified as of three classes: martyrs in will and deed, like Saint Stephen; those in will, but not in deed, like Saint John, who escaped from the death ordained for him by Domitian; and those in deed but not in will, like the Holy Innocents. An account of the life, persecutions and death of the Christian martyr is called a *martyrology* (q.v.). A tomb or oratory erected on the spot where a martyr suffered was called *martyrium*, martyry. Festivals in honor of the martyrs seem to have been observed as early as the 2d century. The Christians offered prayers at the martyry and thanked God for the example which they had given to the world. The rite was concluded with the sacrament of the Lord's supper and the distribution of alms. Eulogies were also delivered and accounts of the lives and actions of the deceased read. These festivals were called the birthdays of the martyrs, because on the day of their death they were born to eternal life. There are 14,000 martyrs commemorated in the Roman martyrology. In the early centuries of Christianity the bishop of the locality certified the names of those who were deemed worthy of the title of martyr, but after 300 their names became more and more reserved to the Pope, especially since 1636.

**MARTYR**, már'ter. See Peter MARTYR.

**MARTYRE DE SAINT SEBASTIAN**, Læ (The Martyrdom of Saint Sebastian), an oratorio by Debussy which had its first performance at Paris on 22 May 1911.

**MARTYROLOGY**, called also calendar of the saints, the acts of the saints, menology, anology, synaxary, a list of martyrs and other saints, in which was sometimes noted the character of their lives, and in the case of a martyr the place and date of his martyrdom and the nature of the sufferings which he underwent. Baronius, an ecclesiastical historian of the 16th century, attributes to Saint Clement of Rome, almost contemporary with the apostles, the first idea of collecting the acts of the martyrs. In the time of Gregory the Great (end of the 6th century) the Church possessed a general martyrology, the author of which is said to have been Saint Jerome, who made use of materials collected by Eusebius of Cæsarea. The only part of it now extant is a catalogue of the martyrs who suffered in Palestine during the last eight years of the persecution of Diocletian. There is a martyrology attributed to Bede (beginning of 8th century), but if not altogether spurious, at least interpolated. Numerous martyrologies were produced in the next century and subsequently. In 1586, under the auspices of Sixtus V, a martyrology was printed at Rome, with notes by Baronius, with the title of *Martyrologium Universale.* Routh's *Acta Primorum Martyrum Sincera* appeared at Paris in 1689, and a new edition of it was published in 1859. The *Acta Sanctorum* (q.v.) of the Bollandists comprises over 60 volumes issued at various times from 1643, but the work is still incomplete. The well-known English work of John Foxe, *The Book of Martyrs* (Protestant), may also be mentioned. Consult Achelis, Die Martyrologen, ihre Geschichte und ihr Wert (Berlin 1900); Lämmer, De Martyrologio Romano, Parerogen Historico-Criticum (Regensburg 1878); Martyrologium Sancti Hieronymi (in *Acta Sanctorum* for November, Paris 1894); Kenrick, Francis P. (ed.), The Roman Martyrology (Baltimore 1907); Delhaye, Le témoignage des martyrologes (in *Analecta Bollandiana*, Vol. XXVI, Paris 1907).

**MARULIC, Marko**, a Croatian poet and historian: b. Spalato in 1450; d. 1524. After studying at Padua he entered a monastery in Spalato, where he wrote most of the works which stamped him as the foremost of Croatian authors and rendered his name one of the greatest in the literature of Ragastra. Among his works were the *Institutione Bene Vivendi,* published in 1511. It was reprinted several times. In his native tongue he wrote mystery plays, the first of their kind in the Croatian language, and several poems, best of which is *The History of Judith.* His poems were republished with a biography (Agram 1869).

**MARVEL, Ik.** See MITCHELL, DONALD GRANT.

**MARVELL, Andrew**, English poet and satirist: b. Winestead, Holderness, Yorkshire, 31 March 1621; d. London, 18 Aug. 1678. He was graduated from Trinity College, Cambridge, in 1638; after activity as poet and tutor became colleague of Milton in the Latin secretariats in 1637; was three times elected to Parliament for Hull, and under the Restoration attacked Charles II and advocated a republic. While a true literary genius most of Marvell's work has little appeal to moderns, because it deals with persons and incidents that are long since passed away and forgotten. His lyrics, however, are immortal, and through them his place in English literature is assured for all time. His chief poem is the *Horatian Ode Upon Cromwell's Return from Ireland* (written 1650; first printed 1767). The shorter poem, *The Bermudas,* is also well known. Consult his *Works,* edited by T. Cooke (2 vols., London 1726); *Works,* edited by E. Thompson (3 vols., London 1776); *Poems and Satires,* edited by G. A. Aitken (2 vols., London 1898); *Poems and Satires,* edited by E. Wright (ih. 1904); Birrell, Augustine, *Life of Andrew Marvell* (in *English Men of Letters Series,* London 1905); Brown, John, *Andrew Marvell* (in *Cambridge History of English Literature, Vol. VII,* Cambridge 1911); Dove, *Life of Andrew Marvell* (London 1832).

**MARVIN, Charles Frederick**, American meteorologist: b. Putnam, Ohio, 7 Oct. 1858. He was graduated as a mechanical engineer from the Ohio State University in 1883, where he had been instructor in mechanical drawing and laboratory practice since 1879. In 1893 he was appointed to the U. S. Signal Service and later was made professor of me-
teorology in the weather bureau, of which he became chief in 1913. He has made many important investigations and discoveries in connection with the weather bureau, and has written quite extensively concerning them.

MARVIN, Enoch Mather, American Methodist Episcopal clergyman: b. Warren County, Mo., 1823; d. 1877. He was self-educated; became a minister of the Methodist Episcopal Church in 1847; held a Congregational position in 1856; and in 1877 he was a member of the Michigan Conference. Upon the division of the Methodist body in 1844 he cast his lot with the Methodist Church South. In the Civil War he was for two years a chaplain in the Confederate army. He was chosen bishop of his Church in 1866 and at the time of his death had just returned from a missionary tour which took him all around the world. He published 'Errors of the Papacy and Transubstantiation' (1856); 'The Life of William Goff Caples' (1871); 'Camping up' (1876); 'The Doctrinal Integrity of Methodism' (1878); 'To the East by Way of the West' (1879); 'The Methodist Episcopal Churches, North and South.' Consult Finney, T. M., 'The Life and Labors of Enos M. Marvin' (Cincinnati 1880).

MARVIN, Frederic Rowland, American clergyman, essayist and poet: b. Troy, N. Y., 23 Sept. 1847; d. 22 July 1918. Son of Rev. Uriah and Margaret Jane (Stevens) Marvin; educated at Lafayette and Union colleges, College of Physicians and Surgeons, New Brunswick Seminary; sometime professor in New York Free Medical College for Women; pastor of Congregational churches in Middletown, N. Y., Portland, Ore., Great Barrington, Mass., retiring in 1895 for study and travel in Europe; settled at Arley, N. Y., since 1900. Among his works are 'Literature of the Insane'; 'Epidemic Delusions'; 'Last Words of Distinguished Men and Women'; 'Book of Quatrains'; 'Excursions of a Book-Lover'; 'Poems and Translations'; 'Companionship of Books'; 'Christ Among the Sheep'; 'The Cattle'; 'Flowers of Song from Many Lands'; 'Love and Letters'; 'Fireside Papers.' Consult also 'The Top of the Wine-Jar,' a volume of selections from the author's 10 works, with a literary estimate by Livingston Stebbins.

MARX, märks, Karl, German Socialist: b. Trefes, 5 May 1818; d. London, 14 March 1883. He was educated at the universities of Bonn and Berlin, and in 1842 took up journalism, becoming editor of the Rheinische Zeitung, a Democratic journal; his socialist articles in this paper caused its suppression in 1843. Marx then proceeded to Paris, where he became one of the editors of the Deutsch-Franzosische Jahrbücher, to which he contributed articles on the Hegelian Philosophy of Right. He was expelled from France in 1845, and retired to Brussels, where assisted in organizing the German Workingmen's Association, was also active in the organization of the Communist League, and with Engels issued the famous Communist Manifesto in 1847, which was the first public declaration of international Socialism. In 1848 Marx started the Neue Rheinische Zeitung, and was active in the revolutionary movements of that year. Banished from Germany in 1849, he went first to Paris, then to London, where he lived till the time of his death. He devoted himself largely to the study of economic questions, and was correspondent of the New York Tribune and other papers. In 1864 he took a leading part in the organization of the International Workingmen's Association (q.v.), was selected to formulate its program and practically shaped its policy for a number of years; he was also interested in the organization of the German Social Democrats who united nationally in 1869. After 1873 he took no active part in politics, but devoted his time to the completion of his work on capitalism, 'Das Kapital' ('Capital'), the first volume of which had been published in 1867 ('English trans. 1886'); the second and third volumes were left in manuscripts, and volume II was published in 1885; volume III in 1894, under the editorship of Engel. He also wrote 'Zur Kritik der Politischen Ökonomie' (1859); 'Lohnarbeit und Kapital' (English trans. 'Wage Labor and Capital'); 'Miniere de la Philosophie' (1847); 'The 18th Brumaire of Louis Bonaparte' (1852); 'Life of Lord Palmerston' (1890), and 'Revolution and Counter-Revolution,' a reprint of a series of letters in the New York Tribune with regard to the Revolution of 1848 in Germany.

Marx was undoubtedly the founder of the modern socialist school, in that he first gave definite scientific statement to the principles of modern Socialism. His greatest and best-known work, 'Das Kapital,' is a monument of acute reasoning, extensive reading and knowledge, though excessively long, obscure and tortuous in its meanings. In this he analyzes carefully his theory of value, which is that the measure of the value of a commodity is the amount of labor 'socially necessary' to produce it, and shows how under the capitalist system the laborers are exploited of what they produce over and above their wages (surplus value). These theories were by no means new, though Marx rather confused than elucidated them. He also traces the development of capitalist production, the growth of the working class or proletariat which is finally to transform or revolutionize society, and lays down the principle that the fundamental factor in the development of society is the method of production and exchange; hence the Socialist movement must simply assist and hasten the changes in progress. Marx was not only a scholar and thinker, but an organizer and agitator of unusual power. (See Socialism.) Consult Aveling, 'The Student's Marx' (London 1892); Deville, 'The People's Marx,' for epitomes of 'Capital.' Consult also Böhm-Bawerk, 'Karl Marx and the Close of His System' (New York 1898); Boudin, L. B., 'Theoretical System of Karl Marx in Light of Recent Criticism' (Chicago 1907); Croce, B., 'Historical Materialism and the Economics of Karl Marx' (New York 1914); Sparrow, John, 'Karl Marx, His Life and Work' (ib. 1910); id., 'Sidelight on Contemporary Socialism' (ib. 1911).

MARY, the mother of Jesus, is known in the Catholic Church as the Blessed Virgin Mary. The name is from the Greek Mary (Maria) or Mapia (Maria), which in turn is from the Heb. Miryam, a word of uncertain meaning. The New Testament narrative is silent as to her parentage and the place and date of her birth. From tradition and other sources we
learn that her father was Joachim and her mother Anne, that by them she was presented in the temple at Jerusalem when she was three years old, and that in the temple she remained until the age of 12 or thereabouts. Her birthplace is variously stated as being Nazareth, Sephoris (Diocesarea), or Jerusalem. In early youth she was betrothed to Joseph, a carpenter, a scion of the house of David. She probably belonged herself to the same royal lineage. At all events, she was a cousin of Elizabeth, wife of the priest Zachary and mother of John the Baptist. While Mary was betrothed to Joseph, and before her marriage, she was visited at Nazareth, a city of Galilee, by the angel Gabriel, who announced to her that, by the operation of the Holy Ghost, she should conceive and bring forth a son, to whom she was to give the same name which, who should be called the son of the Most High, and who should reign over the house of Jacob forever. The angel also said that her cousin Elizabeth had conceived a son in her old age, and was then in the sixth month of her pregnancy. Mary hurried hence to the city of Judah, and, in response to Elizabeth’s salutation, “Blessed art thou among women, and blessed is the fruit of thy womb,” she uttered under divine inspiration the glorious canticle of praise known as the Magnificat.

The visit lasted about three months. On her return to Nazareth, Mary “was found with child of the Holy Ghost.” Joseph, however, was in a dream told by an angel of the true condition of affairs, and, instead of putting her away privately, as was his first impulse, he concluded the ritual marriage with her. Some few months later, in obedience to a decree of Cæsar Augustus prescribing a general enrolment, Joseph went from Nazareth in Galilee to the city of David, Bethlehem in Judæa, because he was of the house and family of David, to enrol himself with Mary, who was then great with child. There was no room for them in the inn, and so in a grotto, which served as a shelter for animals, Mary gave birth to her son. On the eighth day afterward the child was circumcised, and was called Jesus, in accordance with the instruction previously given by the angel Gabriel. Thirty-three days later Mary complied with the law of Moses (Lev. xii, 2-8) by offering herself in the temple at Jerusalem for legal purification, and at the same time she presented her child to the Lord in accordance with Ex. xiii, 2, 12 and Num. xviii, 15. On this occasion Simeon pronounced the canticle of joy known as “Nunc dimittis.” He told Mary that her child was set for the fall and for the resurrection of many in Israel and for a sign that should be contradicted, and that her own soul a sword should pierce. Anna the prophetess, on the same occasion, confessed to the Lord, and spoke of the child “to all that were looking for the redemption of Israel. A great danger threatened the life of Mary’s son. Herod the Great, king of Judæa, having seen and questioned the Wise Men who had come from afar to pay homage to the newborn king, even the matter that they had seen in the East, concealed the alarm which these strange tidings caused him, directed the strangers to Bethlehem as the city indicated by prophecies for the birth of Christ, and enjoined them to let him know, on their return to Jerusalem, where the young king was to be found, so that he too might come and pay him homage. Thus, after offering to the infant Jesus their gifts of gold, frankincense and myrrh, were warned by God in a dream not to go back to Herod, and accordingly they departed by another way into their own country. Herod, not hearing from them, was enraged, and issued an order that every male child two years of age and under in Bethlehem and its borders should be put to death. In the meantime, Joseph, being warned by an angel, had taken the child and his mother and fled into Egypt, and thus the infant Jesus escaped the Slaughter of the Innocents. How long the sojourn in Egypt lasted we do not know. What we are told is that Joseph, advised by an angel of the death of Herod, returned to the land of Israel, but, learning that Archelaus was reigning in Judea in the room of Herod his father, he decided to go, not to Bethlehem, but to Nazareth, and in the latter city the Holy Family took up their abode.

The chronology of Matthew and the chronology of Luke are in conflict with each other, and evangelists who give an account of the events immediately preceding and immediately following the birth of Christ, are at first sight somewhat confusing, but they are not conflicting, and are quite capable of reconciliation, although in this case, as in so many others, the reconciliation will not wholly square with the popular belief.

After the return to Nazareth, Mary makes but few appearances in the Gospel narrative. We learn that she and Joseph went every year to Jerusalem at the solemn day of the passover, and that on one of those occasions they lost Jesus, who was then 12 years old, and did not find him until after a three days’ search. We next find her at the marriage feast at Cana in Galilee, where Jesus, at her request, performed his first public miracle by changing water into wine. After this she accompanied Jesus to Capharnaum. Once the mother and brethren of Jesus sought to speak to him, but could not reach him for the crowd. During the passion, Mary stood by the cross of Jesus on Calvary, and from the cross Jesus commended her to John, who from that hour took her to his own. The last mention of her in the New Testament occurs in the Acts of the Apostles i, 14, where it is written that, between Ascension and Pentecost, the apostles were in an upper room in Jerusalem persevering with one mind in prayer with the women, and Mary the mother of Jesus, and with his brethren. After that time we have no certain information as to where she lived, nor do we know when and where she died. One tradition says that she lived with Saint John at Ephesus and died there; another, that she lived and died at Jerusalem. Baronius, in his ‘Annals,’ gives the date of her death as A.D. 48. In fixing that year he relied on a passage in the ‘Chronicon of Eusebius, but there is grave doubt as to the genuineness of that passage in the ‘Chronicon,’ and the present tendency is to regard it as a later interpolation. The general, perhaps even universal, belief among Catholics, Protestant, and even Mary’s body, as well as her soul, was assumed into heaven; but this bodily assumption has not yet been made a matter of faith. The Catholic Church teaches that Mary was conceived without original, or racial, sin; that she never com-
mitted actual, or personal, sin; that she was truly the mother of God; and that she always remained a virgin. The doctrine of the Immaculate Conception (q.v.) was not explicitly discussed until the 12th century; but it is claimed that it is implicitly contained in the teachings of the early Fathers of the Church. The festival of the Conception of the Blessed Virgin was certainly celebrated in the Greek Church in the 7th century. It was possibly kept in Spain in the same century. It was observed in Ireland as early as 1200, in parts of Italy before 1100, and in England, France and Germany in the 12th century. Saint Bernard, himself a devout client of Mary, unbraided the canons of Lyons for instituting (1140) such a festival without the sanction of the Holy See. He himself did not admit that her conception was sinless. Saint Thomas Aquinas, the Dominican, and Saint Bonaventura, the Franciscan, hesitated to accept the doctrine of the Immaculate Conception on the ground that, unless Mary had been at some time one of the sinful women on earth, she had to be redeemed by Christ. John Duns Scotus, the Franciscan, put forward, on the other hand, the doctrine of pre-redeption. He held that it was as high a tribute to the merits of Christ to assert that Mary was by Him kept free from all taint of original sin, as to say that she first contracted sin and was subsequently delivered from it. This view, at first seriously and even angrily contested, gradually spread, and gathered force and momentum with the progress of time. The Council of Trent declared that in its decrees on original sin it did not include the blessed and immaculate Virgin Mary, Mother of God. At length Pope Pius IX, on 8 December 1854, promulgated the Bull, Ineffabilis Deus, in which is given the authoritative definition, as follows: "We define that the doctrine which holds that the Blessed Virgin Mary, from the first instant of her conception, was, by a singular grace and privilege of Almighty God, in view of the merits of Jesus Christ, the Redeemer of the human race, preserved from all stain of original sin, is a doctrine revealed by God, and therefore to be firmly and steadfastly believed by all the faithful. The dogma of the Immaculate Conception, together with that of the Assumption, by many schisms, and by the sect known as Old Catholics. Scripture and tradition agree in attributing to Mary the greatest personal sanctity, and there is no dispute that the Church has always held her to be free from the commission of actual, or personal, sin. Saint Augustine crystallizes this view when he says (De natura et gratia, c. 36) that, out of honor to the Lord, he wishes no question to be made of the holy Virgin Mary when sin is treated of. Her complete freedom from actual sin is confirmed by the Council of Trent (Sess. VI, can. 23): "If any one say that man, once justified, can during his whole life avoid all sins, even venial sins, unless by a special divine privilege as the Church holds in regard to the Blessed Virgin, let him be anathema."

In the New Testament Mary is called the mother of Jesus (John ii, 1, xix, 25, 26; Acts i, 14) and mother of my Lord (Luke i, 43), and therefore attributed to the usual kindred of motherhood, namely, conception, gestation, parturition, and giving suck; but she is not specifically designated mother of God. The belief that that title was properly her due prevailed, however, in the Church from the beginning. The term Θεοτόκος (Lat. Deipara, mother of God) was probably first formally applied to her toward the end of the 3rd century by theologians of Alexandria. It occurs, for example, in the works of Origen. It came into common use in the 4th century, being found in the writings of Eusebius, Athanasius, Didymus, and Gregory of Nazianzus. As Saint Cyril of Alexandria put it (De Recta Fide ad Regin., c. 9), "This name Θεοτόκος was perfectly familiar to the ancient Fathers. Nestorius, however, contended that Mary was not rightfully called mother of God, as she was the mother, not of God, but of a mere man. Thereupon the Council of Ephesus (431) laid it down as an article of faith that Mary is really and truly the mother of God. The words of the decree are: "If any one does not confess that Emmanuel is truly God and consequently that the holy Virgin Mary is truly the mother of God (Θεοτόκος, Dei genitrice) — inasmuch as she gave birth in the flesh to the Word of God made flesh, according to what is written: 'The word was made flesh' — let him be anathema."

This decree was confirmed by several later Councils, e.g., Chalcedon (451) and Constantinople (553). It may be added that this teaching was sanctioned in the English Church, for in the first Book of Common Prayer (1549) Mary is called "mother of Thy Son Jesus Christ our Lord and God," and it is still accepted by many, perhaps most, Anglican divines.

The title ιβη παρθένου (Lat. semper virgo, ever virgin, always a virgin), which represents a very early belief in the Church, was incorporated in the Creed by the Fifth Ecumenical Council of Constantineople in 553 — qui de coeolis descendit et incarnatus de sancta gloriosa Dei genitrice et semper virgine Maria (ex dyo evδην Θεοτόκος και διαφθοράν Μαγιακός est ex ea). The doctrine of Mary's perpetual virginity, that is, that she remained a virgin before, during, and after parturition, was further emphasized by the Lateran Council in 649 and by the Sixth Ecumenical Council of Constantinople in 680. It is indisputably orthodox both in the Eastern and the Western Church. It is not accepted by Protestants in general, and has been the object of severe attack by modern Rationalists and infidel Bible critics.

The principal feasts held in honor of the Blessed Virgin are the Purification, 2 February (14 February in the Armenian Church); the Annunciation, 25 March; the Visitation, 2 July; the Assumption, 15 August; the Nativity of Mary, 8 September; the Presentation of Mary in the Temple, 21 November; and the Immaculate Conception, 8 December (9 December in the Eastern Church). There are, besides, many minor feasts, some locally celebrated, and others general.

Devotion to the Blessed Virgin has been prevalent in the Church from very early times. It received a fresh impetus from the above-mentioned decree of the Council of Ephesus. The relationship of motherhood in which Mary had been declared to stand to the sonship of Jesus was as authoritative the already existing popular
belief, made invocation of her as a powerful intercessor with her divine Son, a natural corollary, and devotion to her grew apace. In the Middle Ages it was widespread. In England it was so common and entered to such an extent into practical life that that country was long known as Mary’s Dowry. The prominence which Mary had thus attained in Roman Catholic devotions and in popular estimation produced a reaction among the Reformers. They believed indeed in the birth of Christ from a pure virgin, who was consequently to be helped by her Son and the Mediator, but the position, that the justification and salvation of sinful man are accomplished through faith in Christ alone, caused them to repudiate the idea of a mediator with the mediator, of any creature coming as intermediary between the soul and Christ. The inevitable result, among Protestants, was an immediate dethronement of the mother from her high place as intercessor with her Son, and the immediate or later denial and striking away of some of her proudest privileges. It is evident, for example, in the first Book of Common Prayer (1549) of the English Church, in which the words of the Sarum rite, “glorious and ever Virgin Mary,” are changed to “glorious and most blessed Virgin Mary,” and still more evident in the second Book (1552) and in the 15th and 22d Articles of Religion (1553). In some sections the Puritan element in Protestantism carried its feeling against Mary so far as to sculp the singing of the “Magnificat,” and to abandon the use of the “Magnificat” in prayer, and in recent years authorized the singing of it in prose and the recital of the Nicene and Apostles’ Creeds. The English liturgy never abandoned these. Further, it retained, and still retains, in its Calendar, among the “Feasts to be observed,” several festivals of the Blessed Virgin. Many Scottish and English divines have written of Mary in terms of great reverence, tenderness, and beauty.

It may be fairly stated that at no time in the history of the Catholic Church have love of Mary and devotion to her been purer or more extensive and intensive than they are at the present day (1919). The Ave Maria is second only to the Lord’s Prayer in frequency of use. The Rosary and the Litany of the Blessed Virgin are recited publicly and privately by millions of persons every day. Special hymns composed in her honor, like the “Ave, maris Stella,” the “Stabat Mater,” the “Alma Redemptoris Mater,” and the English “Daily, daily sing to Mary,” are frequently said or sung. At the end of every Mass, Ave Marias and the “Salve Regina,” as well as other prayers, are publicly recited in the vernacular by the priest and the congregation. The month of May is dedicated to Mary, and devotions in her honor are publicly conducted every day during that month. Every day in October the Rosary of the Blessed Virgin is publicly recited. Every Saturday in the year is specially dedicated to her. Sodalities established in her honor exist in every land. In all this the Church, following the teaching of the Fathers and the Councils and especially of the Council of Trent (1545–63), always carefully distinguishes between the adoration or supreme homage due to God alone and the reverence that may properly be shown to any of His creatures. Epiphanius long ago laid down the rule: “Let Mary be held in honor. Let the Father and Son and Holy Spirit be adored; but let no one adore Mary” (vén Mariam magis propter humilium). Latria is the name given to the adoration of God; dulia is the name given to the honor shown to the saints or to angels. As Mary is above all saints and angels—“Queen of angels” and “Queen of all saints”—she is entitled in her Litanies—-the degree of veneration shown to her is called hyperdulia, which, while it is greater in degree than dulia, is infinitely below latria and differs in essence from it. The oblation known by other words; but every Catholic, no matter how ignorant otherwise, feels and knows the distinction which they connote.

What Christian art owes to Mary it would be well nigh impossible to tell. Painters, sculptors, architects, musicians, and poets have outdone themselves in celebrating her praise. (See Madonna in Art.) Shrines in her honor sprang up everywhere. In pre-Reformation England the country was studded with such shrines, the most celebrated being our Lady of Walsingham, in Norfolk. Among the modern shrines the famous ones of the Holy House of Loreto in Italy, Einsiedeln in Switzerland, Lourdes in France, and Guadalupe in Mexico may be singled out for special mention.

It is of interest to note that, by decree of the Sixth Provincial Council of Baltimore (1846, confirmed 1847), the Blessed Virgin Mary, conceived without sin, was chosen as the patron of the United States of America.

Bibliography—The study of the reading matter on this subject is, as might be expected, immense both in quantity and range. The following books may with advantage be consulted on the points with which they deal: Locrius, “Maria augusta Virgo Deipara” (Atrebati 1608); Padro, “Mundus Mariae” (Antwerp 1644); Riccardi, “Storia de’ Santiuarii più celebri di Maria Santissima sparsi nel mondo cristiano” (4 vols., Milano 1840–44); Newman, “Development of Christian Doctrine” (London 1845); Passaglia, “De immortalitate semper Virginis conceptu...” (3 vols., Rome 1854–55); Gousse, “La Croyance générale et constante de l’Eglise touchant l’immaculée conception de la bienheureuse Vierge Marie” (Paris 1855); Pusey, “Eirenicon” (Oxford 1855–60); Bousset, “Summa Aurea de Laudibus Beate Marie Virginis” (13 vols., Paris 1866 et seq.); “Hymns to the Virgin and Child” (E. E. T. S., ed. Furnivall, 1867); Northcot, “The Celebrated Sanctuaries of the Madonna” (London 1869); Monseigneur, “La Mère de la Vierge” (E. E. T. S. 1873); F. Poupin, “Vida de la Virgen Maria con la historia de su culto en España” (2 vols., Barcelona 1879); Waterton, “Pictas Mariana Britannica” (London 1879); Jameson, “Legends of the Madonna” (Boston 1881); Kurz, “Mariologie” (Ratisbon...

Matthæi'; 'Historia Josephi fabri lignantarii'; 'Evangelium Mariae'; 'Iàdnon του θεολογῶν λόγου εἰς τὴν κοιμήσιν τῆς ἔνδοτα'; 'Transitus Mariae' (ib. 1908).

P. J. LENNOX,
Professor of English Language and Literature,
The Catholic University of America.

MARY I, queen of England, known popularly as 'Bloody Queen Mary': b. London, 18 Feb. 1558; d. there, 17 Nov. 1558. She was a daughter of Henry VIII. After the death of her mother, Catharine of Aragon, she was declared illegitimate, but was restored to the succession in 1544. She was bred by her mother in the Roman Catholic faith, on which account she was treated with rigor under Edward VI. She ascended the throne 16 July 1553, after an abortive attempt to set her aside in favor of Lady Jane Grey (q.v.). One of her first measures was the removal of the Roman Catholic prelates superseded in the late reign. Her marriage to Philip II of Spain, united as it was with a complete restoration of the Catholic worship, produced much discontent. Insurrections broke out under Cave in Devonshire, and Sir Thomas Wyatt in Kent, which although suppressed, formed sufficient excuses for the imprisonment of the Princess Elizabeth in the Tower and the execution of Lady Jane Grey and her husband, Lord Guilford Dudley. England was now formally declared to be reconciled to the Pope; the original laws against heretics were revived, and about 200 perished at the stake, including Cranmer, Latimer and Ridley (q.v.). Under Philip's influence, a war began with France, which ended in the loss of all the Spanish Netherlands. Spain had been in the hands of the English for about 200 years. This disgrace told acutely upon Mary's already disordered health, and she died after a reign of five years. Consult the 'Life' by Strickland in 'Lives of the Queens of England' (new ed., 1864-65); Lingard, John, 'History of England' (6th ed., London 1855); Froude, 'History of England'; etc. 'The Reign of Mary Stuart' (New York 1910); Stone, 'Mary I, Queen of England'; Mullinger, J. B., 'Philip and Mary' (in 'Cambridge Modern History', Vol. II, Cambridge 1904); Hume, Martin, 'Two English Queens and Philip' (New York 1908).

MARY II, queen of England: b. London, 30 Apr. 1652; d. there, 28 Dec. 1694. She was the daughter of James, Duke of York, afterwards James II. She was married in 1677 to William, Prince of Orange, and when the Revolution was effected which dethroned her father, Mary was declared joint possessor of the throne with her husband, King William, on whom the administration of the government devolved. During the absence of William in Ireland in 1690-91, Mary managed parties at home with extreme prudence, and acted with equal ability as regent in 1693 and 1694. She was strongly attached to the Protestant religion and the Church of England. She endowed William and Mary College, Virginia, originally intended for the training of missionaries. See William III, and consult Burnet, Gilbert, 'Essay upon the Life of Queen Mary'; London 1733; Doehner, 'Memoirs and Letters of Mary II, Queen of England' (Leipzig 1886); Marshall, 'Kensington Palace in the Days of Queen Mary'; Morris, M., 'Reign of William and Mary' (New York 1910); Crew, E. and M. S., 'The Court of William III' (Boston 1910); Rait, R. S., 'Five Stuart Princesses' (ib. 1908).

MARY OF THE INCARNATION, French-Canadian Ursuline nun and educator: b. Tours, France, 1599; d. Quebec, 1672. Her maiden name was Guyard and in her 18th year she became the wife of M. Martin, but was left a widow with an infant son at 19. She eventually took the veil in the Ursuline Convent at Tours, and in 1639 went to Canada as superior of the convent established at Quebec by Madame de la Peltrie. She was extremely successful in administering the school for girls which the Ursulines established, and all with her strong and beautiful personality, which was emphasized by her fine manners and tall stature, and she is one of the most stately and interesting figures in early Canadian history. She wrote an autobiography. Consult 'Les lettres de la vénérable Mère Marie de l'Incarnation' (Paris 1681); Casgrain, 'Life of Mary of the Incarnation' (Montreal 1886); Charlevoix, 'La vie de la Mère Marie de l'Incarnation' (Paris 1724), and her son's life, 'La vie de la vénérable Mère Marie de l'Incarnation' (Paris 1677).

MARY MAGDALEN. See Magdalen; also MARY.

MARY STUART (MARY, QUEEN OF SCOTS), queen of Scotland: b. Linlithgow Palace, 8 Dec. 1542; d. 8 Feb. 1587 at Fotheringay Castle. The only child of James V of Scotland and Mary of Guise, she was proclaimed queen upon his death, 14 Dec. 1542, and was crowned Sept. 24 at Stirling Castle. She governed for her hand by the future Edward VI of England came to nothing in spite of the attempt to effect the betrothal by force of arms. In 1548, having been betrothed to the French Dauphin, she was sent to Paris, where 10 years
later she married the Dauphin, who died in 1560 soon after coming to the throne. Mary returned to Scotland, where her French Catholic training and the Reformation made her position a hard one. She diplomatically yielded to the force of circumstances and surrounded herself with Protestant advisers. A match between the Scottish queen and Don Carlos of Spain, heir of Philip II, was all but arranged when the Earl of Darnley, her cousin, whom she married 29 July 1565. She had hoped to win by this marriage the English Catholics, with whom Darnley had great influence, and to unite all Catholic claims to the English throne, Darnley (see MARGARET TUDOR) being next in succession to Mary; but her husband’s weak ambition made him the tool of the Protestant plot against Rizzio, an Italian favorite of the queen, who was killed 9 March 1566, being brutally dragged from his dining-room. Three months later Mary gave birth to a son (later James I of England). She was temporarily reconciled to Darnley; but on 10 Feb. 1567, Darnley’s house was blown up and he was killed. Mary had been in the house the evening before, and the murder was committed by the Earl of Bothwell, whom Mary married 15 May 1567. This act turned all the nobles against her; she was forced to surrender to her enemies and on 24 July 1567 to abdicate the crown. She was imprisoned in Loch Leven Castle; escaped thence in May 1568; was unmarried; and her system to raise an army acrossed into England, entrusting herself to Elizabeth; and was almost immediately imprisoned. Elizabeth wished to put Mary out of the way, seeing in her a dangerous rival for the English crown, but fear of France and Spain held her back until 1585, while Mary was imprisoned at Tutbury and entrapped into the Babington conspiracy against Elizabeth. Although her complicity was not clearly proved she was beheaded at Fotheringay. The moot point in Mary’s tragic history is whether she was a party to Bothwell’s assassination of Darnley. That she was is apparently proved by letters from her to Bothwell, which the Scottish nobles declared they found in Bothwell’s jewel-case but the originals of these letters are not to be found, and their authenticity is doubtful. The matter is ably discussed in Cowan’s ‘Mary, Queen of Scots’ (1901), and Lang’s ‘The Mystery of Mary Stuart’ (1901). The point at issue is, however, confused by making it depend on the authenticity of these letters, for Mary’s guilty knowledge of the plot against Darnley seems indubitable. But her career had more than a personal significance since in her person were combined the last hopes of Catholic rule in England and an intense devotion to Catholicism. Personally she was of a dazzling complexion, apparently her main claim to beauty, marvelously winning, as her early career shows, and clever in argument, as was evidenced nowhere more plainly than in her trial for treason.

**MARYBOROUGH.** (1) An Australian town in Talbot County, Victoria, about 100 miles north of Melbourne. It contains several factories, machine works and gold mines. Its railroads are of considerable importance on account of its central geographical position. Pop. 1875, 1,675. (2) Another Australian town in March County, Queensland, about 120 miles north of Brisbane. It is also a railroad centre and a gold mining region. The other industries are timber, coal, sugar and sugar refineries, foundries, boot and shoe factories, soap works, saw mills, fisheries, ship yards, etc. Pop. 11,625.

**MARYLAND,** one of the 13 original States, was seventh to ratify the United States Constitution (25 April 1788). Situated on the Atlantic Coast, it extends from lat. 37° 30' to 39° 43' N. and from long. 75° 4' to 79° 33' W. It is bounded on the north by Pennsylvania and Delaware, on the east by Delaware and the Atlantic Ocean, on the south by Virginia and West Virginia and on the west by West Virginia. The entire course of the Potomac River lies in Maryland. The extreme length of the State from east to west is 345 miles and its extreme width from north to south is 125 miles. At its narrowest point near Hancook, the width is only about three miles. The State’s shape is roughly that of a triangle meeting at this narrow point. The total area is 12,210 square miles, of which 2,350 square miles are covered by water, leaving 9,860 square miles of land. Annapolis is the capital and Baltimore is the chief commercial, financial and industrial centre. The State is subdivided into 23 counties, in addition to Baltimore city. For voting purposes the counties are subdivided into election districts, and there are about 100 incorporated municipalities, the largest of which are Cumberland, Hagerstown and Frederick.

**Topography.**—Maryland possesses great variety of physiographic features. The State is divided by the Chesapeake Bay into two parts, known as the Eastern and Western Shores. The Eastern Shore is the smaller division and is a level region, forming a part of the Coastal Plain, the land rising toward the north, in Cecil County, to heights of from 10 to 100 feet, while in Worcester County, at the south, the highest elevation is only about 25 feet. The land is broken by rivers which are navigable, as far as tidewater extends, for they are really tidal estuaries, rather than rivers.

Steamboats ply upon some of these streams, such as the Elk, the Sassafras, the Chester, the Choptank, the Nanticoke, the Wicomico and the Pocomoke, and the rivers frequently serve as county boundaries.

At the head of the Chesapeake Bay, the Susquehanna River enters it, after draining a large section of New York and Pennsylvania; but owing to rapids, the stream is not navigable. The counties bordering upon the western shore of the bay are also for the most part in the Coastal Plain and have similar characteristics to the bay. The eastern side of the piedmont region has higher and more precipitous cliffs of earth, and the land is of slightly greater elevation and is more rolling. The average elevation is about 125 feet. The bay exercises a genial influence upon the climate of the surrounding region. The winters are usually neither long nor severe. The part of the State lying between the bay and the Patapsco River is known as southern Maryland. The Western Shore is also divided by rivers: the Gunpowder, the Patapsco, the Patuxent and the Susquehanna. These rivers differ from those of the Eastern Shore only in that most of their upper courses run into hilly country. The soil on both sides of these streams is capable of producing crops favorable to the production of cereals and tobacco, and in which all kinds of fruits and vegetables thrive.

From the coastal plain the land rises into the Piedmont region to a height of from 300 to 700 feet toward the Blue Ridge. This Piedmont region is undulating in its surface and is well watered by streams which provide considerable water power. Some of these streams empty into the bay, such as the Gunpowder, the Patapsco, the Patuxent; and some are tributaries of the Patowmac, such as the Monocacy, the Great Pine Creek, the Antietam and the Conococheague. Some of the smaller streams, such as Jones' Falls, were called Falls by the early settlers, because of their rapid descent from uplands. Several ridges rise in the Piedmont region, and an elevation of about 800 feet, cross this section, the most important of these being Parr's Ridge, and they divide the country into valleys which are rich and fertile. Beyond the Blue Ridge, the western part of Maryland forms a part of the Appalachian Mountain region, and is traversed by the Allegheny Mountains in Allegany and Garrett counties. Some of the peaks of the Blue Ridge are from 2,000 to 2,400 feet high, and the summits of the Alleghanies vary from 1,500 to 3,000 feet above sea-level. The highest point in the State is Backbone Mountain in Garrett County.

The mean temperature for eastern Maryland for spring is 51.7° F.; for summer, 74.5° F.; for autumn, 55.8° F.; for winter, 36.1° F.; for the southern Maryland, 53.1°; 75.5°; 57.2°; 36.9°; 55.6°; for northern central Maryland, 50.6°; 73.6°; 54.3°; 33.1°; 58°; for western Maryland, 49.4°; 72.7°; 52.7°; 31.7°; 52°.

**Geology.**—Maryland displays a remarkably complete sequence of all the geological foundations. The most ancient rocks here are to be found, as well as those still in the process of deposition, and, between these wide limits, almost every important geological epoch is represented. In the Coastal Plain, a predominance of tertiary foundations is found on the Eastern Shore, and, of Mesozoic and Tertiary beds, on the Western Shore. There are few rocks, the country being overaid with deposits of sand and gravel. In the Piedmont region, on the eastern side of Parr's Ridge (its central watershed), there is a sequence of highly crystalline rocks, in large part, igneous in their origin. On the western side of the ridge, the rocks are only partly crystalline and represent the early Paleozoic time. The rocks of the Frederick Valley are composed of blue-Paleozoic limestone, in part overlaid by red sandstone. The Blue Ridge is made up of Cambrian and Lower Silurian beds, in places so eroded and displaced as to disclose the Archean floor upon which they rest. The Appalachian proper are made up of sharply folded Upper Silurian and Devonian strata, and the Allegheny Plateau is mainly composed of late Devonian and Carboniferous deposits, containing the coal seams of the Cumberland Basin.

Mineral Resources.—Maryland is rich in mineral resources. Iron ore is extensively distributed throughout the Western Shore and in the northern part of the Eastern Shore, and is of good quality for casting and other purposes. The iron industry is of early origin. Forges and furnaces were in operation in the province as early as 1649, and the industry continued, until a recent date, to be an important factor in the prosperity of the State. Most of the old furnaces now have been extinguished, being unable to compete with the great iron and steel plants, using ores produced in foreign countries or in distant parts of the United States. The seat of the steel industry of the State is at Sparrow's Point, in the great works begun in 1887, where Cuban ores are chiefly used, mixed with those from Spain and Algeria. The first Bessemer steel ever produced in Maryland was made there 1 Aug. 1891.

The coal deposits of Maryland belong to the Allegheny field and are semi-bituminous, superior to any other for generating steam. The portion of this field lying in Maryland is of comparatively small size, but constitutes by far the most important of the State's mineral resources. It is called the Cumberland, Frostburg or George's Creek Basin. Situated in an elevated trough, west of the Western Alleghanies and between Dan's and Savage mountains, it is about 20 miles long and 4 miles wide. The principal coal bed is known as the Big, or 14-foot, Vein, and has been the chief one worked. Nearly 100,000,000 tons of coal have been shipped from this vein. The coal contains from 72 to 83 per cent of carbon, and its discovery, about 1804, gave a strong stimulus to the movement for the construction of the Chesapeake and Ohio Canal and the Baltimore and Ohio Railroad.

Three veins of copper are found in Maryland and, before the opening of the Western copper mines, they made it a copper-producing State. Chrome deposits were discovered in Baltimore County in 1827 and have been extensively worked. Some gold has been mined in Montgomery County.

Extensive areas of granite have been quarried for building stone, especially at Port Deposit, in Cecil County; near Woodstock in Baltimore County (much used in the public buildings in Washington city); and near Ellicott
MARYLAND

County. Gneiss has been quarried in the county. The sandstone of Seneca Creek in Montgomery County is the most important and their production is much used in Washington city.

One of the best-known districts in the United States for the production of roofing slate is the Peach Bottom region in Harford County, near the Pennsylvania border. These slates were worked as early as the American Revolution. The most valuable limestone deposits are the highly crystalline marbles at Baltimore County, lying in a bed extending from Lake Roland through Texas to Cockeysville. These quarries produce the white steps for which the Baltimore houses are noted. The Washington Monument in the District of Columbia was built of stone from the Cockeysville quarries.

Some of the Maryland marbles have decorative possibilities, and the "Potomac marble" or "Calcico rock" of Frederick County is used in the old House of Representatives in the National Capitol. Maryland limestone is used as flux for blast furnaces and is largely quarried and burnt to produce quick lime for commercial and agricultural purposes.

Hydraulic cement is manufactured near Cumberland and Hagerstown, and at Union Bridge, in Carroll County. Serpentine stones are quarried on Broad Creek in Harford County. Clays constitute an important feature of the economic geology of Maryland and are used in the manufacture of building brick, terra cotta and tile work, firebrick and pottery. The workable areas of clay suitable for building brick cover a large area of the State, and the Baltimore pressed bricks have been very extensively used. In Harford County there are produced large quantities of flint, which is used in the manufacture of porcelain. Kaolin and feldspar of fine quality are found in Cecil County, and glass sand is used from Anne Arundel County.

Agriculture.—In the provincial period, after a few years in which the fur trade was important, agriculture became the principal employment of the people. The settlers lived on large plantations along the shores of the Chesapeake and its tributary streams and cultivated tobacco, with the assistance of indentured white servants and later with negro slaves. There was an active demand for the staple crop in European markets, and an extensive commerce resulted, which brought wealth to the planters. Tobacco became the currency of the province, and, for a long time, debts and public dues were paid therein. In the early 18th century, the cultivation of grain gradually supplanted that of tobacco, on the Eastern Shore, and, since that time, tobacco growing lands have been limited to the southern part of the Western Shore below the Severn River. For about 175 years there has been a State inspection of tobacco, and the hogheads containing it are brought to the large State warehouses in Baltimore. Indian corn, or maize, was grown by the aborigines and has always been largely produced in the State. Wheat finds a congenial soil and climate, and the grain trade of Baltimore has long been great. The fertile soils of Frederick, Carroll and Washington counties contain some of the best farming land in the United States, and large quantities of grain are also grown in Queen Anne's County on the Eastern Shore.

The sandy soil of Anne Arundel County is well adapted to early vegetables and to small fruits, such as strawberries. Large quantities of tomatoes are grown there, as also in Frederick and Harford counties. The neighborhood of Baltimore and Washington city has caused large numbers of men to raise vegetables for market in Prince George's, Montgomery, Anne Arundel, Baltimore and Harford counties. Dairy farming is also widely practised in Carroll, Baltimore, Harford and Montgomery counties. There is very little vacant land in the State, except some in the swamps of Dorchester County or in the mountains of Garrett County. The value of farm land has considerably increased of recent years on account of greater accessibility to markets, and runs now from $20 to $150 per acre. The unoccupied land belongs to the State, which maintains a land office in Annapolis.

There is an important trade from the Eastern Shore in sweet potatoes, melons and small fruits, to the markets of Baltimore, Philadelphia and New York. For nearly 50 years large orchards of peaches have been grown on the Eastern Shore and in the two latter counties, and there are now considerable areas of ground in Carroll, Frederick and Washington counties devoted to similar orchards; while many apple orchards have been planted along the mountain sides in the two latter counties. In 1890 there were 45,719 farms in Maryland, of which 33,408 were cultivated by their owners. The value of the buildings was $72,751,000, of the farm animals, $30,649,961, of the grain crops of that year, $21,918,730, of the fruits and vegetables then raised, $15,195,620.

Forestry.—The forest trees are principally pine, chestnut, oak (in three varieties, white, black and red), hickory and walnut. A deadly blight has destroyed a large part of the chestnut trees in the past few years. A State department of forestry was organized in 1900, and has done much toward producing proper methods of forest management throughout the State. The trade in lumber for pipe staves was one of the very first industries of the province.

Game and Fisheries.—The streams and rivers of Maryland contain a large variety of fish, including salmon in the streams of the mountains and in the headwaters of the Chesapeake Bay. The ocean waters off the coast contain a large variety of shellfish, especially oysters, clams and crabs. The Chesapeake Bay is a rich source of food for both man and beast.

Manufactures.—The first manufactures in Maryland, outside of the products of household industry, were those of tobacco. The making of tobacco in Cecil County has been in operation for over 150 years. The country adjacent to the Chesapeake possesses neither coal nor water power. The central portion of the State is well provided with water power, and the far western portion contains some coal. Maryland enjoys a strategic position from her nearness also to the sources of production of raw material. From her great facilities in water carriage, and from her good
railroad connection with every part of the continent; she possesses a very favorable position in regard to manufactures. The factories are mostly established in Baltimore, Cumberland, Hagerstown and Frederick, and in the vicinity of the Potomac. Large quantities of flour are ground in mills along the Patapsco River, and in Frederick and Carroll counties, and there is much canning of oysters and fish, fruit and vegetables, in Baltimore, and, indeed, throughout the State. Textile fabrics, especially cotton, are manufactured near Baltimore, and ready-made clothing is extensively made in that city. Bricks, lumber, straw hats, shoes, shirts, cement, copper manufactures, glass, etc., are manufactured there. Large quantities of munitions of war have recently been made in Baltimore, in establishments which had previously made articles of iron and steel for peaceful purposes. Cigars, smoking tobacco, chewing gum and snuff are also largely manufactured in that city. The Bromo Seltzer Company recently been bought by the Seal Company have large factories in Baltimore. This city is the leading market of the South for the manufacture and distribution of fertilizers, of drugs and of chemicals. Large breweries and potteries are also located there.

Ship-building.—The Marylanders of provincial times built small sailing vessels, the most interesting types of which were the bugeye and five log canoes, which are still used in the oyster trade on the Chesapeake. After Baltimore was founded, it became a center of ship-building, and the clipper ships which came from its shipyards were famous around the world for their beauty and speed. They carried on trade with South America, and made voyages to the Pacific, as well as to Europe. When steel ships succeeded wooden, there was established by the Pennsylvania Steel Company, about 1888, an important ship-building plant at Sparrow's Point, near the mouth of the Patapsco River, 12 miles below Baltimore. This plant has recently been bought by the Bethlehem Steel Company, and has been very profitable. The Eastern Shore, except during the Great War. Another important ship-building corporation is the Baltimore Dry Dock Company, located at Baltimore, on White Stone Point near Fort McHenry. There are several lesser shipyards, and the output of Baltimore in the way of ships is quite important.

Communication.—The Baltimore and Ohio Railroad, the oldest one in America, was chartered in 1827, and is still operated under its original charter. In 1830, the first locomotive in the United States was run over this road between Baltimore and Ellicott City. Originally intended to extend to the Ohio River, it now runs to Philadelphia, to Chicago and to Saint Louis. A branch line runs from Cumberland to Pittsburgh. The Philadelphia, Wilmington and Baltimore Railroad, chartered in 1836, and the Baltimore and Potomac Railroad, chartered in 1853, now form part of the Pennsylvania Railroad, as do the Northern Central, running from Baltimore through Harrisburg to Rochester, which was chartered in 1854, and the Frederick and Pennsylvania Line Railroad, chartered in 1867. Another series of branches of the Pennsylvania system are on the Eastern Shore. A third important railroad, the Western Maryland, was chartered in 1852, and now runs from Baltimore to Hagerstown, to Cumberland, whence it goes by two branches into West Virginia and to Pittsburgh. The Maryland and Pennsylvania Railroad runs from Baltimore to Delta. Electric roads lead from Baltimore to Washington and to Annapolis, and another electric road runs from Frederick to Hagerstown, and also to Thurmont. The city of Baltimore has an extensive trolley system, which also serves the suburbs. The first electric railway in the United States, was constructed in Baltimore in 1885. Horse cars had been introduced therein before, and they were superseded by cable cars (beginning in 1889), and trolley cars beginning in 1892. James Rumsey made experiments in the propulsion of boats by steam, in the latter part of the 18th century, upon the Patomac River. The bay and its rivers were the first highways, and several lines of steamboats run from Baltimore to the heads of navigation of these rivers, while ocean-going vessels ply regularly, northward and southward, along the coast and to foreign lands. In 1844 the first line of telegraph constructed in the world was operated between Baltimore and Washington, and telegraph and telephone lines now reach every part of the State. The roads were poor until about 1800, when an era of very considerable construction of macadamized turnpikes in the western part of the State. Most of the turnpikes have now become part of an excellent system of State roads constructed between 1905 and 1915, with links together every county in Maryland. The desire for the improvement of the Potomac River, so as to render it navigable, a project in which George Washington took great interest, led to the beginning of the Chesapeake and Ohio Canal in 1826. Designed to cross the Allegheny Mountains, it was never completed further than from Georgetown, D. C., to Cumberland, and it is now chiefly used for the transportation of coal from the mines to tidewater. A canal along the Susquehanna has long been abandoned, but one for ships across the Eastern Shore, extending from the head of the Elk River to the Delaware River, is still used by daily trips of steamboats from Baltimore to Philadelphia, and is expected soon under Federal ownership to be much increased in size.

Commerce.—Baltimore is practically the only port of entry in the State. In 1916 the imports of merchandise at this port were valued at $8,414,193 of dutiable articles and at $30,527,473 of articles free of duty, and in 1917 at $7,958,139 of dutiable articles and at $29,605,466 of articles free of duty. The greatest value of any article imported on the free list was manganese ore ($8,910,996), next came wood pulp ($6,834,157), nitrate of soda ($3,180,545), pig iron ($2,192,669), crude mineral oil ($1,887,734), copper ($1,751,673), iron ore ($1,392,559). Molasses came first among dutiable articles, with a value of $2,957,060; corks second, with a value of $923,128. The total value of exports for 1917 was $77,623,500, compared with $93,752,216 for 1916, an increase of more than 30 per cent. Copper stood first among exports in 1917, with a value of $44,341,482, and was followed by iron and steel ($3,737,070), wheat ($24,806,823), Indian corn ($2,047,886), flour ($19,532,565), raw cotton ($17,606,807), rye ($15,961,340), oats
MARYLAND

($14,407,329), brass ($14,093,614), tobacco ($12,113,711), chemicals ($9,094,384). During 1917, Canadian articles (valued at $12,992-021) were exported from Baltimore, in transit, the chief articles being wheat ($10,903,879), oak ($619,791) and wheat, flour ($686,465). The city has an important coastwise trade.

State Finances.—The gross amount of the State's debt is $27,448,880, and after deducting productive stocks and the sinking fund, the net debt amounts to $18,655,983. The total assessed value of property in 1916 was $1,183,456,456, of which the valuation of Baltimore city property amounts to $466,493,644 and that of the counties to $535,962,867. The city pays $4.67 per cent of the direct State taxes. The real estate in the counties is assessed at $422,929,436. The State tax rate in 1916 is 364 cents on each $100, and the tax is chiefly levied to pay for the public schools and for the State debt. The tax rate in Baltimore city is usually in the neighborhood of $2 per $100 of value, and that in the counties is little below the full value of property. Tax rates in the counties vary from about $0.90 to $1.40, and in the municipalities, from $0.50 to $1.28.

The receipts of the State for the fiscal year ended June 30, 1917, amounted to $11,876,471, and the balance in the fund of the preceding year was $1,624,095. The disbursements for the year were $11,450,622, leaving a balance of $1,849,904. To this should be added a balance in funds account of $423,715, and deducted on account of dedicated funds, $1,633,200, leaving $640,420 as the balance of general funds. Taxes on gross receipts of corporations brought in $1,029,090; on collateral inheritances, $300,254; on insurance companies' licenses, $412,035; on motor-vehicle licenses, $733,858; on liquor licenses, $1,324,015. For the general government there were expended $499,384; for protection of persons and property, $671,164; for promotion of agriculture, $402,197; for conservation of natural resources, $150,094; for conservation of health, $132,470; for maintenance of highways, $2,664,470; for maintenance of hospitals, homes and asylums, $1,448,274; for maintenance of correctional institutions, $157,750; for education, $1,507,025; and for interest on the public debt, $1,042,195.

Government.—The legislature consists of two houses: a senate of 27 members (one senator from each county and from each of four districts into which Baltimore city is divided), and a house of delegates of 101 members (each county sending from two to six delegates; and Baltimore city ranking as four of the largest counties). Regular legislative sessions are held biennially in the even years, beginning on the first Wednesday in January and may not exceed 60 days. Extra sessions are held at the call of the governor and may not exceed 30 days. There are six representatives of the State in Congress: one from the Eastern Shore, a second from Harford, Baltimore and Carroll counties, and a fourth from health, a third and a fourth from districts entirely in the city, a fifth from southern Maryland and a part of Baltimore city and a sixth from western Maryland. The Democratic party usually has a majority in the general assembly. Senators are elected for four and delegates for two years. The executive department has at its head the governor, elected in 1919 and at four-year intervals thereafter. He receives a salary of $4,500 a year, the use of an executive mansion and an allowance for expenses. The administration is more unified than in many States, as the governor has extensive powers of appointment. His financial control is very great. All bills are submitted to him after passage by the general assembly for approval and veto. For some years he has possessed the power of vetoing separate items of appropriation bills, and it was even held that this power included that of diminishing the amount of appropriations voted by the legislature. In 1916 the people adopted a constitutional amendment which has placed an autocratic power of budget making in his hands. He now prepares and submits to the general assembly a proposed budget of appropriations, which they may diminish, but not increase, from which they may strike out items, but to which they can add only little.

The judicial system of the State consists of three parts. The highest tribunal is a Court of Appeals of eight judges, seven of whom are the chief judges of the circuits into which the counties are grouped, and the eighth is chosen from Baltimore at the behest of the governor. One of these judges is chief judge. A Circuit Court is held in each county, and in each circuit there are two judges (in the circuit composed of Baltimore and Harford counties there are three judges), in addition to the chief judge. In Baltimore city there are 10 judges who sit together as the supreme bench of the county and assign themselves, from time to time, to sit separately in the several city courts. All these previously-named judges are elected for 15 years by popular vote at elections in odd years. A judge who has reached the age of 70 years may not complete his term, unless a special vote in his behalf is passed by the general assembly. Vacancies in judgeships are filled by the governor, whose appointees hold office until the next election.

Petty cases are heard before justices of the peace, who are appointed by the governor for the term of four years. In the counties, these justices are generally paid by fees. In Baltimore, such cases are brought before the county officials serving in regular tribunals, as police courts (criminal), people's courts (civil) or juvenile courts.

Religion.—The first settlers were Roman Catholics and Anglicans. The first Protestant services were held by the Rev. Richard James, on Kent Island in 1632, and the first Roman Catholic services, by Rev. Andrew White, S.J., and Rev. John Altham, S.J., at Saint Mary's in 1634. A considerable settlement of Puritans from Virginia came into Anne Arundel County about 1650, and were largely induced to become Quakers when George Fox came to Maryland about 1670. He also established meetings on the Eastern Shore, one of which Third Haven, near Easton in Talbot County, possesses a Boline of very ancient age. Presbyterians, under Rev. Francis Maden, established churches on the lower Eastern Shore about 1690. Baptist churches were organized in the 18th century. The German-speaking settlers of the years 1720-30 brought the Reformed and Lutheran faiths into the
province. Rev. Philip William Otterbein, pastor of a Reformed church still standing on Sharpe and Conway streets in Baltimore, founded the United Brethren Church in Frederick County in 1800. Robert Strawbridge, one of Wesley's local preachers, held the first Methodist services in the United States in Carroll County in 1761, and, through the labors of Francis Asbury and other devoted men, the church spread rapidly. At the Christmas Conference held on Lovely lane (Redwood street), Baltimore, in 1784, the Methodist Episcopal Church was organized, and its first bishops, Francis Asbury and Thomas Coke, elected. Right Rev. John Carroll, of an old provincial family, was consecrated as bishop of Baltimore in the Roman Catholic Church in 1789, and his see was raised to an archbishopric in 1808. He was the first man to hold episcopal office in that Church in the United States. Right Rev. Samuel Claggett was consecrated bishop of Maryland in the Protestant Episcopal Church in 1789, being the first man to receive such consecration in the United States. In 1821, he was made presiding bishop, or representative of the sovereignty in the government of the Methodist denomination led to a division of its organization in Baltimore of the Methodist Protestant Church. Colored churches were organized under the name of churches and societies in denominations during the 19th century, most of the churches being either Methodist or Baptist. The Roman Catholic Church is the largest denomination in its membership, and among the Protestant denominations, the Methodist, Episcopal, Lutheran, Baptist, Reformed, Presbyterian, and United Brethren, in the order named, lead in their membership. Sunday schools were first instituted in Baltimore about 1815. There are over 2,500 Sunday schools now in the State.

Charities and Corrections.—A Board of State Aid and Charities was established in 1900. The policy of the State has been to subsidize private institutions more than has been the case in most other portions of the Union. For the insane, there are several private institutions: for whites at Catonsville (Spring Grove) in Baltimore County, at Sykesville, in Carroll County at Springfield, and at Cambridge in Dorchester County, and one for colored persons at Crownsville in Anne Arundel County. There are several private hospitals for the insane, the most important of which is the Sheppard and Enoch Pratt Hospital, which has a large endowment and is located near Towson, in Baltimore County. The State penitentiary is located in Baltimore city; the house of correction, for minor offenses, is located near Jessups, in Anne Arundel County. A reformatory school for white boys is located at Loch Raven, in Baltimore County, and one for colored boys at Chelsea in Prince George's County. A similar school for white girls is in Baltimore County, and one for colored girls at Melvylle, in Baltimore city. Saint Mary's Industrial School for Boys, in Baltimore city, is an important reformatory for boys under the care of Right Rev. Samuel Claggett. Each county, as well as Baltimore city, possesses a jail. There is an almshouse for each county and for Baltimore city. The Baltimore city hospitals are paid to provide beds for the indigent sick. For tubercular patients there is a private sanitarium at Edgewood, in Baltimore County, and one owned by the State at Salisbury in Frederick County. The incorporated Charities of Baltimore city are very efficient, and the Henry Watson's Aid Society does an important work. There are also many lesser benevolent institutions.

Education.—During the first 60 years of the history of the province there were almost no schools, because there were no towns, each family living upon its own plantation. Governor Francis Nicholson was an ardent friend of education and under his influence the assembly, in 1694, passed an act for the maintenance of free schools by duties laid on exported furs, which then formed a large part of Maryland's trade. In 1696, King William School at Annapolis was founded, as the first of these schools, and continued in existence until 1784, when it was merged in Saint John's College. Under Governor Nicholson's administration, also, the Anglican Church was established in the province, and the Rev. Thomas Bray, D.D., was sent over as the commissary, or representative of the bishop, within whose diocese the province was considered to lie. He wished to induce worthy clergymen to come to Maryland and, as an inducement to them, set about establishing a parochial library in each parish. He minister, and a provincial or lending library to Annapolis for the use of the clergy and gentry. He succeeded in this plan and the provincial library of 1,100 volumes was the largest collection of books then in the English colonies. Dr. Bray came to Maryland in 1700 for four months and after his return the libraries languished and few books were sent them. The first printing press in the province was established about 1690, and the earliest extant imprint is one of Dr. Bray's sermons. The children of the well-to-do planters were often sent to Europe to complete an education begun on the plantation under private tutors, who were often indentured servants—the Protestant children going to Great Britain, the Roman Catholics to institutions and the Continent.

In 1723 an act was passed looking to the establishment of a grammar school in each county. These schools were the only ones supported by Maryland authorities, until well into the 19th century. Jesuits conducted two schools for boys—one at Whitemarsh, in Charles County, and one at Bohemia Manor in Cecil County. In 1726 the first newspaper in the province was begun, at Annapolis. Negro education and industrial education likewise found their beginning in Rev. Thomas Bacon's charity school in Talbot County about 1750. Toward the end of the provincial period, Charlotte Hall Academy was founded by the union of the county schools in southern Maryland, and Upper Nottingham Academy, in Cecil County, was begun. Rev. Samuel Claggett was principal of the Frederick County Academy, in 1796 published a remarkable book on the 'Principles of Education,' outlining a complete educational system for the State. Thomas Jefferson derived much of the work which he carried out in the University of Virginia from this book, and Knox was the first man invited to a professorship there. Through Knox's efforts the State diverted to the county academies the funds it had begun ap-
MARYLAND

appropriating to the nascent colleges and these appropriations to the academies lasted until these institutions were absorbed into the public school system, a process not completed until the 20th century. A considerable agitation for public schools about the year 1825 led to the organization of such schools for Baltimore city, and the city has always managed its schools independently of the subsequently established State system and in 1817 had 112 schools, with 2,139 teachers and 79,599 pupils. The expenditures for these schools for 1819 amounted to $3,217,554. In addition to primary and grammar schools, there are included in the city system for white children a high school for boys (called the Polytechnic Institute), two high schools for girls and a teachers' training school; and for colored children a high school and a teachers' training school. Although some counties had begun a partial school system, the State had no uniform public schools until the constitution of 1864 was adopted which contained a provision for such a State system, through the efforts of Joseph Hoxie, first member of the State constitutional convention, and Rev. Libertus Van Bokkelen, D.D., who was made first State superintendent of schools. Dr. Van Bokkelen was soon succeeded by M. A. Newell, who continued in office, both as superintendent and as principal of the State Normal School, established in Baltimore, for over 20 years. This school has been transferred to fine new buildings near Towson, in Baltimore County. Rev. E. B. Prettyman succeeded Mr. Newell, and was in office only three years ago by J. M. Bates Stephens, during whose incumbency of the office great advances have been made in the county schools. Since his taking of office, there has been a separate principal of the normal school. A second normal school has been established at Frostburg in Allegany County. High schools have recently been formed in many places.

Teaching colored children was unlawful during the times of slavery. In 1865 a society was formed in Baltimore for negro education. It speedily established schools throughout the State, supported by the generous contributions of individuals, many of whom were members of the Society of Friends. When the State assumed the task of educating negroes, in 1872, the society closed all its schools, except one in Baltimore, which was incorporated as the Colored Normal School. In 1908 the State took over this school also and removing it to Bowie, in Prince George's County, maintained it as Normal School No. 3, adding certain agricultural and industrial features to the course of study. In addition to the expenditure of the State for schools from taxation, the proceeds of which are quarterly distributed to the counties and Baltimore city, according to population, each county raising large sums yearly by local taxation for support of schools. There are 2,605 schools, 6,560 teachers and 246,045 pupils recorded in the report for the year 1917. The State school board consists of six members appointed by the governor for a period of six years. The governor also appoints a school board of three members for each county for a like term. The mayor of Baltimore city appoints the school board therefor, composed of nine commissioners, each to serve for six years.

An extensive system of parochial schools is also maintained in connection with the Roman Catholic churches in Baltimore and in some of the smaller towns in the State. Mrs. Eliza Seton, foundress of the Sisters of Charity in the United States, established a school at Emmitsburg for the education of girls in 1809. The Order of the Visitation conducts schools for girls in Baltimore and Frederick, the Carmelites in Baltimore and the Sisters of Notre Dame also in Baltimore.

Among the important private secondary schools in Maryland are: For boys, the Gilman School, the Boys' Latin School and Marston's School in Baltimore city; the McCulloh Academy and Farm School for needy orphans in Baltimore County, and the Jacob Tome Institute, a largely endowed boarding-school with fine buildings, at Port Deposit in Cecil County. The Hanover Academy at Reisterstown in Baltimore County, the Frederick Seminary in Frederick County and Saint Mary's Female Seminary in Saint Mary's County, are the more important boarding-schools in the State. In Baltimore city the Bryn Mawr School and the Girls' Latin School are day schools of high standard.

The Maryland Institute for the Promotion of the Mechanic Arts was established in Baltimore, in 1847. It formerly conducted exhibitions and gave courses of lectures in its long building upon Market street, which was the scene of several Presidential nominating conventions. After this building was consumed in the fire of 1904, a new building was erected on Mount Royal avenue for the Day Schools of Art and Design, and a building on the old site is used for the night school of mechanical drawing. George Peabody spent part of his early life in Baltimore, and in recognition of that fact he established in 1837 the Peabody Institute, which contains a very fine reference library, a lecture hall, an art gallery and a largely attended conservatory of music.

A school district library law was passed in 1873. In Baltimore the generous gift of about $1,200,000 to the city by Enoch Pratt in 1882 secured the establishment of the free library which bears his name and which was opened in January 1888, with Dr. Lewis H. Steiner as its librarian. This institution, the public library of the city, from its inception was planned to contain a central building and branches in different parts of the city of Baltimore. These branches have increased from 4 to 18 and several more will soon be built. In February 1919 the library possessed 363,646 volumes, and in the previous year it circulated 586,645 books.

The Washington County Free Library at Hagerstown was established by the generosity of B. F. Newcomer in 1899, and has been conspicuously successful, being one of the first county libraries in the country. The other public libraries are small and are not as numerous as in many other States. In 1902 the legislature passed a law establishing a State Library Commission. The Public Library Commission now has its office at the State Normal School at Towson and receives $30,000 a year from the State. It circulates traveling libraries and gives advice and counsel to public libraries and to places desiring to establish them. In Baltimore city, there are also to be found the libraries of the various educational institutions of
the diocese of Maryland, of the Baltimore bar
and of the Maryland Historical Society which
are valuable special collections. The New Mer-
cantile Libr. and the cottage plan, on the same
about 35,000 volumes, should also be mentioned.
In 1854 there was established in Baltimore the
Maryland School for the Blind, a private cor-
poration largely supported by the State. The
school has removed, in recent years, to fine new
buildings on the cottage plan, in the suburbs
of Overlea, where about 100 children are in-
structed, coming from all parts of Maryland and
the District of Columbia. A school for the
colored deaf and blind, situated at a little dis-
tance but on the same grounds and under the
same superintendent, instructs about 70 children.
The Maryland State School for the Deaf, in-
corporated in 1867, is attended by about 120
pupils, and is situated at Frederick City, on the
site of the barracks built during the Revolution-
ary War and occupied by prisoners from Burgoyne's army.

Higher Education.—The Rev. William
Smith, D.D., who had been head of the College
of Philadelphia from the beginning, was forced
by the political associations of that city to move
to Chestertown, where he became rector of the
Protestant Episcopal church. He also took
the principalship of the Kent County school
and so developed it that he secured a college
charter for the institution under the name of
Washington College in 1782. It was the first
instituition named for General Washington, and
the first collegiate institution in Maryland. Its
history has been full of vicissitudes, but the
college has continued its work with fair measure
of success, and is still the only institution con-
fined to the Eastern Shore. Since 1890, women have been admitted
to its courses.

The Western Shore obtained its first institu-
tion of higher learning, when Saint John's Col-
lege was chartered at Annapolis in 1784. For
its site, the State gave the unfinished governor's
mansion and its grounds. According to its
charter, it was united with the Washington Col-
lege into a University of Maryland, but this
union was merely nominal. The State appro-
priated 500 acres of land in 1805, and 1,000
in 1817, to this college; but it languished for a time. From 1837, for 20 years,
Rev. Hector Humphreys, the principal, labored
faithfully for its interests. The college was
suspended and the buildings were used as a
hospital during the Civil War. Reorganized
by Henry Barnard, LL.D., Saint John's Col-
lege has been under the principalship of
Thomas Fell, LL.D., since 1887. The students
are organized in a cadet corps and receive
military training. It has been recognized as the
faculty of arts of the University of Mary-
land for the past few years.

The French Revolution drove from Europe
a large number of ecclesiastics of the Roman
Catholic faith. The Right Rev. John Carroll,
in his desire to provide educational opportunities
for the clergy, was one of the first to start a
school for the education of his Church, invited some of these teachers
to settle in Maryland. Consequently, the Su-
licians began instruction in Baltimore in 1791.
Their institution was called Saint Mary's Col-
lege, and its title was afterward changed to
Saint Mary's College. The college received
academic instruction until 1852, when the col-
lege was closed, in order that the clergy might
devote their entire attention to the theological
training of young men for the priesthood in
Saint Mary's Seminary of Saint Sulpice, which
had been maintained, containing only 40
students, from the beginning, and which is
the oldest Roman Catholic theological school
in the United States. Cardinal Gibbons is its
most distinguished graduate. In 1808, near
Emmitsburg, in Frederick County, Rev. John
Dudoi, a Sulpician, by the State, founded St.
Mary's College. This institution is now
governed by the secular clergy, and in addition
to the preparatory and collegiate courses, main-
tains a seminary preparatory to the priesthood.
A third institution, which requirements of the
Sulpicians, and which is still controlled by
them, is Saint Charles' College founded in 1830,
and endowed by Charles Carroll of Carrollton.
It was formerly situated in Howard County, but
is now located near Catonsville in Baltimore
County. It gives the collegiate courses prepara-
tory to Saint Mary's Seminary. In 1802 Dr.
John B. Davidge opened a medical class in
Baltimore, from which developed the Col-
lege of Medicine of Maryland, chartered in
1807, and the University of Maryland char-
tered in 1812. The university was planned
to contain four faculties. That of medicine
has always been the strongest, and is the
only one which has enjoyed a continuous exist-
ance, always maintaining a course of medical
instruction which ranked well among similar
institutions. It has recently united to itself the
College of Physicians and Surgeons (founded
in 1872 and which had itself absorbed the
Washington Medical College) and the Baltimore
Medical College (founded in 1883) and is ful-
filling the functions of the American Medical Association. The Maryland
College of Pharmacy (founded in 1856) has
recently been annexed, and the department of
dentistry was opened in 1882. No school of
divinity was ever established. The school of
arts had a troubled existence, and finally died,
but has recently been revived by the union of
Saint John's College with the university. The
school of law was maintained for a few years,
about 1840, with David Hoffman as professor,
and was revived the college has maintained high standards, and is the only
law school in the State, having absorbed the
Baltimore Law School (founded in 1900), and
the Baltimore University School of Law
(founded in 1890). Several colleges and professional schools
founded in Maryland at different times no
longer exist. Among these are Cokesbury College (1784–96) at Abingdon in Harford
County, the first Methodist institution of higher
education in the world; Baltimore College
(1803–30); Asbury College (1816–30) in Balti-
city; the College of Saint James (1843–63)
in Washington County; Newton University in
Baltimore city (1844–59); New Windsor College
(1843–50, 1874–1910); and Calvert College
(1852–73); Rockville University, Montgomery
County; the Baltimore Female College (1849–
90); and the Mount Washington Female College
(1856–61). Loyola College in Baltimore
was founded in 1852 by the Jesuits and con-
tinues to educate boys according to their system,
orphaned without dormitories. The Engineerin
Sociological Institute, at College Park in Prince George's
County, was chartered in 1856 by a private cor-
poration, and is in age the second such institution in the country. It early recognized agricultural experimentation as an important part of its operations. The State Agricultural Experiment Station, conducted in connection with the college, was organized in 1887. The students are trained in military drill, and the ownership of the college has lately been transferred to the State, which is largely increasing appropriations to it, and evidencing its curriculum.

The Brothers of Christian Schools, a Roman Catholic fraternity, purchased the Rock Hill Academy at Ellicott City, Howard County, in 1857, and after conducting it for several years procured a charter for Rock Hill College in 1865. The Western Maryland College, a coeducational institution, at Westminster, in Carroll County, under the auspices of the Methodist Protestant denomination was chartered in 1868, and under the long presidency of Rev. Thomas H. Bevins, D.D., has firmly established itself. Goucher College for Women was founded by the Methodist Episcopal Church in 1884, and was opened in 1888, graduating its first class in 1892. It was first called the Woman's College of Baltimore; but, about 1910, the name was changed to Goucher College. As Rev. John B. Goucher, D.D., one of its principal founders and long its president, it ranks among the best institutions for the higher instruction of women. Hood College for young women, beautifully situated near Frederick City, has been conducted successfully for 25 years by its president, Dr. Joseph H. Apple, and gives a good course of instruction, emphasizing domestic science. The Maryland College for Women at Lutherville in Baltimore County is a long-established institution. Morgan College, in Baltimore city, incorporated in 1889 under the auspices of the Methodist Episcopal Church, is the only collegiate institution for the education of the colored youth in Maryland. It expects soon to remove to a suburban location. A branch, Strasburger College in Somerset County, is recognized as the State Agricultural College for colored youth.

The Johns Hopkins University at Baltimore city, incorporated in 1867, was founded by a bequest of about $3,500,000 from the man whose name it bears. It was the largest endowment, and the trustees had an unusual opportunity to establish a distinctive institution. They made the best possible use of this opportunity by calling Daniel C. Gilman, LL.D., to become its first president and giving him free hand as to the places of organization. The university opened its collegiate and graduate philosophical departments in 1876. President Gilman won an instant success and a world-wide reputation for the institution. Among the leading ideas were these: (1) organization of graduate study into systematic training for the degree of doctor of philosophy, including a dissertation on some point embraced in the student's major subject and showing evidence of research; (2) provision, for a university press to publish the results of the investigations of faculty and students; (3) a great use of popular lecture courses; (4) a body of instructors of originality of mind who were carefully selected, with an unerring view to their future eminence; (5) a body of women graduates with the graduate school, who should receive a stipend from the university, have time for original work and

be known as fellows. (Among the early fellows was President Woodrow Wilson); and (6) an undergraduate department, arranged on the group system, with which President Gilman had become familiar. He had conducted it at the Sheffield Scientific School and the University of California, with which institutions he was formerly connected. The undergraduate department was never large, and was largely a local college; but the graduate department speedily enrolled through experiments in the body of men from all parts of the United States, from Canada and from Japan. Many of these graduate students became teachers and spread the influence of the Hopkins far and wide. President Gilman's policy was to spend little money on buildings, and the quarters of the university were inconspicuous throughout the 25 years of his administration. Mr. Hopkins left another bequest, of about the same size as that of the university, to found a hospital which should bear his name, and which should be associated with the medical school of the university. The hospital buildings were completed in 1889, and steps were immediately taken to organize the medical school, whose first class graduated in 1898. The Rev. John B. Goucher, D.D., one of its principal founders and long its president, it ranks among the best institutions for the higher instruction of women. Hood College for young women, beautifully situated near Frederick City, has been conducted successfully for 25 years by its president, Dr. Joseph H. Apple, and gives a good course of instruction, emphasizing domestic science. The Maryland College for Women at Lutherville in Baltimore County is a long-established institution. Morgan College, in Baltimore city, incorporated in 1889 under the auspices of the Methodist Episcopal Church, is the only collegiate institution for the education of the colored youth in Maryland. It expects soon to remove to a suburban location. A branch, Strasburger College in Somerset County, is recognized as the State Agricultural College for colored youth.

It expects soon to remove to a suburban location. A branch, Strasburger College in Somerset County, is recognized as the State Agricultural College for colored youth. Professional schools not previously named are the Woodstock College in Botetourt County, founded in 1867, by the Society of Jesus; a nonsectarian theological seminary; the House of Studies of the Congregation of the Most Holy Redeemer, Mount Saint Clement, at Ilchester, Howard County, established also in 1867, as a school to prepare members of the Redemptorist order for the priesthood; Saint Joseph's Seminary in Baltimore city to educate men for the Roman Catholic priesthood to labor among the colored people of the South; the Westminster (Carroll County) Theological Seminary under the auspices of the Methodist Protestant Church; and the Baltimore College of Dental Surgery, the oldest dental school in the world, chartered in 1839.

Provincial History.—Verazzano in 1524 may have looked into the Chesapeake and landed on the Atlantic seaboard of Maryland, but the continuous story of this territory began, when Capt. John Smith, with 14 men in an open barge of three tons burden, left Jamestown in 1608, and spent several weeks in exploring the bay. On his return he drew a remarkably good map of the shores, so that they became well known. He found the aborigines of the Algonquin stock dwelling in small brick-bark
villages in the midst of forest clearings, in which they cultivated maize, potatoes and tobacco. On the Western Shore, the Piscataway and the Nanjemoy were the important tribes, and on the Patuxent, the head of the broad Susquehanna River, which bears their name, dwelt the fierce Susquehannocks, of Iroquoian stock, who were subjugated and incorporated with the Five Nations about 1670. After that time, the Senecas frequently came down to raid the frontier settlements, and to despoil the peaceful Patuxents and Piscataways of the Western Shore. Gradually the Indian inhabitants of Maryland disappeared, and the Nanticookes, in their migration to the Wyoming Valley in Pennsylvania about 1720, left but few of their race in the province.

After Smith’s expedition, other Virginians sailed into the Chesapeake and the northern fur trade became a well-established enterprise. The trade in fur and timber was cut for pipe-staves. Chief among these Virginia traders was William Claiborne. He associated himself with the London mercantile firm of Clobery and Company, and in May 1631 obtained, from the Secretary of State for Scotland, a commission, authorizing him and his associates to trade in all parts of New England and Nova Scotia, where no trading monopoly had been granted. With this commission, he sailed up the Chesapeake, and in 17 Aug. 1631 established a trading factory on Kent Island, with about 20 or 30 men. From Chisquack in the Northern Neck of Virginia and Kent Island, a delegate sat in the Virginia house of burgesses and Claiborne was a member of the Virginia council.

Sir George Calvert, first Lord Baltimore and formerly Secretary of State for England, retired from office because he had become a Roman Catholic. He had long been interested in colonial projects, and had received a grant of land in the dominion of Navarre on the eastern peninsula of Newfoundland. He went there to live, but found the country so barren and the climate so severe that he determined to settle further to the south. Coming to Virginia, the colonists refused to admit him unless he should take the oaths of allegiance and supremacy, which his religious belief would not permit him to do. He was so delighted with the country, however, that he returned to England and successfully requested from the Crown a grant of the lands about the Chesapeake. To his possession, which was created a patalinate in which the proprietary should have as wide powers as the bishop of Durham in that county, he gave a name, in the courtier fashion, from that of the queen of Charles I, Henrietta Maria, daughter of Henry IV of Navarre. In the Latin of the Charter, the province was called Terra Mariae, or, in English, Maryland. The limits of the grant were much wider than were ever reduced to possession, chiefly because of encroachments of the Dutch on York on the Delaware and of William Penn on the north. Those limits were from Watkins Point on the Chesapeake, due east to the Atlantic Ocean, then along the seashore and Delaware Bay to the 40th parallel of north latitude, and along that parallel westward to the meridian of longitude, which passed through the first fountain of the Potomac River, and thence south to the far bank of that river, the boundary ran to Cinquack, near the river’s mouth, whence a straight line should run to Watkins Point. The province was to be held in free and common socage upon a yearly payment of two Indian arrowheads to the Crown. All Englishmen might emigrate to Maryland, and, having arrived there, they and their descendants should enjoy all of the privileges of Englishmen. The proprietary was given power to make laws, “with the advice, assent, and approbation of the freemen, or of their delegates.” He tried to use this power literally at first by submitting the draft of laws to a mass meeting of freemen, gathering in person or by proxy; but, gradually, the freemen grew too numerous, too widely dispersed and the majority of the whole arrangement to continue. They successfully asserted for themselves the right of initiating laws as early as 1638, and from about 1650 a representative body of freemen sat as a House of Delegates or House of Burgesses in the General Assembly, under the presidency of the Governor, upon whose acts the proprietary had a veto. He was not obliged to submit these acts to the Crown. It is not surprising that the Virginians opposed this charter, which gave a Roman Catholic two-thirds of their noble bay, and cut them off from the profitable northern fur trade.

Before the charter had passed the seals, the first Lord Baltimore died, and it was issued, on 20 June 1632, to his son Cecil Calvert, second Lord Baltimore, a namesake of the great Lord Burghley, under whom the father’s official career had begun. By the charter this first lord proprietary was granted a large country hitherto uncultivated, in the parts of America partly occupied by savages. He was destined never to see his province, but he took well-cared care over it for nearly 45 years. After some months preparation his first colonial expedition sailed from England, on 22 Nov. 1633, under the command of his younger brother, Leonard Calvert, in two vessels, the Ark and the Dove. Leonard Calvert, commissioned as lieutenant-general and governor of the province, was only 28 years old, and was a sincere straightforward man, but had the fatal failing of his family, in being unable to read men and to choose the proper agents to carry out his purposes. With him went several gentlemen, most of whom were Roman Catholics, while the majority of the yeomen and servants were Protestants. It is probable that from the beginning the majority of the Maryland settlers paid no religious allegiance to the Pope of Rome. The voyage from England to America consumed from one to three months at that period, and as Leonard Calvert sailed by the southern route, stopping at the West Indies, he did not arrive in Virginia until 24 Feb. 1634.

The governor there was friendly, but the settlers were so hostile that they soon afterward revolted, seized him and sent him to England, largely because of his friendship to Calvert. Lord Baltimore had wisely enjoyed his brother to have as little to do as possible with the Virginians during the first year, and heed-
ing that advice, the settlers soon sailed up the bay and entered the Potomac River. They landed on Saint Clements' (now called Blackiston's) Island on "Our Blessed Lady's Day in Lent," 25 March 1634, on the first day of the year, according to the calendar, and in the beginning of spring, and "took solemn possesssion of the country, for our Saviour and our Sovereign Lord, the King of England." From the enthusiastic reports of the country sent him, Baltimore prepared and printed in England, in 1634 and 1635, two pamphlets, called Relation, which were in the nature of prospectuses to invite colonists and are the earliest printed accounts of the province. The fears of the aborigines were pacified, and through the advice of Capt. Henry Fleet, an old Indian trader, Calvert bought from them their town of Yocomico, which was renamed Saint Mary's. Claiborne's factory was the only other settlement of Europeans within the province at the time. Calvert had instructions to use Claiborne's chart, and in case of death or failure in his plantation if he would acknowledge Baltimore as his overlord; but this acknowledgment was steadily refused, and a petty warfare arose between the settlers on Kent Island and those at Saint Mary's, which led to a naval combat on the Pocomoke River in 1635. Claiborne's difficulties increased, through differences with his London partners, and he went to England in 1637, leaving the factory in charge of Capt. George Evelin, who was friendly to Baltimore. He vainly endeavored to induce the settlers on the island to accept Baltimore as their ruler, and finally, in February 1638, Calvert led an expedition in person against the factory and overcame the opposition there, while Claiborne failed in England in an appeal to the Lords' Commissioners of Plantations. He never lost his animosity toward Lord Baltimore, and continued to the end of a long life his struggle against proprietary rule. Both in England and in America the Virginians tried to prevent Baltimore from taking possession of the province which had been granted him. The expense of his expeditions and of the litigation in England nearly impoverished him; but neither then nor, when later deprived of the province by force of arms by Cecil Calvert, did he ever cease to fight to maintain himself and his descendants so valuable a possession. Remaining in England, he warded off one threatened danger after another, and his policy, as his letters disclose it, was that of a calm, shrewd, unenthusiastic, far-minded, far-seeing man. He was a faithful member of the Roman Catholic Church, and wished to provide an asylum for his fellow-believers within his patrimony; but he wisely foresaw that any grant of special privileges to the Roman Catholics — still a powerful body in Maryland — would lead to a speedy forfeiture of his patent. He clearly wished the establishment of no other church. Consequently, from the beginning of his settlement he sent two Jesuit priests, that the colonists might have religious counsel and guidance. One of the Jesuits, Father Andrew White, a man of marked devotion to his work, wrote an account of the voyage, in Latin and in English, to which we owe valuable information. The Jesuit order continued to be the chief religious agency of the Roman Catholic Church in Maryland throughout the whole of the provincial period, and their conscientious zeal and faithfulness deserve high praise. They reared from the provincial families a good many Jesuit priests who were very influential in the organization of their Church in the United States and were largely responsible for its American character.

Nearly a year after the landing of the colonists, Governor Calvert called an assembly of the people, which met in February 1635, but its proceedings are lost, and the proprietary vetoed its acts. The second assembly, held in January 1638, failed to place any acts upon the statute books, except one for Clairesbon's attendant. Acting also as a court of law, the assembly tried and condemned in default for public disorder one of Claiborne's followers. During the year 1638 Lord Baltimore yielded his claim to the initiation of bills and a representative assembly of one house, meeting in February 1639, adopted resolutions of Maryland to be sent to Congress at the end of the next General Assembly, or for three years, if there be no assembly within that time. From that date to the present practically all of the statutes of Maryland are preserved, and have been the subject of the Archives of Maryland. The policy of passing temporary statutes was followed throughout the provincial period, and, although it involved much expenditure of time and produced a bulky statute book, it ensured fairly frequent sessions of the legislature, and also a readjustment, from time to time, in the rates of fees, in which shape the remuneration of many of the officers was received.

From Saint Mary's the settlers spread out along the rivers, some of the larger tracts of land being erected into manors. Indented and white servants cultivated most of the land, granted by the conditions of plantation to the settlers, on payment of an annual quitrent. Negro slaves were being introduced, and the colonists gradually devoted the Indians for maize, which was beginning to be raised in considerable quantity by the English. The fur trade slowly lost its importance, and the cultivation of tobacco flourished until it became the staple product of the province and the medium of exchange in all transactions among the planters. The predominance of tobacco lasted throughout the provincial history; but, during the 18th century, the cereals — wheat and corn — were gradually displacing its prominence in agriculture on the Eastern Shore. The upland cot was that which was first grown. A few iron furnaces were established late in the provincial times, but the main industry was agriculture. Transportation was at first by water or along the Indian foot trails. Gradually Roman Catholic lords and landed proprietors freed from taxes. These claims led Balti-
Maryland

more to send out secular priests for a time and to insist upon the supremacy of common law and of the civil power in the state. Leona-
dale. Calvert returned to England in 1642, leaving Giles Brent, a Protestant, to deputize for him. Two years later with the king's commission empowering him to seize ships owned by London mer-
chants who adhered to the Parliamentary side in the English Civil War. He seems not to have used the commission, but it gave an excuse for action to those opposed to proprietary rule. Caliborne came back in the attempt to recover Kent Island. Richard Ingle, a pronounced Parliamentarian, who had previously made sev-
eral voyages to the province, came to Virginia with his ship, in February 1645, seized a Dutch merchantman in the Chesapeake, and with the two vessels terrorized the province. Calvert fled to Virginia, and Ingle ranged the province, during this "plundering year," seized the Jesuits property and carried them to England. Calvert recovered control of Saint Mary's in the autumn of 1646 and of Kent Island in April 1647. Shortly afterward Leonard Calvert died, naming Thomas Greene as governor. A year later, the proprietary substitute, William Stone, a Catholic, brought into Maryland immigrants a considerable number of Puritans from Virginia, where they had failed to find religious freedom. The Puritans made their settlements about the banks of the Severn, near the site of Annapolis, and a third county was erected for them, bearing the name of Anne Arundel, the wife of Cecil Calvert. With Stone's commission Baltimore sent a draft of a brief code of 16 laws, which he desired the general assembly to enact. The most famous of these, the "Act concerning religion," was amended and passed in April 1649. This notable act was well summarized, in its purpose and content, by Charles, third Lord Baltimore, as passed that the province might "have a gen-
eral toleration settled there by a law, by which, all of all sorts, who professed Christian-
ity in general, might be at liberty to worship God in such manner as was most agreeable to their respective judgments and consciences, with-
out being compelled to assent to any thing for their doing so, provided the civil peace were preserved. And, that for the securing the civil peace and preventing all heats and feuds which were, generally, observed to happen amongst such as differ in opinions upon occasion of re-
proachful nicknames and reflecting upon each other's opinions, it might, by the same law, be made penal to give any offense in that kind." The credit for this act belongs in the first in-
stance to Cecil, Lord Baltimore, and, secondly, to the assembly which adopted it. The coming of the Brooke family into Maryland led to the formation, in 1654, of a fourth county, bearing the name of Calvert, and situated on the north side of the Patuxent River.

When the Commonwealth had been established in England, five Parliamentary commis-
sioners were appointed to reduce Virginia from her allegiance to the Crown and their commis-
sion, by craft or accident, was extended to "all the plantations within Chesapeake Bay." Two of these commissioners were Caliborne and Bennett, the head of the Puritan party in Vir-
ginia; the other three were Englishmen, but only one of these arrived in America. He acted with the two Virginians, and they seized the government of Maryland in 1652. Baltimore's hostility to Caliborne had been so great that he had exempted him and Ingle from a general pardon. Caliborne's counter-influence may doubtless be seen back to 1633, when, at the request of the governor, that writs should henceforth run in the name of the keepers of the liberty of England, instead of the proprietary, as provided by the provincial charter. Governor Stone refused to obey this order and was removed from office. Three months later he yielded and was re-
stored, but after two years of compliance he again ordered writs to run in the proprietary's name. The Puritans of Providence, as they called their settlement on the Severn, promptly rose in revolt and compelled Stone to resign his office. When Baltimore rebuked him for yielding so easily, Stone gathered an armed force and a battle took place near Annapolis in March 1655 between the two parties, in which conflict the proprietary's party was routed and Stone was taken prisoner. From July 1654 to 1657 the provincial government was in the hands of a body of commissioners, appointed by Bennett and Caliborne, and serving as executive, provincial council and upper house. When the Toleration Act was repealed. Cromwell, how-
ever, confirmed Baltimore's title to the province in 1656, and in March 1657 his authority was restored, a general amnesty being proclaimed and the Toleration Act confirmed. So complete was the pacification that some of the Puritan commissioners sat in the General Assembly of 1659.

A new county, Charles, named for the proprietary's heir, was organized in 1658 from the western part of Saint Mary's County. The re-
stored proprietary government had as its gov-
ernor Capt. Josias Fendall, an energetic man, who organized the militia and then came into conflict with the Quakers, a growing body in the province. When Fendall had been governor for two years he proved himself faithless to the proprietary, surrendered his commission as governor and accepted a new one from the assembly, which claimed the right to make laws without Baltimore's consent. When news of these disloyal acts whatever was sent out with an amnesty, his half-brother, Philip Calvert, as governor in Fendall's place. As soon as Calvert arrived in Maryland, the rebellion collapsed, and the lenient governor was content with inflicting fines as punishment, together with perpetual disfranchisement for a few leaders. Shortly afterward the proprietor substituted his only son, Charles Calvert, for his brother, Philip, who was given the chancellors-
ship of Maryland as a solace. Leonard Cal-
vert's son was soon made provincial secretary, and for 30 years a period of family government continued.

The Dutch had unsuccessfully attempted a settlement upon the Delaware in 1631, and the Swedes had been more successful in 1638. New Sweden had been reduced by the Dutch of New Netherland in 1655. Maryland's representative was sent to notify the Dutch that they were within the provincial boundaries and must ac-
knowledge her jurisdiction or depart. Govern-
or Stuyvesant, on his part, sent two envoys to Saint Mary's, one of whom was a Bohemian, Augustine Herman, who was so charmed by the land through which he traveled, that he re-
moved into it and took up a tract in Cecil
County — Bohemia Manor — for which he paid by executing the first good map of Maryland. A brisk trade sprung up between the English settlers on the Chesapeake and the Dutch and Swedes on the Delaware. This lucrative trade was illicit, under the navigation laws which dated from about 1650, and was partly the reason why the provincial authorities hesitated to take decisive action against the Dutch, until it was too late to do so; for the Delaware settlements were seized by the English fleet in 1664, and granted by the king to his brother, the Duke of York, as part of his province of New York. For several years there was friction between the two governments, and Calvert sent officers, from time to time, to summon the Delawareans to admit his overlordship, while he also granted lands in that region.

Cecil Calvert, first lord proprietary, died in 1675, and was succeeded by his son, Charles. During the years preceding this event, the boundary between Maryland and Virginia on the Chesapeake shore was in dispute, with some loss to the province through imperfect surveying; the tobacco trade flourished, and the settlements spread down the Eastern Shore, so that Talbot, Somerset and Dorchester counties were organized, and along the head of the Chesapeake, so that Baltimore and Cecil counties were established.

The second lord proprietary had as stormy an experience as his father. Indian troubles led to a joint expedition with the Virginians against the Susquehannocks in 1673. In shameful violation of a safe conduct, the Maryland commander weakly yielded to the Virginians' clamor, and five of the chiefs were wickedly put to death. After a month's siege of their fort, the Indians fled; some of them fleeing southward began that course of rapine which led to Bacon's Rebellion (q.v.) in Virginia, while others went northward to unite themselves to their Iroquois kindred, bringing down with them, from time to time, Senecas and Onondagas in hostile incursion against the English settlers and the friendly Indian tribes in Maryland.

In 1680 a disturbance arose, headed by Pendall and John Coode, a renegade Anglican cleric. It failed, and the Popish Plot in England, with the fear shown there for the overthrow of the Protestant religion, found reflection in Maryland, in the suspicion felt by many toward the Roman Catholic proprietary. But the discontent increased, and the "Popish Plot" in England, with the fear shown there for the overthrow of the Protestant religion, found reflection in Maryland, in the suspicion felt by many toward the Roman Catholic proprietary. In July 1689, Nehemiah Blackistone, collector of royal customs, and an old enemy of Baltimore, rose in revolt, together with Coode and other Protestants. The agitators were so determined, and Baltimore's supporters were so lukewarm, that their "Protestant Association" was supreme within a month, and the proprietary government was overthrown. The new rulers asked the Crown to administer Maryland as a royal province, and their request was granted, the first royal governor coming in 1692. The charter was not forfeited, however, and the title to land and other private rights was left to Baltimore.

The royal governors brought a greater regularity and formality into the proceedings of the government. Both the Proprietors, Philadelphia and the Dutch, and the proprietors, the Duke of York and the Privy Council, as well as the proprietors, the Duke of York and the Privy Council, as well as the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, were highly trained and able body of lawyers, who gave the Maryland bar its earliest renown. Francis Nicholson, as governor, saw the establishment of the Church of England in the province, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, were highly trained and able body of lawyers, who gave the Maryland bar its earliest renown. Francis Nicholson, as governor, saw the establishment of the Church of England in the province, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, were highly trained and able body of lawyers, who gave the Maryland bar its earliest renown. Francis Nicholson, as governor, saw the establishment of the Church of England in the province, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, and the proprietors, the Duke of York and the Privy Council, were highly trained and able body of lawyers, who gave the Maryland bar its earliest renown.
The Protestants soon found that there were no grounds for apprehension lest the Calvert family should lean too much on the memories of their ancestors' religion. The Roman Catholics were soon rudely disillusioned of their hope that they might regain, at least, a part of their old influence and position. They were even disfranchised, as a result of a violent contention between Carll and the assembly on the one side, and Hart and the assembly on the other. Some little suspicion of Jacobitism made the Roman Catholics still more unpopular, and repressive laws against them continued in force throughout the whole of the provincial period.

Charles Calvert, a relative of the proprietary, was governor from 1720 to 1727. During this time the general assembly passed in 1723 a law for the establishment of a free school in each county, and a notable controversy arose between the proprietary and the legislature as to whether the English statutes extended to Maryland. This controversy lasted for several years, before the victory of the provincials whose bold resolutions were long remembered:

'\[\text{that this Province is always happy and free under the Common Law, and such general statutes of England, as are not restrained by words of local limitation, and such acts of the Assembly as were made in the Province, to suit its particular constitution, as the rule and the standard of its government and judicature.}\]

Those who maintained the contrary, "intend to infringe our English liberties, and to frustrate the intent of the Crown" in the original grant of this province.

Benedict Leonard Calvert, younger brother of Lord Baltimore, came out to Maryland as governor in 1727, and died of consumption on his way home, in 1731. The promise of his high-minded, scholarly, lovable nature had not time for fulfilment. He had studied at Oxford, had made the "Grand Tour" on the continent of Europe and was a friend of Hearne, the antiquary. While he was governor, William Parks began at Annapolis the first newspaper in the province, though there had been a printing press there as early as 1696. Ebenezer Cook, who called himself "Laureate of Maryland," in his vigorous Hudibrastic satire, "The Sot Weed Factor," gave a lively picture of social life in Maryland and R. Lewis, master in King William's school, wrote poetry and edited a Latin poem, printed in Annapolis. During Calvert's administration occurred two important events which changed Maryland from a rural plantation province to a commercial and agricultural border state. In 1729 Baltimore town was laid out, at the head of navigation on the Patapasco, and grew to a great city, being near to the fertile western country. About this time, along the valleys of the Blue Ridge, from Pennsylvania down toward Georgia, came the sturdy, God-fearing, hardworking, German-speaking immigrants from the Rhineland, who came to Philadelphia, and so had their ties with the Pennsylvanians, rather than with the Virginians. This opening of the back country started that struggle between Philadelphia to gain a commercial reputation. From Philadelphia he was called to New York to defend John Peter Zenger in a famous libel case, having known Zenger long before, when both were neighbors in Chesterstown in Kent County.
their colony. The Germans in Maryland were not slaveholders, and devoted their attention to the growth of cereals rather than tobacco. They also began manufactures on a small scale, and thus diversified the industry on the pato-
tinate. Charles, Lord Baltimore, came to
Maryland in 1732, in an attempt to settle the
boundary dispute with Penn's sons and heirs.
He yielded to them all that they demanded, for
some inexplicable reason, and permitted them the
several million acres of land to which they had
no right. Pennsylvanians had settled Phila-
delphia south of the 40th parallel, but they had
no settlements west of the Susquehanna River.
Beyond it Marylanders were already building their
cabins near the north boundary of the
province, and, under Capt. Thomas Cresap,
they even fought for their rights. Baltimore
agreed, nevertheless, to accept a line run due
west on a parallel 15 miles south of Philadel-
phia, so far as the provinces had a common
boundary. When he realized what he had
done, he refused to run this boundary and ap-
lled to the English courts. The case dragged
on until 1760, when the line of 1732 was finally
accepted, and was surveyed between 1762 and
1767 by Charles Mason and Jeremiah Dixon,
two excellent English surveyors. During the
long governorships of William Bladen and
Samuel Ogle, the province grew in population
and wealth. Worcester County, on the Atlan-
tic seaboard, was organized in 1742, and
Frederick County, in the extreme west, in 1748.
The Baltimore Gazette, established in 1752,
published graceful and correct poems written by
colonial gentlemen. The English magazines
printed the results of the scientific observa-
tions in southern Maryland of Dr. Richard
Brooke, physician and politician. In 1753,
Horatio Sharpe came out as governor, and con-
tinued in that office until relieved in 1768 by
the last proprietary governor, Sir Robert Eden,
the brother-in-law of the last Lord Baltimore.
Sharpe was a wise and popular man, who had
a difficult position to fill during the French and
Indian War in which Fort Cumberland and
other garrisons were placed in the west of the
province; but in which Maryland played a dis-
creditable part, owing to a niggardly propri-
tary and a narrow-minded, unpatriotic legis-
lature.

Maryland joined with the other colonies in
repudiating the Stamp Act, and forced the
stamp distributor to resign his office and flee
from the province. The general assembly
passed bold resolves, refusing to admit taxa-
tion without representation, and claiming that
the provincial legislature had the sole right
to lay taxes, or impositions, on the inhabitants
of their province, or their property or effects.
When the day arrived on which the Stamp Act
should go into operation there was no stamped
paper in the province. How could business be
transacted, if unstamped paper was illegal?
The Frederick County Court took a bold but
sensible course, and declared that its business
should be carried on without stamps, and the
other courts of the province followed it in that
course. Maryland was represented in the
Congress of Stamp Act Congress and took part
in the non-importation agreement and in the
respondence with the other colonies, so as to
present an united front against the British acts.

The people of Annapolis burnt a vessel, The
Peggy Stewart, laden with tea. Yet the prov-
ince was conservative, and, in Sharpe and
Eden, had two governors of popular
quality. In 1774 Eden went to England for a
few months. In June, during his absence, there met
at Annapolis a "general congress of deputies
from all the counties,\(^9\) to consider measures of
opposition to England. This body was the first
of a series of conventions, which chose dele-
gates to continental congresses and appointed
a Committee of Safety to act as an executive
committee during the intervals between con-
ventions; which enlisted troops and sent them
to fight the British in Massachusetts; which
directed the choice by each county of a Com-
mittee of Observation to care for local matters;
and which, by the Association, a document of-
tered in 1775 for subscription by the freemen
of the province, expressed approval of the
measures adopted by the Continental Congress
in opposition to Great Britain, and united the
people *in maintenance of good order and the
public peace.*

Eden had not only difficulties to contend
with in connection with the British revenue
acts, but also had to meet two local troubles.
A strong party of Quakers, who were provided for the support of the clergy, had not
been properly passed, and so was void. A
struggle over officers' fees caused great excite-
ment. The acts fixing these fees were tem-
porary, so that the legislature might readjust
their rates every few years, and the chief of
the clergy held the chief offices and naturally desired
large fees. When the fee act expired in 1770
all attempts to pass a new law failed, because
of dissensions between the two houses of the
assembly. What should be done in this emer-
gency? Eden issued a proclamation forbidding
any officer to take fees greater than those al-
lowed in the old law. Of course, he was
thereby virtually authorized to take fees at the
old rate, and so the proclamation fixed the
fees. A fierce controversy followed over the
governor's right to do this. In which contro-
versy, Daniel Dulaney, the younger, who had
attacked the Stamp Act, defended the governor,
and Charles Carroll of Carrollton, a young
Roman Catholic, who was the wealthiest land-
owner in the province, attacked him. The ma-
jority of the people undoubtedly agreed with
Carroll, but the governor held the whip hand
and fees were collected at the old rate, until
British rule was overthrown.

In 1771 Frederick, sixth and last Lord
Baltimore, died, and the title became extinct.
He left the province to his illegitimate son,
Henry Harford, the sixth and last lord
proprietary. In his honor, Harford County,
on the west side of the Susquehanna, was
named, and, at the same time, Caroline County,
the only county on the Patuxent, was created
and named in honor of Lady Eden.

Eden's influence could not prevent acts of
lawlessness from time to time, but his tact
and good-fellowship with the colonial leaders,
and the conservatism which had always shown
itself in Maryland, kept the "ostonable forms of
government\(^9\) intact, so that on 17 May 1776
the Provincial Convention denied that it was
necessary to suppress the royal government,
and, on 21 May, expressed the hope for a *re-
union with Great Britain on constitutional principles. Eden saw that the provincials would "not long be able to stem the torrents which, to which her own independence her own independence." He declined to accept the proposition of the convention that he remain as governor of Maryland, promising to take "no active hostile part, nor to correspond with the British government." Instead, he embarked on a British war of war on 21 June 1776, and sailed for England, where, in August, he was created Baronet of Maryland, an honor still worn by his descendants, in return for his skilful administration of the affairs of the province. Baltimore town and Frederick County eagerly sought independence. Samuel Chase, like a flame of fire, preached it throughout Maryland, Matthew Tilghman, William Paca, Charles Carroll the barrister and Charles Carroll of Carrolton urged it. So the convention voted on 21 June, to allow its deputies in the Continental Congress to unite with delegates from other colonies, in declaring independence and forming a confederation. On 3 July, the convention adopted her own declaration of independence, and, thereafter, began to prepare a permanent written constitution for the new State.

State History—Maryland was equal to any other of the 13 original States in her zeal and fidelity to the common cause. On 2 Aug. 1776, her delegates to the Continental Congress signed the Declaration of Independence, and, in November, elections were held for officers in the new government, which was finally instituted, when the convention adjourned sine die in March 1777, and Thomas Johnson was inaugurated as the first governor. The State constitution was not submitted to the people. It was provided for changes by passage of the amendment at two successive assembly sessions. The constitution contained a bill of rights and a frame of government, consisting of a governor, chosen annually by the legislature, and a general court of two chambers; a House of Delegates, elected annually, consisting of four Delegates from each of the 19 counties and two each fromAnnapolis and Baltimore; and a Senate of 15 members, chosen quinquennially by an annual town meeting of freeholders from each county and one from Annapolis and Baltimore. A governor's council was also provided, to be chosen annually by the legislature and to act upon his nominations. The judiciary was to be appointed by the governor. Suffrage was based upon the possession of property, and so there were a few negro voters.

Maryland entered into the Revolutionary War with zeal, and her troops were the only ones which were found in every campaign. At the battle of Long Island, on 27 Aug. 1776, the Maryland line won its first renown, and that renown was heightened in the Southern campaigns by its bravery in the battles of Camden, 16 Aug. 1780; the Cowpens, 11 Jan. 1781; Guilford Court House, 15 March 1781; and Eutaw Springs, 8 Sept. 1781. General William Smallwood, their commander, Gen. Mordecai Gist, and Col. John Eager Howard especially distinguished themselves. Tench Tilghman, a Marylander, bore the news of the surrender of Cornwallis and his army at Yorktown, on 19 Oct. 1781, from General Washington to Congress at Philadelphia, and Dr. James McHenry of Baltimore, afterward Washington's Secretary of War, was one of the general's aids, or military family.

While Maryland was full of acrality for the common cause, for a moment she refused to sign the Articles of Confederation, fearing danger from the claims of the great States, notably Virginia, to vast tracts of land west of the Allegheny Mountains. Maryland proposed to the Continental Congress that the far-extending territory he granted to the Union, and held as the common property of all the States, and refused to accede to the articles until this proposal was adopted, and Virginia, the most important of the claimants and the only one who had reduced her claims into possession, had made such a cession. This perseverance won, the desired cessions were made, the Western lands became the nation's domain and Maryland entered the Confederation as the 13th State on 1 March 1781. One of her delegates, John Hanson of Frederick County, was the first presiding officer of Congress under the new government. During the war, the State had confiscated the proprietary's lands and those of some of the Tories, who had among their number some men of wealth and fame, especially on the lower Eastern Shore. In 1776 Frederick County was divided, the middle portion keeping the old name, the eastern one becoming Montgomery County, named after Gen. Richard Montgomery of the Revolutionary army, who was killed at Quebec, and the western portion becoming Washington County.

In November 1783, by invitation of Maryland, the Congress met in her State House at Annapolis, and in the senate chamber there General Washington resigned his commission on 23 Dec. 1783.

Maryland and Virginia had a common interest in the commerce of the Chesapeake and the Potomac, and, to arrange for its regulation, commissioners were appointed, who met at Alexandria and Mount Vernon in 1785. At that meeting the desirability of uniform commercial regulations throughout the Union was considered and a convention for the discussion of such questions was called to meet at Annapolis in 1786, to be represented, and, through dissensions in the Maryland legislature, there were no Maryland delegates. Alexander Hamilton was a delegate, and, through his efforts, a second convention was summoned to meet in Philadelphia in 1787, which gathering drafted the Federal Constitution. Maryland's delegation to the convention divided, Luther Martin (an able lawyer and subsequently an ardent Federalist) and John Francis Mercer refusing to sign the document; while James McHenry, Daniel Carroll and Daniel of Saint Thomas Jenifer, did so. The people of the State elected delegates of strong Federal inclination to the convention called to consider the constitution, which ratified it 28 April 1788, by a large majority,—a vote which was considered to have had a considerable effect in Virginia.

In 1791 Maryland ceded to the Federal government, as a site for the seat of government, about 61 square miles on the north bank of the Potomac River at the head of navigation, and this, with a cession from Virginia, formed the District of Columbia. The portion taken from Virginia was later retroceded to her, so
that the territory of the present district was once entirely a part of Maryland. In 1796 Allegany County was formed from the western part of Washington County. During the early part of the 19th century, the Jeffersonian party in the State became organized, its leaders being two brothers, Gen. Samuel Smith, who sat on the United States Senate, and Robert Smith, who became Secretary of State.

When war was declared between the United States and Great Britain in 1812, Baltimore sent forth about 60 fast sailing vessels, which preyed as privateers. Gen. Samuel Smith, who sat on the United States Senate, and Robert Smith, who became Secretary of State.

Admiral Cockburn sailed into the Chesapeake with a British fleet. He made a number of landings, and had skirmishes with the people. The Federal authorities were inefficient. Finally, in August, 1814, a reinforcement of British troops having arrived under command of General Ross, the British fleet sailed up the Patuxent River and disembarked a considerable expedition. The British forces were met by the Americans near Bladensburg, and the latter was defeated. Gen. Jackson, in command, was taken a prisoner; and Ross, taking the Federal capital—Washington—advanced and took the Federal capital—Washington. After a short time, they retired, reembarked on the fleet and sailed up the bay to attack Baltimore. The army under General Ross landed at North Point, and attacked the Maryland militia, driving them back several miles upon the defenses of the city. In the attack, General Ross was killed. A landing party to the southwest of the city was unsuccessful. Fort McHenry, on the end of a peninsula, was the only place that was bombarded by the fleet. During the night of the bombardment, Francis Scott Key, a lawyer of fine ability, who was detained on a British ship, who had gone to endeavor to effect the release of a prisoner, wrote the "Star Spangled Banner." Having failed to take the city, the British withdrew. After the conclusion of peace, the farseeing merchants of Baltimore planned Western routes to secure trade for their city, and the Baltimore & Ohio Railroad came into being.

Maryland was a close State politically, and was so conservative that the Federalist party lingered there for years after it had gone out of existence elsewhere. In 1806 the property qualification for voters was abolished, a radical one being substituted. The growth of Baltimore and the larger counties rendered the people therein discontented with the constitutional rules of equality of representation in the legislature. In 1837 the Democratic electors for the senate of the State, who numbered 19 out of 40 (the quorum being 24), refused to go into the body, in the hope of accomplishing constitutional revision. They failed to prevent the election of a senate, and the party was repudiated by the voters at the ensuing election, but the constitutional amendments desired were accomplished. The governor's council was abolished; the governor's election made by the people for a three-year term; and the senate made also a body elected by the people, one member coming from each county and one from Baltimore city. Annapolis lost its representation in the general assembly. In 1836 Carroll County was established out of parts of Frederick and Baltimore, and took its name from the venerable Charles Carroll of Carrollton, who had been the last survivor of the signers of the Declaration of Independence, and had died in 1832. William Wirt, an eminent lawyer and a resident of Baltimore city, was nominated for the Presidency by the anti-Masonic party, and received the electoral vote of Vermont at the election of 1832. From 1830 to 35 years, Baltimore was the place at which many National political conventions were held.

At this time, in Maryland, as in other States, large amounts had been borrowed to aid works of communication, such as railroads and canals. A financial crisis in return, and toward the failure of the Bank of the United States to obtain a recharter, and Maryland was in danger of bankruptcy. That this evil was averted and the State's credit maintained was due to the high integrity of Thomas G. Pratt, then governor, and to the great helpfulness of George Peabody, then a London banker, but formerly in business in Baltimore. The failure to recharter the United States Bank was mainly due to two men, President Andrew Jackson and Roger B. Taney. The Bank was called to the President's Cabinet as Attorney-General, and, having already conceived a distrust for that bank, had not only agreed with the President in his opposition to it, but had increased his hostility. Taney was transferred to the Treasury Department, so as to accomplish more against the bank, by removing the Federal government deposits from it. The Senate refused to confirm the appointment—an unprecedented act. Jackson nominated Taney again to the Senate, but the Senate refused to confirm him, and the nomination was rejected. A vacancy in the chief justiceship gave Jackson a third opportunity to honor Taney, and a change in the membership of the Senate secured his confirmation, so that he presided over that august tribunal from 1838 to 1864. The Maryland bar was a famous body of men. William Pinkney, who served as a Minister to England and won laurels as an orator in the United States Senate, was considered the leader of the American bar, until he died, and after Daniel Webster died, for 20 years, Reverdy Johnson, the most prominent American lawyer. Johnson was a Whig, served as Attorney-General in Taylor's administration, was twice senator from Maryland and was Minister to England.

Troops from Maryland played a gallant part in the Mexican War. The agitation for rotation in office and for a greater number of elective offices was so strongly felt in Maryland that a new constitution was adopted in 1851. The term of the governor was increased to four years, at which it has remained. At this time, Howard County was created out of part of Anne Arundel, and Baltimore city was made independent of Baltimore County. To use the English phrase, it was created a county borough. Maryland had given considerable support to the colonization of 1820, the issue achieved by the compromise act. H. B. Latrobe, an eminent lawyer, was for many years president of the Colonization Society, but there was little abolition sentiment in the State. The Republican party was not organized in Maryland until 1866, but there was very conservative Unionism in the State, and the Whigs had been powerful there. There was also a strong nativist element, which was brought into politics by a considerable foreign immigration to Baltimore about 1850, and by the
fact that these immigrants usually voted the Democratic ticket. As a result of the combination of these elements, Fillmore carried the State (the only one he did carry) as the native Abraham Lincoln; Grant for the Presidency in 1860, and Thomas H. Hicks, the candidate of the same party, was chosen governor in 1857. Baltimore city, about that time, was characterized by election riots and disturbances between mobs, composed of partisans of Know-Nothings and of Democrats, and also between mobs, composed of adherents of rival volunteer fire companies. The police force there was inefficient, and, as a result, in 1860 it was placed under State control, under which it still remains. When the Presidential election of 1860 came, Breckenridge, the candidate of the Southern Democracy, carried the State by a narrow plurality, over Bell, the Conservative Union candidate, supported by the Old Line Whigs. As soon as Lincoln's election was announced, the Gulf States began to secede. Maryland was in a difficult situation. She was a border State, slaveholding, conservative, Union loving, having ties both to North and to South. Governor Hicks was a Union man, but not a man of strong personality. Lincoln called for troops. On the 9th of April, the Sixth Massachusetts regiment reached Baltimore. Locomotives were not then allowed to draw trains through the city, but mules pulled the cars from one station to the other along Pratt street. The commander of the regiment permitted his men to remain in the cars, and the crowd, seeing them so transported, became menacing. Stones were thrown, shots were fired and several men were killed on either side — the first bloodshed of the Civil War. Governor Hicks promptly called a session of the legislature to meet in Frederick, the centre of the Unionist part of the State, where the local influences overawed the Secessionists in the legislature, so that the question of disunion was never brought to a vote. Later, the Federal officers arrested some prominent disunionists and confined them for several months. Baltimore was reduced to quiet and obedience to Federal law, when Gen. Benjamin F. Butler, with Union troops, took post in May on Federal Hill, early carded as the most important of their kind. The Union army also contained a large number of Maryland soldiers; the chief officers being Gen. John R. Kenly and Gen. Charles E. Phelps. Union troops were stationed along the Potomac, and many important campaigns took place there, notably the decisive battle of 1862. General Lee came into the State with the Army of Northern Virginia, and met General McClellan and the Army of the Potomac, near the village of Sharpsburg, on Antietam Creek, in Washington County, fighting there a bloody battle, after which Lee was forced to retire into Virginia. This Maryland campaign had, as one of its incidents, the occupation of Frederick by Stonewall Jackson, which gave rise to the poem of "Barbara Frietchie." In 1863 Lee crossed the State twice on his way to and from Gettysburg, and in 1864 Gen. Jubal A. Early entered Maryland, and fought the battle of the Monocacy near Frederick against Union forces under Gen. Lew Wallace. They were defeated, but the delay they caused the Confederate army, together with a second delay, occasioned by Early's stopping to collect a ransom of $200,000 from Frederick, gave the Federal authorities time to bring troops to Washington and avert danger of the capital's falling into the Confederate's hands. A raiding party came within five miles of Baltimore at this time. During the war, James R. Randall wrote the song, "Maryland, my Maryland," to encourage the secession element in the State.

Augustus W. Bradford, a Union man, was chosen governor in 1861, and, under his administration, was held the Constitutional Convention of 1864, the result of whose deliberations was declared adopted in October, by a very small majority, made up by the soldiers' vote. This constitution abolished slavery, increased the representation of Baltimore, making it equivalent to three counties; provided for a lieutenant-governor, instituted registration of voters and established a State system of public education. It also prohibited, in the strictest terms, any persons who had sympathized with the Confederate States from holding office or voting, and provided that all voters must take an oath that they have been truly and loyally on the side of the United States. Thomas Swann was elected governor, and C. C. Cox, lieutenant-governor, on the Union ticket in November 1864. When the Civil War ended in 1865, the Union party, which had been a coalition one, fell into pieces. Governor Swann became a Democrat, while Lieutenant-Governor Cox and Henry Winter Davis organized the Republican party, which was a minority one for 30 years. Reaction from the extreme loyal position of the constitution of 1864 led to the assembling of another Constitutional Convention in 1867, which drafted the constitution under which the State is still governed, the people having declined to accept the 1864 constitution. The Constitutional Convention — a proposition which the constitution directed to be laid before them every 20 years. This constitution abolished the office of lieutenant-governor and the "iron clad oath" of loyalty, and rearranged the judiciary. By this constitution, Wicomico County was established on the Eastern Shore, out of Dorchester and Somerset. In 1872 the western part of Allegany County was created into Garrett County, named for John W. Garrett, president of the Baltimore and Ohio road. This is the last county to be organized. Oden Bowie was the first governor under the new constitution, and he was succeeded in 1872 by William Pinkney Whyte, a lawyer of marked ability, who held, at one time or another, nearly every elective office. He was, in 1880, the head of the Democratic organization until about 1880. Then Arthur P. Gorman, who had been a prominent member of the legislature, succeeded him as the director of Democratic politics, and continued to keep the organization in the hands of himself and his friends until his death in 1906. During
most of that quarter of a century, he was a member of the United States Senate. The legislatures of 1869 and 1870 were unanimously Democratic, but, in that of 1872, a small Republican minority appeared, under the leadership of Dr. Lewis H. Steiner of Frederick County.

A one-party State is apt to find that abuses creep in, and such became the condition in Maryland. An independent reform movement in the Democratic party led to refusal on the part of many to accept the nomination of John Lee Carroll of Howard County for governor in 1875. A reform ticket was nominated, headed by J. Morrison Harris, a Republican, and containing the name of S. Teackle Wallis, a Democrat and the leader of the Baltimore bar, as candidate for the attorney-general. This ticket carried the counties, but gross frauds in Baltimore city were sufficient to show Carroll's election on the face of the returns. The Court of Appeals, in a decision welcomed as a precedent by Republicans in the Presidential contest of the succeeding year, decided that it could not go back of the returns, and Carroll became governor. The reform Democrats and independent Republicans then organized the Baltimore Reform League, which, for 30 years, waged an unparalleled conflict against the dominant party organization. Gradually, the independent voters came to hold the balance of power, especially in Baltimore. No independent ticket was nominated, but the League steadily continued for good election laws, honestly administered and from time to time supported such Republican candidates as stood for the same purposes as the League. This policy led both parties to nominate better men and much improved political conditions.

In 1873 the most bitter strike of working men occurred, which Maryland has yet known, when a reduction in wages of the employees of the Baltimore and Ohio Railroad led to such rioting that the National Guard was insufficient to quell it, and the assistance of Federal soldiers was requested. The efforts of the reform element led to the nomination, by the Democratic party in 1879, of William T. Hamilton of Washington County, for the governorship. He was elected by a large majority, and, though hampered by an unfriendly legislature, accomplished some reform. In 1882, the Reform League achieved its first victory in Baltimore, electing "new judges," in coalition with the Republicans, over the old judges, who had been renominated by the Democrats.

Robert M. McLean was elected governor in 1883, but, being appointed Minister to France, he did not complete his term. In 1887 the Baltimore and Ohio Railroad ceased to pay dividends, and many citizens who were stockholders suffered severe losses. The road struggled along until 1896, when it went into the hands of the receivers, John K. Cowen and Oscar G. Murray. They were two remarkable men; the one, an able lawyer; the other, a skilled railroad operator, and, by the daring issue of receiver's certificates, and by extensive re-construction of the road, they were able, after a life of eight years, to return it to its pre-receivers stockholders under the original charter. Cowen became the first president of the reorganized road. A tunnel was dug under Baltimore, in order to secure direct connection between the lines on the east and those on the west of the city.

In 1887 Elihu E. Jackson was elected governor. In 1889 disastrous floods in western Maryland so damaged the Chesapeake and Ohio Canal that it was never afterward successfully operated. Fifteen years later, it was sold to the Western Maryland Railroad. In 1890 the financial interests of the State suffered a great shock, by the discovery of the misappropriation of over $100,000 of the State's funds by the State treasurer, a man who had been universally trusted. The loss to his bondsmen was heavy, and the incident gave an especial incentive to the founding of bonding companies in Baltimore. The long-continued complaint of intimidation and fraud at elections, especially in Baltimore city, led to the passage of an Australian Ballot Law in 1890. This statute much improved the conditions, but was a measure which needed much later amendment.

Frank Brown, o' Carroll County, was chosen governor in 1891, and in 1894 he found it necessary to call out the National Guard to preserve order in consequence of a miners' strike in Allegany County. In that year's Congressional elections and for 10 years afterward, the State, at large, had a majority in the State. This fact gave the party fresh courage, and, in 1895, it nominated a strong candidate for governor, Lloyd Lowndes of Allegany County. The Reform League supported him, as did ex-Governor Whyte, and many other Democrats, who had become dissatisfied with conditions in their party and in the State. Special efforts were exerted to prevent intimidation or fraud in Baltimore city. The election resulted in a Republican legislature and a large popular majority for Lowndes. For many years, one United States senator had been chosen from either shore of the bay, but now that rule was broken, and a Republican, George L. Wellington of Allegany County, was chosen senator, the other senator being Arthur P. Gorman of Howard County. The same session saw the passage of an excellent ballot law, prepared by the Reform League (which did away with all riot and intimidation, and almost all fraud at the polls), and the establishment of the State Geological Survey, whose achievements have been very extensive, and of a remarkable scientific character.

In 1896 William J. Bryan was nominated for the Presidency, by the Democratic party, and this choice was not received with favor in Maryland, where the sentiment in favor of a gold standard was strong, and where the party had always called itself the Democratic-Conservative party. The prohibitionists nominated Joshua Levering of Baltimore, but his vote was small. William McKinley, the Republican nominee, carried the State by 32,000 plurality, and every Republican candidate for Congress was elected. President McKinley called to his Cabinet, as Postmaster-General, James A. Gary, of Baltimore, a prominent manufacturer. In 1897 a general assembly was chosen, Republican in both branches, the only time such has been elected. They adopted a new city charter for Baltimore. The city government was established, and empowered to prepare an annual budget for the city. Louis E. McComas of Hagerstown, an experienced jurist, was elected to the United States Senate. In the Spanish
War, which occurred during that year, Maryland troops did not have the opportunity of service outside of the country, but two natives of the State gained renown: Adm. Winfield Scott and Gen. G. O. C. Lowe, both of whom were born in Frederick.

The Democratic party won the gubernatorial election of 1899, owing in part to dissensions among the Republicans, and John Walter Smith of Worcester County defeated Governor Lowndes, who sought re-election. Governor Smith succeeded to the leadership of the Democratic State party organization, when Senator Gorman died. Four years after the close of his term as governor he was elected to the United States Senate. In 1900 the State cast its electoral vote for McKinley, by nearly 14,000 majority. Governor Smith called the legislature in extra session in 1901 to amend the ballot law and to provide for a State census, since certain frauds, which were afterward corrected by the Federal officials, had been discovered in the National Census of 1900. The Democratic party now entered upon a continuous policy for suppressing the votes of negroes and the election law adopted in 1901 abrogated the former to the extent of the ballot, and included other provisions, making it easy for election officials to throw out ballots. The election of 1901 turned upon the question of approving, or condemning, this election law, under which so-called trick ballots, difficult to vote, were used in certain counties. A Democratic legislature was chosen, but, of the two State officials elected by small majorities, one was a Republican. In 1902 the Republicans carried the State on the Congressional vote; but, in 1903, Edwin Warfield of Howard County, head of one of the Baltimore bonding companies, was elected governor on the Democratic ticket. About this time, an era of construction of public buildings occurred at Annapolis. The state house, erected in Governor Eden's administration, was enlarged; a building was erected for the Court of Appeals and the State Library; and the United States Naval Academy, established during the administration of President Polk, when George Bancroft was its first Superintendent, opened in 1845. On Feb. 1904 occurred the great fire in Baltimore, which burnt over about 160 acres of ground in the centre of the city, and destroyed nearly $100,000,000 worth of property. A Burnt District Commission was created to deal with the emergency. Streets were widened and new piers built. An adequate sewer system, at a cost of $25,000,000, was installed about the same time, and the city entered upon a new era of progress.

In the autumn of 1906 the erection of a new Young Men's Christian Association building was made possible in Baltimore, by the raising of over $400,000, through the first of those intensive canvasses which have since been so often resorted to in the city.

The legislature of 1904 proposed to the voters an amendment to the Constitution, failing to meet the suffrage, usually known as the Poo Amendment, from the name of John P. Poe, Esq., a prominent lawyer who drafted it. It included the so-called "grandfather clause," and gave officers of registration considerable power, the object being to prevent most of the negroes from voting, and so render the success of that party certain. However, the amendment was opposed by the governor, the attorney-general and many other prominent Democrats, as well as by the united body of Republicans, and was defeated at the polls in the election of 1905, by a majority of 33,000, although a majority was chosen in the general assembly then selected. Twice subsequently, a futile attempt was made to have a similar amendment incorporated in the State constitution, before the effort was finally relinquished. In the Presidential elections of 1904 and 1908 the electoral vote of the State was divided, so close was the result.

In President Roosevelt's Cabinet, Charles J. Bonaparte, Esq., of Baltimore, who had been prominent in reform movements, served as Secretary of the Navy and as Attorney-General. In 1906 the legislature passed the bill for oyster culture, usually known by the name of B. Howard Haman, a Baltimore attorney who drafted it, and this was the commencement of the conservation movement. Shortly afterward a State Forestry Commission was appointed, which has done good work.

In 1904 the movement for good roads began, which had such remarkable development during the gubernatorial term of Attorney-General Altch, of Elkton, Cecil County, which lasted from 1908 to 1912. Isidor Rayner, Esq., an eloquent man, was elected to the United States Senate, in 1904, by the Democrats. F. Phillips Lee Goldsborough, of Cambridge, Dorchester County, who was chosen governor in 1911 was the second Republican to attain that office. His administration was efficient and characterized by progress. He was succeeded by Governor Emerson C. Harrington, also of Cambridge, a Democrat, who was chosen in a close election. The enactment of the budget amendment to the constitution occurred during his administration. The first popular election of a United States senator resulted in the election of Dr. Joseph I. France, the Republican nominee. The electoral vote in 1912 and 1916 was cast for the Democratic candidate. Governor Harrington appointed a Council of Defense which rendered valuable service during the Great War. Maryland contributed nearly 500,000 to the United States army,—the 115th and 313th regiments, especially, being almost entirely composed of Maryland men, and they gave a good account of themselves on the battlefield. Several army camps, etc., were located in the State, the most important ones being Camp Meade at Admiral, in Anne Arundel County, Camp Holabird, in Baltimore County, and the Edgewood Proving Grounds in Harford County.

Population.—Maryland had a population in 1790 of 319,728; in 1820, 583,034; in 1870, 780,844; in 1890, 1,042,300; in 1900, 1,188,044; in 1910, 1,295,346; in 1917 (estimated) 1,373,673. The principal cities are Baltimore (558,485 in 1910, large district annexed in 1917, now estimated, 669,891); Cumberland (21,859); Hagerstown (16,607); Frederick (10,411); and Annapolis (8,609).

The Press.—There are three morning daily papers published in Baltimore: the American (Republican), established in 1774, the Sun (Democratic), es established in 1777; and the Daily Record (legal); and there are three afternoon papers: the News, Evening Sun and Star. Several weekly and monthly religious
and trade magazines are published in Baltimore, as are the magazines issued by the Johns Hopkins Press, the oldest of American university presses. In each county-seat there are usually two newspapers printed, and in the smaller cities there is generally found a daily newspaper.

The following is a list of the governors of the State:

LORDS PROPRIETORS OF MARYLAND.
1721-1731. Charles Calvert, Fifth Lord Baltimore.
1731-1771. Frederick Calvert, Sixth Lord Baltimore.
1771-1776. Henry Har福德.

PROPRIETORS GOVERNORS OF MARYLAND.

Leonard Calvert. 1634-47
In absence in Virginia in 1638, he left John Lawyer and Thomas Cornwallis in charge of the province. In 1641 he left Cornwallis again in charge for two months. From October 1642 to September 1644, he was in England, leaving Giles Brent as acting governor. In October 1645, Sir Thomas Erel, was acting governor. In February 1645, Edward Ingles usurped the province. Anarchy prevailed from the middle of 1645 to July 1646; when Edward Hill was given the government by the council and confirmed by Calvert, from Virginia. Calvert resumed rule in the fall of 1646.

Thomas Greene. 1647-49
William Stone. 1649-54
During the time Stone was in office in 1649 and 1650, Thomas Greene and Thomas Hatton acted as governor.

In March 1652, Richard Bennett, Edmund Clifton, and William Claiborne took possession of the government. In June, Stone was restored.

Commissioners, appointed by Parliament or Commissioners by Provincial Court. 1654-58
Josias Kendall. 1658-60
Francis Pelham. 1660-61
Charles Calvert (became Lord Baltimore 1675).

1661-1666, Philip Calvert, (acting governor).

Cecilius Calvert. 1667
Nobility governor. Deputy governor Jesse Wharton actually carried out duties.

Thomas Notley. 1667-79
Charles, Third Lord Baltimore. 1667-84
Benedict Leonard Calvert (nominal governor).

Council exercised power. Vincent Loe, president.

William Joseph (President of Council). 1681-83
Protestant Associates. 1689

Creation of Freeman and John Coode, commander-in-chief.

Nehemiah Blakiston. 1690-92

ROYAL GOVERNORS

Sir Lionel Copley. 1692-93
Sir Thomas Lawrence (President of Council). 1693-95
Sir Edmund Andros. 1693-94
Col. Nicholas Greenbury (President of Council). 1694
Sir Thomas Lawrence (President of Council). 1694
Francis Nicholson. 1694-99
Nathaniel Blakston. 1699-1702
Thomas Tench (President of Council). 1702-04
John Seymour. 1704-09
Edward Lloyd (President of Council). 1709-14
John Hart. 1714-15

PROPRIETORS GOVERNORS (RESTORED)

John Hart. 1715-20
Charles Calvert. 1720-27
Robert Eden (Third Lord Calvert). 1727-31
Samuel Ogle. 1731-32
Charles, Fifth Lord Baltimore. 1732-33
Samuel Ogle. 1733-42
Thompson Braden. 1747-53
Samuel Ogle. 1753-58
Benjamin Edgar. 1758-59
Horatio Sharpe. 1759-60
Robert Eden. 1760-76
(Richard Lee, President of Council, acting governor 1774)

The Convention and Council of Safety. 1776-77

STATE GOVERNORS OF MARYLAND.

John H. Howard. 1777-81
George Plater. 1781-82
James Brece. 1782-83
Thomas Sim Lee. 1783-84
John H. Stone. 1784-97
John Henry. 1787-98
Benjamin Ogle. 1798-1801
John F. Mereror. 1802-05
Robert Bowen. 1806-09
Robert Wright. 1810-11
Edward Lloyd. 1811-12
Levin Winder. 1812-15
Charles Ridgely of Hampton. 1815-18
Charles Goldsborough. 1818-20
Samuel Spring. 1820-21
Samuel Stevens, Jr. 1822-23
Joseph Kent. 1823-25
Daniel Martin. 1825-27
Thomas K. Carroll. 1827-29
David Martin. 1829-30
George Howard. 1830-31
Whig. 1831-33
James Thomas. 1833-35
Thomas W. Venable. 1835-38
William Grayson. 1838-41
Francis Thomas. 1841-44
Charles G. Pratt. 1844-47
Philip Francis Thomas. 1847-50
Brook Lovett. 1850-53
Thomas Watkins Ligon. 1853-58
Thomas Holiday Hicks. 1858-61
Augustus W. Gordond. 1861-64
Thomas Swann. 1864-68
Democratic. 1868-72
William Pinkney Whyte. 1872-74
James Black Groom. 1874-76
John L. Carrington. 1876-78
William T. Hamilton. 1878-80
Robert M. McLane. 1880-83
Henry Lloyd. 1883-85
Elthu E. Jackson. 1885-87
Frank Brown. 1887-88
Lloyd Lowes. 1888-90
John W. Smith. 1890-94
Edwin Warfield. 1894-98
Austin L. Crothers. 1898-10
Philip L. Goldsbrough. 1900-04
Emerson E. Harrington. 1904-10

Bibliography.—Bozman, McMahon, McSherry, Scharf's 'Histories of Maryland,' Browne's "Maryland in 'American Commonwealths,' Hall, 'Lords Baltimore'; Maryland Archives (Provincial History, 38 volumes have so far appeared), Maryland Historical Society Fund Publications, Maryland Historical Society Magazine, Fiske's "Old Virginia and Her Neighbors," numerous monographs in Johns Hopkins University Studies in Historical and Political Science, etc.

BERNARD C. STEINER,
Librarian of The Enoch Pratt Free Library,
Baltimore.

MARYLAND AGRICULTURAL COLLEGE, a State institution founded in 1856 at College Park, Md., for education in agriculture and its ancillary sciences. At present it has the following departments: agriculture, horticulture, biology, chemistry, mechanical engineering, civil engineering, electrical engineering, mining and preserving, and training courses in agriculture for teachers and a summer school. A great part of the college plant was destroyed by fire 29 Nov. 1912. The college was housed for a time in temporary structures, but new buildings have since been erected, of which the principal buildings are Merrill Halls. The college plant is valued at $525,000 and the annual income is about $170,000. There are 10,000 volumes in the library. The faculty numbers 40 and the student body about 500.

MARYLAND CAMPAIGN OF SEPTEMBER 1862. The Union army under General Pope having been defeated and driven to
the defenses of Washington, General Lee, 3 Sept. 1862, marched from Chantilly for Leesburg. At the end of the first day's march Lee wrote to Jefferson Davis that the time seemed propitious for the Confederate army to enter Maryland, and gave her material aid in the recovery of her liberties. The next day he reached Leesburg, and again wrote that he was fully persuaded of the benefit that would result from an expedition into Maryland, and should proceed at once to make the movement, unless it was delayed further; also that it was deemed unadvisable upon political or other grounds. Without waiting for a reply to his two communications he crossed the Potomac at White's Ford, near Leesburg, on the 4th, 5th and 6th, with an army of over 60,000 men, and marched to Frederick, Md., where, on the 8th, he suggested to President Davis that the position of affairs "placed it in the power of the government of the Confederate States to propose with propriety and with the recognition of our independence." On the same day he issued an address to the people of Maryland, stating his mission among them and that he was prepared to assist them in regaining their lost territory; he announced his intention to cross the Potomac at Shepherdstown Ford, at the same time sending an order to Jackson to march from his position of Harper's Ferry up the south side of the Potomac and cover the crossing. He crossed the Antietam in the morning of the 15th, where he hoped that McLaw might join him, but Franklin confined McLaw in Pleasant Valley. At noon he heard that Jackson had captured Harper's Ferry, whereupon he concluded not to retreat across the Potomac, but to give battle to McClellan on the heights and banks of the Antietam, and ordered Jackson to join him as soon as possible. McClellan followed Lee on the morning of the 15th, defeated Fitzhugh Lee's cavalry brigade in the streets of Boonsboro, and in the evening reached the banks of the Antietam to see Lee's army drawn up on the heights beyond. Franklin was left in Pleasant Valley to watch McLaw and relieve Harper's Ferry, and on the morning of the 16th, bringing Walker's division with him; McLaw eluded Franklin, passed out of Pleasant Valley, and through Harper's Ferry, and joined Lee very early in the morning of the 17th. The battle of Sharpsburg, the bloodiest one-day battle of the war, was fought on the 17th; both armies remained inactive on the 18th, and that night Lee recrossed the Potomac at Shepherdstown. McClellan followed on the morning of the 19th to the banks of the Potomac. On the 20th a part of Fitz-John Potter's Fifth corps crossed the Potomac at Shepherdstown Ford, (q.v.), and was attacked and driven back across the river with great loss. This ended the campaign. From the beginning of the campaign to its close 226,000 Confederates were engaged, the Union losses, including Harper's Ferry and Maryland Heights, were 2,671 killed, 11,766 wounded and 13,542 captured or missing, an aggregate of 27,979. The Confederate losses were 1,797 killed, 9,007 wounded and 11,915 captured or missing, an aggregate of 22,722. The results of the campaign were momentous and far-reaching; the Confederate cause lost prestige and the National cause brightened. Recognition of Confederate independence by Great Britain and France was withheld, and 22 September Abraham Lincoln issued his preliminary proclamation of emanci-
MARYLAND HEIGHTS, a bold, wooded elevation in Maryland, rising 1,000 feet above the Potomac opposite Harper's Ferry (q.v.), W. Va. In these heights, Elk Ridge, lying west of South Mountain, from which it is separated by the narrow Pleasant Valley, terminates. The heights are almost inaccessible, capable of strong defense, and completely command Harper's Ferry, which lies below it in the angle formed by the junction of the Potomac and Shenandoah rivers. When Harper's Ferry was seized by the Virginia forces in April 1861, Col. T. J. ("Stonewall") Jackson promptly occupied Maryland Heights, and they continued in Confederate possession until June of that year, when Gen. J. E. Johnston withdrew from the line of the Potomac and fell back to Winchester. The heights were then occupied by Union troops, and 5 Sept. 1862, when Lee crossed into Maryland, they were held by Col. T. H. Ford with about 2,000 men and some heavy siege and field artillery. When Lee, at Frederick, Md., found that Harper's Ferry and the heights were still held by the Union troops he sent three columns to surround and capture the garrison of more than 12,000 men. Jackson moved from Frederick on the morning of 10 September, crossed South Mountain and the Potomac, and, driving everything before him, bivouacked on the 13th near Bolivar Heights. Walker crossed the Potomac south of Harper's Ferry and seized Loudoun Heights. McLaw's, with 10 brigades, marched from Frederick late on the 16th, camped that night near Brownsville Gap, crossed Blue Ridge Gap the next day, and on the 12th crossed Pleasant Valley, ascended Maryland Heights, with Kershaw's and Barksdale's brigades at Solomon's Gap, five miles north of Harper's Ferry, drove in some skirmishers and, marching southward on the crest of the mountain, was checked near nightfall by Ford's men behind a barricade of logs. In the morning of the 13th he renewed his attack, which was stoutly resisted by Ford's men, who meanwhile had been reinforced by troops from Harper's Ferry. The Union troops were finally driven from the heights into Harper's Ferry, abandoning four guns, and at 4.30 P.M. McLaw's was in complete possession, and put guns in position commanding Harper's Ferry, whose garrison surrendered on the 15th. The Union loss at Maryland Heights was about 150 killed and wounded; the Confederate loss was 35 killed and 178 wounded. After Lee had been driven across the Potomac the heights were occupied 20 September by troops of the 12th corps. The position was strongly fortified, and when, 15 June 1863, Milroy was defeated and driven from Winchester, General French moved his garrison from Harper's Ferry to the heights. Under General Meade's order French abandoned the position and distributed his troops at Frederick and on the line of the Baltimore and Ohio Railroad. When Lee was defeated at Gettysburg the heights were reoccupied 7 July, by the Union forces and continued in their possession until the close of the war. On 2 July 1864 General Early reached Winchester on his way to menace Washington. General Sigel, who was commanding the Union forces in and around Martinsburg, abandoned his position the night of the 3d, crossed the Potomac at Shepherdstown, and on the 5th established himself on Maryland Heights, with six regiments of infantry, 2,500 dismounted cavalry, two batteries of heavy artillery and 26 field-guns, while General Stahl was at Weverton and in Pleasant Valley, with 1,200 to 1,500 cavalry and four guns. Early followed Sigel across the river at Shepherdstown Ford, drove Stahl back and confined Sigel within his works; a heavy cannonade was kept up all night of the 6th, and there was sharp fighting next day, but no impression, and unable to maneuver Sigel out of his position, Early drew off and crossed the South Mountain toward Frederick.

E. A. CARMAN.

MARYLAND HISTORICAL SOCIETY. The, was first proposed as a project by John H. B. Latrobe in 1835, and was organized in his law office on 27 Jan. 1836, through the zeal and execution* of Brantz Mayer. It was incorporated in 1845, and, joining with the Baltimore Library Company, a proprietary library founded in 1796, solicited gifts for a building to be called the Athenaeum, a solicitation so successful that the organizations removed to permanent quarters therein on 23 Oct. 1848. In 1852 the Baltimore Library Company disbanded, giving its books and its share in the building to the Society. The Mercantile Library Company occupied a part of the Athenaeum on a lease from the beginning until about 1880. In 1916 Mrs. H. Irvine Keyser gave the Society, as a memorial to her husband, the former residence of the late Enoch Pratt, at the corner of Monument and Park streets in Baltimore, and erected on the rear of the lot a fireproof library and art gallery. The buildings were opened with suitable exercises 18 Feb. 1919. The Society has about 800 members. Its presidents have been Gen. John Spear Smith, 1844 to 1866; Col. Brantz Mayer, 1866 to 1871; John H. B. Latrobe, Esq., 1871 to 1891; Severn Teackle Wallis, Esq., 1892 to 1894; Rev. John G. Morris, D.D., 1895; Albert Ritchie, Esq., 1896 to 1904; Mendes Cohen, Esq., 1905 to 1914, and Hon. Edwin Warfield, 1914 to the present. The Society possesses a valuable collection of books and manuscripts, including the Calvert Papers, purchased from a descendant of the last Lord Baltimore. It has published a series of publications from a fund given by George Peabody, and now prints the quarterly Maryland Historical Magazine. As far as known for the State it has published or arranged the printing of 38 volumes of Maryland archives, dealing with the Provincial and Revolutionary periods of the State's history, most of which volumes were edited by the late Dr. William Hand Browne.

MARYLAND YELLOWTHROAT, one of the most familiar of North American warblers (Geothlypis trichas). It is about 5.5 inches
MARYLEBONE—MASACCIO

in length, migratory, makes a neatly concealed nest on the ground, almost always in a swamp or near a stream, and lays pink-white eggs delicately dotted with red. The plumage is bright yellow; the body is brown; the tail is dark. A small, dark olive-greens; under parts nearly white; and a characteristic jet-black mask across the face and on the sides of the head. The summer cry is a sharp questioning "Where's he gone? Where's he gone?" The genus contains several related and similar species, but the Kentucky warbler (Opornis gracilis) is no longer included.

MARYLEBONE, mə'rɪ-lə-bound or mər'li-bən, a metropolitan borough of London, England, in the northwest quarter. It contains the Coliseum, Middlesex Hospital, University College, Bedford College, Regent's Park and several railway terminals. Among its famous residents have been Edward Gibbon, Michael Faraday, Charles Dickens and Turner. Its population is 117,184. See London.

MARYSVILLE, mə-riz-əl, Cal., city, county seat of Yuba County, at the junction of the Yuba and Feather rivers and on the Northern Electric, the Southern Pacific and Western Pacific railroads, 52 miles by rail north of Sacramento.

Charles Covilland, a Frenchman, founded Marysville in 1849, after the discovery of gold in California. A trading-post named Mecklenburg had been established some years before. Covilland called the place Yubaville, which name it retained until 1850, when Marysville was adopted, and the following year it was chartered as a city. Its location at the head of navigation and proximity to valuable mines contributed to its growth, so that in 1860 it was the third city in size in the State. Since 1865 it has declined in importance and population. The chief manufactures are cars, and care for fruits, olive oil, flour, cigars, woolen goods and foundry products. It has considerable trade in the products of the surrounding farms, especially in grains, fruits, olives, rice, prunes, raisins, sheep, wool and cattle. The mines of the vicinity contribute to its industrial wealth. The city is the seat of the College of Notre Dame (Roman Catholic) for women, public and parish high schools, and it has a fine public library. The city hall and courthouse are handsome, well-built edifices. Levees costing $2,000,000 protect it from floods which occur periodically. Pop. 5,430.

MARYSVILLE, Kan., city, county-seat of Marshall County, on the Big Blue River, and on the Union Pacific, the Saint Joseph and Grand Island and the Topeka and Northwestern railroads, about 80 miles in direct line northwest of Topeka. The manufactures are flour, cigaars, furniture, foundry and machine-shop products. The city has the largest cigar factory in the State, considerable trade in wheat, corn, fruit and livestock. Pop. 2,266.

MARYSVILLE, Ohio, village, county-seat of Union County, on Mill Creek, and on the Cleveland, Cincinnati, Chicago and Saint Louis and the Toledo and Ohio Central railroads, about 30 miles northwest of Columbus. It is situated in an agricultural, livestock and dairy region, in which the farm products are mostly wheat, corn and oats; dairying and sheep. The chief manufactures are dairy products, wagons, carriages, cooperage products, lumber, plumber's supplies, brass stamping, silos, cigars, evaporated milk, etc. Among the important buildings are the State Reformatory for Women, State Armory and Carnegie Public Library. Pop. 3,576.

MARYVILLE, Mo., city, county-seat of Nodaway County, on the Omaha and Saint Louis line of the Wabash, and Creston and Saint Joseph line of the Burlington railroads, 46 miles north of Saint Joseph and 90 miles southeast of Omaha. It is in a rich agricultural region and is an important centre for the raising of fine livestock. The chief manufactures are cigars, lighting-rods, acetylene, generators, harness, cement blocks, work garments, sheet metal products. It is in an important banking and retail trading centre. There are two daily and two weekly newspapers. It is the home of the Fifth District State Normal School and the Maryville Business Club. There is a well-equipped Catholic hospital. Other important buildings are post office, high school, courthouse and seven churches. Pop. 6,720.

MARYVILLE, Tenn., village, county-seat of Blount County, on the Knoxville and Arkansas Railroad, about 16 miles south of Knoxville. It was settled as early as 1795. It is in an agricultural and stock-raising region and near valuable marble quarries. Coal is found in the vicinity. The chief manufactures are flour, lumber, woolen goods and dairy products. It is the seat of the Maryville College (Presbyterian), founded in 1819; the Freedmen's Normal Institute (Friends); and a normal school. Maryville has a fine courthouse and some good church buildings. The Aluminum Company of America has located one of its plants here and employs several hundred men. The present population is about 7,500.

MARYVILLE COLLEGE, an institution in Maryville, Tenn., founded in 1819 under the auspices of the Presbyterian Church. The school is coeducational, and in 1913 had over $900,000 property and endowment, 55 instructors, 771 students and about 15,000 volumes in the library. It has a four-year preparatory department and the college course leads to the degree of A.B.

MARZIALS, Théophile, or Theophilus, English musician; b. Brussels, Belgium, 21 Dec. 1850. He was a pupil of music at London of M. L. Lawson and studied also at Paris and Milan. From 1870 he was employed in the British Museum, where he became superintendent of the department of music. He is best known as a vocal composer ('Twickenham Ferry'; 'Three Sailor Boys'; 'Wait till you Come to Forty Years'; 'Ask Nothing More'); and he also published 'A Gallery of Pigeons and Other Poems; 'Pan Pipes' (1904), etc.

MASACCIO, mā-sāch'ō, Tommaso, properly Guidi, gwe'de. Italian painter; b. San Giovanni, Tuscany, 24 Dec. 1402; d. Rome, about 1428. He went while very young to Rome, where he painted in the church of Saint Clemente a series of frescoes, the finest of which represents Saint Catherine and the doctors before Maxentius. In 1421 he was admitted into the guild of the Spinario. After the works of Masaccio are the frescoes in the Brancacci Chapel of the Carmine, the 'Expulsion from Paradise'; 'Saint Peter's Sermon';
the 'Tribute'; 'Saint Peter Baptizing'; and the 'Raising of the King's Son', the last of which was partly painted by Filipino. Consult Masaryk, Masaccio et le Florentinisme malerikons (Copenhagen 1875); Delaborde, Les œuvres et la manière de Masaccio (Paris 1876); Schmarsow, Masaccio Studien (Cassel 1895).

MASAI, mā-sē, an East African race, speaking the Hamitic language and occupying the Lake district. The Masais are men of large stature and magnificent physique. They are a warlike people and live mostly in military kraals, eating nothing but beef and drinking nothing but milk. The labor is done by slaves, women and children. They are to a certain degree nomadic, live in huts constructed of boughs and enclose their villages with huge horn fences. Because of the climate they are better clothed than tribes of the warmer regions. Consult Hollis, A. C., 'The Masai: Their Language and Folklore' (Oxford 1908); Merker, M., 'Die Masai' (2d ed., Berlin 1910); Thomson, Through Masai Land (London 1885).

MASAMPO, Korea (Chosen) treaty port on the south coast opened to foreign trade 1 May 1899. It has a good harbor, with steamer connection with Fusan. Since the advent of the Japanese a naval station has been constructed and a Japanese city is being erected. The commercial growth of Fusan has eclipsed somewhat that of Masampo, which, nevertheless, is forging ahead as the leading commercial and industrial centre of southern Korea. Pop. about 35,000.

MASANIELLO, mà-sā-nē'ē-lō', the commonly received name of Tommaso Angello, Italian revolutionist; b. Amalfi, 1623; d. Naples, 16 July 1647. He was a fisherman at Sorrento, and in 1647 roused and led an insurrection against the Spanish viceroy, the Duke of Arcos. He was successful and obtained the abolition of unjust taxes and the revocation of an order to establish the Inquisition at Naples. The fruit taxes were abolished and the old civic rights restored. But the people soon rose against him, too, and he was assassinated. An opera, music by Auber, libretto by Scribe and Dorival, based on history, was presented in 1828 in Paris as 'La Moette di Portici,' and in 1829 in England in English as 'Masaniello.' Consult Saavedra, 'La insurrección de Napoli en 1647' (Madrid 1849).

MASARYK, Thomas (Tomáš) Garrigue, author and first president of the Czech-Slovak Republic; b. Göding, Moravia, 7 March 1850. A Slovak by race and the son of poor parents, young Masaryk was apprenticed to a blacksmith after receiving an elementary education. He soon forsorked the stilly and studied philosophy at Vienna and Leipzig. Appointed lecturer on logic at Vienna in 1879, he made his mark by a study on 'Suicide' as a pathological symptom of the condition of contemporary Europe, attributing its chief cause to the decline of religious sentiment. He became professor of philosophy in 1882 at the new Czech University in Prague, where he remained for thirty-five years. Meanwhile, he became an interpreter of modern political and social tendencies to a growing body of students drawn from all branches of the Slav family. Commenting on the movement for reunion and reconciliation among the Serbs and Croats al-ready in 1909, Hermann Bahr (q.v.) wrote: "So strong has been the influence of the lonely Slovak at Prague that his pupils had "inspired their shattered dreams with belief in the future." Elected to the Austrian Parliament in 1891, Masaryk boldly criticized the bureaucratic policy of Austria in Bosnia-Herzegovina and resigned his seat in 1893 as a protest against the negative policy of Czech Nationalists. For a number of years he edited Athenaum, which he founded in 1883, and later Nashe DoBo (Our Epoch), dealing with religious criticism and Church history. He exposed as modern forgeries two manuscripts (of Grunenberg and Königshof) which had long been treasured as national heirlooms. While later, in a famous 'blood ritual' trial, he demonstrated the absurdity of the ritual murder charge brought against a Jew. Professor Masaryk married an American and as a political economist is well known in the United States through his lectures at the University of Chicago and other American institutions. He himself has been strongly influenced by the teachings of Comte, Spencer, Tolstoy and Dostoyevsky. His works were mostly written in German, but subsequently in Czech. He has published 'Ueber den Hypnotismus' (Vienna 1881); 'Der Selbstmord als Soziale Massenerscheinung der modernen Zivilisation,' the most important of his works (Leipzig 1887); 'Ueber das Studium der Dichter Werke' (2 vols., Leipzig 1884-86); 'Grundzüge einer konkreten Logik' (1885); 'Unsere heutige Krisis' (1893); 'Die Moderne Evolutionen—Philosophie' (1896); 'La Question bohémienne' (1895); 'Die philosophische und sozialistische Grundlagen des Marxismus' (Vienna 1898); 'Die Stellungnahme der Sozialistenpartei zur Ethik' (1896); 'Ideale der Humität' (1902); 'Intelligenz und Religion' (1907); 'Freie wissenschaftliche und kirchlich gebundene Weltanschauung' (Vienna 1908); 'Russland und Europa: Soziale Skizze' (1913).

Among these historical and philosophical writings, his powerful criticism of Marxist Socialism and the great work on 'Russia and Europe' stand foremost. He rendered great service in his 'Notes toward a Peace' which he wrote in 1915 and published in the form of a book in 1918. He was a leading figure in the Czech literature in Bohemia, where his influence also permeated the entire younger generation, as it did among the Southern Slavs and among the Ruthenes. In 1907 he was re-elected to the Austrian Parliament. During the Friedjung trial in 1909 (see AUSTRIA-HUNGARY AND THE WAR, Vol. II, p. 637) he helped to expose the forgeries upon which Count Aehrenthal based his annexation of Bosnia and Herzegovina. When the European War broke out he remained in Prague till December 1914, when he went to Italy to avoid the risk of being interned in Russia in time to avoid arrest. He then became lecturer in the School of Slavonic Studies at the University of London. On 6 Dec. 1916 the Austrian Clerical organ, Reichpost, announced that Professor Masaryk had been sentenced to death in contumacia for high treason. Meanwhile, the 'World' had rapidly gained wide recognition among the Allies as the leader of the national struggle for Czech-Slovak independence. Together with Dr. Benes and Colonel Stefanik, he formed the triumvirate which was ultimately
recognized by the Allied governments as the trustee for the future government of Bohemia. In 1917 Professor Masaryk was called to Russia by Professor Miluykov, but soon realized the hopelessness of the Russian situation and devoted strenuous efforts to organize the Czecho-Slovak army. He preceded this force to Vladivostok and went on to Tokio and Washington. He had several audiences of President Wilson and addressed many public meetings. The republic of Czechoslovakia was recognized by Great Britain on 3 Aug. 1918; by the United States on 2 Sept. 1918 by Japan 9 Sept. 1918 and by Italy on 23 April 1918. The Declaration of Independence was formally published in Paris on 18 Oct. 1918 and the republic was formally proclaimed at Prague on 29 October. The Constitution was drafted in Geneva by 2 Nov. 1918, when the government was chosen. On 21 Dec. 1918 President Masaryk made a triumphal entry into Prague and then took oath to the new republic. In his first message to the members of the National Assembly delivered on 26 Dec. 1918 in the presence of representatives of the Allied governments, the President sketched the policies and the aims of the two opposing groups of the great conflict and expressed the "gratitude and unshakable fidelity" of the republic toward the Allies. See CZECH-SLOVAKS; SLAVS; WARS, EUROPEAN.

MASAYA, má-stā, Nicaragua, town, in the western part, about 12 miles north of Lake Nicaragua and near Masaya volcano, which is 3,000 feet in height. The town is connected by railroad with the cities of Leon, Managua and Granada. Masaya is situated in an agricultural region, of which tobacco is one of the principal productions. Coffee, sugar and rice are also grown in the vicinity. The inhabitants are mostly Indians. Pop. 13,000.

MASBATE, mās-bātā, Philippines, an island of the Philippines in the eastern part of the Visayan Sea, south of Luzon and north-west of Samar; greatest length, 82 miles north-west to southeast; width, 45 miles; area, 1,236 square miles. It is very mountainous, the central chain being semi-circular in shape, extending from southwest to southeast, and there are several rivers of considerable size. Communication between towns and villages is mostly by water, as there are few roads or even trails. The staple products are sugar cane, cotton, chocolate and hemp; tobacco of a strong quality is also raised. One of the chief industries is that of stock-raising (cattle, horses and hogs); over 1,000 head of cattle are ordinarily shipped monthly to other parts of the Philippines, mostly to Manila. This industry has been menaced in recent years by the rinderpest. Other important industries are the manufacture of sugar sacks from the buri palm, the manufacture of palm mats of superior workmanship and coloring, weaving, lumbering and fishing; there is also an active trade with Manila. In March 1901 the island was united with Ticao (140 square miles), Burias (258 square miles) and the small adjacent islands, to form the province of Masbate; area of the whole province 1,732 square miles. Civil government established in 1901. The inhabitants are nearly all Visayans, but there are over 2,000 Bicolos and about 580 Tagalogs. Pop. of province 43,000; Masbate and Ticao (q.v.) 30,000.

MAFATE, Philippines, a pueblo and the capital of Mafate province, situated in the northeastern part of the island of Mafate on a peninsula dividing Palanog Port from Mobó Bay. It is a port of entry, and has a considerable trade. It has a church, a school and some well-constructed buildings. Pop. 2,900.

MASCAGNI, Pietro, pě-pā-trō mās-kān'ë, Italian composer; b. Levoire, Tuscany, 7 Dec. 1863. He was educated at the Milan Conservatoire and in 1890 his opera 'Cavalleria Rusticana' brought him immediate recognition in the musical world. From 1895 to 1903 he was director of the Rossini Lyceum at Pesaro. His songs and ballads are popular and his successful career as a composer has been further aided by his operas 'L'Amico Fritz' (1891); 'Les Rantzau' (1893); 'Iris' (1898); 'Le Maschere' (1901); 'Amica' (1905); 'Isobel' (1911); 'Parisa' (1913); 'T'Alodorettia' (1915), etc. In 1902 he visited the United States on an operatic tour. Consult Bastianelli, G., 'Pietro Mascagni' (Naples 1910); and Pompei, E., 'Mascagni nella vita e nel arte' (Rome 1912).

MASCAGNITE, mās-kān'ë-tē, or MASCAGNINE, a native sulphate of ammonium, occurring notably at Sasso in Tuscany, where it was discovered by Mascagni, from whom it was named.

MASCARA, Algeria, fortified town and capital of an arrondissement in the province of Oran, 45 miles southeast of the city of that name, at the base of the Little Atlas Range. The town stands on the site of a Roman colony, is surrounded by walls, but has few ancient remains. It is purely of the French colonial type. For two centuries down to 1800 it was the capital of a Turkish beylik; in 1832 it became the capital of Abd-el-Kader; in 1833 it was ravaged by the French, but was reoccupied by Abd-el-Kader in 1838 only to fall finally to the French in 1841. Wine, cereals and oil are the principal items of trade. Pop. 24,250.

MASCARENE (mās-kā-rēn') ISLANDS, a collective name for the islands of Bourbon, Mauritius and Rodrigues, named after Mascarenhas, a Portuguese navigator, who discovered Bourbon in 1545.

MASCARON, Jules, French preacher; b. Marseilles, 1634; d. Agen, 1703. He became a member of the Congregation of the Oratory and soon established a great reputation as a preacher in the provincial cities. He preached at court in 1666 and thereafter he was a favorite of Louis XIV. Mascaron was consecrated bishop of Tulle in 1671 and eight years later was translated to the more important diocese of Agen. He still continued to preach at court and in 1675 delivered his last sermon at the funeral of Marshal Turenne. His principal sermons were edited by a member of the congregation, Father Borde, in 1704. Consult 'OEuvres de Mascaron' (Paris 1828).

MASCART, Eleuthère Rée Nicolas, French physicist; b. Quaraubole, Nord, 1837; d. 1908. He received his education at the Ecole Normale Supérieure and in 1872 became professor at the Collège de France. From 1878 to 1907 he was director of the Government Central
MASCHERONIANA — MASCOTS AND HOODOOS

Meteorological Bureau. He was also member of the International Bureau of Weights and Measures, and elected a corresponding member of the Academy of Sciences in 1884 and became its president in 1904. He was made commander of the Legion of Honor in 1889. Mascart's investigations were mainly confined to spectroscopy, electricity and terrestrial magnetism. He published 'Éléments de physique' (1869); 'Traité d'électricité statique' (1876); 'Leçons sur l'électricité et le magnétisme,' with Joubert (1882); 'Méthode de mesures et applications' (1882); 'Traité d'optique' (1889); 'Traité de magnétisme terrestre' (1890).

MASCHERONIANA. The 'Mascheronian' of Vincenzo Monti (1754-1826) is an unfinished epic "vision" in five cantos of terza rima. It represents the third of four periods into which Monti's intellectual and artistic life may be divided. The first is the period of the Arcadian lyrics and the tragedies; the second that of the 'Bessivianna' (1793), a diatribe against the French Terror; the third, that of the Napoleonic poems, the 'Prometeo' (1797), the 'Mascheronian' (1801) and the 'Bard of the Black Forest' (1806); the fourth (1815-19) that of the 'Austrian' poems, the 'Mystic May', 'La Fille d'Agamemnon', and 'Astrea', the 'O'Invitation to Pallas', the classic translations and the critical works.

Monti's permanent and most interesting distinction is that, as a man thoroughly penetrated with the cult and mental traits of the Old Régime, he lived through the Revolutionary period without understanding any aspect of it. In the course of his life he assumed with equal sincerity the position of each dominant party. He assailed the Revolution and then accepted it. He hailed Napoleon the liberator, and then Napoleon the despot. Italians like to find in all these gyrations a thread of consistency: the concept of resurrected Italy. Unfortunately, however, Monti also embraced and sang the Austrian restoration.

Ancestral qualities, say moral perversity, has its counterpart in Monti's poetry. He is fundamentally an Arcadian, who vaguely perceives the emotions and the character of a new age, without visualizing them clearly as an artist and with an underlying propitious formal expression. In a sense this makes his poems extremely interesting; for wholly in the Arcadian manner, they are admirably calculated to show the limitations of that manner. The 'Mascheroniana', which owes its popularity in Italy to its nationalistic spirit, aims to project the miserable Italy of the revolution upon the great Italy of the past and a greater Italy of the future, of which to be sure Napoleon is to be the artisan. Here is a trite theme but one of potentiality. Monti, however, being Monti, transports it into the Arcadian world, a world by itself, apart from, perhaps superior to, any real world. It becomes "literature" through "plot" and "form." As regards plot, Monti invents a vision of the papal city, a vision of the goddess, a vision of the goddess in the guise of one woman or another, and modern civilization has not destroyed this cult. The belief in the mask for luck, or the hoodoo for ill-luck, is an indication of weakness and lack of decision. In the 'Iliad,' when Hector is told that the birds are against him, the ill-fated, unlucky, the Trojan hero makes answer:
"Without a bird his sword the true man draws; and asks no omen but his country's cause." See also Owen; Superstition.

MASCOUTEN, a belligerent tribe of Algonquians, the French Nation du Feu, "Fire Nation," dwelling along the Illinois River. They were at constant warfare with their neighbors, and are first mentioned by the earliest French missionaries as inhabiting southern Michigan. According to the tradition of the Ojibwas and Ottawas, they had been driven by the latter from the region around modern Mackinaw. In 1712, united with the Foxes and Kickapoo, they were almost exterminated, first by the French and afterward by the Pottawatomis and their allies. The remnants migrated westward and are last mentioned in 1779 as living with the Piankishaws and Kickapoo on the Wabash River. The name is derived from Mashkodainsug, little prairie people, a title now borne by a tribe of Pottawatomis Indians resident in Kansas.

MASEFIELD, John, English poet and dramatist: b. 1875. In his youth he shipped before the mast on the Conway, in which he made several voyages. For a time also he was engaged as a farm laborer and in the 90's spent a short time as attendant in a Sixth avenue saloon in New York. These early experiences he later turned to account in his literary work. After his wanderings Masefield settled near London and became a regular contributor of prose and verse to the periodicals of the metropolis. He was awarded the Edmond de Polignac prize for poetry in 1912 by the Royal Society of Literature. Masefield won literary fame mainly through his sea ballads and the narrative poems, 'The Everlasting Mercy' and 'The Widow in the Bye Street.' His verse is intensely realistic, full of pathos, although the verse form is often crude. His stories for boys represent his best efforts in prose and are reminiscent of Marryat at his best. His plays lack technique and are little suited to stage presentation, but give evidence of growing power. His works, in addition to the already mentioned, are 'Salt Water Ballads' (1902); 'A Mainsail Haul' (1905; 1913); 'A Tarpaulin Master'; 'Ballads'; 'Captain Margaret'; 'The Tragedy of Nan and other Plays' (1910); 'The Tragedy of Pompey the Great' (1910); 'Multitude and Solitude'; 'The Street of To-day'; 'Poems and Ballads'; 'William Shakespeare'; 'Dauber'; 'The Daffodil Fields'; 'Philip the King' (1914); 'Personal Recollections of John M. Synge'; 'The Faithful'; 'Sonnets and Poems'; 'The Locked Chest'; 'The Sweeps of Ninety-Eight'; 'Good Friday'; 'Gallahpoli'; 'Lollingdon Downs,' etc. Masefield edited 'The Voyages of Captain William Dampier' (1905); and wrote introductions to 'Hakluyt's Voyages,' 'The Travels of Marco Polo,' etc. The following plays have been produced: 'The Campden Wonder'; 'Nan'; 'Pompey the Great'; 'Sweeps of Ninety-Eight'; 'Philip the King'; 'The Faithful'; 'Mrs. Harrison'; 'Good Friday.'

MAESTA, Abigail Hill, Lady, confidante and favourite of Queen Anne of England: b. London, 1670; d. 6 Dec. 1734. A cousin of Sarah Jennings, Duchess of Marlborough, and also related to Robert Harley, Earl of Oxford, she passed from the service of Lady Rivers, thanks to the influence of the Duchess of Marlborough, into that of Queen Anne, in whose favor she soon displaced her cousin, made a baroness, and was permitted to turn the queen from the Marlboroughs and Whigerry to Toryism and even Jacobitism. She was married to Samuel Masham in 1707; had him made a baron in 1712; brought him kinsman Oxford into power, but soon turned him out; and, in short, was the power behind the throne, succeeding her cousin Marlborough. She retired after Queen Anne's death. She was a fine, homely, red-nosed woman, much berayed by Swift and accused of vulgarity, meanness and covetousness by the Whigs. See Anne, Queen of England.

MASHAM, Samuel Cunliffe Lister, 1st Baron, English inventor: b. Calverley Hall, near Bradford, 1 Jan. 1815; d. Swinton Park, York, 2 Feb. 1906. In 1838 his father started Samuel and his brother John as worsted manufacturers in a mill at Manningham. About 1845 he invented a wool-combing machine which revolutionized the textile processes and made the inventor wealthy. He secured a profit of £5,000 on every machine sold. From 1855 to 1860 he spent huge sums in perfecting a silk-combing machine and at one time was perilously near bankruptcy. The machine was brought out in 1864 and enabled him to produce valuable yarn from the hitherto useless silk waste. Masham also perfected a velvet loom for pile fabrics, and after 1878 his income from his inventions exceeded £1,000,000 annually. He opposed free-trade because the American protective tariff seriously limited his business. He was created 1st Baron Masham in 1891. He wrote 'Lord Masham's Inventions' (1905).

MASHKODAINSUG. See Mascouten.

MAISONLAND, ma-sho'n-a-land, South Africa, a province forming the northeastern portion of South Rhodesia, between the Zambezi and Matabeleland. It consists largely of open plains and table-lands, is well watered by the Umniate and other rivers of the Zambezi and is very fertile. The Mashonals belong to the Kaffir race and were formerly masters of the whole territory between the Limpopo and the Zambezi, but were coerced within their present territory by the powerful Matahele, whom they were unable successfully to resist. They are a peaceful people, clever as smiths and as weavers of cotton fabrics. The country came under the management of the British South Africa Company in 1890. It is rich in gold, which has been mined here at some remote and unknown period, old workings being still visible, and Mashonaland is with some degree of probability identified with the biblical Land of Ophir. Salisbury is the chief town. The population of Mashonaland is estimated at 12,000 whites and 495,450 natives. Other towns are Hartley, Garumna, Umtali and Victoria. Salisbury is connected with Beira, Portuguese East Africa, by a railroad. From Salisbury north another railroad extends 580 miles through Bululwayo to the Victoria Falls, where is a new bridge over the Zambezi. This road is a section of the Cape to Cairo Railway. For the antiquities, anthropology, history, etc., of Mashonaland, consult Bent, J. T., 'Ruined Cities of Mashonaland' (London 1892); Hall, R. N., 'Prehistoric Rhodesia' (Chicago 1910); etc., 'Great Zimbabwe' (London 1903); Darter, A., 'Pioneers of Ma-
shonaland’ (ib. 1914); Randall-MacIver, D., ‘Medieval Rhodesia’ (ib. 1906); Selous, F. C., ‘Travel and Adventure in South-East Africa’ (London 1893); Waal, D. C., ‘With Rhodes in Mashonaland’ (Cape Town 1896).

MASHPEE, a New England Indian group, originally located in Barnstable County, Mass. They were placed on a reservation as early as 1660. At present there are about 200 individuals of pure Indian descent and many more of mixed negro, white and Indian blood.

MASINISSA, mās-i-nész’s, or MASSINIASSA, king of Numidia: b. 238 a.c.; d. 148 a.c. He was at first ruler only of the east portion of the country, but latterly of the whole, having, by the help of the Romans during the Second Punic War, defeated Syphax, king of Western Numidia, taking him prisoner with his wife, Sophonisba, whose hand had formerly been promised to Masinissa. Masinissa now made her his wife, but Scipio Africanus, fearing of her influence, claimed her as a prisoner of Rome. Unable to resist, Masinissa sent her a poisoned chalice, of which she voluntarily drank. Masinissa commanded the Roman cavalry at the battle of Zama, which ended the Second Punic War (201 a.c.). As a reward the Romans gave him the territory formerly held by Syphax. In peace he proved himself an efficient administrator and did much to civilize his people. His army and fleet, and the large proportions he made raids into Carthaginian territory. In 150 a.c. Carthage made war on him, but with the Romans as his allies, Carthage fell to rise no more.

MASK, a covering for the face, often shaped so as to form a rude representation of human or animal features. They have been in use from the most ancient times. Among the Greeks they were used, particularly in the processions and ceremonies attending the orgies of Dionysus. Some of the ancient masks seem to have been, like the modern ones, merely coverings for the face, but it was more usual for them to cover the whole head, and represent, with the features, the head, hair and eyes. They were at first made of the bark of trees, then of leather, after which came wood which the artist fashioned according to the design of the poet. The comic masks were distinguished by a grotesque, laughing countenance; the tragic ones had more dignity, but were sometimes frightful. There were also satyr masks and orchestrical, or those with regular features, for dancers. They had mostly very large open mouths, within which were metallic bars or other sounding bodies to strengthen the voice of the speaker—a contrivance which was required by the construction of the old theatres. The mask used at modern masked balls or masque-rades is a covering for the head and face made from a light stuff, with which a person may disguise himself and remain unknown, or perhaps represent some other character. There were whole and half masks—for example, masks for the nose and the eyes. A death mask is one of plaster made of the face after death. See also CARNIVAL; MASQUE, and consult Dalí, ‘Masks, Labrets and Certain Aboriginal Customs’ (Washington 1885); Hart, C. H. (ed.), ‘Brouwer’s Life Masks of Great Americans’ (New York 1899); Fichorini, ‘Le maschere sceniche e le figure comiche d’antichi Romani’ (Rome 1736).

MASKEGON (swamp people), a remnant of a tribe of Indians, part of the old Algonquin stock, who formerly lived by hunting and fishing. They are now in the “swamp region” of Canada, between Hudson Bay and Lake Winnipesaukee, and are classed with the creoles and the blacks. To some extent they are now engaged in lumbering and a few do some farming. The estimated number of Maskegons is 2,000.

MASKELL, William, English theologian: b. Bath, about 1814; d. Penzance, 12 April 1850. In 1836 he was graduated at University College, Oxford, and in 1837 took holy orders. He was named rector of Corcombe, Dorset, in 1842. During his five-year incumbency he made researches in Anglican Church history, the results of which he embodied in ‘Ancient Liturgy of the Church of England’ (1844); ‘History of the Martinmas Evens’ (1845) and ‘Monumenta Ritualia Ecclesiae Anglicanae’ (1846). In 1847 Dr. Maskell was appointed vicar of Saint Mary’s, near Torquay, and domestic chaplain to the bishop of Exeter. About this time appeared his ‘Holy Baptism’ (1848) and ‘Enquiry into the Doctrine of the Church of England upon Absolution’ (1849). Maskell took part with his bishop in the Gorham controversy, and disagreed at the secession of the bishops and their attitude on the question of the sacramental grace of baptism, with Manning he went over to the Roman Catholic Church. In 1850 he issued two letters to the Privy Council on ‘The Present Position of the High Church Party.’ Other works by him are ‘Protestant Ritualists’ (1872) and ‘Ivories, Ancient and Mediaeval’ (1875). He never took orders in the Catholic Church but lived in retirement pursuing his historical researches.

MASKELYNE, māsk’lī-n, Nevil, English astronomer and mathematician: b. London, 6 Oct. 1732; d. Greenwich, 9 Feb. 1811. He was educated at Westminster School and Corpus Christi College, Cambridge; devoted himself to astronomy; and in 1765 was appointed astronomer royal and director of Greenwich Observatory. He made careful studies of terrestrial density, introduced into navigation the method of taking longitudes by lunar distances and made many improvements in astronomical apparatus. In 1767 he founded the Nautical Almanac. He wrote ‘British Mariner’s Guide’ (1763) and ‘Astronomical Observations’ (1765).

MASKINONGE, or MUSKELLUNGE, the giant pike (Esoc nobilar) belonging to the Esocide or pike family. It is found in the Saint Lawrence River, Lake Champlain, the Great Lakes and in the waters of western Canada. This fish is the largest of the pike family and, being predaeous, is not favored in most localities, as other fish soon disappear after its introduction. The name is applied to smaller but closely related species, of which the lake pickerel is one of the most common. The maskinonge reaches a length of from four to eight feet and a weight of from 40 to 100 pounds. It is caught with a hook and line, it is swift and strong and a redoubtable fighter; it is highly prized by anglers. Its color is a
dark gray, sides of a silver gray with black spots of unequal size and spotted fins.

MASÓ Y MARQUEZ, Bartolomé, Cuban politician. b. near Manzanillo, 1834; d. 1907. His education was received in France, and on his return to Cuba he became a planter, in which avocation he amassed considerable wealth. In the Ten Years’ War (1868-78), he espoused the patriot cause and became colonel in the Cuban patriot army. He was made supern-
tendent-general of the treasury and rendered efficient service under the Palma régime. He was imprisoned by the Spaniards after the war, but in 1883 returned to his plantation where he remained until the Insurrection of 1895. In September he became vice president of the insurrectionary government and two years later became its president. In 1901 he was considered again for the Presidency and opposed Palma. Masó y Marquez opposed the Platt Amendment as a denial of Cuban sovereignty and went before the electorate on this platform, but withdrew before the day of election because of alleged fraud in Palma’s campaign.

MASOCISM, a term used in analytic psychology to denote a tendency, usual in in-
sane, whereby the individual's drives are sublimated in later life, to take pleasure in having pain inflicted upon oneself. The term is derived from von Sacher-Masoch, an Aus-
trian novelist, in whose stories many of the main characters exhibited this trait in an ex-
cessive degree. A mild degree of masochism is evinced by many average men and women, particularly those who spend much of their time complaining about wrongs, injuries, pains, etc., suffered by themselves, the inference being that this masochistic mechanism drives them to be occupied mentally with pain and the de-
tails of its effect upon themselves. Many of the temperamental pessimists of the world af-
ford examples of an imperfectly sublimated masochism (see Sublimation), and if pre-
ponderating in the characterological make-up of the individual suggests a certain degree of
disease, which it would be most advisable for such persons to get rid of.

MASON, mă’son, Alfred Edward Wood-
ley, English novelist. b. 7 May 1865. He was educated at Oxford and among his works, the majority of which have been reprinted in the United States, are ‘A Romance of Wastdale’ (1895); ‘The Courtship of Morrice Bunkler’ (1896, dramatized 1897); ‘The Philanderers’ (1897); ‘Lawrence Clavering’ (1897); ‘Mi-
manda of the Balcony’ (1899, dramatized in New York 1901); ‘The Watchers’ (1899); ‘Clementina’ (1901); ‘The Four Feathers’ (1902); ‘The Truants’ (1904); ‘Running Water’ (1905); ‘The Broken Road’ (1907); ‘All the Wrong Roys’ (1910); ‘The Turnstile;’ (1912). His plays include ‘Colonel Smith’ (1909); ‘The Witness for the Defense’ (1911); ‘Open Windows’ (1913).

MASON, Charles, English astronomer and
surveyor. b. England, about 1730; d. Philadel-
phia, February 1787. He was for years asso-
ciated with the astronomer James Bradley, and was sent on various expeditions in the service of science. In 1763 he was employed with Jeremiah Dixon to survey the boundary line between Maryland and Pennsylvania and they were engaged in this undertaking until

1767, the line established becoming famous in American history as the "Mason and Dixon’s Line.” They returned to England and Mason was thereafter engaged in professional ob-
servations and researches until the time, the precise date of which is not known, when he returned to America. His work upon the lunar tables of Tobias Mayer which were published in London in 1787 under the title ‘Mayer’s Lunar Tables’ was a work by Charles Mason,’ enjoyed a high reputation for reliability. In 1850 many of his papers were acci-
dentially discovered at Halifax, N. S. Consult Bliss, Porter C. (in Historical Magazine July 1861).

MASON, Daniel Gregory, American com-
poser and writer on music. b. Brookline, Mass., 20 Nov. 1873. In 1895 he was graduated at Harvard University; he studied music in Bos-
ton, New York and Paris. He is assistant professor of music at Columbia University and is well known as a lecturer on music. His compositions include an elegy for piano (1901);
sonata for violin and piano (1912); pastorale for violin, clarinet and piano (1913); and
‘Country Pictures’ for piano (1913); quartet for piano and strings (1914); symphony (1915). He has published ‘The First and Gropam to Be’ (1902); ‘Beethoven and his Forerunners’ (1904); ‘The Romantic Composers’ (1906); ‘Students’ Guide to Music’ (1909); ‘A Neg-
lected Sense in Piano Playing’ (1912); ‘Music as an International Language’ (1913); ‘Guide to
Music’ (1914).

MASON, Francis, American missionary
and Orientalist. b. York, England, 2 April 1799; d. Rangoon, Burma, 3 March 1874. He was the son of a shoemaker; studied by himself; came to the United States in 1818; worked as a shoemaker through Massachusetts; prepared for the ministry at Newton Theological Seminary; joined the Baptist Church in 1825; and in 1827 was licensed to preach; sailed for Burma in 1830; and settled in Tavoy, where he worked for 22 years. He was a brilliant linguist; re-
duced two Karen dialects to writing; in 1853, upon his removal to Toungoo, published a Karen version of the Bible. He made special study of Pali literature and of physical and ethnic peculiarities of Burma, publishing in 1852 ‘Tenasserim, or the Fauna, Flora, Minerals and Nations of British Burma and Pegu’ (re-
vised 1860; 3d ed., 2 vols., by Thohald 1883). His other works include ‘Life of the Karen Apostle,’ a memoir of his wife (1847); ‘Mem-
oir of San Quan’ (1850); ‘Pali Grammar’ (1868); and ‘The Story of a Workingman’s Life, with Sketches of Travel,’ an autobiogra-
phy (1870).

MASON, George, American statesman. b. Stafford (now Fairfax) County, in the ‘Northern Neck’ of Virginia, 1725; d. 7 Oct. 1792. He spent his early life on a ‘plantation’ in the same region produced his two earliest collaborators, the cause of the American Revolution. Richard
Henry Lee and George Washington (q.v.). Mason seems to have been tutored at home, being grounded in a knowledge of the classics, both Latin and English. His younger brother, Thomas, was sent to London to study law at the Middle Temple. George Mason was married in 1750 to Ann Eilbeck, she died in 1773. Of this union there were several chil-
dren. He was married again in 1780 to Sarah
Brent. The family, after 1758, resided at "Gunston Hall," in Stafford County, a famous seat still standing on the banks of the Potomac. His energies were given to extensive planting interests.

As a member of the Ohio company, he was identified with his neighbor, Gen. Washington, in the initial stages of the French and Indian War, growing out of the concerns of that company. In 1759 he entered the Virginia house of burgesses, at the same time with Washington. He early protested against slavery. In 1765 he wrote: "The policy of encouraging the importation of free people and discouraging that of slaves has never been duly considered in this colony, or we should not at this day see one-half of our best lands in most parts of the country remain unsettled and the other cultivated with slaves; not to mention the ill effects such a practice has upon the morals and the manners of our people." He drafted the "Non-Importation Association," which George Washington presented in 1769 in Williamsburg, and the "Resolves" adopted at a general meeting of the freeholders of Fairfax County, 18 July 1774. These "Resolves" urged "that a Congress should be appointed to consist of deputies from all the colonies, to concert a general and uniform plan for the defense and preservation of our common rights; and "that during our present difficulties and distress, no slaves ought to be imported into any of the British colonies on this continent; and we take this opportunity of declaring our most earnest wishes, to see an entire stop forever put to such a wicked, cruel and unnatural trade." Sparks says of these Fairfax resolves that "they constitute one of the ablest and most luminous expositions of the points at issue between Great Britain and the colonies which are to be found among the public documents of that period. Embracing the great principles and facts, clothed in a nervous and appropriate style, they are equally marked with dignity, firmness, intelligence and wisdom." These "Resolves" served as the basis of the association formed by the Virginia Convention of August 1774 and that of the general Congress at its first session the following September.

He was a member of the Virginia Convention held in Richmond, July 1775, which took measures and arm the colony and appointed a committee of safety. He declined appointment in Congress as Virginia's representative in the seat made vacant by Washington's acceptance of the command of the American forces. The mind of Mason was dominant in the Virginia Convention of 1776, so creative in State and National policies. He was the author of the Virginia Declaration of Rights, adopted by the convention on 12 June 1776. (See Virginia Convention of the Revolution.) A copy of the first draft of this historic paper, in the handwriting of George Mason, is on loan from the Virginia State Library. At the foot of the manuscript the author added these words: "This Declaration of Rights was the first in America; it received few alterations or additions in the Virginia Convention (some of them for the better), and is imitated by the other United States." The small table upon which it is believed Mason wrote this "Declaration" is preserved at the Virginia Historical Society in Richmond.

Mason's chaste and concise statement of the fundamental principles of free government deserves to rank with the foremost political charters of the English-speaking world. James Madison styles him "the master-builder of the Constitution." His work on 12 June 1776, the natal day of the commonwealth.

Mason was a member of the Virginia assembly from 1776 to 1780, and from 1786 to 1788. He was one of the committee to revise the laws of Virginia, in accordance with the changed political conditions. The other members of this committee were Thomas Jefferson, Edmund Pendleton, George Wythe and Thomas Ludwell Lee. Mason again declined a seat in Congress, to which he was elected by the Virginia assembly on 22 May 1777.

Mason took an active part in the Constitutional Convention of 1787, reaching Philadelphia 17 May. He urged that the President be elected by Congress, and that he be ineligible for a second term; that the States should have equal representation in the Senate; that the Supreme Court should be Executive in the exercise of the veto power; that Congress be empowered to enact sumptuary laws; that no law in the nature of a Navigation Act be passed before the year 1808, without the consent of two-thirds of each of the Legislatures; and, finally, that Congress should be given the control of slavery. Madison reports Mason's speech in favor of giving Congress the control of slavery as follows: "This infernal traffic originated in the avarice of British government; the British government constantly checked the attempts of Virginia to put a stop to it. The present question concerns not the importing States alone, but the whole Union. . . . Slavery discourages arts and manufactures. The poor depise labor when performed by slaves. They prevent the emigration of whites, who really enrich and strengthen a country. They produce the most pernicious effect on manners. Every master of slaves is born a petty tyrant. They bring the judgment of heaven on a country. As nations cannot be rewarded for wickedness in the external world, they must be in this. By an inevitable chain of causes and effects, Providence punishes national sins by national calamities. He lamented that some of our eastern brethren had, from a lust of gain, embarked in this nefarious traffic. . . . He held it essential in every point of view, that the General Government should have power to prevent the increase of slavery." It was chiefly the failure to insert his views as to Congressional control of slavery and Navigation Acts which led Mason to reject the Constitution. Shortly before his death he told Thomas Jefferson that "the Constitution as agreed to for a fortnight before the Convention rose was such a one as he would have set his hand and heart to. . . . With respect to the improvements it is left to the States and Congress. This disturbed the two southernmost States who knew that Congress would immediately suppress the importation of slaves. Those two States, therefore, struck up a bargain with the three New England States, that if they would join to be joined in the convention, the two southernmost States would join in changing the clause which required two-thirds of the Legislature in any vote. It was done.
Under the coalition, the great principles of the Constitution were changed in the last days of the Convention. Such was Mason's own explanation of his refusal to sign the instrument in Philadelphia and for his stalwart opposition to its ratification in the Virginia Convention, which met at Richmond in 1788. Two years later he declined an appointment to a vacancy in the United States Senate. He died at 'Gunston Hall,' where he lies buried. Mason's statue forms one of the circle of the Revolutionary fathers surrounding the equestrian monument of Washington at Richmond.

Thomas Jefferson described George Mason as 'a man of the first order of wisdom among those who acted on the theatre of the Revolution, of expansive mind, profound judgment, cogent in argument, learned in the lore of our former Constitution, and earnest for the Republican change on Democratic principles. His eloquence was neither flowing nor smooth, but his language was strong, this manner most impressed by a dash of biting cynicism when provocation made it necessary.'

Consult Rowland, 'Life and Writings of George Mason' (2 vols., New York 1892).

MASON, James Murray, American legislator: b. Mason's Island, Fairfax County, Va., 3 Nov. 1798; d. near Alexandria, Va., 26 April 1871. He was graduated from the University of Pennsylvania in 1818, studied law and upon being admitted to the bar established a practice at Winchester, Va. He was in public office much of the time and in 1847 was elected to the United States Senate, representing Virginia, where he proved a consistent and strong adherent to the policies favored by his State. He was the author of the Fugitive Slave Law of 1850 and at the outbreak of the Civil War he resigned his seat in the Senate to enter the service of the Confederacy. He was sent to England with Slidell as Confederate commissioner, but was captured on the steamer Trent (see TREATY AFFAIR) and taken to Boston where he was confined in Fort Warren until 1862 when he sailed for Europe and the remainder of the war endeavored to secure recognition of the Confederacy. After the war Mason lived in Canada until 1868, being in fear of the Federal government, but returned to Virginia some years before his death.

MASON, Jeremiah, American lawyer and politician: b. Lebanon, Conn., 27 April 1768; d. Boston, 14 Oct. 1848. He was graduated at Yale in 1788, admitted to the bar in 1791, and began to practise law at Woonsocket, N. H. In 1794 he removed to Wallpole, N. H., and in 1797 settled at Portsmouth, where he lived for 35 years. At the New Hampshire bar, then the most famous in the country, Mason soon reached pre-eminence, among his fellow members being Daniel Webster and Jeremiah Smith. In 1802 Mason was appointed postmaster-general of New Hampshire and in 1813 became a United States senator. He was a strong Federalist and took a leading part in the senatorial debates on matters relating to the War of 1812, his speech on the Embargo, delivered in 1814, and that on the war, delivered in 1819, being notably among public utterances of the time. In 1817 he resigned his seat to resume his practice, but afterward served for several terms as a member of the New Hampshire legislature and rendered great assistance in the codification of the State laws. He removed to Boston in 1832 and practised in the courts until he reached 70, when he retired, with reputation fully maintained, to the more private work of his profession.

MASON, John, American colonist, founder of New Hampshire: b. King's Lynn, Norfolk, England, 1586; d. London, December 1635. In 1610 he served in the navy against insurgents in the Hebrides; in 1616 went as governor to Newfound-land, of which, in 1620, he published a description and in 1626 a map. In 1617 he explored the coast of New England; obtained in 1622 a grant of region called Mariana (northeastern Massachusetts) in the same year, with Sir Ferdinando Gorges, procured a patent for the province of Maine; and in 1623 sent a colony to the Piscataqua River. In 1629 he obtained a patent for the New Hampshire colony, also taking one with Gorges for Laconia, a tract including Lake Champlain. Among various prominent positions which Mason held in England was that of judge in Hampshire 1635, and in the same year was appointed vice-admiral of New England. In 1691 his rights in New England were sold to Gov. Samuel Allen. Mason was buried in Westminster Abbey. New Hampshire became a royal province 44 years after Mason's death.

Consult Tuttle, 'Memoir of Captain John Ma- son, the Founder of New Hampshire,' in an edition of Mason's description of Newfound-land (Boston 1889).

MASON, John, American colonial commander: b. in England, about 1600; d. Norwich, Conn., 1672. Under Sir Thomas Fairfax he served in the Netherlands; in 1630 settled at Dorchester, Mass.; in 1633 was appointed to a military command at Boston; and two years later joined with others in founding Windsor, Conn. In 1637 he was given command of an expedition of English and Indians against the Pequots (q.v.), whom he almost annihilated, completing their destruction in a second movement a little later. He removed first to Saybrook, and afterward to Norwich. For 30 years he was a major of the Connecticut forces, was a magistrate for many years and deputy gover- nor 1650-70. From 1642 to 1663 he was judge of the colonial court. His 'Brief His- tory of the Pequot War,' written at the request of the General Court, was reprinted by Increase Mather in his 'Relation of Trouble by the Indians' (1677, republished by Prince, Boston 1736). Consult Ellis, G. E., 'Life of John Mason of Connecticut' (in Sparks' 'Li- brary of American Biography,' Vol. XIII, Bos- ton 1864).

MASON, John Mitchell, American divine: b. New York, 19 March 1770; d. there, 26 Dec. 1829. His father was pastor of an Associate Reformed Church, and the son was graduated at Columbia College in 1798, and after studying theology under his father's care for one year went in 1791 to the University of Edinburgh. He was recalled in 1792 by intelligence of his father's death, and became his successor in his pastoral charge in 1793. He planned a theological seminary to be under the authority of his denomination, and visited Great Britain for the purpose of obtaining contributions; his pulpit efforts abroad gaining him repute there as one
of the first preachers of the time. The seminary being established in New York City in 1804, he was appointed its first professor of theology. In 1806 he projected the Christian's Magazine, which he conducted for several years, and in which he entered on a controversy with Bishop Hobart. In 1811 he assumed the presidency of Columbia College, and by his talents and energy raised that institution to a higher character than it had ever before possessed. In 1821 he exchanged his pastorate for the presidency of Dickinson College, Carlisle, Pa., and the next year entered the Presbyterian ministry. He was one of the great pulpits orators of his day and his discourses on the deaths of Washington (1800) and Hamilton (1804) are masterpieces of their kind. Consult the Life, by Van Vechten (New York 1856).

MASON, John Young, American politician: b. Greensville, Sussex County, Va., 18 April 1799; d. Paris, 3 Oct. 1859. He was educated at the University of North Carolina; was admitted to the bar in 1819; became a judge in State and Federal courts; served several terms in the Virginia assembly; and from 1831 to 1833 was a member of Congress. Then till 1844 he was judge of the United States court for the district of Virginia, and in that year became Secretary of the Navy in the Cabinet of President Tyler. Although he served temporarily as Attorney-General under Polk, he re-entered the Navy Department. President Pierce, in 1853, appointed him Minister to France, and until his death he continued to fill this diplomatic position. With James Buchanan and Pierce Soulé (q.v.) he signed the Ostend Manifesto (q.v.).

MASON, Sir Josiah, English pen manufacturer: b. Kidderminster, 23 Feb. 1795; d. 16 June 1881. He was the son of a carpenter-and-weaver and at an early age began to earn his livelihood by hawking cakes and fruits in the streets. At Kidderminster he successively tried his hand at shoemaking, baking, carpentering, smithing, painting, and weaving. In the midst of his avocations he taught himself to read and write. He removed to Birmingham in 1814 where he became a toymaker. He set up a shop of his own in 1824, turning out split key rings by machine and in which he burned; a controversy in this venture he added the manufacture of steel pens in 1829. In the latter branch of industry he became the largest producer in England. In 1874 he transferred his interest to a limited liability company. Mason was also interested in electro-plating, copper smelting and India rubber ring manufacture with George R. Elkington. In 1860 he established a great orphanage at Erdington, upon which he expended £1,500,000. He was knighted in 1872. Mason College, now part of the University of Birmingham, was founded by him with an endowment of £1,000,000. Consult Bunce, J. T., Sir Josiah Mason: A Biography (London 1882).

MASON, Lowell, American musician: b. Medfield, Norfolk County, Mass., 8 Jan. 1792; d. Orange, N. J., 11 Aug. 1872. His general education was small; in music he was self-instructed. As a boy, being choir leader in Medfield when 16, and a teacher in Savannah, where he removed in 1812. He came to Boston in 1827, was president of the Handel and Haydn Society there, and in 1832 founded the Boston Academy of Music. He visited Germany in 1837 in order to acquaint himself with improved methods in teaching music. In 1821 he published a collection of psalm tunes based on Gardner's 'Sacred Melodies', but composed in his own compositions. He is best known for his hymn tunes, notably Cowper 'There is a Fountain,' and missionary hymn 'From Greenland's Icy Mountains.' Mason's more important publications were: 'Juvenile Psalmist' (1829); 'Lyra Sacer' (1833); 'The Psaltery' (1834); 'Carmina Sacra' (1841); 'New Harries' (1852); 'Musical Letters from Abroad' (1853); 'Sabbath Hymn and Tune Book' (1859). Mason's musical library is now the property of Yale University.

MASON, Otis Tuton, American ethnologist: b. Eastport, Me., 10 April 1838; d. Washington, D. C., 5 Nov. 1908. He was graduated from Columbia University in 1861 and from 1861-84 was at the head of its preparatory school. From 1884-1908 he was curator of ethnology at the United States National Museum. He was a member of various scientific societies and published 'Cradles of the American Aborigines' (1883); 'From Primitive Culture' (1894); 'The Origin of Inventions' (1895); 'Indian Basketry' (2 vols., 1904). He was coeditor of the 'Standard Dictionary' and edited the anthropological department of the American Naturalist.

MASON, Rufus Ogden, American physician: b. Sullivan, N. H., 22 Jan. 1830; d. New York, 1903. He was graduated from Dartmouth College in 1854 and from the College of Physicians and Surgeons in New York in 1859. During the Civil War he was an acting assistant surgeon. He was almost as well known as an author as he was a physician and among his books are 'Sketches and Impressions, Musical, Theatrical and Social' (1876) and a History of the Philharmonic Society of New York' (1887); 'Telepathy and the Subliminal Self' (1897); 'Hypnotism and Suggestion in Therapeutics' (1901).

MASON, Stevens Thomson, American politician: b. Leesburg, Va., 27 Oct. 1811; d. New York City, 4 Jan. 1843. He was the son of Gen. John T. Mason of the noted Mason family of that State. He received his education at Transylvania University, Lexington, Ky., to which place his father had removed in 1814. On 12 July 1831, when not 20 years of age, he was appointed secretary and acting governor of the Territory of Michigan, a position he continued to occupy until 8 Sept. 1835. The death of George B. Porter, the territorial governor during his term, left Mason for several years the actual governor. Although vigorously opposed by the people of the Territory at the time of his appointment on account of his minority, his stand in the controversy with Ohio, known as the Toledo War, brought him such popularity that he was unanimously chosen governor by the people upon the adoption of the constitution by the State on 2 Nov. 1835, a position to which he was re-elected in November 1837. In 1840 he removed to New York City to take up the practice of law. On 4 June 1805, under the authority of the Michigan legislature, his remains were transported from New York.
and reinterred in Capitol Park, Detroit, the site of the first capitol of the State.

He is known in the history of Michigan as the "Boy Governor," as he was the youngest person ever elected to an important executive position in the history of the nation.

MASON, William, English poet: b. Hull, 12 Feb. 1724; d. York, 7 April 1797. He was educated at Cambridge and his first publication was "Lisla, a poem, satirizing the Jacobitism and High Church principles which prevailed in the University of Oxford." In 1762 he published "Elfride," a tragedy, with choral odes, on the ancient Greek model. Having taken orders in the Church he obtained the living of Aston, in Yorkshire, and was appointed one of the royal chaplains. In 1759 appeared "Caractacus," a drama. Some years after Mason was made precentor and residentiary canon at York. One of his principal works, the "English Garden," a poem, appeared between 1772 and 1782, and was translated into French and German. In 1775 he published the "Bible" (G. B.) with memoirs of his life. His principal subsequent publications are "Odes," "Life of William Whitehead," with his poems (1798); "Essay on Church Music" (1795). There is a tablet to his memory in the Poets' Corner, Westminster Abbey. In 1811 a complete edition of his works appeared.

MASON, William, American musician: b. Boston, 24 Jan. 1829; d. New York, 14 July 1908. He studied music in Germany under Moscheles, Hauptmann, Moritz, Dresyschoek and Liszty, made tours as a pianist in Europe and the United States. In the year 1854, with Theodore Thomas and others, he established the Mason and Thomas recitals of chamber music, which were continued until 1868. His compositions, many in number, are mainly for the piano. He published "Two Transpose Methods" (with E. S. Hoadley); "Pianoforte Techniques" (with W. S. B. Matthews); "System for Beginners" (1871); "Touch and Techniques" (1878); "Primer of Music" (1894); "Memories of a Musical Life" (1901), etc.

MASON, William Ernest, American legislator: b. Franklinville, N. Y., 7 July 1850. He removed with his parents to Bentonport, Iowa, in 1858, and after teaching school, 1866-70, was admitted to the bar and began practice in Chicago, Ill., in 1872. He was a member of the Illinois general assembly in 1879, of the State senate in 1881-83 and of Congress 1887-91. In 1887 he was elected United States senator, in which capacity he warmly advocated the cause of Cuban independence. He was elected to the 65th Congress (1917-19) and is senior member of the law firm of Mason and Mason, Chicago. He has published "John the Unafraid" (1910).

MASON, Mich., city, county-seat of Ingham County, on the Michigan Central (Saginaw Branch) Railroad and the Michigan United Interurban, 12 miles south by east of Lansing. It was settled in 1839, in 1855 incorporated as a village and annexed to the county. It is the home residence city with good streets and pavements, cement walks and curbing,  situated in a rich farming region. The grain elevators, cold storage, beanery, hay barns, cream and poultry stations, stockyards, lumber-yard and gravel pit are all of great importance. In 1908 the Masons, five persons, represented eighteen different states of the Union, who were the parents of several prize winners in Holstein exhibiting and excels in fine horses. The principal buildings are the courthouse, schools with an annex, churches and fine homes. The city owns and operates the electric light and waterworks. Pop. 1,742.

MASON—BEES, a name given to the small wild bees of the genera Osma, Ceratosmia and Chalcidoma, which construct their nests with sand or gravel, agglutinated together by means of a viscid saliva, and fix them on the side of walls, under stones, within the hollows of plant stems whence the pitch has been removed, or avail themselves of some other cavity for that purpose. The mason-bees, like the carpenter-bees, leaf-cutters and other allied forms of the family Megachilidae, are solitary in habits, not living in communities, although groups of cells are usually found near together, made by the same mother-bee, and each containing a single egg and food—a mixture of honey and pollen. Consult Howard, L. O., "The Insect Book" (latest ed., New York 1914), which contains an extensive bibliography. Gressitt, W. F., "Life of William Whitehead," with his poems (1798); "Essay on Church Music" (1795). There is a tablet to his memory in the Poets' Corner, Westminster Abbey. In 1811 a complete edition of his works appeared.

MASON CITY, Iowa, city, county-seat of Cerro Gordo County, on the Chicago, Milwaukee and Saint Paul, the Chicago and North-western, the Minneapolis and Saint Louis and the Chicago, Rock Island and Pacific, also Mason City and Clear Lake Railway (Interurban) and the Chicago Greatwestern railroads, about 115 miles in direct line north by east of Des Moines. It was settled in 1855 and its present charter was granted in 1870. It is an agricultural and stock-raising region; fire-clay and valuable sandstone quarries are in the vicinity. Its chief industrial interests are connected with the manufacturing of brick and mortar, tile, cement—two large cement mills with a capacity of 11,000 barrels daily and lime, and the quarrying of sandstone. It has a large foundry and considerable trade in livestock and grain. The city is a trade centre and distributing point for a large area, and has several wholesale establishments. The government is on the commission plan and consists of three commissioners. The waterworks are owned and operated by the city. Pop. 17,221.

MASON AND DIXON LINE. See BOUNDARIES OF THE UNITED STATES.

MASONIC FRATERNITY, The, an organization of associated societies to which, by common consent, has been accorded the primacy among fraternal orders. Divided into groups of degrees, overlying one another like the foundation and superstructure of a symmetrical building, these constitute the three great rites of universal recognition, namely, English, American, and Scottish Masonry. The first and second are acknowledged to compose the great Masonic institution as it exists in Great Britain and dependencies, and in its residence city with good streets and pavements, cement walks and curbing, situated in a rich farming region. The grain elevators, cold storage, beanery, hay barns, cream and poultry stations, stockyards, lumber-yard and gravel pit are all of great importance. In 1908 the Masons, five persons, represented eighteen different states of the Union, who were the parents of several prize winners in Holstein exhibiting and excels in fine horses. The principal buildings are the courthouse, schools with an annex, churches and fine homes. The city owns and operates the electric light and waterworks. Pop. 1,742.

MASONIC FRATERNITY

presidents and governors, together with scholars, statesmen and men of affairs, as well as those of lesser stations in church and state. The full legal title is, "The Ancient and Honorable Fraternity of Free and Accepted Masons and Concordant Orders."

The Appeal to Antiquity.—During the 18th and first half of the 19th century Masonic writers professed to have discovered the possible origin of the society in the remote ages of the past. Absolutely without any historical basis of record as were most of these theories, yet men of learning loaned their influence to perpetuate the fables extant concerning the fraternity. Some asserted (a) that the history of the race was the story of Masonry, beginning with the migration from the Garden of Eden; others (b) that it sprang from the Priestly period; and still others contended (c) that the society was the successor of the ancient mysteries of the Orient; (d) that the Temple of Solomon was its cradle; (e) that the Crusaders and the Knights Templars carried it forward from their times; (f) that the Roman colleges of artificers and builders of the Middle Ages handed down the system to posterity; (g) that it began in Great Britain of the 15th and 16th centuries, and subsequent political events, made the institution possible; (h) and a later class of writers placed its origin to the credit of the Rev. James Anderson, D.D., and the Rev. John Theophilus Desaguliers, LL.D., F.R.S., and their compatriots of "The Revival of 1717 A.D." Several of these authors changed their views later in life; and, during the past 50 years, the intelligent Masons of Great Britain and the United States have attempted to build up from the broken fragments of the past—contained in fugitive lodge records extending back nearly three centuries,—a reasonable history of the "operative" Masonry of the British Isles and the continent of Europe, as well as that of the present "scatological" system. In this effort assistance has been rendered by scholars not connected with the fraternity. The critical reader will note, in the enumeration above, that many plausible theories might be founded both on history and legend, but the strongest factor in the appeal to antiquity, nevertheless, is the "Legend of the Third Degree." In one form or another the allegory of the fall of man, the sacrificial redemption of the race, the doctrines of the resurrection and immortal life, permeated the peoples of every age and became the motive of many migrations. This fact is likewise of record,—established by the discoveries made in Bible lands during the 19th century,—dating four millennia B.C. When, therefore, a society arose which claimed to solve some of these mysteries,—may, even to have descended from those periods,—it is not singular that the cult should have attracted disciples; especially when shielded from public gaze by a veil of secrecy, the universality of the printed page not having yet been established.

In Britain and on the Continent.—The consensus of reliable historical opinion affirms that the premier Grand Lodge of England, organized 24 June 1717 A.D., is the mother of all regular Masonic lodges of the three craft degrees, and, therefore, peculiar interest centres in its landmarks, legends, and authentic narratives pertaining to the English rite itself, as well as in the American rite, the daughter thereof, so to speak. The apocryphal history of Masonry recites that it was introduced into England by Prince Edwin, 920 A.D., and that lodges were "warranted at York," by King Athelstan. This "Legend of the Guild" and much other traditional story is based upon curious manuscripts called "Old Constitutions," or "Old Charges of British Freemasons." The oldest of these is "The Constitution," published in 1735, and registered as the "Regius MS.," or Halliwell Poem. The next in age,—beginning of the 15th century,—is called the "Matthew Cooke MS."—both in the British Museum. In that century, also, Henry VI asked, "Where did Masonry begin?" On being told that it began in the East, his next inquiry was, "Who did bring it westerly?"—and he received for answer, "the Phenicians." These answers were predicated on the traditions of the order, as they had been transmitted from generation to generation. Many Freemasons believe this to be the true origin of their institution. Within recent years many more documents have been discovered and published in facsimile, so that the catalogue contains about 75 entries. These manuscripts are not all in English, because of certain characteristics common to two or more,—the whole forming a valuable collection of ancient Masonic remains. Each manuscript consists of three parts: (a) the introductory prayer, declaration or invocation; (b) the alleged history of the order, or the "Legend of the Guild"; (c) the peculiar statutes and duties, the regulations and observations, which Masons in general, or the craft as a unit, were bound to uphold and inviolably to maintain. The precise value of the "Old Charges" lies in the fact that they were the formulas used in the ceremonies of initiation by our Masonic ancestors of from two to five centuries antecedent. All known copies are of English origin, even those used in Scotland; and, being of a distinctly Christian character, it has been thought they indicate ecclesiastical supervision and composition. A manuscript version of 1583 A.D., in possession of the United Grand Lodge of England, has the following "introduction prayer," and is quoted as an example:

The might of the Father of Heaven and ye wysdome of ye glorious Soonne through ye grace and ye goodness of ye holy ghoste, ye three poones & one God, be wvs vs at o' beginning and give vs grace so to govrne vs here in or lyving that wee maye come to his bliss that never shall have ending. AMEN.

Signs, tokens and words, by which the Masonic craft became differentiated from all other trades than builders, do not appear in the earlier forms. In time, however, this initiation was exclusively its own; and in the Melrose manuscript 1581 A.D. (known to posterity by the transcription of 1674), reference is made to "Ye privilidge of ye compass, square, level, and ye plum-rule." The early records show that the lodge system was used from the 13th century for preserving the art of building as a monopoly. The secret of the organization was then,—in contradistinction to all others,—"the way to build"; and tyed lodges contributed most toward this end. But, in spite of another body of operatives arose,—called "Cowans" by the regulars,—which in spite of its lack of prestige, not being in possession of "Old
Charges" and the "mason's word," contrived to prosper, eventually breaking down the monopoly and prepared the way for the "speculative" society. The term "speculative," has reference to a class of members who were not operative and had no intention of becoming artisans, but were denominates "accepted" Masons. The admission of this element proved the wisdom of the fathers, and to it is probably due the permanency of the institution and its continuity to succeeding ages. By its influences the Masonic fraternity secured governmental favor and became "free of the guilds," that is, free of the restrictive laws, which even now, regulating the "Friendly Societies" of the British Empire,—enjoying a liberty which did not inhere in the organization of exclusively operative masons who were not "Free-Masons, the so-called "Cowans." (Free + Mason, originally written as two words, not mentioned prior to the 14th century). Just what proportion, or membership was speculative during the earlier or operative period unfortunately is not known, the first lodges record preserved being of a meeting held "Ulmno, July 1599," but of its mixed character there is no doubt. Old records, recently discovered, and a grant of present-day research, have led Masonic writers to revise the usually accepted assertion that the cathedrals and other public edifices in Great Britain, erected during the Middle Ages, were planted by masons, and by which the architects be identified, and the wage scale regulated. The Masonic "reformation" originated in London. By the dawn of the 18th century the decadence of the society had become so serious that four of the surviving lodges proceeded to a reorganization in 1717, and this movement is known in history as "The Revival." These four lodges were probably joined by others, though the records do not exist. Two clergymen, James Anderson (b. Edinburgh, 5 Aug. 1684) and John Anderson (d. 12 March 1683) became the architects and authors of the new régime. A distinguished gentleman named Anthony Sayer was installed as grand master. He was of the "speculative" and "accepted" class. The Grand Lodge instituted was a "governing" body, and in no wise a successor of the "General Assemblies" of the operative or legendary period. To Dr. Anderson was entrusted the duty of compiling the "general records and faithful traditions from the beginning of time," and to enable him to do so all the available documents were collected for his use. These were afterward destroyed,—an irreparable loss. In 1723 the "New Constitutions" were published, when it was discovered that Dr. Anderson and Desaguliers had completed their work at different times. The term "speculative," from Christian to the adoption of a universal creed based on the Fatherhood of God and the Brotherhood of Man,—so as to admit men of all religions, nationalities and stations in life. The last named was not known before, nor was it known that the transactions of the craft from 1717 to 1722 A.D., when the official records commence. The second edition of the "New Constitution" was published in 1738, with "New Regulations" added, which became the basis of the Freemasonry of the present day. From 1717 the evolution of the society was rapid progress, both as to the increasing area of its operations, and in the multiplicity of its degrees. But the Masons of "the revival" and their immediate successors did not long dwell together in unity. Those at York organized a "Grand Lodge of All England" in 1725, and kept it alive for some 20 years. A reorganization took place in 1761, and the body ceased to exist in 1792, never having chartered lodges outside of England. In 1731 a great schism occurred, whereby a part of the premier Grand Lodge withdrew and instituted a rival. In common parlance the latter body became known as "ancients," the former as "moderns," a transposition which is firmly settled in history. A deputation from the Grand Lodge of All England, dated 29 March 1779, created still another body called the "Grand Lodge of England South of the River Trent," and this survived until 2 May 1790. The rival Grand Lodges,—"Moderns" and "Ancients,"—happily entered into a concordat on Saint John's Day, 27 Dec. 1813 A.D., constituting the present United Grand Lodge of England by declaring that the English Rite of Freemasonry "Consists of three degrees and no more, namely: those of the Entered Apprentice, the Fellow Craft, and the Master Mason, including the Supreme Order of the Holy E. M. A." Scotland enjoys the honor of "Mother Kilwinning Lodge, No. 0," universally recognized as the oldest in existence. Its records comprise a minute of 1599, and others ranging from 20 Dec. 1642 to 5 Dec. 1758, A.D., and these communications were held in Kilwinning. Traditional history ascribes to the architects of the abbey of Kilwinning the preeminence which inhered to the Masons of York, in England. A dozen other old lodges are of record, possessing fragmentary minutes and "Old Charges" of rare Masonic merit and antiquity, but the Scottish Craftsmen did not follow the examples set by England and Ireland until Saint Andrew's Day, 30 Nov. 1736 A.D., when Baron William St. Clair of Roslin (Earl of Orkney and Caithness), was chosen master for the following year he was succeeded by George, the third and last Earl of Cromarty. It will be noted that in Scotland, as well as in England and Ireland, the craft was patronized by those of exalted civil rank and station. Scotland's "Masonic gem" is the "Prentice's Pillar," standing in the chancel of Roslin Chapel, Edinburgh. In Ireland no Grand Lodge records are extant of date prior to 24 June 1780 A.D. It is known that there was a lodge at Cork, the first minute of which is dated "December ye 8th, 1726." The city archives refer to a charter for a "Society of Freemasons," and a "Grand Lodge of Munster;" and it is known that other lodges existed prior to 1726. There was also a Grand Lodge of Cork, and one at Dublin. The last named was of record in 1722, reorganized 1731 A.D., electing Lord Kingston, who is described as "Grand Master of all the lodges of Free Masons in the Kingdom of Ireland." Irish Masons possessed "Old Charges," and like their English brethren propagated the order far and wide. It was in 1784, of Irish register,—warranted in 1735,—that the Hon. Mrs. Richard Aldworth (Eliza-
MASONIC FRATERNITY

beth St. Leger), was initiated, and became the celebrated and only "Female Freemason" of history. She only received the first degree. The Continent, historically, the building crafts of Continental Europe with the operative masons of Britain and Scotland. But, in Germany, in pre-Reformation times, the "Independent Stonemasons" arose, coming out from the monastic orders as the need for buildings, magnificent edifices, under ecclesiastical patronage, declined. These "lay brothers" were possessed of "Old Charges," but no authentic documents remain which refer to their most flourishing period of existence. Within the short space, however, of from 10 to 20 years, following the revival in England, Masonry of the British type had obtained a foothold in all the countries of Europe. It had crossed the sea to America, and in a list of lodges published in 1734, No. 125, of English register, is shown as located at "Boston, in New England,"—known since 5 March 1792 as Saint John's Lodge. "England became the great central point of Masonry for the whole world," said Charles W. Moore, Grand Secretary of the Grand Lodge of Massachusetts, in an address on 29 December 1876 at Boston. "As this source have lodges, grand and subordinate, at various times, been established, and still exist and flourish—in France and Switzerland; in all the German states, save Austria (and there for short seasons); all up and down the shores of the Rhine... Sweden, Denmark, Russia; in Italy and Spain (under cover of secrecy); in various parts of Asia; in Turkey; in Syria (as at Aleppo, where an English lodge was established more than a century ago); in all the East India settlements... in China... Africa... in all the larger islands of the Pacific and Indian Oceans... Saint Helena, Mauritius, Madagascar... Australia in New Zealand; in Greece... in Algeria, Tunis, Morocco... and wherever else in the Old World the genius of civilization has obtained a standpoint, or Christianity has erected the Banner of the Cross." The speaker further enumerated the spread of the order in the fifteen states in South America and in the United States. In the 63 years which have elapsed since these words were uttered, the growth of Freemasonry has been still more extraordinary.

In France, Masonry has drifted away from the tenets preached and practised among the fraternity in other lands. All Masonic lodges throughout the world except the Grand Orient of France do homage to a Divine Being, symbolized as Horani, the Great Architect of the universe, and in the beginning the French lodge also recognized the designer of the Temple. But in 1877 the Grand Orient formally repudiated the Great Architect and atheism was made a condition of membership. The "Frères Trois Points," as they are commonly called in France, were granted the right to hold distinct bodies, and were termed the "Invisible Order," and have been blessed with an almost omnipotent occult ring. The Grand Orient was threatened with losing its character of being a "serious" institution, and it was thoroughly defeated when it massed all its forces to oppose the election of General Boulanger in 1888. The Confederation Générale du Travail, the great Socialist machine, rose up against the Grand Orient, and latterly all the better feeling of France revolted against it. Notwithstanding the allegations made against French Freemasonry, that body includes all grades of political and anti-religious eddies, and to this day the Grand Orient is the only one in Europe without which the affairs of France are not regarded.

In Russia Freemasonry first appeared in 1721 in the reign of the Empress Elizabeth, and through the middle of the 17th century. In 1737, a lodge was engaged to execute a monument to the memory of the late Tsar Peter I, and in 1745 it purchased the first charter. It was, however, not till 1793 that any definite steps were taken to form a grand lodge. The Grand Master of Russia, George I of Prussia, declared that he had no objection to the establishment of a grand lodge in Russia, and accordingly the lodge was chartered in 1793. The Grand Lodge of Russia was formed in 1793, and its Grand Master was the Grand Master of the Grand Lodge of England. The Grand Lodge of Russia was not only the only grand lodge in Russia, but also the only grand lodge in Russia.
quite apart from regularity and the sanction of Grand Lodges. This was the fact in Philadelphia, in 1730–31; and, again, in New Hampshire soon afterward (the last named appeared by law in 1735). Daniel Coxe of Burlington, N. J., was appointed Provincial Grand Master of the provinces of New York, New Jersey and Pennsylvania, in America, by the Duke of Norfolk, Grand Master of the Premier Grand Lodge of England. On 30 April 1733, Lord Viscount Montague, Grand Master, issued a like deputation to Henry Price of Boston, appointing him Provincial Grand Master of the province of New England, the dominions and territories thereto belonging. Masonic historians agree that Coxe took in establishing the society, but there is a complete record of the acts of Price. Because of this Massachusetts was acknowledged to be the mother jurisdiction for nearly 150 years; while it was in Boston that the Grand Lodge of Pennsylvania, and Libre B., of the Historical Society of that Commonwealth, appear to give the primacy to the Keystone State. In support of this contention evidence discovered during the last half of the 19th century goes to show that on 29 Jan. 1731, Coxe visited his Grand Lodge at London, and that a toast was there drunk in his honor, as Provincial Grand Master of North America; that from 1732, and for several years, a list of Grand Lodge officers was regularly printed in the Pennsylvania Gazette, published in Philadelphia; that, in 1734, Benjamin Franklin being elected Grand Master thereof, wrote to Provincial Grand Master Price in Boston, as to the status of Masonry in Pennsylvania; that in June of that year Franklin met Price in Boston and was recognized to the extent of being further instructed in the Royal Art, by the Provincial Grand Master; and that Grand Master Franklin himself visited the Grand Lodge of England, in 1735.

The rival Grand Lodges in England, together with those of Ireland and Scotland, chartered lodges everywhere, at home and abroad. Patronized by the royal family and nobility of Great Britain the craft acquired greater prestige than history records of any other society, and a system of military lodges fostered expansion. The roll of warrants issued during the 18th century and subsequent to 1730 would make a large volume. From these beginnings as to Lodges were formed in America, composed of lodges of English (ancients and moderns), Irish, Scottish and Army register, increased in number by those holding Provincial Grand Masters' warrants, together with lodges chartered by the early states, Grand Lodges were formed in the Revolutionary States and Canada, until regular governing bodies existed in every state, province and territory. Thus the craft has followed the flag wherever unfurled. Unfortunately the early records of many of the lodges existing in the American colonies previous to the Revolution are lost to history. In the royal forces at Louisburg, Crown Point and Lake George were lodges in which many of the king's soldiers (who were Americans) were initiated. Among the many prominent Americans who belonged to the fraternity besides Franklin were Washington, who was made a Mason while in the service of the Crown, under Gen. William Braddock, and became master of a lodge in Alexandria, Va.; Presidents Jefferson, Monroe, Adams, Jackson, Polk, Fillmore, Harrison, Buchanan, Johnson, Lincoln, and McKinley. Jackson was a Grand Master and McKinley a Knight Templar. Some historians claim Presidents Madison, Taylor and Pierce as Freemasons, but owing to the political disputes of 1826–30 they made no statement as to their connection with the craft. Mr. Taft and Colonel Roosevelt both became Masons after they became President. Other members were Lafayette, Fulton, Montgomery, Sherman, Burr, Rush, Whipple, Paine, Hamilton, Gerry, Steuben, Stark, Livingstone, DeKalb, Warren, Paul Jones, Witherspoon, Revere and Hancock.

Knights Templars and Masonry.—The tradition that the Baldwin Encampment, which, up to the middle of the 19th century, had been conceded to be the mothers of the Knights Templars were descendants of the Knights of the Crusades, is not now accepted. Its earliest accredited document bears date 20 Dec. 1780. The first reference to the Knights Templars, as allied to Masonry, is contained in the (lodge warrant) minutes of Saint Andrew's Royal Arch Chapter, Boston, Mass., dated 28 Aug. 1769; the earliest in England is that of Phoenix Lodge, No. 257, Portsmouth, 21 Oct. 1778. Kilwinning Lodge of Scotland, on 8 Oct. 1779, by its master, Earl Eglinton, warranted the "High Knights Templars of Ireland," at Dublin. The Grand Lodge at York sanctioned the degree of "Knight Templar" in 1780. Similar references,—at dates between the Saint Andrew's Chapter's record and the institution of the Grand Encampment, Knights Templars, U. S. A., 11 June 1816,—may be found scattered throughout the fugitive minutes of lodges and chapters wherever the British army had been stationed. Whence, then, came the modern "Knight Templar"? An answer, founded upon historical facts, has never been made. Two theories have been advanced: (a) It is within the range of possibility that a connection existed between the chivalric order of Knights Templars and the fraternity of Operative Masons of medieval times, because bodies of skilled workmen erected Templar strongholds in the Holy Land, and built their preceptories, priories and round churches in Europe. The famous Temple Church, London, is an example. What, then, was more natural than that the Knights Templars in the 14th century, proscribed, persecuted and despoiled of all things, should seek their perpetuation among the affiliated bodies of mechanics of whose universality and antiquity they had abundance in both American colonies and the Revolutionary States and Canada, until regular governing bodies existed in every state, province and territory. Thus the craft has followed the flag wherever unfurled. Unfortunately the early records of many of the lodges existing in the American colonies previous to the Revolution are lost to history. In the royal forces at Louisburg, Crown Point and Lake George were lodges in which many of the king's soldiers (who were Americans) were initiated. Among the many prominent Americans who belonged to the fraternity besides Franklin were Washington, who was made a Mason while in the service of the Crown, under Gen. William Braddock, and became master of a lodge in Alexandria, Va.; Presidents Jefferson, Monroe, Adams, Jackson, Polk, Fillmore, Harrison, Buchanan, Johnson, Lincoln, and McKinley. Jackson was a Grand Master and McKinley a Knight Templar. Some historians claim Presidents Madison, Taylor and Pierce as Freemasons, but owing to the political disputes of 1826–30 they made no statement as to their connection with the craft. Mr. Taft and Colonel Roosevelt both became Masons after they became President. Other members were Lafayette, Fulton, Montgomery, Sherman, Burr, Rush, Whipple, Paine, Hamilton, Gerry, Steuben, Stark, Livingstone, DeKalb, Warren, Paul Jones, Witherspoon, Revere and Hancock.
was a direct importation from England, and in its infancy and for many years was confined to the upper classes, without the least admixture of the artisan. This was true in Germany, where the French language, that of the court and Freemasonry, was the common tongue, and the early lodges bore French names. In 1740, however, in contradistinction to England, a Scottish Masonry arose,—reputed to hail from Scotland, but having no real connection with any regular society; and though the Freemasons have endeavored to divorce most of the traditions relative to the alleged transmission of the chivalric degrees from the Knights Templars, of whom Jacques de Molai,—executed 11 March 1314 A.D.,—was the last Grand Master. In order to prove the Templar succession, and the legend of Scottish Masonry, it becomes necessary to account for an interregnum between the year 1309, when Walter de Clifton, Preceptor of the Scottish Knights Templars, admitted the dispersion of his brethren, and the year 1314, when Jacques de Molai perished, during the 18th century at Boston, manifestly a historical impossibility. Nevertheless, *history* fails to record much that actually occurs; much that subsequent ages would gladly immortalize. No less than three, and in 1854 an authorized edition of *The Templars’ Chart,* by Jeremy L. Cross, published in New York, gave a succession of Grand Masters from Jacques de Molai—based on a clumsy forgery of the Swedish Templars,—to the year 1838 A.D. Like many another ingenious theory framed to connect the *old* with the *new* dispensations, tradition may be true, but it is unsupported by documentary evidence.

The Secret Monitor.—In Freemasonry there are, in addition to what is known as Craft Masonry, which in England and Wales and the Overseas Empire is under the jurisdic-
tion of the Grand Lodge of England, of which the Duke of Connaught is Grand Master, certain extraneous Masonic associations to which only regularly initiated Freemasons can belong, but which are not recognized by the Grand Lodge. For example, in England Mark Masonry is not recognized by the Grand Lodge of England, although the Duke is also the Grand Master of the Mark Master Masons. Red Rose Arch Masonry was, however, officially recognized by the Grand Lodge of England. One of the associations outside of *official* Freemasonry is the *Order of the Secret Monitor.* It is claimed that the *Brotherhood of David and Jonathan,* from which this Order developed, is as old as Freemasonry itself. The earliest existing records of an organized system of the Brotherhood are found in Holland, where it is said to have been founded in 1773. It was carried by Dutch emigrants to America, where it spread rapidly. In 1845 the Order was established in Malta; in the following year in the West Indies, in 1848 in Jerusalem and in 1865 it became known to English Freemasons. It was not till 1887 that a definite attempt was made to organize the Order in England by the Bon Accord Lodge of Mark Master Masons. A Grand Council was formed and four con-
claves (or lodges) came into being. Seven more conclaves were formed in 1888, and there are now about 45 under the jurisdiction of the Grand Conclave of the United Kingdom. Some of these conclaves are held in India, Burma, South Africa and other parts of the empire.

Masonic Unity.—At the outbreak of the war in 1914 there were six *foreign* lodges in London under the jurisdiction of the Grand Lodge of England, and L’Escale Cordiale have only Frenchmen as members; two—Deutschland and Der Pilger were German lodges; one—Loggia Italia—is composed of Italians; and one—America Lodge—is limited to Freemasons born in the United States. Each year a united festival of these lodges was held. For some years prominent Masters in Great Britain expressed a desire that there should be an extension of this international ideal. In March 1913 Lord Ampt-
hill said at Birmingham: "I may be a dreamer, but I fancy a time may come when Freemasonry for improving the relationship among nations." A society was formed in June to advance simple Masonic truths and principles; to promote the practice of the ritual in English, German and French; and to study of English, American and European Continental Masonic history, so that members might become more familiarized with the original aims of Freemasonry; and the arrangement of international tours. In short, the object was to weld together into one associated body the Freemasons of the world. The occurrence of the war will undoubtedly retard that movement for many years. It is a remarkable fact that none of the rulers or statesmen connected with the outbreak of the war was a Freeman.

Organization and Degrees.—Craft Mas-
sonry was universally organized on the basis that within the lodge the Lodger and the officers of the entire institution. A Grand Lodge once duly established must *sui generis* be sovereign in its jurisdiction, the bounds of which soon became restricted to a state, province or other recognized political division. The territorial limits of a Grand Lodge being sacred from invasion, and this principle enforced, Masonry has escaped the successful competition of alleged rival rites purporting to be the craft itself, and also has been secure in its privileges from any and all plans to confederate these bodies into one centralized government,—a guaranty of the perpetuation of the democracy inherent therein. But the symbolism of "Solomon’s Temple" as the most glorious edifice of ancient times, probably introduced by David, Solomon and Desaguliers (whether from the lost manuscripts, or otherwise, is not essential), required a more ornate adornment and furniture than a foundation and the bare superstructure upon which Operative Masons had wrought,—hence, naturally, suggested degrees above the original three of the Revival, *et seq.* For more than a
century men toiled to perfect the society,—often building better than they knew,—until the three Rites became settled as at present established. The best minds contributed toward this end. As in the Old World, so in the New, the institution had attracted to itself men of high character and standing in the governments thereof, and men of letters contributed their full quota to develop the fraternity, which was expected to end in that toward which it was moving. It had already existed, for ages. France, in particular, was prolific in the fabrication of degrees and rites, the great volume of which survive only in the musty tomes of 18th century literature. As before inferred, the so-called Scottish Masonry became the forerunner of a rite that, perfected by scholarly Masons, ultimately became the Ancient and Accepted Scottish Rite. This title is now applied to a system which was first definitely organized at Charleston, S. C., May 1801. The rite in question of its degrees can boast of a very respectable antiquity, having descended from a Council of Emperors of the East and the West, at Paris in 1758. It is also based on the three craft degrees, and its postulants must be Master Masons in good standing, in whatever other regular rites their membership may have. The original Supreme Council in America passed through an experience similar to that of the premier Grand Lodge of England before its authority as Mother of the Rite was fully established in the Masonic world; but peace came finally, and two bodies exist in the United States: the primate, as the Southern Jurisdiction, and the present Northern Jurisdiction, established by a concordat, signed at Boston, Mass., by several rival Supreme Councils, May 1865. This rite was introduced into England in 1845; and other Supreme Councils of this obedience exist in Scotland, Ireland, Canada, Egypt and colonies of Great Britain; in France and dependencies, and in other countries of Europe, excepting Russia; in South and Central America; and in the West Indies. As before stated, the Masonic government is complex, no two rites — nor even Grand jurisdictions of the same rite, being alike, owing to variances in the sequence of their degrees. The English and American are substantially in unison as to chronological order: Craft, Capitular, Cryptic and Chivalric degrees. In the American Rite its degrees follow this notation exactly, being the Royal Arch Chapter, Council and Templar systems, respectively. England, Scotland and Ireland, working the English Rite, are not altogether in accord,—additional degrees and orders being incorporated,—but eventually all arrive at practical universality, nevertheless. The A.A.S.R is divided into grades and degrees: symbolic, the three Craft degrees, which are not conferred, however, in jurisdiction of the English and American Rites, Ineffable, Historical, Philosophical, Historical and Philosophical, Chivalric, Official and Executive, conferred in lodges, councils, chapters, consistory and supreme councils.

The Arabic Order of Nobles of the Mystic Shrine (q.v.) has fostered and developed the social side of Freemasonry, in its higher degrees, principally in America.

The Order of the Eastern Star is not a Masonic organization, but a secret sisterhood to which only Freemasons and certain female relatives can belong.

It is estimated that there are considerably over 2,000,000 Freemasons in the world, of which by far the majority are in the United States.

HENRI F. KLEIN,

MASONRY (Fraternity). See Masonic Fraternity.

MASONRY AND BUILDING. Masonry, from the French, maçonnierie, meaning stone or brick work, derived from the Latin, maceria, a wall, is the operation of laying up natural or artificial stones, generally held together or made a single mass by mortar, plaster or earth. It is the most important part of stone and brick structures, and a mason frequently becomes the general contractor for a whole building of this class. The different trades required in mason building begin with building masons or the workmen who raise or demolish old buildings; then come the excavating, dr-inage, grading, paving, piling, foundations, rubble, cut stone, including cut moldings, modeling and stone carving, brick masonry, concrete work, fireproofing, terra-cotta work. After this heavier construction follows lighter mason work: plastering on metal or wood lathing, and stucco. The ideal of good masonry is a structure of natural or artificial stone that shall stand as the permanent skeleton of the building,
firm and enduring; its great first cost shall mean no further care or expense.

History.—The Egyptian stonework that has survived for centuries is generally of enormous blocks jointed with astonishing accuracy, so as not to mar the effect of the bas-reliefs which covered several courses. Assyrian walls were laid up with bricks forming the exterior surface and whose faces were laid with touches of tufa or triangular brick were used for the exterior surface and the interior was filled with concrete. The characteristic of Greek masonry was to use local stone, accurately cut and jointed if the stone would bear it; otherwise covered with stucco. From the lintel or beam architecture of the Greeks to the arch construction of the Romans was an advance in the possibility of size of construction, but a change from a system of making the constructive forms visible and decorative to a custom of covering rough walls with a decorative shell not expressing the supporting masonry work behind. This method of building gave the Romans an opportunity to make their enormous structures at a low cost, because unskilled labor could be employed to much better advantage, needing only a small number of foremen. Romanesque masonry was very crude and the thrusts of the arches were taken care of by a mass of abutments which were practically monolithic. In Byzantine work the arch and domes were made from small blocks of stone and the thrusts were studied with much greater care. In Gothic work the arch became "alive," carrying the weights and thrusts of the upper parts of the building on slender shafts, and through flying buttresses with the utmost skill to the outer walls and buttresses. Modern work has come to partake of the character of the ancient Roman construction, that is, a veneer on interior supporting masonry of a different character. In our time, however, instead of the huge concrete monolithic buildings, an iron skeleton is used, and a thin shell often not more than four inches in thickness covers a frame work of steel beams that in a high building is little more than an iron bridge on end. The old Roman flat arch construction is held together by strong cement forming domes not over six inches thick and easily spanning 15 feet or 20 feet is also used.

Men and Material.—The workmen employed on masonry are stoncutters, who generally work in stone yards away from the building, except for such trimming as may be necessary in setting the stone; stonemasons who work on the building, setting the stone; bricklayers who work on platforms continually raising and placing the brick accurately; and laborers for delivering the stone, mortar, etc., and for mixing mortar and concrete. The materials used are stone, cement blocks, brick, terra-cotta, broken stone, cinders; and adhesive materials: limes and cements, which are used with sand to make a mortar for binding the masonry; and water. In very crude construction, mud and clay are used for a binding material. Foundation walls may be of stone laid dry; of concrete; of stone laid in Portland cement mortar or half-cement mortar, the latter consisting of sand, cement, lime, with cement and lime in equal proportions. In case of the soil under the building not being sufficiently firm, it is necessary either to drive wooden piles or to spread the foundation so far that the pressure per square foot on the soil will not be sufficient to cause the building to settle. In Chicago the footings are very large, of steel beams and concrete, making what is practically building usually below a very soft soil. Where the foundations are under water, as under a bridge pier, it is necessary to adopt special methods, generally sinking caissons so that workmen may go down and work under water.

The outer row of stones of a wall are termed the facing; those within the filling; those at the rear the backing. A horizontal laying of either stone or bricks is a course; a sloped surface of a well is a batter; a protecting often projecting course on top is a coping. A bond is a stone going through two or more courses to bind them together; a quoin is a squared stone at a corner; a stretcher is greatest in horizontal length, a header shortest, the latter being a bond. A cramp is a bar of iron or steel let into a wall to brace it. Ashlar are squared stone; rubble irregularly shaped stones projecting as a balance-weight; a sill, a broad stone at the base of an opening; a template, a large stout stone for supporting the end of a girder or beam.

Ashlar Facing.—The stonework of the outer face of a wall when it is cut and differs in character from the back of the wall is called ashlar. The coursing of ashlar is done in different ways. The simplest form is when it is laid out in continued courses. In this case it is called "regular coursed ashlar." Ashlar is also laid without long horizontal joints. In this case it is called "broken ashlar." This is generally used when stone cannot be easily obtained of equal heights. It takes longer to lay this up, which makes it cost more than the regular coursers, but a very attractive looking wall, having more freedom and texture. It is customary to cut the stone at the stone yard certain heights; for example, two, four, six and eight inches, so that they can be laid up without cutting any joint except the end joint, at the thicker. This should be built and bonded in at the same time as the ashlar in order to make a solid wall. If the stones are not high, the thickness of the ashlar should vary so that the backing can bond in and it is generally specified that the ashlar should include one through bond stone in every 10 square feet of wall. If
the facing is thin (two inches to four inches), the pieces are clamped back into the backers by iron clamps. Random rubble is where untrimmed stones are used, and selected to fit as well as possible.

In public work and important buildings, every stone should be shown on the drawings, except when random ashlar is employed. In this case the arrangement of the stones is made by the foreman on the building, to follow a sample piece of ashlarn set up and approved by the architect. Ashlar is usually from four inches to eight inches thick. In figuring the quantity an average of six inches in thickness is generally taken. The heights vary from 10 inches to 14 inches. For exterior work the ashlar should not be under four inches thick. The ashlar may be laid with V joints, or with rustication. In the latter case the face is generally rock-face or pointed and a drafthine an inch wide is carried around the edge of the stone.

Bond stones are stones that go into the wall to hold the wall together. If there are many small stones these should be frequent. In laying out the brick wall is used in the sixth course, and then lay headers for the sixth course. Face brick bond is as a rule laid of stretchers and bonded either by clipping the corners of the bricks, which tie the face of the wall to the backing, or with metal wall ties, which are made of wire, cramped metal or of tin fastened to steel wire. Flemish bond is the bond which is most frequently used to give an interesting wall surface, more pleasing than what is obtained with common bond. It is laid up with alternate headers and stretchers. The smallest size of bond used at the corners is called closer. English bond consists of courses of headers and stretchers alternating. A variety of this, called English cross bond, has the alternate courses of stretchers arranged with the joints below the middle of the bricks above, making a figure resembling a cross. Sometimes every fifth course of brick is laid Flemish bond with the others straight bond. Every fifth course may be set in or back an inch, forming rustic wall. When walls have hollow or vaulted spaces not over two inches wide in the centre the bond is made by bricks laid across the space and cut in diagonally, or by the use of metal ties every four to eight courses. In arches, the face of the arch is made with the same bond as that shown on the wall. Common arches are made with successive rings or rowlocks, of headers.

Brick.- Despite the great increase of concrete and steel construction, bricks seem to be used as much as ever, as they are not affected by the weather, fire or city atmosphere, which affects the softer building stones seriously. They are cheaper than stone and can be used with cut stone or terra-cotta trimmings. Hard burned bricks are used for piers, though not so good for this purpose as stone work, and in very dry soils are sometimes used for foundation walls. If there is any dampness of the soil, the outside of brick foundation walls is sometimes painted with water-proof paint. Bricks are made from sand and clay, the clay in different localities making bricks of different characteristics. A sand clay is more desirable. For the better kinds of brick clay is often chosen from different places and combined with the greatest care. (See Brickmaking Machinery). Terra-cotta and pottery are burned in kilns which are arranged to let in heat half way up the kiln so that it will be drawn down on to the pile of terra-cotta and through the floor of the kiln into the chimney. This is said to give a more even heat. If there is iron in the clay the color of the brick will be red; the ordinary white bricks are generally due to lime. The proportion of iron makes the red of various shades, according to the amount. Lime and iron make a cream-colored brick. Brown bricks are due to the presence of magnesia; and magnesia and iron make a yellow brick. Different clays give varied effects, and a mixture of clays with mortar colors, or painting the exposed surfaces, gives desired effects. Bricks should not absorb more than from one-twentieth to one-tenth of their weight of water. This is a test that can be easily applied. Soft bricks may absorb as much as a quarter of their weight. Bricks should ring when struck, as cracked or soft bricks will give a dull sound. They should not have any cracks or large lumps or foreign substance, such as lime or coarse gravel. They should run all the way dimensions with true surfaces, though for rustic work rough bricks are often desired. The approximate size of a brick is 2 inches x 4 inches x 8 inches. In the Eastern States 7 3/4 inches x 3 3/4 inches x 2 1/4 inches; but in the Western States the dimensions are slightly larger. In every case where brick work has to be figured for cutting stone trimmings, the brick should be laid up and measured. Pressed brick are generally 8 inches x 4 1/2 inches x 2 1/2 inches in size. Brick is of three kinds, long and 1 1/2 inches thick. Norman brick is 12 inches long and 2 inches thick. Bricks weigh four or five pounds apiece.

MASOOLA, ma-s0o'-la, a boat common on the east coast of India, adapted to be beached on the surf-beaten shore. The planks are sewed together with coir, over wads of the same material, which press upon the seams. The boats are 30 to 35 feet long, 10 to 11 feet beam, 7 to 8 feet deep, and are rowed by 12 men, oars double hanked, and a steersman with an oar at the stern.

MASORA, maz'-roa, or MASSORAH, MASSORETH, a Hebrew word signifying 'tradition,' the name of a collection of notes referring to the Hebrew text of the Old Testament, and written in Chaldee chiefly on the margin of Hebrew manuscripts. These notes
Maspero — Masqueray

are various in their character, critical, grammatical and explanatory. Since in early Hebrew writing no vowel signs appeared, great confusion arose in time from the many modes of reading and supplying vowels to the consonantals. The Masora set a fixed reading to each word and thus put an end to the multiplicity of readings. At what time the accumulation of these notes was commenced cannot be ascertained. According to some, the notes are as old as the time of Moses; according to others they were begun in the time of Ezra. It is more likely that they are the result not of one period but of many centuries of compilation and emendation. A useful edition of the Masora is the translation of Dr. Ginsburg (3 vols. London 1880–87). See JUDAISM — The Masorah. Consult Cornely, ’Introduction in V. T. Libros Sacros’ (Vol. I, Paris 1894); Ginsburg, C. T., ’Introduction to the Hebrew Bible’ (London 1890); Driver, S. R., ’Notes on Hebrew Text of the Books of Samuel, with Introduction to Hebrew Paleography’ (2nd ed., Oxford 1913); Harris, ’Rise and Development of the Masorah’ (in Jewish Quarterly Review, Vol. I, London 1889).

Maspero, Sir Gaston Camille Charles, gäs-ton kä-mél sharl mäs-pé-ró, French Egyptologist b. Paris, 23 June 1846; d. 30 June 1918. He studied in the Lycée Louis-le-Grand, 1853–65, and before entering the École Normale in 1865 had already made considerable progress in the study of Egyptology. He remained in the latter college two years and attracted the attention of Mariette, the distinguished Egyptologist. In 1867 he published in the Revue Archéologique an Egyptian text and translation under the title ’Stele du Songe,’ and in the same year appeared separately his ’Mémoire sur la grande Inscription d’Aydog and la Jeunesse de Sésostris.’ On leaving the École Normale he went to South America to carry out researches in the Quichua language. Further memoirs on ancient Egypt extended his reputation and secured his appointment in 1869 as professor of the Egyptian language and archaeology at the École des Hautes Études. In 1871 he issued an important essay, ’Des Formes de la conjuration en Égyptien ancien, en démotique et en copte’; and in 1873 ’De Carchemis Oppidi Situ et Historia antiquissima’ and ’Du genre épistolaire chez les anciens Égyptiens.’ In 1874 he succeeded Rougé as professor of Egyptian philology and archaeology at the Collège de France. Sent to Egypt in 1880 as head of a government archaeological mission, he succeeded Mariette in the following year in the directorship of excavations and antiquities. He founded and directed an archaeological institute at Cairo, had charge of the museum at Bulak, now in Gizeh, carried out many excavations, with important results, and in 1886 returned to France to resume his duties at the collège. In 1888 he was named to the Egyptian ministry as director of excavations and antiquities. In 1914 he left Egypt and became permanent secretary of the Academy of Inscriptions and Belles-Lettres. Maspero’s great work is his ’Histoire ancienne des Peuples du Orient’ (1875), which has been republished in an enlarged and revised form (1894–99). The three volumes of the later edition have been translated into English under the titles ’The Dawn of Civilization’ (1894), ’The Struggle of the Nations’ (1896) and ’The Passing of the Empires’ (1900). His other works comprise the following: ’Contes populaires de l’Égypte ancienne’ (1884, translated by him as ’Contes Égyptiens’ (1886–91)); ’Archéologie Égyptienne’ (1887; Eng. trans. ’Egyptian Archaeology,’ 1888); ’Lectures historiques’ (1890); Eng. trans., ’Life in Ancient Egypt and Assyria,’ ’Études de Mythologie et d’Archéologie Égyptiennes’ (1893); a valuable to the student of the religion of ancient Egypt; besides contributions to the ’Mémoires’ of the French Archaeological Mission at Cairo; ’Les monnaies royales de Deir-el-Bahari’ (1889); ’Caisseries d’Egypte’ (1907; Eng. trans., as ’New Light on Ancient Egypt,’ 1909); ’Egypt, Ancient Sites and Modern Scenes’ (1911); ’Art in Egypt’ (1912), and text and translations of the inscriptions upon the pyramids of the fifth and sixth dynasties in ’Recueil de travaux relatifs à la philosophie et archéologie égyptiennes et assyriennes’ (Vols. I–XIV), etc. In 1879 Maspero was made a knight of the Legion of Honor, and in 1895 commander. In 1883 he became a member of the Académie des Inscriptions and in 1887 an honorary Fellow of Queen’s College, Oxford, and an honorary D.C.L. of that university. In 1909 he was made knight commander of Saints Michael and George. See Egyptology.

Masquerade, mäs-kär-d, a popular amusement, in which persons of both sexes masquer or disguise themselves and engage in dancing or festivities. Masquerades date from a very early period in which they were connected with religious ceremonies and observances. We find traces of the masque in the Bacchanales of Greece, the Saturnalia of Rome and in the Purim of the Hebrews. In the Middle Ages they were at times held in the churches, for instance the ceremony of the boy bishop, the feast of fools, etc. The clergy succeeded in putting a stop to these relics of paganism in connection with the church in the 16th century. Masquerades of the modern purely secular type are said to have been the invention of Granacci, an Italian, who lived in the beginning of the 16th century. See Carnival; Festival.

Masqueray, Emmanuel Louis, American architect b. Dieppe, France, 10 Sept. 1861; d. Saint Paul, Minn., 26 May 1917. He was educated at Rouen and Paris. Having decided to become an architect he studied at the École des Beaux Arts, Paris, and in 1879 was awarded the Deschambeau prize by the Institute of France. He also received the Chandesaignes prize in 1883. While in Paris he was also an attached of the Commission des Monuments Historiques. Mr. Masqueray came to New York in 1887, and was at first connected with the office of Carrère and Hastings and later in the office of William M. Hunt. He opened an office here in 1893 and founded the Atelier Masqueray for the study of architecture according to French methods. This was the first wholly independent atelier opened in this country. He served as a city architect in 1901 when the commissioner of architects of the Saint Louis Exposition selected him to be chief of design or consulting architect. This monumental undertaking included the Trans-
MASQUES—MASS

MASQUES. The old masques, fashionable in England in the 17th century, were in reality the kind of private theatricals that then generally prevailed at the courts of Europe. Their name is understood to have originated from the use of the head masque, representing either romantic, historical or allegorical types on occasion of importance. The first of these masques (or ballets, as they were called in Italy and France) that we find recorded was that given by Bergonzio di Botta, at Tortona, to celebrate the marriage of the Duke of Milan in 1551, in talk of all the elite of the Western World. Originally a parade or festival, a form of dramatic masque quickly developed in England under the wits of men as deft as Ben Jonson and Fletcher, aided and abetted by the master-designer, Inigo Jones (q.v.), reaching a height of twodrury theatrical beauty that died out almost as quickly as it had flamed. At Versailles and other courts the masque or ballet survived for over a century longer. The masque of to-day is philosophical in character. It is the drama of personified ideas. It is akin to allegory. Its dramatic purpose is the presentation of universal truths; and in this indirect way to bring their lessons home to the mind and heart alike. The pageant and masque are distinctly antithetical in character. The one is essentially concrete, the other is essentially abstract. The one depends on realism to tell its story, the other depends on symbolism, though either may make use of the elements of the other in subordination. Mr. Pemberton, deutz (1903), a mass of music performed in that city in 1914, was perhaps the soundest achievement of the American poet in this new form which has yet to find its authentic masters. During the Shakespearean tercentenary celebrations of 1916 many commemorating masques were written and performed. For these and sundry lists of "Masques and Festivals" lately held in the United States consult the bulletins of the American Pageant Association. See FESTIVAL; PAGEANT. A list of masques on the English masques are Evans, H. A., "English Masques" (London 1898); Reyher, Paul, "Les Masques Anglais: etude sur les ballets et, la vie de cour en Angleterre, 1512-1640" (Paris 1909); Brotenack, Rudolf, "Die Englischen Musikspiele" (Vienna 1902).

MASS, in physics, the quantity of matter in a body. The mass of a body is the same wherever the body may be in the universe. Two bodies have equal masses if the gravitating forces with which another body acts upon them are exactly equal at equal distances. (See GRAVITATION.) Hence two bodies have equal masses if their weights are the same at the same place on the earth; so that if the metallic "weight" used by a grocer is carried from place to place, the quantities of sugar and tea balanced by it in a good pair of scales will always be the same. Razors, or sugar in every case equal to the mass of the metallic "weight." It is to be clearly understood that as the force of gravity is different at different places on the earth, the weight of any body is different at different places. To distinguish between the mass (or quantity of matter) and the weight (or force which tends to move it downward) of a body is very important in beginning the study of physics.

MASS. The. According to the teaching of the Catholic Church, the Eucharist is the Sacrament which contains the body and blood, soul and divinity, of Jesus Christ under the appearances of bread and wine. At the Last Supper (see LORD'S SUPPER), the night before He died, Christ, in the presence of the 12 apostles, instituted the Eucharist (q.v.) by taking bread, giving thanks, breaking it, and giving it to the apostles, saying, "Take ye and eat. This is my body," and then by taking the cup of wine, giving thanks, blessing the wine, and giving it to them, saying, "Drink ye all of this. This is my blood which shall be shed for the remission of sins. Do this for a commemoration of me." The Church teaches that, when Christ said, "This is my body," the substance of the bread was, by His almighty power, changed into the substance of His body, and that, when He said, "This is my blood," the substance of the wine was similarly changed into the substance of His blood, while the appearances of bread and wine remained. The Church further teaches that the change of bread and wine into the body and blood of Christ, called Transubstantiation (q.v.), continues to be made by Jesus through the ministry of His priests, to whom through the apostles and their successors, He gave this miraculous power when He said, "Do this for a commemoration of me." The priests exercise this power of Transubstantiation through the words of consecration over the bread and wine. What, then, is the Mass? The Mass is the solemn memory, with a narrative, of Christ's passion and death. It is the perpetual sacrifice of the New Covenant. In the eucharist it is described as the unbloody sacrifice of the body and blood of Christ. It is, specifically, a sacrifice of adoration, thanksgiving, propitiation, and illumination. As, in the offering of this sacrifice, certain words and actions in fixed form are used, the Mass may be defined as the aggregate of prayers and ceremonies which constitute the service of the Eucharist in the Latin, that is, the Roman and Gallican, rites. This service was known at first by many names: Ex?uar?ia, gratiarum actio, thanksgiving; ?estinr?ia, liturgy, rite; pl?os?ia, oblation, offering; ?l?on ??nov, fructio panis, breaking of bread; eprogramma, Domini, the Lord's supper; ?ovwia, communio, communion; ?wain, meeting; solemnia, dominica solemnia; dominica passio; spiritualia acc celestes sacramentum; Dominicum; passio; sacrificium. As the word Mass still survives in the Eastern Church, and corresponds exactly to the word Mass. This latter
term has become the recognized and almost exclusive technical name for the liturgy of the West. Its derivation is even yet not quite certain and it is generally said to be a late Latin verbal noun for missio (Latio: missio), from the verb mittere, to send, send away. Primarily, missa was used in the sense of "dismissal" with reference to the concluding part of the service, and then, by a gradual process well known to linguists as well as to students of liturgy, it was extended to the whole rite. The first time we know for certain that it was employed in its present sense was in the 4th century, about 385 or 386, in a letter of Saint Ambrose to his sister, in which occurs the statement, missa facere copi (=1 begin say Mass). A 2d century instance of the use of the word missa in this sense is of doubtful authenticity. From the 4th century onward it becomes more and more frequent, until in the 'Sacramentum Leo. Tertianum' (Leonine Sacramentary), of the 5th or 6th century, it is understood throughout (item alia = item alia missa), and in the 'Liber Sacramentorum Romanae Ecclesiae,' usually known as 'The Gelasian Sacramentary,' of the 6th or 7th century, it is considered as expressed. Thereafter, the word Eucharist remains the normal name for the sacrament, Missa, or one of its derivatives in other languages like Mass in English or Messe in French, has been the regular title given to the Eucharistic sacrifice in the Roman and Galian rite.

So much for the word, which is clearly much later than what it denotes. The history of the Mass itself has its origin in the New Testament in the four accounts of the Last Supper found in Matthew xxvi, 26-28; Mark xvi, 14-20; Luke xxii, 19-20; and Paul i Cor. xi, 23-26. What Christ then did is the foundation of the Mass. It is because He told the apostles to do, in memory of Him, what He himself on that occasion had done, that the liturgy of the Mass has been extended and has continued through the ages. That liturgy, fluid and variable in detail, but uniform in outline and in many formulas, always the same in essentials, and from constant repetition tending ever to be- come fixed and more or less certain through the 1st century in different parts of the New Testament, in the 'Didache' or Teaching of the Twelve Apostles (c. 80-100), in the First Epistle of Saint Clement of Rome to the Corinthians (c. 90-100), in the Epistle of Barnabas (c. 96-98), and in the letters of Saint Ignatius, bishop of Antioch (d. 107). In the 2d century there is very probably an interesting allusion to the Mass from the outside, in a letter written by the pagan, Pliny the Younger (C. Plinius Secundus, governor of Bithynia, to the Emperor Trajan about 111-113. The eucharistic service, mentioned by Saint Polycarp, bishop of Smyrna (died c. 155), by Athenagoras of Athens (c. 177), and by Theophilus, bishop of Antioch (c. 180), is set out in considerable descriptive detail by Saint Justin Martyr (put to death, c. 165) in his First Apology addressed to Antoninus Pius (138-161), and is also treated of by Saint Ireneus, bishop of Lyons (d. c. 202). In the 3d century we begin already to see traces of these different practices in different countries which led to the different liturgies. For the rite followed in Alexandria and Egypt, we have as spokesmen Clement of Alexandria (d. c. 215), Origen (d. 251), and Dionysius of Alexandria (d. 264); for that of Antioch and Syria we have the fragments (lambanisma) of the 'Apostolic Constitutions' (which, however, was not written down until the 5th century as the diatessaron twn omyw apostolwn), as well as the complete text of a liturgy in the Syriac which bears the same title; for Rome and the West we have vague allusions in the second bridings of Hippolytus (c. 235) and Novatian (c. 250); and for the African Church or Church of Carthage we have Tertullian (d. c. 220) and Saint Cyprian, bishop of Carthage (d. 258). The liturgy given in the eighth book of the 'Apostolic Constitutions,' as well as being an early form of the rite of Antioch, is also possibly an example of an early type of the rite of the whole Church. When we reach the 4th century we have much fuller liturgical information, at least for the East, not only in the writings of Saint Athanasius (d. 373), Saint Basil (d. 379), Saint Cyril of Jerusalem (d. 386), and Saint John Chrysostom (d. 407), but also in the ecclesiastical, or service books, which from this time on must be compiled for Church use. From this time, too, we have the specifically different rites which were already foreshadowed in the 3d century. It is generally accepted that the fairly uniform type of liturgy previously used everywhere developed into four great parent-rates, from which all others now in use in Christendom are derived. These four are the liturgies of Antioch, Alexandria, Gaul, and Rome. I. The rite of Antioch, found pure in the Greek 'Apostolic Constitutions,' was modified at Jerusalem into the Liturgy of Saint James, which itself took the place of the older liturgy at Antioch, and was used throughout the whole patriarchate, embracing all western Syria. This modified liturgy is found in (1) the Greek Saint James, now used only once a year at Saint James in Jerusalem; (2) the Syriac Jacobites and Uniates; and (3) the Maronites in Syria. The Syriac rate, used by the Syriac or Eastern Uniates, is, Arabic written in Syrian characters. The second rate derived from the primitive one of Antioch is the East-Syrian or Chaldean, which is found in two forms, (1) that used in Syria, by Nestorians and Chaldean Uniates, and (2) the Malabar rate, which is used, also in Syria, by Malabar Uniates. The third derivative of Antioch is the Byzantine rate, used in Greek, Arabic, Old Slavonic, Rumanian, and many other languages, by all the Orthodox and by Melchites and other Byzantine Uniates. Next to the Roman Mass, this is the most widespread Christian liturgy. The fourth and last rate derived from Antioch is the Armenian, which is used, in classical Armenian, by Armenians, whether Gregorian (i.e. schismatical) or Uniate. II. The second eastern rate, the Alexandrian, gives us (1) the Greek liturgy of Saint Mark, which is now no longer used; (2) the Saint Mark in Coptic, used by the Copts, both Monophysite and Uniate; and (3) the Ethiopian liturgy, used by the Monophysite Church of Abyssinia. The two great western parent liturgies are the Gallican and the Roman. III. The Gallican rate, in Latin, was used in
North Italy, Gaul, Germany, Spain, Britain, and Ireland. It was imported about the 4th century from one or two places. It still survives under the title Ambrosian at Milan, in Italy, and under the title Mozarabic at Toledo, in Spain. In each case it is greatly Romanized, particularly so at Milan. IV. Finally, we have the liturgy of Rome. The original pure Roman rite is now no longer used, nor is the African rite, which belonged to the same family and had many features in common with the present Roman Mass, not the least being that its language was Latin even at a time when Greek was still employed at Rome and elsewhere. The present Roman rite, by far the most widespread of all, is used, in Latin, by nearly the whole Roman patriarchate. It occurs, however, in a Slav dialect in parts of Dalmatia and occasionally in parts of Rome. In parts of southeastern Italy, Sicily, and Corsica, although they belong to the Roman patriarchate, the Byzantine rite is used. There are various medieval modifications of the Roman rite peculiar to the religious orders of the Dominicans, Carthusians, and Carmelites. There were also modifications adopted in certain dioceses, and a few of them, Lyons for example, still keep these local forms; but in most cases the local usage has been abolished.

In the early period the liturgical language used at Rome was Greek, for Greek was spoken by the Roman Christians as well as by those of other centres of Christianity, such as Alexandria, Antioch, and Jerusalem. For example, Pope Clement I (c. 91-104) uses Greek in the famous "First Epistle to the Corinthians," to which reference has been already made, and the earliest inscriptions in the Roman catacombs are certainly in Greek. As far as is known, the first Christians to use Latin were those of Africa (Carthage). Pope Victor I (190-202), who was born in Africa, is often said to have been the first Roman pontiff to use it; but this has been disputed. The question turns on whether Victor or Saint Cyprian was the author of the tracts "De Sacramentis," "De Vita et Mortibus." The 3rd century popes, Cornelius (251-53) and Stephen (254-57), write in Latin. It may perhaps be fairly said that from about the 3rd century Latin became the customary language spoken by Christians at Rome, and gradually from that time onward the only one. It is difficult to say when Latin replaced Greek for Church use. Some authorities place the change at as early a date as the second half of the 3rd century; others are of opinion that Greek remained the liturgical language until the end of the 4th century. Ambrose's De Sacramentis (c. 400) and in a letter of Pope Innocent I (401-17) to Decentius of Eugubium (c. 416) we find that the Mass was then said in Latin. It is probable that there was a transition period, during which the two languages were employed side by side. We know from the first Roman Ordo (c. 770) that as late as the 8th century lessons were read and psalms were sung in Greek. As a matter of fact, Greek has not, even now, entirely disappeared. We still have the Kyrie Eleison in every Mass and the Trisagion, Agios O Theos (O Holy God), Agios anthanatos, eleison imas (O Holy Immortal One, have mercy on us), in the Mass of the Presanctified on Good Friday.

The development of the Roman Mass into its present form is also difficult to trace, at least in some of its earlier stages. Clement of Rome, Justin Martyr, Hippolytus, and Novatian are in substantial agreement as to the liturgies which they describe or mention; but our information as to the developments of the Roman rite during the latter half of the 3d and nearly the whole of the 4th century is extremely scanty. What we find is that between the 2d and the 5th century certain important changes were made. When we reach the 5th century we are on surer ground, for the 'De Sacramentis' and Innocent the First's letter to Decentius prove not only that the Mass was then said in Latin but also that it is in essence the rite still in use. In the 'Gelasian Sacramentary,' of the 6th or 7th century, showing the service considerably shortened, we have what is practically the present Roman Mass. Pope Saint Gregory I (590-604) made various modifications, and left the Roman liturgy largely in the state in which it exists to-day. He it was, in particular, who gave the final touches to the Canon. 4No pope," says Benedict XIV (1740-

59), "has added to or changed the Canon since Saint Gregory." The Council of Trent (1545-63), wishing uniformity everywhere in the celebration of the Roman Mass, appointed a commission to examine and revise the Missal and restore it to its earlier form, "according to the custom and rite of the holy Fathers." This commission, named on 16 Feb. 1562, had not finished its labors at the close of the Council, 4 Dec. 1563, and its authority was continued and action on its report left to the Pope, Pius IV (1559-65). It was not, however, until the reign of his successor, Pius V (1566-72), that the revision was completed. On 14 July 1570 the reformed Missal — 'Missale Romanum ex decreto ss. Concilii Tridentini restitutum'— was published by the Bull, Quo Primum, commanding that that Missal alone should be used wherever the Roman rite is followed. That command put an end to most of the medieval derived rites. There was, however, an exception. Any liturgy that could prove a prescriptive right by an existence of not less than two centuries was allowed. It is by virtue of this exception that the independent Gallican liturgies at Milan and Toledo, as well as the modified rites of certain religious orders and the local usages of some dioceses, were preserved. This Missal of Pius V is the one still in use. It has, however, since undergone various corrections in non-essentials. A second edition of the Missal was published by Clement VIII (1592-1605) by the Bull, Cum Sanctissimum, of 7 July 1604. Again on 2 Sept. 1634 Urban VIII (1623-44) by the Bull, Si quid est, published yet another revision. The last revision of the text, with a correction of the rubrics, was made by Leo XIII (1878-1903). His missal was "published by the decreto ss. Concilii Tridentini restitutum, S. Pii V Pont. Max. iussu editum, Clementis VIII, Urbani VIII et Leonis XIII auctitate recognitum"—was published in 1884. The
changes effected by Pius X (1903-14) have reference to the music.

Of the Mass, set, instituted, developed, reformed, authorized, and promulgated, it remains to say a few words. It is, indeed, not within the scope of the present article to give in detail the many complicated rules and the minute rubrics that are to be observed in the celebration of Mass, which must be mastered before ordination by every aspirant to the priesthood, are to be found fully set forth in books on ceremonial. All that can be given here is a general outline of the prayers and of some of the ceremonies used. The norm is Missa Solemnis, or High Mass, sung by celebrant, deacon, subdeacon, and choir. The following sketch therefore refers to High Mass and, further, to High Mass as celebrated on an ordinary Sunday. The procession, consisting of thurifer, acolytes, master of ceremonies, subdeacon, deacon, and celebrant, all appropriately vested in accordance with the rubrics, having reached the foot of the altar, the celebrant makes the sign of the cross, and he and his assistants say certain preparatory prayers, including the Kyrie, versicle, Psalm and the Confiteor or General Confession. Going up to the altar, the celebrant says silently two short prayers asking forgiveness of his sins. Then, having blessed the incense and incensed the altar, he reads the Introit, consisting of an antiphon, a verse of a psalm, and the little doxology, Gloria Patri, etc. The Introit has previously been sung by the choir. The Kyrie Eleison follows, said by the celebrant and the assistant ministers, and sung by the choir. The celebrant then intones the first words of the great doxology, Gloria in Excelsis Deo, and he and the ministers say the remainder of it together, while the choir sings it. Turning to the congregation, the celebrant greets them, in his singing voice, with the salutation, Dominus vobiscum (The Lord be with you), to which the choir answers, Et cum spiritu tuo (And with thy spirit). He then sings the word, Oremus (Let us pray), and, turning his face to the altar, he sings the prayers known as Collects, which are different every day. These are followed by the Epistle, which the celebrant reads while the subdeacon chants it. After the Epistle comes the Gradual, consisting of two separate chants, of which the first is the Gradual proper and the second is the Alleluia or, in Lent and on certain fast days, the Tract. Five times in the year, as well as in all Requiem Masses, the Gradual chants are followed by a canticle known as the Sequence. The celebrant then says silently the prayers, Munda cor meum, etc. (Cleanse my heart, etc.), and Dominus sit, etc. (May the Lord be in my heart and on my lips, etc.), reads a selection from one of the four Gospels, and blesses the incense. The subdeacon then holds the Gospel-book and the deacon incenses it, and then sings the Gospel as previously read by the celebrant. At the end the response, Laus tibi, Christe (Praise to thee, Christ), is said. At this point, a sermon, if there is one, is preached, in the vernacular of course. After the sermon, the celebrant intones the first words of the evening prayer, then says the Creed in unum Deum (I believe in one God), and says the remainder, which is sung by the choir. When the singing of the Creed is fin-

ished, the celebrant sings Dominus vobiscum and, after the response as before, he sings the word Oremus (Let us pray). Then follow in order the three principal parts of the Mass, namely, the Offertory, the Consecration, and the Communion. The Offertory is the beginning of the action of sacrifice. While the choir sings the Offertory antiphon, the celebrant offers the gifts, which must be made before ordination; the deacon, with the prayer, Suscipe, sancte pater, etc. (Accept, holy father, etc.). Then, blessing the water and mixing a little of the water with the wine in the chalice, he says the prayer, Deus, qui humanae, etc. (God, who didst wonderfully create, and still more wonderfully renew, the dignity of man's nature, etc.). Next, offering the chalice, he and the deacon say, Offerimus tibi, Domine, calicem salutaris, etc. (We offer unto thee, Lord, the chalice of salvation, etc.). Bowing before the altar, the celebrant says the prayer, In spiritu humiliatis, etc. (In the spirit of humility, etc.), and then blesses the bread and wine with the prayer, Veni, sanctificator, etc. (Come, Sanctifier, etc.). He then blesses the incense and incenses first the bread and wine, then the altar, etc. (May this incense, etc.), and then the altar with the prayer, Dirigatur, Domine, oratio mea, etc. (Let my prayer, Lord, be directed, etc.). Handing back the censer to the deacon, he says, Accedat in nobis Dominus, etc. (May the Lord enkindle in us, etc.). Here the celebrant, the ministers, the clergy present, and the congregation are all incensed. Washing his fingers at the side of the altar, the celebrant recites the Lavabo, that is, the last seven verses of Psalm 25 [26], concluding with the little doxology. Then, bowing before the middle of the altar, he says the prayer, Suscipe, Sancta Trinitas, fane oblivionem, etc. (Receive, holy Trinity, this oblation, etc.). He then turns to the congregation and gives the exhortation, Epitate, fratres, etc. (Brethren, etc.), to which the ministers make answer, Suscipiat Dominus sacrificium, etc. (May the Lord receive the sacrifice, etc.). Next follow the Secreta, or secret prayers, which, like the Collects, are different every day. The last Secret is the Offertory act, he brings to a close with the Epphonesis, Per omnia secula seculorum, sung aloud, to which the choir responds, Amen. There follow three short chants sung dialogue-wise by the celebrant and the choir. The celebrant then sings the Preface, which ends with the Sanctus, etc., said by him and sung by the choir. At the Sanctus a bell is rung thrice. The Canon, which is the fundamental part of the Mass, follows. Its form never varies, except for slight changes (1) when the Roman See is vacant, (2) when the Episcopal See is vacant, (3) when the Mass is celebrated (a) in Rome and (b) in some French churches, (4) when it is celebrated by (a) a Pope or (b) a bishop, (5) when a bishop is being consecrated, (6) on Maundy Thursday, and (7) at the time of the five chief feasts of the year, namely, Christmas, Epiphany, Easter, Ascension, and Pentecost. The Canon is said in a low tone (secreto) by the celebrant. He beseeches God to accept the Nicene Creed and to guard and protect the Church, the Pope, and the bishop; he prays for the living, present and absent; he commemorates the saints; he again
begs the acceptance of the sacrifice; he asks for peace and for deliverance from eternal damnation; he once more implores God to bless, appear, and ratify the sacrifice, that the people become the body and blood of Jesus Christ. Then, reciting what Christ did with the bread the day before He suffered, he consecrates the Host by saying, secretly, plainly, and attentively, the words, Hoc est enim corpus meum (For this is mine). Immediately he genuflects on one knee and adores and elevates the Host, to show it to the people. Next, reciting what Christ did with the cup of wine, he consecrates the wine by saying the words, Hic est enim sanguis mei, novi et aeterni testamenti: mysterium fidei: qui pro vobis et pro multis effundetur in remissionem peccatorum (For this is the chalice of my Blood, of the new and eternal testament: the mystery of faith: which shall be shed for you and for many, for the remission of sins). Adding the words, Hac quotiescumque feceritis in mei memoriam facietis (As often as ye do these things, ye shall do them in remembrance of me), he again genuflects on one knee and adores the precious Blood and elevates the chalice containing it. During each elevation, a bell is rung thrice, additional lighted candles are borne by the acolytes, and the thurifer incenses thrice the consecrated bread and thrice the consecrated wine. Proceeding with the Canon, the celebrant says the Anamnésis prayer, in which a solemn commemoration is made of Christ's passion, resurrection, and ascension, and offers to the Lord the victim now on the altar, asking the Almighty Father to accept the offerings, and to command them to be carried by the hands of the holy angel to the altar on high, so that those who receive the most sacred Body and Blood of His Son may be filled with all heavenly blessing and grace. He next prays for the dead, prays again for the living, and makes a further commemoration of the saints, closing with the second Epponhesis, Fer omnia sancetur, etc. The answer, Amen, sung by the choir, brings the Canon to an end. Here follows that part of the Mass known as the Communion. The celebrant sings a short exhortation and clause, and then sings the Pater Noster as far as the word, tentationem. The choir sings the last petition, Sed libera nos a malo (But deliver us from evil). After this comes an Embolism, containing a further prayer for deliverance from evil and for peace, said by the celebrant, and ended by the third Epponhesis, the words of which are the same as those of the two former ones. During the last part of the Embolism, he breaks the Host in the middle, over the chalice. Following the Epponhesis and its response, he sings the greeting, Pax Domini sit semper vobiscum (May the peace of the Lord be always with you), to which the choir replies, Et cum spiritu tuo. Putting a particle of the Host into the chalice, with the prayer, Hac commixtio et consecratio, etc. (May this mingling and consecration, etc.), he genuflects, bows down, strikes his breast thrice, and says the Agnus Dei, etc. (Lamb of God, etc.), which contains two petitions for mercy and one for peace. The choir sings the Agnus Dei. The celebrant, having made a further prayer for the peace and unity of the Church, gives the kiss of peace to the deacon, who in turn gives it to the subdeacon, and he in turn to the clergy present. The celebrant then prays for deliverance from his iniquities and from all evils, and prays that the participation of Christ's body may not turn to his judgment and condemnation, but may profit him to the safety and health of soul and body. Having said the words, Panem coelestem accipiam, et nomen Domini invocabo (I will take the Bread of heaven, and will call upon the name of the Lord), he recites three times the Domine non sum dignus, etc. (Lord, I am not worthy, etc.), a bell being rung each time, and, with specified and appropriate short prayers, he eats the consecrated bread and drinks the consecrated wine. During the two ablations, that is, of the chalice and of his fingers, which follow, he says two other short prayers. While the choir sings the antiphon known as the Communio, the celebrant reads it, and this ends the Communio act. The last division of the Mass now begins. The celebrant, having sung the Post-Communion prayers, sings also the Dominus vobiscum, to which the choir gives the customary response. Then the deacon sings, Ite, missa est (Go, the Mass is ended), or, in penitential seasons, Benedicamus Domino (Let us bless the Lord), and the choir answers, Deo gratias (Thanks be to God). The celebrant says a final prayer, Placeat tibi, Sancta Trinitas, obsequium servitutis meae, etc. (Holy Trinity, may the performance of my homage be pleasing to thee, etc.), and blesses the congregation. He then reads the last Gospel, which is normally the beginning of the first chapter of the Gospel of Saint John (vv. 1-14), and, when he finishes, the ministers respond, Deo gratias. So ends the Mass.

Low Mass (Missa privata), in which the celebrant supplies the part of the absent ministers and uses the speaking instead of the singing voice, is a late abridgment. It became a necessity when, in the early Middle Ages, the pious custom grew up for practically every priest to say Mass once a day. By the 9th century we find that many priests were in the habit of saying Mass several times a day. By the 13th century this multiplication of Masses began to be forbidden. By special indult (1746) of Pope Benedict XIV, priests in Spain and Portugal were permitted to celebrate three Masses on All Souls' Day (2 November), a privilege extended quite recently to all other countries. The rule now is that, except on that day and on the feast of Christmas (25 December), when three Masses are also allowed, and on Sundays and certain holy days when, in case of necessity, authorization for two Masses is given, a priest may say only one Mass a day. Pius the Fifth's Missal (1570) recognized Low Mass and specifically arranged its order. By direction of Pope Leo XIII certain prayers in the vernacular, in which the congregation participates with the celebrant, are recited after every Low Mass. In some countries (e.g., Ireland) the 129th [130th] Psalm (De Profundis) is said after the Low Mass and before the vernacular prayers. There are special rites for a Pontifical Mass, high or low, and additional special rites for a Papal Mass. A Missa Cantata, without deacon and subdeacon, is sung with celebrant, choir, and singing as at High Mass, is a compromise. The Mass of the
Presanctified (Missa praesanctificatorum, λειτουργία τῶν προηγαμένων), which is really not a Mass at all but a service of Communion from an oblation consecrated and reserved at a previous celebration, was once common in Eastern and in the Western Church. In the Byzantine rite such a service still occurs several times in the year, but in the Roman rite it is now used only on Good Friday. Conventional or Chapter Mass (Missa conventualis or capitularis) is an official Mass celebrated in such churches as are bound to have the whole office every day. A Missa solitaria is a Mass said without an assistant. Such Masses, forbidden by many synods, may nevertheless be celebrated by dispensation given under special circumstances. Missa sola, or dry Mass, was used on occasions when a real Mass could not be said, as, for example, at a wedding or a funeral in the afternoon. It consisted of the prayers of the Mass with the essential parts—offertory, consecration, communion—but the Missa solitaria was Missa nautica, said at sea when the rolling of the ship rendered a real Mass dangerous or impossible, and Missa venatoria, said for hunters. The dry Mass was in vogue from at least the 14th century, but by the end of the 17th century it was nearly entirely abolished. Requiem Mass is said for the dead, and Nuptial Mass (pro sponso et sponsa) for a marriage.

In the early ages the Mass was divided into two distinct parts, the Mass of the Catechumen (the Mass of the Faithful) and the Mass of the Faithful (Missa fidelium). This distinction, at one time fundamental, gradually disappeared as the discipline of the catechumenate fell into disuse. It has now long been lost, and the division is so hidden in the present rite that but few people advert to it. The Dominus vobiscum and the Oremus, following the Gospel (or the Creed, when it is said) and preceding the Offertory Act, show the line of demarcation.

The celebrant of Mass must be in priest's orders and free of irregularity and censure. He must also be in the state of grace, and be fasting from at least the previous midnight. He is bound to observe the rubrics and the laws concerning the matter (azyme bread) and the wine. The vestments, liturgical vessels, and the ceremonies. Mass should be celebrated in a consecrated or blessed church and on a consecrated altar or altar-stone. In special cases, however, it may be said in a private oratory or even in an ordinary room. It is offered in the morning, though, for good and sufficient cause, the time may be extended to a limited period after mid-day.

The two great distinguishing marks of the Roman Mass are (1) that it is a sacrifice and (2) that it is a Mass of Transubstantiation. These were the two features to which the Reformers particularly objected. They took the position that “the Eucharist and Holy Supper of the Lord" was a remembrance of Christ and a solemn setting forth of his death, and not a sacrifice, and that Transubstantiation did not take place. They were anxious, indeed, to retain a Eucharistic service, but one stripped of what to them appeared to be its objectionable parts. They were also insistent that the service should be in the vernacular, and that communion, when administered to the faithful, should be administered under both kinds, that is, in the form of bread and wine, and not of bread alone as was the practice of the Catholic Church. At first they repelled the charge that they were opposed to the Mass, and the Augsburg Confession, against the Reformation that it abolishes Mass, but the logic of events was too strong for this contention, and ultimately the Reformation, as far as it could, did away with the Mass. In his Latin Mass (1523) and his German Mass (1526) Luther put forth the basis of the numerous liturgies propagated by his followers in the 16th century. In the former he laid down the principle that we cannot deny that Mass and the communion of bread and wine is a rite divinely instituted by Christ. He therefore allows the Mass, as it stood in the ancient missals, to be consonant with primitive purity, except the Offertory and the Canon, that is, everything that savored of oblation. He did not recognize Transubstantiation. He developed instead the theory of Consubstantiation and interpreted the elements as being both real and physically present, during the celebration of the Lord's Supper, in, with, and under the substance of bread and wine, in a union not hypostatic, not of mixture, but of both, and not of both yet, but real and mysterious, so that the elements may with propriety be termed either bread and wine or the body and blood of Christ. Zwinglius and Oecolampadius, and with them the main body of Helvetian Protestantism, went farther. They rejected all notion of a real presence and recognized only figurative symbols in the elements which Christ had appointed as a commemoration of his death. Bullinger modified Zwinglius's doctrine without changing its essentials, and, by divesting it of its merely commemorative character, and admitting the presence in the communion, gave it the form in which it was adopted by the Helvetic churches. Bucer did not acknowledge the local or real presence of Christ's body and blood in the bread and wine after consecration, but contended that the body and blood were really, and without figure, received by the worthy communicant, through faith. Calvin taught that the body of Christ is present in the Eucharist, but "dynamically," not objectively; that the believer knows of it only by faith; that the elements are unchanged; and that therefore the Catholic Mass is idolatry. In England the Reformers maintained that in the Lord's Supper there is no Transubstantiation and no other oblation than a giving of thanks and a commemoration of the death and the Lord: in other words, that, as Cranmer phrased it, the Roman Mass is "heinous and abominable idolatry." These views found practical expression in the Book of Common Prayer, the first vernacular liturgy of the Church of England, published in the reign of Edward VI, and effective on Whitsunday, 9 June 1549. The Eucharistic part of the service was indeed named "The Supper of the Lord and holy Communion, commonly called the Mass," but the whole of the oblation and offertory prayers were swept away and the former Canon changed in many of its most material parts. In the second Book of Edward VI, which went into force on 1 Nov. 1552, the word Mass was omitted, and any language in the Canon that might imply either the doctrine
of Transubstantiation or of sacrifice also disappeared. The attitude of the Anglican Church on this subject is crystallized in the 31st of the Articles of Religion: "There is no other sacrament of the Mass, in which it was commonly said, that the Priest did offer Christ for the quick and the dead, to have remission of pain or guilt, were blasphemous fables, and dangerous to receive. Law Presa and containing several penalties for saying or hearing Mass. So important did it seem to condemn the Roman sacrifice that, for centuries, the occupant of the English throne was bound by the oath taken at coronation to repudiate the doctrine of Transubstantiation and of the Mass. It was not until 1910 that, by the Accession Declaration Act, the oath was purged of its objectionable clauses.

Modern unbelief, which denies the divinity of Christ and rejects every supernatural institution, does not of course recognize the sacred character of the Mass. Using the so-called historico-religious method, it accounts for the Eucharist and the Eucharistic sacrifice as a result of a spontaneous development in the religious life of Christ; but this line of argumentation neither explains nor explains away the Mass, and succeeds only in raising still more difficult problems for solution.

Despite all the attacks to which it has been subjected, the Mass remains the great central act of the Catholic Church, the distinctive feature of the Catholic religion, the everlasting witness and guarantee of the bond which unites all Catholics with the Roman See. Catholics are required, under pain of grievous sin, to attend Mass on Sundays and holy days of obligation. It is not prevented from being said on reasonable grounds, such as sickness or too great distance from a church. Some lay Catholics, it is true, shirk their duty in this respect; but the crowded condition of the churches both in town and country in every land during the hours of celebration shows how generally and how generously the law is observed. In practice, multitudes of Catholics hear Mass and receive holy Communion every day.

Bibliography.—The bibliography on this subject is enormous. The following books are tentatively suggested for further study: Bona, 'Rerum liturgicarum libri duo' (Paris 1672); Martene, 'De antiquis ecclesiae ritibus' (3 vols., Rouen 1700-02); Lebrun, 'L’Explication litéraire, historique et dogmatique des prières et des cérémonies de la messe' (Paris 1716-26); Pope Benedict XIV (1740-58), 'De sacrosancto sacrificio missae libri tres' (ed. Schneider, Mainz 1879); Rock, 'Hierurgia, or the Holy Sacrifice of the Mass' (2 vols., London 1840); Daniel, 'Codex liturgicus ecclesiae universalis' (4 vols., Leipzig 1847); Probst, 'Liturgie der drei ersten christlichen Jahrhunderte' (Tübingen 1870); 'Die ältesten römischen Sacramentar und Ordines erklärt' (Münster 1892); 'Die ältesten der Articuli Sacri diversae liturgiae subden Reform' (Münster 1893); 'Die abendländische Messe vom fünften bis zum achten Jahrhundert' (Münster 1896); de Fleury, 'La Messe: études archeologiques sur ses monuments' (Paris 1898); Cæsarius and Bishop, 'Edward VI and the Book of Common Prayer' (London 1890); Gihr, 'Das heilige Messopfer dogmatisch, liturgisch und ascetisch erklärt' (6th ed., Freiburg i. Br. 1897); Magani, 'L’antica liturgia romana' (3 vols., Milan 1897-99); Rieschel, 'Lehrbuch der Liturgik' (2 vols., Berlin 1900); Gere, 'The Elizabethan Prayer-book and Ornaments' (London 1902); Duchesne, 'Origines du Culte chrétien' (3d ed., Paris 1903); Bishop, 'Genius of the Roman Rite' (London 1904); Baumstark, 'Liturgia romana e liturgia dell’Esercito' (Rome 1904); Warren, 'Liturgie of the Ante-Nicene Church' (New York 1906); Cabrol, 'Les origines liturgiques' (Paris 1906); Yorke, 'The Roman Liturgy' (San Francisco 1906); Nieuwbrunn, 'The Holy Sacrifice and Its Ceremonies' (trans. from the Dutch by Bouman, New York 1909); Le Vavasseur, 'Manuel de Liturgie' (10th ed., 2 vols., Paris 1910); Fortescue, 'The Mass: A Study of the Roman Liturgy' (New York 1912).

P. J. LENNOX,
Professor of English Language and Literature,
The Catholic University of America.

MASSA, mass-sah, or MASSA DI CARRARA, Italy, the capital of the province of Massa e Carrara, situated on a hill three miles from the Gulf of Genoa, 25 miles north of Pisa and 20 miles by rail southeast of Spezia. It is an episcopal see, has a cathedral, public library, and academy of arts and sciences, and an ancient ducal palace now used as the prefectoral building. The chief industry is the quarrying of the superior white marble in the vicinity; tobacco, silk, cotton, paper and oil are manufactured. Massa was once the capital of the principality of Massa and later capital of the duchy of the same name. In 1859 it was annexed to Modena. Pop. 30,850.

MASSACHUSETTS, mas-ah-chooz'it, a tribe of North American Indians of the Algonquian stock, formerly living in the neighborhood of Massachusetts Bay, between Salem and Plymouth. Their capital, Massachusetts, was where Quincy now stands. A pestilence in 1617 greatly reduced their number and on the arrival of the white settlers the tribe was reduced but a fraction of its former hosts, about 500. In 1633 this number was further depleted by the ravages of smallpox. They were placed by the whites in the missions of Natick, Nonantum and Ponkapog in 1646 and gradually disappeared. See ALGONQUIAN; INDIANS.

MASSACHUSETTS, one of the 13 original States of the Union, and the most populous of the New England States; between lat. 41° 14' and 42° 53' N., and between long. 69° 55' and 73° 32' W. from Greenwich. Its greatest length is 184 miles and greatest breadth 113 3/4 miles, the average breadth being 47 3/4 miles. Capital, Boston. Population State census, 1915, 3,693,310, as compared with 3,666,416 shown in the National census of 1910. Its familiar name "The Old Bay State" is due to its location upon Massachusetts Bay, an inlet of the Atlantic Ocean which forms the eastern boundary of the State. It is bounded on the north by the States of New Hampshire and Vermont; on the west by the State of New York; on the south by the States of Rhode Island and Connecticut, together with the Atlantic which, skirting the southeastern coast, forms between the oceanic islands of Martha’s Vineyard and Nantucket, belonging to the State, a broad waterway known
as Nantucket Sound and an inlet called Buzzard's Bay, beyond the eastern extremity of Long Island Sound. The name "Massachusetts" is compounded from Indian words meaning "Great Hills Place." It clung probably to half a million of acres, one of the highest parts of land near the coast in the vicinity of Boston. The present State seal, adopted in 1780, in place of other devices previously in use, shows an Indian holding in his right hand a bow and in his left an arrow pointing downward. The lower part, or blue shield, in the upper corner, above the right arm of the Indian, a silver star having five points. The motto, adopted for Massachusetts by the Provincial Congress in 1775, is, in Latin, "Ense petit placidam subobo libertatem," or in English, "With the sword she seeks quiet peace under liberty."

Topography.—The area of the State comprises 8,315 square miles, 8,040 square miles being land surface, and 275 water. A portion of the Appalachian Mountain system forms two distinct ranges crossing the western part of the State from north to south. Of these, the Taconic range on the extreme western border has as its highest elevation Mount Greylock (3,335 feet), the northwestern corner of the State, while the Green Mountains has also the highest elevation found within Massachusetts. Thence the range falls to an elevation of 2,624 feet near the southwesterly corner. The other or Hoosac range farther east has, as its highest peak, Spruce Hill (2,588 feet), its general height ranging, however, from 1,200 to 1,400 feet. Mount Tom (1,214 feet) and Mount Holyoke (955 feet) are conspicuous elevations rising above the valley of the Connecticut River. Mount Wachusett (2,102 feet) and Mount Watatic (1,847 feet) in the north central part of the State are also noteworthy. An elevated plateau, 1,100 feet high at its greatest elevation, forms the central portion of the State and slopes gradually toward the east, the highest point near the coast being the Great Blue Hill of Milton (610 feet). The sandy peninsula known as Cape Cod is a distinguishing feature of the topography of the State, enclosing between the bend and the main coast the considerable body of water known as Cape Cod Bay. The arm of the cape is by a ship canal shortening the route between the port of Boston and southern waters. The main coast line of the State, some 300 miles in extent, affords excellent harbors, especially at Boston, New Bedford, Gloucester and Salem. See BOUNDARIES OF THE UNITED STATES.

Rivers and Lakes.—The principal rivers are the Connecticut, crossing the State from north to south, approximately 40 miles east from the western boundary; the Housatonic, flowing south, and the Hoosac, north, between the Taconic and Hoosac ranges; and the Merrimac, in the northeastern part of the State, having its source in New Hampshire and flowing into the Atlantic on the eastern coast. These rivers, except the Merrimac for some 15 miles from its mouth to Haverhill, are joined by the Blackstone, flowing from the centre of the State southerly across the Rhode Island boundary, and numerous other small streams, afford water power of the highest efficiency which has been fully utilized in the industrial development of the State and contributed largely to the extension and growth of manufacturing, the chief source of the wealth of its people. The Merrimac river, flowing into Boston Harbor, and the Taconet, entering the bay at Fall River, are tidal streams each navigable for a short distance inland. There are numerous small lakes or ponds throughout the State, adding much to the beauty of the landscape, and, in many cases, utilized as sources of water supply for the inhabitants.

Geology.—The rocks are principally metamorphic of the Archean and Paleozoic systems. In the river valleys and elsewhere there are masses of glacial drift, including sand and boulders, some of the latter being of large size. No mineral deposits of great value exist, except stone for building purposes, limestone and sandstone of the highest quality being quarried in the Connecticut Valley and west of the Connecticut, and granite of several varieties and superior character at Cape Ann, Quabbin, and to a lesser extent in other eastern sections. The elevations of the lower Connecticut Valley are composed of foliated gneiss, feldspathic and calcareous gneiss. There are extensive Mesozoic sandstone beds and shales in the Connecticut Valley, with small areas of syenite on each side, and an area of gneiss extending easterly from the Connecticut to the central part of the State. Syenite and porphyry are found in the east; feldspathic gneiss and granite in Plymouth and Bristol counties; gneiss and hornblende schist in Middlesex County; syenite in Essex and Norfolk counties; carboniferous deposits in Bristol and Plymouth counties, and Cambrian, Silurian and Devonian limestones, quartzites, schists and slates west of the Connecticut.

Climate and Scenery.—The temperature is variable and, especially in the eastern parts of the State, subject to frequent and wide fluctuations. In the early spring easterly winds prevail upon the coast, which are peculiarly trying to persons of delicate constitution. The winters are moderately severe, although near the sea there is much milder weather than on the interior, and during the winter months, the fall of snow is not excessive. The summers are frequently marked by periods of excessive heat and sometimes by prolonged drought. The mean average rainfall for the State is about 48 inches. The normal temperature rises above the freezing point at Boston about 7 March and the normal temperature of 60° for the day reaches Boston about 24 May. It falls to 60° about 25 September. Observations extending over 25 years show that upon the average the warmest week at Boston follows 13 July. On the other hand, the coldest week follows 24 February.

The scenery in the western counties is exceedingly picturesque, notably in the valleys of the Connecticut, Hoosac, Deerfield and Housatonic rivers. Here are found the celebrated Berkshire Hills. The northeastern coast line, extending southerly from Cape Ann is bold and rocky, while the southern and southeastern shores of Cape Cod and Buzzard's Bay are low and sandy. The islands of Martha's Vineyard and Nantucket and the group known as the Elizabeth Islands mark the characteristics of the neighboring mainland.

</table>
History.—The native inhabitants of Massachusetts were Algonquins of various tribes, each with its distinctive name. The Indian nomenclature of hills, rivers, lakes and local districts is still preserved in many cases. The first fully authenticated visit of a European explorer is that of Bartholomew Gosnold in 1602, although there are traditional accounts of the visits of others, particularly of Northmen under Lief Erikson, some 600 years earlier, with subsequent settlements maintained during three centuries, of which, however, no undisputed traces exist, although a commemoratory tablet erected on Charles near Boston is claimed to mark the site of a Norwegian settlement named Norembega. Gosnold skirted the coast from Salem southward, named Cape Cod and discovered the neighboring islands. A settlement made upon one of these was soon abandoned. Subsequent attempts at settlement by Pynne (1603) and Waymouth (1605) also failed. The Pilgrim Fathers, so-called, a company of English separatists who, seeking religious freedom, had, under the guidance of their pastor, John Robinson, left England for Leyden in Holland in 1607–08, and Delft in 1620, and soon afterward, 102 in number, from Plymouth, England, in the Mayflower (q.v.), with the intention of forming a settlement south of the Hudson River. Under stress of weather, however, they were forced to land in Provincetown Harbor 11 Nov. 1620, and finally upon the mainland at Plymouth 11 December (old style), where a settlement was established under a constitution or compact signed by all before leaving the ship, John Carver being the governor for one year. Despite much hardship this settlement was never abandoned and formed the basis of the Plymouth Colony.

A settlement made at Cape Ann in 1623 by English fishermen was in 1626 abandoned in favor of a location at Salem. A company of English Puritans under John Endicott, having obtained a grant of land on Massachusetts Bay, joined them in 1628. Under a charter granted the following year the colony of Massachusetts Bay was named, and in 1631 it received large accessions under John Winthrop, and the seat of administration was soon transferred, first to Charlestown and finally to Boston. These two colonies, Plymouth and Massachusetts Bay, advanced side by side, the last named growing in importance by constant accessions, although less tolerant than the former in religious matters. The original government was indeed theocratic, based upon the Congregational form of church government, which was established by law in 1631. A confederacy including the two colonies and that of Connecticut was formed in 1643, followed by one upon a somewhat broader basis in 1653.

In the Massachusetts Bay Colony religious intolerance was frequently exhibited during the early years. Roger Williams and others whose opinions were thought to be dangerous to the community were banished.

Troubles with the Indians, the original inhabitants of the country, involved both colonies, the more important being the Pequot War (1636–37), and the war with King Philip (1675–76). Gradually relations with the mother country became strained. After the restoration of Charles II a royal commission was appointed to administer the government, but was prevented from exercising its powers by the colonial authorities. The English High Court of Chancery in 1694 declared the charter of Massachusetts forfeited; and a succession of governors appointed by the Crown administered the colonial government, generally with much friction engendered by an adverse public opinion. Plymouth and Massachusetts Bay colonies were consolidated under a new charter in 1692. The territory of Maine, New Hampshire and Vermont formed part of the original province, separation being progressively accomplished and finally completed by the creation of the independent State of Maine in 1820.

In the colonial wars between France and England, and in difficulties with the Indians prompted by French influence adverse to the English colonies, Massachusetts was largely involved. Especially in the French and Indian wars (1744–48 and 1758), the colony took an important part, contributing in great measure to the success of the expedition against Louisburg and other Canadian campaigns. In these military operations, the colonists learned to estimate their strength and acquired experience which was of great value in the final struggle which resulted in independence.

Measures of taxation devised by the home government and restrictions upon the growing commerce of the colony led to a constantly increasing spirit of resistance and, finally, to riots in Boston (1765–68) against the enforcement of the Stamp Act (q.v.). In 1770 three citizens of Boston were shot by British soldiers, part of a garrison quartered upon the town without consent of the people. In December 1773 a cargo of tea, subject to a duty disliked by the colonists, was destroyed by being thrown into the harbor of Boston by a company of townpeople disguised as Indians. This episode is now widely known as "The Boston Tea Party" (q.v.). The port of Boston was closed in retaliation. The meeting of the General Court at Boston being postponed indefinitely, its members assembled at Salem. On 19 April 1775 the first blood of the Revolution was shed at Lexington not far from Boston, and a few days later at the fight at Concord Bridge. On 17 June occurred the battle of Bunker Hill at Charlestown, which, although counted as a British victory, exhibited the effective strength and stubborn power of resistance of the colonial forces, who, about 1,200 in number, resisted more than 3,000 British regulars, only giving way when after the third assault their ammunition failed. Throughout the war Massachusetts took a prominent part, notwithstanding the emigration of a considerable number of loyalists to the eastern British provinces. She provided 67,907 troops and $820,000 in revenue. At the close of the war, Massachusetts entered the Union, its State constitution being adopted in 1780 and the Constitution of the United States ratified January 1788. In the naval operations incident to the war with England in 1812, the seamen from Massachusetts won special credit.

The State was closely identified with the anti-slavery movement by the growth within her borders of a strong popular sentiment in favor of abolition. William Lloyd Garrison (q.v.), Wendell Phillips and many other prominent men were influential in this movement.

VOL. 18 — 26
In the War of the Rebellion the State furnished 159,165 men to the Union army and navy, paying the bounty interest on bounty loans of more than $26,000,000, besides large sums in State and military aid. At the close of the war, the war debt of the State approximated $15,000,000. In the late war with Spain also, the quota from Massachusetts was promptly furnished, the men being among those first in the field. And in the great European conflict the State acted in conformity with its honorable traditions.

Population.—The yearly rate of increase in the population of the State is about 2 per cent. The industrial development of the last 40 years has stimulated the growth of factory towns and the population is now more than three-fourths urban, that is, concentrated in cities and towns having 8,000 population or more. Since there were, in 1910, upon the average, 418.8 persons per square mile of land surface the population is more dense than in any other State except Rhode Island. Although many persons born in Massachusetts have emigrated to other States, 356,337 such persons having been found in other parts of the country in 1910, nevertheless that loss has been more than compensated by accessions from abroad, from Canada and indeed from adjacent States of the Union. By the State census of 1915, the native born in the population numbered 2,541,265, and of foreign born, 1,152,045. The increase in the native born in 1915 as compared with 1905 amounted to 21.4 per cent as against 26.4 per cent increase in the foreign born.

The number of foreign born does not of itself fully indicate the effect of immigration upon the population. This is more clearly shown by the number of persons of foreign parentage, which in 1910 aggregated 2,221,497, white persons only being considered. Less than a half of the inhabitants therefore are now of wholly native parentage.

The following table (derived from the United States census of 1910, the latest date for which such a comparison is possible) shows the place of nativity of the more numerous classes among the foreign born, and also the number of persons in the population having one or both parents born in the countries named:

Of the entire population 98.8 per cent was white in 1910, the remainder being persons of negro descent, Chinese, Japanese and Indians. The growth of population and its concentration have led to the incorporation of numerous cities, of which there are now 37 as against 317 towns. Although the towns numerically preponderate, nevertheless more than 70 per cent of the entire population is now under city government. Dense as the population is when considered in the aggregate this density is confined to the cities and towns engaged in manufacturing, or which share in the residential growth promoted by the metropolitan city of Boston, which of its own has extensive miscellaneous industries. The area of the cities and towns in Massachusetts in excess of 2,500 is, approximately, 3,935 square miles, and the population within such places shows a density of about 756.14 persons per square mile. Outside of these places there is in the Commonwealth an aggregate area of approximately 4,645 square miles of land surface, more than a half of the entire area of the State, containing a population of but 238,248, or an average of about 51.29 persons per square mile. Every census since 1875 has shown a considerable increase in population upon occupied by towns above the 2,500 limit in 1900, and, conversely, an almost constant decline in the towns outside this area. The towns which have lost are the smaller agricultural towns of the State, and while the increase in the percentage of foreign born, proportionately to the total population, has been greater in these places than in the other cities and towns, nevertheless the population in them remains to-day as in 1875 largely native born. The persons of foreign birth rapidly become assimilated and take their place in the social and political life, and in the industrial life of the State. The presence of this element has been due very largely to the industrial development of the Commonwealth, but that part of it which appears in the smaller towns is due to the taking up of agricultural land by persons of foreign birth.

Incorporated Cities.—The table (page 403) shows the cities of the State, arranged in order of size, with the population, from the censuses of 1900 and 1910, and the State census of 1915. Boston, the capital, is the chief city of the Commonwealth and in the census of 1915 ranked fifth among the great cities of the Union. Identified with the growth of the State from its beginning its historical landmarks are of profound interest to the visitor, and the traditions of the city, its development in modern times, its unrivalled suburbs distinguished by large numbers of tasteful and well-kept residences, its beautiful parks, public buildings and points of literary and artistic interest, give it an important and in many respects a unique place among American cities. Other cities closely connected with the early history of the Commonwealth are Salem and Newburyport, located on the eastern coast in Essex County. Cambridge, near Boston, with which it is connected by several bridges spanning the Charles River, is the seat of Harvard University, and the former home of Longfellow and Lowell. Lowell and Lawrence upon the Merrimac, Fall River and New Bedford in Bristol County, and Holyoke in Hampden County, are all extensively engaged in textile manufacturing. Holyoke also, with Springfield, is especially inter-

all others, more than 900,000 persons in the Commonwealth being of that faith. In church membership, the Orthodox Congregationalists rank next to the Roman Catholics, with approximately 115,000 members; followed by the Baptists (of whom there are several different bodies), with about 70,000; the Methodists (of different bodies), with about 60,000; the Unitarians, about 35,000; the Protestant Episcopalians, 30,000; and many other lesser bodies, of whom few, if any, exceed the limit of 10,000 in membership. These figures must all be regarded as below the actual, although relatively the bodies stand as stated. In the value of church property, although recent exact statistics are not available, and conclusions must therefore be based upon estimates, the rank of the several denominations is the same except that possibly the Roman Catholics change place with the Orthodox Congregationalists.

Government.—Originally based upon church membership, the conditions surrounding the suffrage have been subject to successive modifications. Dissenters from the Established Church were released from paying taxes for church purposes in 1815, and in 1833 all classes were given equal standing before the law. Since the adoption of the original State constitution (1780) it has been three times revised by constitutional conventions held in 1820, 1833 and 1817-19. Numerous amendments to the original articles have been made and new articles adopted from time to time. All male persons 21 years of age and upward, able to read and write in the English language, and neither paupers, imbeciles or convicts are entitled to vote. The State legislature, called the General Court, consists of the senate, 40 members, and the house of representatives, 240 members, elected in senatorial and representative districts respectively. Annual sessions are held beginning on the first Wednesday of January and continuing until the expiration after the completion of the business of the session. One of the most important articles in the recently revised Constitution provides for legislation subject to popular initiative and referendum, so that a specified number of voters by petition may initiate constitutional amendments and laws, or may require laws enacted by the General Court to be referred to the people for ratification or rejection.

The executive branch of the State government consists of a governor, lieutenant-governor, eight councillors who are the governor's constitutional advisers in the matter of appointments and other minor executive duties, and who are chosen in councillor districts, a secretary of the Commonwealth, treasurer and receiver-general, auditor of accounts and attorney-general. Beginning with the election of November 1920 these state officers and the members of the legislature, all of whom have heretofore been elected annually, will be chosen biennially; but annual sessions of the legislature will be continued as in the past. The governor is by virtual of his commander-in-chief of the military forces of the State. He has a constitutional power of veto over the acts passed by the legislature, but, notwithstanding this, vetoed bills may be passed over the veto by a two-thirds vote of both branches. Important executive functions are
exercised by commissions of from one to three or more members, appointed by the governor, including among others the boards of agriculture; education; charity; conciliation and arbitration (dealing with labor disputes); the industrial accident board; the board of labor and industry; the commissioners of insurance, banks; waterways and public lands; the public service commissioners; the commission on mental diseases (lunacy); the bureau of prisons; the department of health; and the director of the bureau of statistics (controlling the census, social and industrial statistics), etc. The recently revised Constitution requires that, on or before 1 Jan. 1921, these commissions and boards, and all other executive and administrative work of the Commonwealth shall be organized in not more than 20 departments in which every executive and administrative office shall be placed, except those directly controlled by the governor and council. All judges are appointed by the governor and hold offices during good behavior. The judicial system comprises police, district and municipal courts, having original jurisdiction in minor civil and criminal cases, sometimes exclusive of the Superior Court and sometimes concurrent therewith; a Superior Court with original jurisdiction in higher cases; a Court of Common Pleas or General Court with original and concurrent jurisdiction with the Supreme Judicial Court; and a Supreme Judicial Court, which has general supervision over all courts of inferior jurisdiction, hears appeals, decides questions of law, etc. This court has also original jurisdiction in certain cases, and original and concurrent jurisdiction with the Superior Court in others. The Superior and Supreme Judicial Courts hold regular term sittings in the several counties. The judicial system also includes courts of probate and insolvency in each county, and there are trial justices and justices of the peace, with limited jurisdiction.

Cities are incorporated by special legislative charter, the minimum population required being 12,000. City governments are administered by a mayor and city council. Towns are independent municipal bodies other than cities, the chief executive officers being the board of selectmen, elected in town meeting by those entitled to vote. The town meetings also make appropriation and decide, by a two-thirds vote, on important matters relating to the affairs of the towns.

The cities and towns are grouped into counties, 14 in number, namely, Barnstable, Berkshire, Bristol, Dukes, Essex, Franklin, Hampden, Hampshire, Middlesex, Nantucket, Norfolk, Plymouth, Suffolk and Worcester. The chief executive officers in the counties are county commissioners, elected annually.

Militia.—All able-bodied male citizens between the ages of 18 and 45 are in emergency liable to perform military duty. The ordinary State militia force consisted in 1916 (including officers) of land forces numbering 9,649 men, and a naval force of 842 men. These were organized in five regiments of infantry (in two brigades), one squadron of cavalry, one regiment of field artillery, one field battalion of signal troops, one corps of cadets, one naval brigade and a department of sanitary troops comprising one ambulance company, one field hospital company and several detachments for the various regiments. During the late war, by special legislation, the land forces were much enlarged by a so-called home guard, recruited by voluntary enlistment.

Wealth, Debt and Taxation.—Massachusetts is one of the wealthiest States of the Union. Much of the capital of its citizens is invested in enterprises out of the State. The value of real estate as fixed by the assessors of the various cities and towns for purposes of taxation was for the year 1918, $3,884,193,442. The total personal estate returned from the same source was $250,260,497, bringing the aggregate to $4,734,453,939, and even this is probably an underestimate.

The aggregated tax levy for State, county and municipal purposes, for the year covered by the latest report, amounts to $95,138,742. Of this $2,007,040 is a poll tax assessed under a provision of law requiring the payment of such a tax, limited to $2 per capita, by every male inhabitant of the Commonwealth above the age of 20 years, whether a citizen of the United States are citizens of the State. The rate of local taxation in the different cities and towns is from $1 to $1,000 of valuation, real and personal, varies from $2.50 to $42; rates from $2.50 to $9.80 being assessed in 11 towns; $10 to $14.60 in 52 towns; $15 to $19.80 in 6 cities and 122 towns; $20 to $24.60 in 26 towns; $25 to $42 in 6 cities and 24 towns.

Under the tax system of the State real estate is taxed to the owner wherever residing, the tax being payable in the city or town where the estate is located. Taxes on intangible personal property are payable in the city or town where the holder resides, but a new statute in operation since 1917 taxes the income only of intangible personality, and also income in excess of $2,000 from business, trade or profession, through the office of the State commissioner of taxation, the proceeds being distributed to the municipalities wherein the person taxed resides. Sworn returns are required under penalty.

Corporations are subject to a tax upon their capital stock, assessed and payable through the office of the State commissioner of taxation, the proceeds being distributed to the municipalities wherein the stockholders reside, in proportion to the amount of shares held by them respectively. Other important corporations are therefore exempted from local taxation. Real estate and tangible personal property in general is, on the other hand, subject entirely to local assessment, and, theoretically, at its full value. Property held solely for religious, charitable or educational purposes is exempt from taxation.

The State's bonded debt, less the amount of sinking fund applicable to its reduction, contracted for State purposes only, namely, loans for the construction of hospitals and other public buildings, the abolition of railway grade crossings, unpaid remainders of war debt, etc., amounted to $32,058,102 as reported 30 Nov. 1918. The Commonwealth carries temporarily an indirect indebtedness which, less sinking fund accounted for, is $22,265,194, as compared with $24,012,107 the date to $53,001,804, this representing loans contracted for the benefit of certain municipalities and metropolitan districts, within which the credit of the State was pledged to aid the development of public water systems, sewerage construction and armory construction, the com-
massachusetts 405

manuities benefited being assessed annually for the payment of interest, and finally for the payment of the principal. The net debt of the State, direct and contingent, was then $85,000,000, being the larger part of this was contingent municipal indebtedness supported by the State credit.

Banks.—The report of the Comptroller of the Currency to September 1916 reports the number of national banks in the State as 126, doing business in Boston. The total surplus of the national banks in the State was $52,143,000, with $40,361,000 surplus, $707,823,000 total assets and $432,333,000 deposits. The total capital of the Boston national banks was $25,300,000, the surplus $23,950,000 and the deposits $199,095,000. This is a leading reserve city.

Trust companies doing a banking business in the State numbered 91, with $30,375,000 aggregate capital and $436,031,581 in deposits.

The banks for savings are governed by a carefully guarded statute, and these institutions as well as co-operative banks (co-operative savings and loan associations) and trust companies are under the supervision of the State comptroller. The number of banks at the close of the year covered by the latest published report (1917), numbered 196, the number of deposit accounts being 2,491,646; the amount of deposits, $1,022,342,583; the increase over the previous year being $24,647,765. The average amount to each account was $410.31, the deposits amounting on the average to about $263 to each person of the population. The savings banks throughout the State have been managed conservatively and very few losses have occurred; but the expense of management is remarkably low, the percentage of expense to total assets being but 2.87. The co-operative savings banks, which are really building associations, receiving deposits from their members in regular monthly payments, accumulating interest thereon, and loaning the amounts received to members only, principally upon first mortgages on real estate, have been uniformly successful and numbered (in 1917) 184, the shareholders numbering 247,725 and the assets amounting to $101,838,832.

The Massachusetts statute governing these institutions is a model in legislation of this kind, carefully protecting the interests of the members, who, by the method of regular savings inherent in the system, are gradually accumulating considerable sums in cash, or acquiring home ownership.

In their relation to commerce the financial interests of the State are largely centred in Boston. The first bank in this city, one of the earliest institutions of the kind in the country, was established in 1784 and still continues. Banking operations here have generally been conducted with conservatism and prudence. Since 1898 the aggregate banking capital invested in the city has been much reduced, and weak banks eliminated or strengthened by consolidation.

Education.—From the earliest years the education of the people has been a vital subject of public concern. Harvard College at Cambridge was founded in 1636, and as early as 1647 it was provided in the colonial laws "to the end that learning may not be buried in the graves of our forefathers..." that every township after the Lord hath increased them to the number of fifty households, shall appoint one to teach all children to write and read; and when any town shall increase to the number of one hundred families, the town shall set up a grammar school, the master thereof to be able to instruct youth so far as they may be fitted for the University; provided that if any town neglect the performance hereof above one year, that every such town shall pay five pounds to the next school till they shall perform the order." The spirit of this early law still continues. It has always been the policy of the Commonwealth to preserve the principle of local control of the schools, thus promoting the direct interest of the taxpayers in the several municipalities. Hence while the State law provides under penalty that schools shall be maintained in every city and town, these are administered by local boards termed school committees, elected by the people and clothed with broad general authority. Women as well as male voters, may vote for the election of these officers. The State Board of Education, appointed by the governor, has advisory powers, intended to foster and promote the highest efficiency of the public schools, but no direct control of local schools, except in certain matters of general concern, such as the distribution of the income of the State school fund in aid of the schools in the poorer towns. This board through its agents exercises limited supervisory authority wherever aid is thus furnished. The board also directly administers the State normal schools established for training teachers. Such schools exist at Framingham, Westfield, Bridgewater, Salem, Worcester, Fitchburg, North Adams, Hyannis and Lowell, besides a State Normal Art School at Boston, expressly devoted to the training of teachers in drawing and the arts of design. The buildings provided by the State for normal instruction are of the highest character, of modern construction and all fully equipped. The number of pupils in attendance approximates 2,900.

School attendance is compulsory between the ages of 7 and 14, or if under 16 if certain educational standards have been attained and specified requirements concerning education complied with. Public schools must be maintained at least 30 weeks in each year, providing instruction in specified subjects, except that in towns in which the taxable valuation of property is under $200,000, the time may be reduced to 28 weeks. Cities and towns containing 500 families must maintain high schools for at least 40 weeks annually, unless exempted by the State Board of Education for valid reasons, and under conditions fixed by the board. Towns not subject to this must pay for tuition of their children in the high school of some other municipality, but sums so paid are reimbursed by the State to towns wherein the valuation does not exceed $1,000,000, or if the valuation exceeds this amount but if the town contains less than 500 families, 50 per cent is reimbursed. If a town containing less than 500 families, nevertheless, maintains a high school of its own, the State grants to it $500 annually under certain conditions. Cities having 20,000 inhabitants must provide manual training. Cities and towns may establish industrial schools, and any city or town may, or under
certain industrial conditions affecting illiteracy, must maintain evening schools for instruction of persons over 14 years of age, and cities of 5,000 inhabitants must maintain evening high schools. Cities and towns may provide free lecture courses of educational value, and vacation schools are authorized, also nautical schools on shore or shipboard, and provision is made for State-aid vocational instruction, including agriculture, trades, crafts, and manufacturing industries. A system of continuation schools provides for the education of illiterate minors between the ages of 14 and 16 who are at work. Municipalities must employ superintendents of schools, and provision is made for the joint employment of such superintendents by the smaller towns grouped in superintendency unions, aided by the State under certain conditions.

Children under 14 are not to be employed for wages while the public schools are in session, and unless certain educational requirements are complied with employment under 16 is prohibited in factories, workshops or mercantile establishments. There are also stringent provisions as to the employment of minors between 16 and 21, intended to prevent illiteracy. Indeed the educational requirements are so correlated with provisions as to employment and such effective means are provided for enforcement of the laws that the intellectual, moral and physical status of minors of either sex is carefully guarded. In every respect the legislation of Massachusetts of this character is upon a high plane.

There is a provision for the certification of the qualifications of high school teachers by the board of education, and a State-wide retirement system for teachers in the public schools, with annuities and pensions.

A department of university extension, under direction of the State Board of Education, organizes and maintains a comprehensive system of extension teaching designed to supplement, or to fill gaps in, other established educational agencies, by means of vocational and cultural classes conducted by part-time teachers or by correspondence courses. Many such courses are offered for which the fees do not duplicate educational opportunities given at nominal fees by other institutions. There are no fees for instruction in such classes. Twenty students must enroll in order to form a class.

The number of children attending the public schools during the year ending 30 June 1918, covered by the latest published returns, was 604,023; the average membership, 547,288, and the average attendance, 506,474, or 93 per cent of the average membership. At the same time there were 464,621 children in the State between the ages of 7 and 14. The law requiring school attendance is very well enforced.

The total annual expenditure for public school support and outlay for the same year was $30,600,068, of which $3,929,213 was for new buildings, alterations and permanent repairs. Of the whole amount required for annual support about 97 per cent was derived from local taxation. The average cost to the towns in taxation for the support of each child in the average membership, (not including outlay for new buildings) requiring an expenditure of $5.45 for each

$1,000 of the State's valuation, or about 27 per cent of the average tax for all purposes.

The effective ventilation of school buildings is required under the provisions of law enforced by the State inspector of factories and public buildings, and in the larger towns and cities these buildings are generally of the highest types of such edifices in this and in all other respects, large numbers having been erected within recent years.

The higher educational institutions within the State include the following: Harvard College (q.v.) at Cambridge, founded 1636; Williams College (q.v.) at Williamstown, 1793; Amherst College (q.v.) at Amherst, 1821; Mount Holyoke College (q.v.), for women, at South Hadley, 1837; College of the Holy Cross at Worcester, 1843; Tufts College (q.v.) at Medford, 1850; Massachusetts Institute of Technology at Boston, 1861; Boston College at Boston, 1863; Massachusetts Agricultural College at Amherst, 1863; Worcester Polytechnic Institute at Worcester, 1865; Boston University at Boston, 1869; Wellesley College (q.v.), for women, at Wellesley, 1870; Smith College (q.v.), for women, at Northampton, 1871; Clark University and Carleton College at Worcester, 1887-1902; Simmons College at Boston, 1889; Massachusetts College of Pharmacy at Boston, founded 1823, incorporated 1852; Middlesex College of Medicine and Surgery at Cambridge, founded 1846, incorporated 1848; Massachusetts College of Osteopathy at Cambridge, established 1897, incorporated 1898; Wheaton College at Norton, founded 1834, incorporated 1812, and Northeastern College at Boston, 1916. Radcliffe College at Cambridge and Jackson College at Medford having certain affiliations with Harvard and Tufts, respectively, but no legal connection with them, are devoted to the collegiate education of women, and there are also many seminaries and private schools of various grades in the State.

Libraries.—Free public libraries form an important element in the educational equipment of the State. These institutions, free to all the citizens in the various cities and towns, are practically universal, only a fractional percentage of the towns having no public libraries. The establishment of such libraries has in recent years been fostered by grants of money from the State treasury, and by the creation of a Free Public Library commission, appointed by the governor, established to promote public library usefulness and to aid in founding such institutions wherever not then existing. This commission makes annual reports to the legislature upon matters within its jurisdiction. There are also numerous circulating and association libraries, not free to the public. The latest returns from the public libraries within the State show more than 400 such libraries, containing about 6,700,000 bound volumes and having a circulation for home use of more than 14,033,000 volumes. The annual appropriation from taxes for such libraries by the various cities and towns totaled about $1,355,600. The Boston Public Library, housed in a building which is one of the most noteworthy architectural monuments in the United States, is (except New York) the largest free public circulating library in the country, and contains about 1,175,000 volumes; the Harvard University Library has more than 1,230,000; the Bos-
ton Athenaeum, 265,000; and the public libraries at Springfield and Worcester; the State Library in the State House at Boston, and that of the American Antiquarian Society at Worcester, each exceed 200,000 volumes. (See Libraries.)

Charitable and Penal Institutions.—The State institutions dealing with the defective classes include hospitals for the insane at Worcester, Taunton, Northampton, Danvers, Westborough, Medfield, Monson, Boston, Foxborough and Grafton; a State colony at Gardiner, the Massachusetts School for Feeble-Minded at Waltham and the State school at Wrentham. These institutions are under the general supervision of the State Board of Insanity and directly controlled in each case by a board of seven trustees, of whom five must be men and two women, one to be appointed annually by the governor and council, the place of the senior member being vacated each year.

General remedial institutions include a State hospital at Pondville for inebriates and venereal patients; five state hospitals, one for patients at Baldwinsville, with five trustees; the Massachusetts Charitable Eye and Ear Infirmary at Boston, two trustees on behalf of the State; the Massachusetts General Hospital, four trustees on behalf of the State; the Massachusetts Homeopathic Hospital at Boston, five trustees on behalf of the State; the Peter Bent Brigham Hospital at Boston, two trustees on behalf of the State. There are several sanitariums for consumptives under a State board of seven trustees. All the State trustees are appointed for fixed terms by the governor. The Perkins Institution and Massachusetts School for the Blind at Watertown has four trustees on behalf of the State, similarly appointed; and the Soldiers' Home at Chelsea, three. There are special educational institutions for the deaf in which the State is interested and to which edicable children of this class may be sent, in accordance with the policy of the Commonwealth which makes schooling free for all children regardless of physical defects of this nature forbid their attendance upon the public day school. These comprise the American School for the Deaf at Hartford, Conn.; the Clarke School for the Deaf at Northampton, Mass.; the School for the Deaf, Boston; the Sarah Fuller Home for Little Deaf Children, Medford; the New England Industrial School for Deaf Mutes, Beverly, and the Boston School for the Deaf. The Massachusetts Hospital School at Canton provides for the care of educational crippled and deformed children. The penal and reformatory institutions include the Lyman School for Boys at Westborough; the State Industrial School for Girls at Lancaster; and an Industrial School for Boys at Shirley, all controlled by the trustees of training schools, appointed by the governor; the State Prison at Boston (Charlestown district); the Massachusetts Reformatory at Concord; the Reformatory Prison for Women at Sherborn, and a prison camp and hospital for convicts at Waltham, all controlled by the State prison board. The State harbor of Boston was leased in 1883 to the Massachusetts State Board of Charities and Correction.

The State institutions for paupers include the State Infirmary at Tewksbury and the State Farm at Bridgewater.

Local poverties, hangers-on settlements under the law in the cities and towns, are cared for in local almshouses maintained by the municipalities. There are jails, houses of correction and truant schools in the counties. The charitable institutions established and maintained by religious bodies or other private agencies are widely distributed; and, especially, hospitals for the treatment of accidents and disease, and homes for the aged have, in recent years, been numerously established throughout the Commonwealth.

By the latest returns covering the year ending April 1918, the total number of persons receiving public charity relief of all grades (i.e., supported or relieved in institutions, in families or in their own homes, but not including vagrants and wayfarers), was 83,562. The paupers in State institutions numbered 10,626, and the city and town poor in local almshouses, 7,451. The total net cost of pauper relief for the year was $5,168,294, or about $1.34 to each inhabitant of the State. For the year ending 1 Feb. 1919 the whole number of insane persons in the State in care of the State Commission on Mental Diseases was 13,231, besides 3,953 other mental defectives, chiefly feeble-minded. (See Pauperism.)

The total prison population 1 March 1919 aggregated 4,031; of whom about one-half were confined in county jails and houses of correction and the rest in the State prisons.

Vital Statistics.—Upon the estimated population of the State, the birth rate per 1,000 of persons living, for the year 1916 the latest for which complete figures are available, was 24.8; the marriage rate 18.2, and the death rate 14.9, the excess of births over deaths per 1,000 of persons living being 9.9. The death rate is slightly higher in the cities than in the towns. The total number of deaths for the year was 56,366, the number under each of the principal classified causes being as follows: From general diseases, 14,111; diseases of the nervous system and organs of special sense, 5,774; of the respiratory system, 7,859, and of the digestive system, 5,076.

Manufactures.—The State is largely devoted to manufacturing, the energies of its people having been early turned in this direction, and developed by more than a century of industrial training. No special advantages exist based upon the possession of raw material, or due to natural resources, except water power, which, although changes in the methods of developing power render this less essential than formerly, is still an important factor. The climate of the southeastern part of the State is especially favorable to cotton spinning. In colonial days much was done to foster manufactures, invention has been promoted and improved craftsmanship stimulated, and the effect has been significant throughout the industrial history of the State. The power loom, first constructed by Francis C. Lowell of Boston and Paul Moody of Amesbury, and put in operation at Waltham in 1814, revolutionized the cotton industry in the United States. The first cotton mill in the country was built at Beverly in 1798. As a general rule, there were 57 cotton mills in the State with 46,650 spindles. The first attempt at woolen goods manufacture was at Rowley, in Essex County, in 1643, followed by more or less successful efforts in the same direction elsewhere in the State in the 17th and 18th centuries. The industrial his-
For the first printing in the American colonies was at Cambridge in 1639; and from this small beginning onward the printing and publishing business has been important in the State. Much of the history of paper-making in the United States is the history of the industry of Massachusetts. The manufacture of India rubber goods in this country originated at Roxbury, now part of Boston, in 1833. Manufactures of metal, machinery of all kinds, wooden goods, jewelry, clothing, cordage, rattan and other furniture have always been important.

The following table shows the returns, according to the census of 1915, covering the returns of the previous year, of all industries in the aggregate and of the principal industries in detail:

* Embracing the following with product as specified: Cotton goods, $195,481,626; woolen and worsted goods, $327,351,434; wool scouring, $1,406,674; hosiery and knit goods, $17,357,319; silk and silk goods, $10,678,681; wool shoddy, $1,903,916; dyeing and finishing textiles, $22,453,086; hats, fur, felt, $864,721; carpets, other than rug, $10,981,344; linen goods, $3,050,254; felt goods, $2,997,080.

In textiles, the most important industrial group shown in this table, the cotton industry leads with a product value of $195,481,626. The spindles employed in this industry numbered, in 1900, 7,784,687, increasing 1,960,169, or 33.7 per cent since 1890, being 40.6 per cent of the total increase in the country. In 1910 Massachusetts had 9,375,004 cotton spindles, and its spindles and looms in the industry approximated one-half of those in the country, and the State is first in rank among the States in the manufacture of cotton goods. The State led all other States in the manufacture of cotton goods, the annual product in 1911 reaching $127,351,434. It also holds first place in the boot and shoe industry, the figures being shown in the table. It has long been first in the manufacture of fine writing papers, the value of this product approximating three-fourths of the total produced in the United States. The paper used by the national government for currency and bonds is produced within the borders of Pittsfield, but near the Dalton line, in a mill especially devoted to its manufacture. In the production of rubber boots and shoes the State ranks first, and in the manufacture of jewelry is preceded only by Rhode Island and New York. The labor employed in the factories of the State is highly skilled, its operations well organized and its productive capacity correspondingly high. Labor difficulties have not been numerous nor protracted. The factory legislation, as a whole, is in advance of other States, and is well enforced, being supported by an effective public opinion. The laws against the employment of children (referred to under Education) are especially stringent, and such employment is reduced to small proportions. There is provision for efficient factory inspection under the State Board of Labor and Industries, with a corps of inspectors covering all parts of the Commonwealth.

Agriculture.—The agriculture of the State, as compared with that of the great farming States of the West, is not important. The industry has always been secondary to manufacturing. Following the lines of least resistance, it has turned chiefly to the production of milk, eggs, poultry and such vegetables as find a ready market in the growing factory towns and cities almost at the farmer's door. Considered from this standpoint and measured by the value of the product annually sold, no decline is shown in recent as compared with earlier years. For example, the total value of product for the year covered by the United States census of 1910 was $228,272,900; it returned 10 years previously. The returns in the State census are more favorable than those secured in the national enumeration, since taxes in the autumn and possibly with greater care; but inasmuch as comparisons with other States can only be made by using the national figures.
they will be relied on here. The total number of farms (1910) was 36,917; and the total acre-
age, 2,875,941, of which 1,164,501 was improved. The farm property was valued as follows: Land and improvements, except buildings, $105,332,166; buildings, $50,638,449; implements and machinery, $11,563,894; live-stock, $20,741,366. The animals upon the farms in the State, 15 April 1910, included 252,416 neat cattle; 64,283 horses; 10,009 lambs (under one year); 32,708 sheep (one year and over); 103,000 swine; and poultry numbering 1,692,961. The total value of domestic animals on farms was $19,208,712. The persons, 10 years of age and over, engaged in agriculture, forestry and animal husbandry numbered 74,666, and the agricultural laborers (working out) 4,515. The farms operated by owners, part owners or managers constituted 91.9 per cent of the whole number, only 8.1 per cent being carried on by tenant farmers. The State ranked twelfth among the States with respect to the number of farms which derive their chief relief from the soil and dairy produce, and the total dairy product for the year amounted to $15,187,774, the amount sold-being $14,840,927, the remainder being consumed on the farms. The value of milk sold was $12,297,654; cream, $428,824; butter and butter fat, $1,063,859; and of cheese, $3,610. The total value of poultry raised and sold during the year was $1,287,829; and the egg product aggregated 13,305,540 dozen. About 55,000 acres were devoted to cereals, the product in 1910 being valued at but $1,617,121, only a small per cent of the total crop value. Of the principal cereals the acreage and bushels produced in 1910 are corn, 41,755 acres, 2,029,381 bushels; oats, 7,927 acres, 286,500 bushels; rye, 6,474 acres, 39,183 bushels; barley, 349 acres, 9,021 bushels; buckwheat, 1,630 acres, 32,926 bushels; wheat, 109 acres, 2,404 bushels. The acreage devoted to hay and forage crops, exclusive of cornstalks, was 519,503, and the value of the crop, $11,230,989. Certain sections of the State are devoted to special products of considerable importance. Among these are tobacco raised in the Connecticut Valley, cranberries in Barnstable County and general market produce in parts of Middlesex County near Boston.

The fishing industry has, from the earliest years, been an important element in the prosperity of the coast towns and the hardy seamen of Gloucester and Marblehead, engaged in this industry in times of peace, have won renown in the naval operations of the country in times of war. The latest complete returns relating to the fisheries of the State show 8,780 vessels engaged valued at $3,680,163, with apparatus valued at $891,213, and the following annual product: Fish, $7,589,789; mollusks, $1,320,200; crustaceans, $447,167; aggregating $9,537,156. The total number of persons engaged in the fisheries was 11,814. Of the value of the vessels, 39.51 per cent; of apparatus, 27.21 per cent; and of food fish product, 44.69 per cent are credited to the city of Gloucester. New Bedford having 8,422 per cent of the value of vessels, 7.06 per cent of the value of apparatus and 2.35 per cent of the food fish product, besides $217,967 product of the whale fishery. Provincetown had 5.41 per cent of the value of vessels, 1.07 per cent of apparatus and 8.96 per cent of food fish, besides $4,500 product of the whale fishery. Boston had 24.11 per cent of the value of vessels, 13.67 per cent of apparatus and 33.88 per cent of the food fish product.

Commerce.—By the statistics of 1916, fairly reflecting normal conditions preceding the late war, the total imports of the Massachusetts Customs District amounted to $210,900,943, or 9.60 per cent of all imports to the country. The exports amounted to $131,221,946, or 3.03 per cent of all exports. There were entered during the year 146 sailing and 240 steam vessels (American), carrying 439,484 total tonnage; and 269 sailing and 839 steam vessels (foreign), having 1,981,163 total tonnage. The vessels cleared numbered 129 sailing; 175 steam (American), total tonnage 332,063; and 272 sailing, 861 steam (foreign), total tonnage, 1,267,436.

Boston, of course, is the chief port of entry, and in the aggregate value of investments and earnings derived from ocean commerce exceeds all others. The city is extensively engaged in European commerce, from dairy which is regularly imported under foreign flags. Lines of passenger and freight steamers regularly ply between Boston and European ports, and the coastwise passenger and freight traffic to the east and south is important.

Railroads.—Transportation facilities have kept pace with the industrial development of the State. Boston, the metropolis, is connected with the West by two railway systems, and these communicate either directly or by branches with all the leading industrial centres. One general system, with its various divisions, communicates with the South by way of New York, uniting important manufacturing cities and towns, while a network of main and branch lines connects the northern and eastern factory centres of the State with each other, with the seaboard and with the railway systems leading south and west. There are in the State 2,141 miles of main and branch railroad line, besides 1,072 miles of second, third and fourth main track, and 1,755 miles of side track, making the total length of railroad track within the State 4,908.

Various companies as originally chartered are now operated (under leases) in three general systems, the Boston and Albany, Boston and Maine and the New York, New Haven and Hartford. The Boston and Maine system, after receivership, has recently (1919) undergone reorganization. The gross assets of the companies, 31 Dec. 1916, aggregated $863,525,164, and the gross liabilities $833,908,900. The total gross revenue from operation for the year was $163,463,010; and the total expense of operation, $110,802,255; yielding $52,660,755 net. Electrical street railways have multiplied until they now connect all of the principal cities and towns. In the city of Boston subway and elevated railway construction of the highest class, completed and in process, has already transformed til: methods of street transit, and will finally solve the problem of rapid communication between different parts of the city and its suburbs. The Massachusetts street railway companies now own, according to the returns, year ending 31 Dec. 1916, 2,357 miles of main track, 529 miles of second main track and 196 miles of side track, these aggregating 3,082 miles. The gross asset value of these companies aggregated $220,308,549. The total operating revenue for the year amounted to $43,150,201, and the total expense
of operation to $30,753,333. In recent years the prosperity of both steam and street railroads has been curtailed by causes which it is hoped are temporary. The street railways have especially felt the increase in operating expenses due to advancing wages and cost of supplies, without proportionate increase in revenue, since to a large extent they have been confined to fixed rates of fare. And the principal systems are now (1919) operating under remedial legislation, limiting the principal service at cost, with State control and, to a certain extent, guaranteed returns upon invested capital.

GOVERNORS OF MASSACHUSETTS.

GOVERNORS OF PLYMOUTH COLONY
Chosen annually by the People
1620 Nov. 11, John Carver.
1621 April —, William Bradford.
1634 Jan. 1, Edward Winslow.
1636 Mar. 27, Thomas Preston.
1638 Mar. 1, Edward Winslow.
1640 May 5, Thomas Preston.
1639 June 3, William Bradford.
1644 June 5, Edward Winslow.
1645 June 3, William Bradford.
1657 June 3, Thomas Preston.
1673 June 3, Josiah Winslow.
1680 Dec. 18, Thomas Hinckley.*

GOVERNORS OF MASSACHUSETTS BAY COLONY
Chosen annually under the First Charter
1629 Mar. 4, Matthew Cradock.†
1630 April 30, John Endecott.
1639 Oct. 20, John Winthrop.†
1634 May 14, Thomas Dudley.
1636 May 14, John Leverett.
1636 May 25, Henry Vane.
1637 May 17, John Winthrop.
1640 May 13, Thomas Dudley.
1641 June 2, Richard Bellingham.
1642 May 18, John Winthrop.
1644 May 29, John Endecott.
1645 May 14, Thomas Dudley.
1646 May 6, John Winthrop.
1649 May 29, John Endecott.
1650 May 22, Thomas Dudley.
1651 May 7, John Endecott.
1654 May 3, Richard Bellingham.
1655 May 3, John Leverett.
1655 May 3, Richard Bellingham.
1672 Dec. 12, John Leverett (acting).
1673 May 17, John Leverett (acting).
1679 May 28, Simon Bradstreet (to May 20, 1680).

THE INTER-CHARTER PERIOD.
May 25, 1686, Joseph Dudley became president of New England under royal commission, holding the office until 20 December, the same year, when Sir Edmund Andros became governor of New England, appointed by King James II. On 18 April 1689, Governor Andros was deposed by a revolution of the people. After the dissolution of the first charter, Simon Bradstreet was governor from 7 June 1689 to 16 May 1692.

GOVERNORS OF THE PROVINCE OF MASSACHUSETTS BAY
Appointed by the King under the Second Charter
1692 May 16, Sir William Phips.
1693 Sept. 11, William Stoughton (acting).
1699 May 26, Richard Coote (Earl of Bellomont).
1700 July 17, William Stoughton (acting).
1702 June 11, Joseph Dudley.
1715 Mar. 11, Joseph Dudley.
1715 Nov. 9, William Teller (acting?).
1716 Oct. 5, Samuel Shute.
1721 Jan. 1, William Dummer (acting).
1728 July 19, William Burnett.
1728 Sept. 7, William Dummer (acting).
1730 June 11, William Teller (acting).
1730 Aug. 10, Jonathan Belcher.
1749 Sept. 11, Spencer Phips (acting).
1753 Aug. 7, William Shirley.
1756 Sept. 25, Spencer Phips (acting).
1757 Aug. 3, Thomas Powel.
1760 June 3, Thomas Hutchinson (acting).
1769 Aug. 2, Francis Bernard.
1769 Aug. 2, Thomas Hutchinson (acting).
1771 Mar. 14, Thomas Hutchinson.
1774 May 17, Thomas Gage.

UNTIL THE CONSTITUTION
1774 Oct., A Provincial Congress.

UNDER THE CONSTITUTION
Goverors elected annually
1780-85, John Hancock.
1785-87, James Bowdoin.
1787 (to Oct. 8, 1793), John Hancock.§
1793 (from Oct. 8, 1793), Samuel Adams (acting)¶.
1794-97, Samuel Adams.
1797 (to June 7, 1799), Increase Sewell (Federalist).
1799 (from June 7 to May 20, 1800), Moses Gill (acting)¶.
1803-07, Caleb Strong (Federalist).
1807 (to Dec. 10, 1808), James Sullivan (¶Dem.-Rep.)
1808 (from Dec. 10, 1808, Levi Lincoln (acting)¶Dem.-Rep.)
1809-10, Christopher Gore (Federalist).
1810-12, Elbridge Gerry (Democratic-Republican).
1812-16, Caleb Strong (Federalist).
1816-23, John Brooks (Federalist).
1823 (to Feb. 6, 1825), William Rustia (¶Dem.-Rep.)
1825 (from Feb. 6, 1825, Marcus Morton (acting)¶Dem.-Rep.)
1825-34, Levi Lincoln (Democratic-Federalist).
1834 (to Mar. 1, 1835), John Davis (¶Whig).
1835 (from Mar. 1, 1835, Samuel T. Armstrong (acting)¶Whig)
1836-40, Edward Everett (¶Whig).
1840-41, Marcus Morton (Democratic).
1841-43, John Davis (¶Whig).
1843-44, Marcus Morton (Democratic).

1853-54, John H. Clifford (¶Whig).
1854-55, Emory Washburn (¶Whig).
1858-61, Nathaniel P. Banks (Republican).
1861-66, John A. Andrew (Republican).
1866-69, Alex. H. Bullock (Republican).
1869-72, William Claflin (Republican).
1872 (to May 1, 1874), Wm. B. Washburn (¶Republican).
1874 (from May 1), Thomas Talbot (acting)¶Republican.
1875-76, William Gaston (Democratic).

* Mr. Hinckley was governor till the union of the colonies in 1692, except during the administration of Sir Edmund Andros.
† A royal patent (3 Nov. 1620) created the Council for New England with definitions of territory. 19 March 1628, the council granted to Sir Henry Rosewell and others the territory afterward confirmed by royal charter to the "Governor and Company of the Massachusetts Bay in New England." This charter which passed the seals 4 March 1629, designated Matthew Cradock as the first governor of the company. On 13 May 1639, Cradock was removed by the company, but never came to New England. 20 Oct. 1629, John Winthrop was chosen governor by the company. John Endecott had been the candidate of the fishermen. 30 March 1628. While Cradock was the nominal governor a commission was sent out, dated 30 April 1629, to Endecott at Salem appointing him "Governor of London's Plantation in the Massachusetts Bay in New England." In the exercise of his duties he was subordinate to the governor in London. Cradock and Endecott were respectively, until 20 Oct. 1629, the date of the commission of Winthrop who had not then arrived; and Winthrop and Endecott were chief and local governors, respectively, until the arrival of Winthrop at Salem, with charter, 12 June 1630; when Endecott's powers were merged in the general authority of Winthrop.
‡ On 9 Nov. 1715, Eliseus Buxton was proclaimed governor, he having been commissioned 17 March 1715, but he never came over to perform his duties, and resigned in April 1716.
¶ Died in office.
§ Lieutenant-governor, acting governor during a vacancy.
¶¶ One of these, Moses Gill, died while so acting, 20 May 1800, and the Commonwealth, for the only time under the constitution, without a governor or lieutenant-governor. The council, Hon. Thomas Dawes, president, continued until the 30th of the month, when Caleb Strong was inaugurated governor.
|| Resigned upon election to the Senate of the United States.

Public Documents: The census reports of the United States; reports of the decennial State census; annual State reports on the statistics of manufactures and on the statistics of labor bulletins, etc., issued by the State Bureau of Statistics; annual State reports of the boards of education on railroads, savings banks, lunacy, charity, prisons, agriculture, etc.; reports of the treasurer and receiver-general, the auditor and reports upon vital statistics, and upon polls, property and taxes, issued by the secretary of the Commonwealth.

Horace G. Woodlin, Librarian Emeritus, Boston Public Library.

MASSACHUSETTS AGRICULTURAL COLLEGE, at Amherst, Mass., a coeducational institution, chartered in 1863 and opened in 1887 by the State. The college farm is 660 acres in extent, about 175 acres of which are devoted to the campus, 75 to the experiment station, 100 to horticulture and 250 to farming. The work is experimental on the part of the students. The regular course extends over four years, but special courses are given for women desiring to study dairying, market gardening and some other subjects. Winter courses are provided for those unable to take the four years' work. The regular courses lead to the degrees B.S., M.S., M.Agr. and Ph.D. In 1918 the number of instructors was 60 and the students in attendance about 570. The library had about 45,000 volumes; the buildings and grounds were valued at $850,000 and the equipment at $450,000.

MASSACHUSETTS BALLOT. See BALLOT.

MASSACHUSETTS BAY, an arm of the Atlantic indenting the eastern shore of Massachusetts and extending from Plymouth Harbor on the south to Cape Ann on the north, a distance of 42 miles. It is triangular in shape, the north and south shores inclining toward each other until at the entrance to Boston Harbor they are about five miles apart. The depth from the base of the triangle to Boston Harbor is about 21 miles. The northern shore is rocky and irregular, the southern low and sandy. The principal inlets are: on the north coast, Gloucester and Nahant bays and Salem, Marblehead and Lynn harbors, and on the west Boston Harbor. Along the shores are a number of capes and headlands, and off the coast a number of small islands. At the entrance to Boston Harbor there are several islands, on some of which are fortifications. Cape Cod Bay on the southeast is sometimes included in Massachusetts Bay.

MASSACHUSETTS BAY COLONY. See MASSACHUSETTS, History.

MASSACHUSETTS HISTORICAL SOCIETY. An association founded at Boston in 1791 and incorporated three years later, for the purpose of collecting and preserving Americana and documents relative to the early history of the Massachusetts Bay Colony. Since 1792, 70 volumes of 'Collections' and 50 volumes of 'Proceedings' have been printed. It supports a museum of relics and a library containing 60,000 volumes and over 120 brochures, etc. Its prize collections are the Winthrop manuscripts on the early settlement of New England and the Parkman manuscripts dealing with French Canada.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY. The was founded in 1865, at the close of the Civil War, when the need was beginning to be felt for schools which should train men to deal with the new industrial problems. It was the plan of President Rogers, the first president, to have a school of technology which should give a thoroughly practical training in the application of scientific princic-
ples to practice in the arts, but not primarily training in mere technics, in the narrow sense. Accordingly they planned that each of its courses should embrace enough general studies to impart the elements, at least, of a liberal education; and, above all, they laid down that the most truly practical training, even in an industrial sense, must be grounded in a thorough knowledge of scientific laws.

Founded on these principles, the Institute of Technology began a career of steady development; and, as the largest school of its class in the United States, the widest in scope of instruction and in many respects the best equipped. The total number of its students in 1916 was 1,900, the total number of instructors 300. The number of volumes in the library was 100,000. Though 60 per cent of the students come from Massachusetts, among the remainder are found residents of 46 States of the Union, and of 28 foreign countries. In all 48 classes have graduated, aggregating over 6,000 persons. Except in seasons of financial depression, the demand for these graduates is always in excess of the supply.

The undergraduate studies of the school are divided into 15 distinct courses, each of four years' duration, and leading to the degree of bachelor of science. These courses are as follows: Civil engineering, mechanical engineering, mining engineering and metallurgy, electrical engineering, chemical engineering, sanitary engineering, naval architecture and marine engineering, engineering administration, chemistry, electrochemistry, biology and public health, physics, geology, general science and architecture. Between the departments which maintain these several courses there is the closest connection and mutual support. Consequently the instruction is specialized to a degree which would be impossible in a smaller college, with a less numerous staff of instructors. Again, the instructors, though connected in a special sense with one department, and giving instruction, it may be, to students from many others. This mutual helpfulness of the departments is seen first in the fundamental subjects, such as chemistry in the first year and physics in the second, which are given to several classes or, as it is often called, the large number of optional lines of work offered. Within most of the regular courses the student is allowed considerable latitude of choice, in the later years of his study, and many thus select that group of studies which is best adapted to the particular branch of his profession for which he is preparing.

For 50 years from its establishment the institute occupied buildings on or near Boylston street in Boston. From the first structure built by President Rogers the number increased to nine, eight of which were devoted to technical instruction. The most interesting aspect of the equipment were the extensive laboratories. Many of them when first instituted represented an attempt to apply the laboratory method in a way up to that time unknown in the history of scientific instruction in this country. The laboratories of physics and of chemistry were the first to offer laboratory instruction in these subjects to students in large classes; and the mining and metallurgical laboratories, the steam laboratory and the laboratory for testing the strength of materials also represent a marked advance over previous methods, either in the subjects taught or in the scale on which the work is done.

Lack of space in which to expand in the congested business and residential section which grew up around it forced the Institute to seek a location adequate to its needs for constantly growing activities. It purchased in 1912 a plot of 50 acres in Cambridge, on the bank of the Charles River Basin facing Boston, and on 14 June 1916 the new Technology was dedicated. The main teaching buildings are to be completed late in 1916. They are devoted to the educational purposes. This will increase the area of the old buildings and still leaves room for growth to twice the present size.

The laboratories which were so excellent have been rearranged with greater space and some of them are the most remarkable in the country.

The boiler plant is itself a laboratory, with a capacity of 2,000 horse power, the boilers of standard type with their steam lines. They are especially adapted to experiment. This powerhouse will care for the heating, lighting and motor force of the great buildings and is built on the lines of a big central station.

Steam is conveyed from the boilers to the steam laboratory in mechanical engineering through a subway seven feet square in section and the supply is carried in 20 and 10-inch pipes. The electrical equipment at the boilers includes three turbines directly connected to generators of 75 kilowatts, 50 kilowatts and 150 kilowatts, respectively, furnishing three phase current at 2,300 volts. In addition there are one 150-kilowatt turbine, two 150-kilowatt motor-generators furnishing direct current at 110 and 220 volts and two 35-kilowatt exciters.

The steam laboratory equipment includes a Curtis turbine of about 75 kilowatts capacity, a 38 horse-power Corliss with dynamometer, a 225 horse-power McEwan tandem compound, a compound and generator of the same make of 250 horse power, and a triple expansion Corliss, especially adapted for experimental purposes.

In the same laboratory there is a Brown engine driving a three-stage compressor which will work up to 2,500 pounds per square inch. There are other compressors and a great many small engines and models of different types.

The hydraulic laboratory is fitted with 700 feet of canals, some of them 40 feet cross section, with reservoirs, weirs, tanks and all kinds of measuring devices. Two pump wells 26 feet deep will serve for the testing of large pumps on a commercial scale. A pump of the capacity of 22,000 gallons a minute lifts water to the second floor above which is discharged through a canal of 25 feet cross section into a penstock for the testing of water wheels. Natural heads up to 35 feet and artificial heads of some hundreds of feet may here be used. The battery of pumps includes a Douglass triplepump, a Gould triplex and a Davis triplex, a 150 horse-power turbine with direct connected centrifugal pump, a 100 horse-power Terry turbine, a three-position electric pump, two duplex pumps each of the capacity of an ordinary steam fire engine, and the great pump which is
MASSACHUSETTS MEDICAL SOCIETY—MASSAGE

driven by an angle compound engine of 325 horse power.

The chemical laboratory is fitted with a central heating furnace for the purpose of elevators for quick service within the department, electrical heating devices for the various processes and three systems of ventilation, the regular house system, the hood and a mushroom ventilator applied to every table. The laboratory has its electrical supply independent of the lighting or power systems of the buildings.

The aerodynamical laboratory is equipped with a four-foot blowing tunnel and an aerodynamical balance, a replica of that at Teddington, England. The electrical laboratory is somewhat better than the old Lowell laboratory, but the improvement has been of necessity in details and convenience.

The transmission laboratory is of unusual excellence. The equipment includes a 2,500 nautical mile, artificial cable, corresponding to a regular ocean cable; a 2,500-mile long-distance artificial aerial line corresponding to a long-distance trans-continental telephone line, two artificial power transmission lines of 800 miles and an artificial power transmission line of 35 miles. Besides these items there is a span of power transmission, 150,000-volt capacity. For experiments with this a special laboratory has been built at the foot of one of the towers.

These are some of the new special equipment, but the other laboratories, notably those for testing materials, for industrial chemistry, for biology, etc., find themselves newly placed in improved surroundings with increased facilities and apparatus. The sewage laboratory, being located near one of the great outlets of the principal drainage of the metropolis, will not be moved.

With this unusual laboratory equipment, it has been possible for the Institute to do much of its experimental work on a scale approaching industrial operations. The laboratories of mining and metallurgy, for instance, are designed to treat ores in quantities approximating those used in actual practice, and ranging from 500 pounds to 3 tons, and the control facilities and apparatus from this laboratory are well known. In the laboratory for testing the strength of materials, again, were conducted the first systematic and extended tests of beams of commercial size.

Throughout all the work of the Institute the aim of instruction is so to adjust the theoretical and experimental work that the acquisition of principles in the classroom shall prepare the student for his laboratory exercises, and that these in turn shall fix methods and results in his memory, and give him capacity for new experimentation. Throughout it is intended to guide the student rather than to instruct him, and, whether in the four-year courses above described or in the graduate courses with which the student shall be supplied when he is trained to work with less and less dependence upon his teachers. This training should result in a considerable increase in his powers of ascertaining facts and overcoming difficulties, and so should increase his capacity for original research.

MASSACHUSETTS MEDICAL SOCIETY, an association incorporated at Boston, Mass., 1 Nov. 1781, and holding regular sessions from that date to the present. Its charter was signed by John Hancock, first State governor of Massachusetts and eight surgeons, who have made their medical studies in colleges approved by the society and who have been examined by its censors and are of known probity, are eligible to membership.

Women were first admitted in 1884. Since 1870 it has regularly issued its 'Communications.' It also issues a 'Pharmacopoeia' and 'Publications,' various reports and essays, an annual directory, and, since 1789, a triennial catalogue. The society is a potent force in maintaining a high standard in the medical profession. It has about 3,500 members.

MASSACRE (French, massacre, slaughter, probably connected with Latin, macellum, a meat-market), the indiscriminate and unnecessary slaughter of human beings, and, in a transferred sense, of animals. In the case of human beings it implies the absence of all forms of law or of sufficient grounds.

MASSACRE OF THE INNOCENTS, the slaughter of the children in and about Bethlehem by the soldiers of Herod, whose superstitious fears caused him to see a rival to the babe of whose birth he was apprised by the wise men (Matthew II, 1-16). The story has been for centuries a favorite subject with artists, especially those of the Flemish and Italian schools. Intense realism is usually injected into the scene and also a wealth of detail. Among the greatest examples are those by Tintoretto in the Scuola di San Rocco, Venice; Reni in the Gallery of Bologna; Daniele da Volterra in the Uffizi Gallery, Florence; Rubens in the Pinakothek of Munich and Breughel in the Gallery of Vienna.

MASSAGE, a procedure, usually performed by the hands, such as friction, kneading, rolling and percussion of the external tissues of the body, either to relieve pain or to assist a cure, or with some hygienic object in view. A male massagist is known as a masseur, a female as a masseuse. Massage in some crude form has always been used by savages as well as by the civilized. It was mentioned by Homer and Hippocrates, having been one of the luxuries of the ancient Greeks and, among the Romans, was largely used by gladiators, and to make slaves more comely by rubbing out their tissues. Sometimes it was done by medical practitioners, often by slaves and priests and those appointed to anoint the wrestlers before and after they exercised. Hippocrates says that "rubbing can bind and loosen, can make flesh and cause parts to waste; hard rubbing; soft rubbing loosens; much rubbing causes parts to waste; moderate rubbing makes them grow." Manual treatment of the body was long ago practised by the Chinese, and the Japanese, Turks, Egyptians and people of various nationalities have employed it in some form from early times.

Often the use of massage is associated with that of certain active and passive movements known as the Swedish movement-cure (q.v.), established by Pehr Henrik Ling. His system of gymnastics became popular in spite of opposition and of the fact that it was largely a revival of old methods of treat-
ment. In 1873 Megzer, of Amsterdam, and in
1877 S. Weir Mitchell of Philadelphia pushed
forward the cause of massage. To-day it is
considered by physicians as a branch of medi-
cal treatment, useful in certain cases if rightly
administered, but capable of doing harm when
improperly applied. Unfortunately the lay
frequently look upon it as a sole means of re-
lief or cure. Much depends upon the judgment
and skill of the masseur, as the special reaction
of the individual patient to be massaged for
and, on the other hand, a skilful operator can
accomplish more in a quarter of an hour than
an ignorant one can in an hour. The procéd-
ures in massage may be placed under four
heads: stroking (the effleurage of the French),
kneading (malaxation), friction and percus-
sion. Stroking is performed over surfaces
with the palm of the hand or its radial border,
or with the palms of the fingers, or the sides of
the knuckles. Kneading is the grasping of muscles,
etc., with both hands or between the thumb and
fingers of one hand, and rolling and squeezing
them. Friction is a peculiar and forcible cir-
cular rubbing. Percussion is the striking or
beating of a part, either with the hand or an
instrument called a percussion or muscle-beater.
A special technique of massaging the face, and
particularly the ears and eyes, has had surpris-
ingly gratifying results in preventing deafness
and curing certain types of blindness, for in-
stance, where an embolism of a central artery
of the retina has been removed by massage.
It is claimed that the modern system of mas-
sage makes the blood circulate more freely,
strengthening muscles, causes effusions and
exudations to be absorbed, improves secretory
and excretory action, and invigorates the whole
body. A notation of no small importance is that
after satisfying a desire for stroking, knead-
ing, friction and percussion. Such a method of
curing their ills will make an immediate and
a strong appeal to their instincts. This pre-
supposes a physical and mental make up, pre-
disposed by early development, to seek and get
satisfactions from the skin and muscle sensa-
tions derived from manipulation at the hands of
another. This mental disposition is in mod-
tern times well recognized in psychoanalysis
(q.v.), which, however, goes at the treatment in
Force the following question: Does a person
helped by massage, there is a cause in the
way in which the mind unconsciously regards
the pleasures derived from the manipulation
of the skin and muscles. If, for instance, the
individual is of such a mental temperament,
because of early environment he has been led
to derive more than ordinary pleasure from
being stroked, kneaded, rubbed or even beaten
(and the history of the development of massage
shows that such persons are quite numerous);
such an individual will be the more likely to
contract diseases of the type which are on rec-
ord as having been remedied or cured by mas-
sage. He will develop those diseases instinct-
vively without knowing the connection between
them and the unconscious wish which is the
cause of the unconscious wishes for just such 15
stimulation of the muscular, tendinous and
cutaneous end organs. The patient will do
well under such a treatment, at least, partly be-
cause a source of unconscious gratification
closed to him, possibly the ear of childhood
has been through massage reopened to him.

M assaget, mä-sä‘t-të, in ancient his-
tory, a name given to nomadic tribes of north-
ern Asia who dwelt to the east and south of the
Caspian Sea. Herodotus says they wor-
shiped and offered horses to the sun, had a
community of wives, killed and ate their aged
people, lived chiefly on the milk of their
herds and on fish, and fought on foot and
on horseback with lance, bow and double-edged
axe. They are chiefly mentioned in connection
with Persian history. Cyrus the Great perished
in war with the Massaget, 529 B.C. Accord-
ing to some they belonged to the Mongolian
stock, according to others to the Aryan.

M assait, mä-sä‘it, American Indian
chief, sachem of the Wampanoags: b. Massa-
husets, 1580; d. 1661. His dominion extended
over nearly all the southern part of Massachu-
setts, from Cape Cod to Narragansett Bay; but
his tribe, once estimated at 30,000 in number,
shortly before the landing of the Pilgrims
at Plymouth been reduced by a disease, sup-
poused to have been yellow fever, to barely 300.
On 22 March 1621, a little more than three
months after the founding of Plymouth, he
appeared before the infant settlement with 60
of his warriors, armed and painted, for the
purpose of forming a friendly league with the
white men. Although the tribe were reputed to
be cruel and treacherous, the open and friendly
greeting of Massait so favorably impressed
Governor Williams, while on his way to
Providence, that, after the preliminary nego-
tiations were concluded, he formed in behalf
of the colony a treaty of peace and mutual
protection with the Wampanoags, which for 50
years was sacredly kept by both parties. The
friendly disposition of Massait toward the
colonists never relaxed. He lived within the
limits of what is now the town of Warren,
R. I., near an abundant spring which yet bears
his name, where he often entertained wander-
ing pilgrims or administered to their necessi-
ties. Roger Williams, while on his way to
Providence, was for several weeks his guest
at this place. Massait was just, humane and
honest, never violating his word and constantly
endeavoring to imbue his people with a love
of peace. In person, Morton says, in his
Memorial, he was "a man of great age, grave of
countenance, spare of speech." His second son, Pometacom, called by the col-
onists King Philip, who ultimately became
sachem of the Wampanoags, was of a less plac-
able disposition, and allowed the encroachments
of the colonists to hurry him into the bloody
contest known as King Philip's War. Consult
Baker, Virginia, 'Massasoits' Town Sowams in Pokanoket' (Warren, R. I., 1904).

MASSASAUGA, mās-sā-sā-ga, the ground rattlesnake of the central United States. See Rattlesnake.

MASSÉNA, André, an-dra mā-sā-nā, marshal of France: b. Leven near Nice, France, 6 May 1758; d. 4 April 1817. In 1775 he entered the French army and after 14 years' service left the army and returned to Nice, where he married. During the Revolution he entered a battalion of volunteers, and in 1793 was made general of brigades. In 1794 he took command of the right wing of the French army in Italy, where, at Rivoli and elsewhere, he highly distinguished himself. In 1799 he defeated the Austrian and Russian forces at Zürich, and in 1800, by his defense of Genoa for three months, gave Bonaparte time to strike successfully at Marengo. In 1804 he was created marshal of the empire. In 1805 he received the chief command in Italy, where after the Peace of Presburg he occupied the kingdom of Naples. In 1809 he was appointed to the command of the right wing of the French army in Poland, and soon after received the title of Duke of Rivoli. In 1809 he distinguished himself against the Austrians, and at Esslingen his constancy and firmness saved the French army from total destruction. Napoleon rewarded him with the dignity of Prince of Esslingen. In 1810 he took command of the army in Portugal, and forced Wellington within the lines of Torres Vedras, till want of provisions compelled Masséna to make a retreat by Louis XVIII, and though on the return of the emperor he acknowledged his authority, took no active part in the events of the Hundred Days. Consult his 'Mémoires,' edited by Koch (7 vols., Paris 1848-50); Fitzmaurice, G., 'Massena' (in Royal United Service Association Journal, Vol. LVII, London 1913); Gachet, Edouard, 'Histoire militaire de Massena' (Paris 1908); Toselli, 'Notice biographique sur Massena' (Nice 1889).

MASSENA, mā-sē-na, N. Y., village, in Saint Lawrence County, on the Grasse River, and on the New York Central and Hudson River and the Grand Trunk railroads, about 35 miles northeast of Ogdensburg. It was settled by people from Vermont, about 1802, and was incorporated as a village in 1856. It is situated in a rich agricultural region, in which the chief products are hay, potatoes, dairy products and apples. Massena Springs, just outside the village limits, is one with the village in commercial and industrial interests, and is a famous resort on account of its medicinal springs. Great opportunities for manufacturing are afforded by the plant of the Saint Lawrence River Power Company, which has a capacity of 40,000 horse power, and which can easily be increased. This power has been secured by diversifying a small portion of the water power of the Saint Lawrence River through a canal, three miles long, into turbines, which have direct connection with electric generators, and thence into the Grasse River. The canal starts at the site of the Long Sault rapids in the Saint Lawrence, and is 200 feet wide and 18 feet in depth. Owing to the peculiar formation of the country here, the point at the head of the rapids is 45 feet higher than the point where the canal enters the Grasse River, which is a tributary of the Saint Lawrence. The Grasse acts as a tail race, carrying the water back into the Saint Lawrence, thus two water wheels span the canal. By using the Grasse River and the canal there is now a passage wholly within the United States for steamers around the un navigable rapids. The power plant at Massena is second only to Niagara as a centralized power supply station. The use of iron works, reduction works, iron and steel works, sash and door works, aluminum factories, and factories. There are several churches, banks, a high school and public schools. Massena is the business center for a population of 60,000. Pop. 2,951.

MASSANET, Jules Emile Frédéric, zhil a-mēl frā-dā-rēk mā-sā-nē, French composer: b. Montaub, France, 12 May 1842; d. Paris, 13 Aug. 1912. He was the youngest of 21 children; his father, a blacksmith, had served in the engineers under Napoleon. After studying at the Paris Conservatoire under Reber, Laurent, Thomas and Savard, he gained the first prize for pianoforte in 1859, the first for fugue, and the Prix de Rome for his cantata, 'David Rizzio,' in 1863. He had done some traveling in Italy and Germany before he made his debut in Paris at the Opéra Comique in 1868 with 'La Grand-Tante.' He was appointed professor of composition at the Conservatoire in 1878 and made a member of the Académie des Beaux Arts. Among his operas are 'Poème du Souvenir' (1860); 'Poème d'Avril' and 'Suite d'Orchestré' (1868). His first import ant work was the opera, 'Don César de Bazan,' which was performed in the same year by 'Les Erinnyes,' a tragedy by Leconte de Lisle, and a sacred drama, 'Marie-Madeleine.' An oratorio, 'Eve,' was performed in 1874; the opera, 'Le Roi de Lahore,' in 1877; a sacred legend, 'The Virgin' in 1880; and 'Herodiade' in Brussels, 1881. 'Manon' appeared in 1883; 'Le Cid in 1885; 'Esclarmonde,' a romantic opera in 1889; also a large number of popular melodies, pianoforte pieces, and a series of seven 'Suites d'Orchestré,' including 'Scènes Pitttoresques,' 'Scènes Alsatianes,' 'Scènes Hongroises,' 'Scènes Napolitaines,' and 'Scènes de Féerie,' as well as ballets, 'Narissa' and 'Biblis.' He also wrote some entr'actes and stage music for Sardou's dramas the 'Crocodile' and 'Theodora.' His opera 'Le Mage,' (words by Jean Richerpin) and a drame lyrique, adapted from Goethe's 'Werther,' were performed in 1891. 'Thais' was first produced at the Paris Opera 16 March 1894, the libretto having been adapted from the novel by Anatole France; a short one-act piece, 'Le Portrait de Manon,' was performed at the Opéra Comique in the same year, and in 1895 he wrote the music for Jules Claretie's 'Le Navarraise.' Of his latest works, the opera 'Don Quichotte' was produced in London in May 1912, and his last opera, 'Panurge,' was completed just before his death. His music, always melodious, has been described by critics as being excessively sugary.

MASSEY, mas'e, Gerald, English poet: b. Gamble Wharf, near Tring, Hertfordshire, 29 May 1828; d. 29 Oct. 1907. He received but little education, and at eight was employed in a silk factory. Going to London about 1843, he
became an errand boy, and in 1849 editor of The Spirit of Freedom, a Radical paper, becoming at the same time a member of the Workingmen's Association, and joined the Christian Socialists. In 1854 he published 'Ballad of Babe Christopher,' and other poems. The volume attracted the notice of Landor, and the poems issued in succession to it met with no little popularity. Other books of his have been 'The Secret Drama' (1864–72); 'Havelock's March, and Other Poems' (1861); 'A Tale of Eternity and Other Poems' (1869); 'Concerning Spiritualism' (1872); 'A Book of the Beginnings' (1883); 'The Natural Genesis' (1883); 'My Lyrical Life,' a collection of poems (1889). For some years he lectured at home and in the United States and Australia on spiritualism and various social and socialist subjects.

MASEY, Hart Aimeri, Canadian inventor: b. Haldimand, Northumberland County, Ontario, 1823; d. 1897. He received his education at Watertown, N. Y., and Victoria College, Cobourg, Ontario. He assisted in managing his father's farms and while thus engaged set about improving the agricultural implements then in use. His father established a factory at Newcastle which Hart became sole owner in 1855. He perfected mowing and reaping machines, the first of their kind in Canada, and introduced improvements in many other farm implements. In 1879 the factory was removed to Toronto. Massey received awards at Paris in 1878, Philadelphia 1876 and at Antwerp in 1885. He was also a noted philanthropist.

MASCLOC. A mineral consisting of monoxide of lead, PbO, containing about 92.8 per cent of that metal and an ore in many mines in Colorado and Idaho.

MASEILLON, Jean Baptiste, zhwaN bah-taste ma-se-yon, French preacher: b. Hyères, Provence, 24 June 1663; d. Clermont, 18 Sept. 1742. In 1681 he entered the Congregation of the Oratory; then taught theology at Montbrison and Vienne; went to Paris in 1696 as director of the Seminary of Saint Magloire, and won great favor, even at court, by his eloquent and searching attacks on the Jesuits, and on the materialist philosophy of the day. He was particularly famous. In 1718 he was appointed preacher to Louis XV, then only nine years old, and for him composed the Petite Cærème, a notable series of sermons. Maspillon was elected to the French Academy in 1719; in the same year he retired from Paris to Clermont, where he died of apoplexy. His works were edited in 1728 by Guillon and in 1886 by Blamigian, whose biographical sketch, 'Maspillon d'après des Documents inédits' (Paris 1879), should be consulted. Consult also de Jullièville, Louis Petit, 'Histoire de la langue et de la littérature française' (Paris 1898).

MASESILLON, mas-il-on, Ohio, city, in Stark County, on the Tuscarawas River, the Ohio Canal, and on the Wheeling and Lake Erie, the Pennsylvania and the Baltimore and Ohio railroads. It is about 100 miles in direct line northeast of Columbus and eight miles west of Canton. Massey was established in 1825, and in 1853 was incorporated as a village; the city charter was granted in 1868. It is situated in the Tuscarawas Valley, noted for its large bituminous coal fields and for its excellent farm lands. In the vicinity of the city are quarries of white sandstone. Some of the industrial establishments are foundries, rollingmills, machine-shops, bridge works, potteries, fire brick, enamelled ware, paper, glass-works, steel tubing, furnaces, flour-mills and creameries. In addition to the manufactures of the city there is a large trade in coal, sandstone, grain and livestock. The State Normal Institution and the Insane Asylum in Massillon. The city has a number of fine buildings; chief among them are the churches and schools. The government is administered under the charter of 1868, its first charter, and is vested in a mayor, who holds office two years, and a council. The board of education is chosen by popular vote; the boards of health and equalization are elected by the council. Other administrative officials are appointed by the board subject to the approval of the council. Pop. 14,912.

MASSINGBERD, Francis Charles, Anglican clergyman: b. Lincolnshire, 1800; d. 1872. He received his education at Rugby and at Oxford; took orders, and, was appointed rector of South Ormsby in 1823. In 1847 he became prebendar of Lincoln Cathedral and chancellor in 1862. He published 'Reasons for a Session of Convocation' (1833); 'Church Reform' (1837); 'The Educational and Missionary Work of the Church in the Eighteenth Century' (1857); 'History of the Leaders of the English Drama' (4th ed., 1864); 'The Law of the Church and the Law of the State' (1859); 'Lectures on the Prayer-Book' (1864); 'Sermons on Unity, with an Essay on Religious Societies' (1868).

MASSINGER, mas-im-jer, Philip, English dramatist: b. Salisbury, November 1563; d. Southwark, London, March 1640. He studied at Saint Alban Hall, Oxford, went to London in 1606, and soon became a well-known playwright. He collaborated with Nathaniel Field, Thomas Dekker, Cyril Tourneur and Robert Daborne, and regularly with Fletcher in 1617–25. Independently, he wrote 15 plays, including comedies, tragedies and tragi-comedies. They are frequently based closely on Italian and Spanish originals, but show much skillfulness in the development of the dramatic situation and the requirements imposed by stage presentation. 'Henry VIII' in its present form was probably written by him with Fletcher. Among the plays wholly or partly by him are 'The Bondman' (1624); 'The Roman Actor' (1629); 'A New Way to Pay Old Debts' (1632); 'The Guardian' (1655). 'A New Way to Pay Old Debts' kept the stage in England to the end of the 19th century. There is an edition of his plays by Cunningham (1867); and of Selections from Symon (1887–89). (See New Way to Pay Old Debts.) Consult Coleridge, Hartle, 'Dramatic Works of Massinger and Ford' (rev. ed. 1883); Symons, A. (ed.), 'Selected Plays' (London 1887–89); 'Transactions of the New Shakespeare Society' (1880–86); 'Frye, 'Biographical History of the English Drama' (London 1891); 'Cambridge History of English Literature' (Vol. VI, Cambridge 1910); Ward, A. W., 'History of English Drama Literature to the Death of Queen Anne' (New York 1899).

1907. He was educated at Marischal College and Edinburgh University; in 1852 was appointed to succeed Clough in the chair of English language and literature at University College, London, where he was also editor of Macmillan's Magazine 1859-68, and was professor of rhetoric and English literature in the University of Edinburgh 1865-95. He is best known for his elaborate and comprehensive study of Milton's life and times (3 vols., 1858-80) — a work valedictory as a contribution to English biography and to the history of English literature. Other works by him are 'British Novelists and their Styles' (1859); 'Recent British Philosophy' (1865); 'Drummond of Hawthornden' (1873); 'The Three Devils—Luther's, Milton's and Goethe's' (1874). He also published the Cambridge edition of Milton's Poems with introductions, notes, and an essay on Milton's English (3 vols., 1877); the Golden Treasury edition (2 vols., 1874); the Cabinet edition (1890) and the Globe edition (1871); 'De Quincey' in 'English Men of Letters' series (1878); an edition of De Quincey's works (14 vols., 1889-91), and 'Edinburgh Sketches and Memories' (1892). In 1893 he was appointed Historiographer-Royal for Scotland. He also wrote 'Art Style in Person and in His Writings' (1885); 'Edinburgh Sketches and Memories' (1892).

MASSON, Frédéric, frā-daȳ-rēk mā-sōn, French historian; b. Asnières, 1847. He was librarian in the archives of the Foreign Office, and after the overthrow of the empire became secretary to Napoleon, and was entrusted with the arrangement of the Prince's papers and collections. He is known as the author of nearly 20 volumes in a still incomplete series of works on Napoleon I. His method is anecdotic, and he has based his statements on original documents—correspondence, accounts, and note-books, and the like, many of which he himself owns in his large collection of Napoleonic material. Among the titles of his studies are 'La Révolution de Toulon en périodique à l'II' (1875); 'L'Impératrice' (1877); 'Le Marquis de Casati' (3d ed., 1890); 'Les diplomates de la Révolution' (1884); 'Napoléon et les femmes' (21st ed., 1897); 'Napoléon chez lui' (1894); 'Les cavaliers de Napoléon'; 'Napoléon inconnu' (1895); 'Marie Walewska' (1897); 'Joséphine de Beauharnais, 1763-96' (1899); 'Joséphine, impératrice et reine' (1898); 'Joséphine répudiée 1809-14' (1901); 'L'Impératrice Marie-Louise' (1902); 'Napoléon et son fils' (1904); 'Napoléon et sa famille' (9 vols., 1897-1907); 'Le sacre et le couronnement de Napoléon', 'Autour de Sainte-Hélène' (1908); 'Sur Napoléon' (1909); 'Napoléon à Sainte-Hélène, 1815-21' (1912); 'L'Académie-Française, 1660-1793' (1912); 'Pour l'Empereur' (1913). In 1903 he was elected to the Académie Française to succeed Gaston Paris.

MASSON, Louis François Rodrigue, Canadian statesman; b. Terrebonne, Quebec, 1833; d. 1903. He received his education at the College of Saint Hyacinthe, province of Quebec, and at Georgetown College, District of Columbia. He was admitted to practise law in 1859. In 1866 he served as a Conservative member from Terrebonne and continued to hold his seat until 1882. He served as Minister of Militia and Defense in 1878-80; became president of the council in the latter year; and in 1884-87 served as lieutenant-governor of Quebec province. He was called to the Senate in 1885 and a second time in 1892. He published 'Le Hérosois de la compagnie du Nord-Ouest' (1889).

MASSON, Thomas Lansing, (Tom Mason), American editor; b. Essex, Conn., 21 July 1866. He received his education in the New Haven public schools; entered journalism in New York and since 1899 has been literary and managing editor of Life. He published 'Yankee Navy' (1899); 'A Corner in Women' (1903); 'The Von Blumers' (1906); 'A Bachelor's Baby and Some Grown-Ups' (1907); 'Best Stories in the World' (1914). He edited 'Humorous Masterpieces of American Literature' (1904); 'In Merry Measure' (1905); 'Humor of Love in Verse and Prose' (1907).

MASOWAH, mā-sō-wā, or Massewah, mā-se-wā, or Masa-wah, northeastern Africa, a seaport and the principal town of the Italian colony of Eritrea, on a small coral island in the Red Sea, at the northern end of Arkeeb Bay, separated from the mainland by a caurway. The town is built of stone, is defended by several forts, and is supplied with water from the neighboring M'Kuhl heights. The town is hot and unhealthful, but the M'Kuhl hills have a much better climate. A railway 17 miles long connects with Saati inland and continues to Asmara, the capital 60 miles further inland. The chief imports are grain and flour, cotton manufactures, glass-wares, arms, cutlery, spices, wines and spirits; principal exports, rhinoceros-horns, gold, ivory, honey, pearls, gums, ostrich feathers, skins and wax, brought by caravans from the interior. In normal years the total commerce is valued at about $3,750,000. Formerly dependent on Egypt, the town and strip of coast were ceded to Italy in 1885. POP. about 2,275, including 524 Europeans and about 500 Asians.

MASSYS, mā-sīs'. See Matsys, Quentin.

Mastaba, an Arabic word meaning bench, applied by Egyptologists to certain Egyptian tombs which were common under the Memphite dynasties. Remains of hundreds of these tombs still exist. They are in size from 18 by 26 feet to 85 by 172 feet. They are oblong, bench-like structures, with flat roofs of stone slabs. Consult 'Bulletin of the Metropolitan Museum of Art' (Vol. VIII, New York 1913); Erman, Adolph, 'Life in Ancient Egypt' (New York 1894) and Mariette, A. E., 'Les mastabas de l'ancien empire' (Paris 1881-87).

MASTER OF ARTS (M.A. or A.M., artium magister), an academic honor conferred by universities of the United States, Great Britain and other countries, upon students after a course of study and a previous examination in the chief branches of a liberal education, particularly philosophy, theology, mathematics, physics and history. The title magister, connected with a qualifying phrase, was used among the Romans as a title of honor; but its present meaning must be traced to the time of the establishment of the oldest universities. Regularly used in the Middle Ages, it is not now known as they now exist in the universities. The whole circle of academic activity

Vol. 18 — 27
was limited to the seven liberal arts (see Art); and they who received public honors on the completion of their course of studies, for their diligence and knowledge, and had already received the degree of baccalaureus (bachelor), were called magistri artium (masters of the liberal arts). In American and English universities this degree follows that of bachelor. The degree of arts is inferior to that of doctor of letters (D.Litt.), and in the German universities the title was formerly conferred, but has been superseded by that of doctor of philosophy (Ph.D.), which practically corresponds to the degree of M.A. in other universities. This title is an indispensable preliminary to the attainment of the position of docent in the German universities, that is, one who has obtained the right to deliver academical lectures. See Academic Degrees; Costume; Academic; University. 

MASTER OF BALLANTRAÉ, bäl-ahn-trā. The, a novel by Robert Louis Stevenson, published in 1889. It is a Scottish romance of the 18th century, beginning with the Stuart uprising of 1745. It is a sombre tragedy of the enmity of two brothers, of whom the elder, James Durrie the Master, takes the side of the Stuarts, the younger, Henry, that of King George. 

MASTER BUILDER, The. The tendency toward symbolism, to be observed in the early romantic works of Ibsen, and occasionally in his dramas of social awakening, becomes dominant in 'The Master Builder' (By master Solness?), published in 1892 and played the next season. Already in 'The Wild Duck' and 'The Lady from the Sea,' Ibsen had mingled symbolism with naturalism; but only in 'The Master Builder' does the hidden allegory threaten to warp his surface story out of consistency. The piece, which begins with matter-of-fact scenes and situations from middle-class life, ere long develops into a tenuous fable that suggests much more than it presents. 

Of the drama of ideas 'The Master Builder' emphasizes two notions: the peril of selfish individualism, already shown in 'Rosmersholm,' and 'Hedda Gabler'; and the struggle of age against youth. Ibsen, conscious of his advancing years, felt the inevitable passing of power from the elder to the younger generation. He felt, also, not only the fear of youth, but its fascination, especially in his innocent affair with Emilie Bardach, a girl of 18 whom he, at the age of 61, had met in the Tyrol during the summer of 1889, and with whom he later corresponded. He has universalized these merely personal sentiments, setting forth the problem of every man who lives long enough to regret what is gone and to strive desperately to hold what is slipping from him. This particular conflict of the homely type isولة the full larger conflict between individualism and altruism. 

Solness, the master builder, has achieved success at the expense of his wife and his business associates. He has checked the rise of Knut Brovik, and refused to young Ragnar Brovik permission to build independently. He has employed the latter's sweetheart and captured her affections only as a ruse by which to retain Ragnar's services. Obsessed, as he admits, with dread of the younger generation, yet thinking himself at last secure from it, he succumbs when the younger generation knocks at his door in the person of Hilda Wangel. Hilda, who had already appeared in a minor rôle in 'The Lady from the Sea,' is a strange and wilful maiden who induces Solness to relax his selfish schemes, and, at the same time, to attempt to mount, as he once was wont, to the top of a lofty tower. He can no longer safely climb to such heights, and yet, inspired by Hilda's faith, he makes the attempt, only to fall. Though he forfeits life, Hilda professes satisfaction, inasmuch as, when he stood at the dizzy summit, she has heard 'harpers in the air.' 'Hilda is the puzzle of the play, an influence for both good and evil, a symbol of youthful aspiration, or perhaps of youth as the enemy of age and of woman as the enemy of man. The charm of the drama lies in its tantalizing hints of concealed significances; its defect lies in its lack of proper correspondence between the human action and the allegory. Much in the later portions of the work is scarcely intelligible as a natural representation of life. 'The Master Builder' has been translated by Edmund Gosse and William Archer (1893). It is discussed in the monographs on Ibsen by Otto Heller (1912), Jennifer B. Lee (1907), M. J. Moses (1908), and Henry Rose (1908), and, by P. H. Grummann, in 'Nebraska University Studies' (1910). 

Frank W. Chandler. 

MASTER OF THE HORSE, an official having charge of the horses, hounds, etc., of a sovereign, as of England. He is there a member of the ministry and the third dignitary of the court. The office is appointive, and he has the use of the royal horses and servants. The office exists to-day in Germany and formerly also in France. 

MASTER OF THE ROLLS, a member of the Supreme Court of Judicature in England, who presides with the lords justices in the Court of Appeals, and ranks next to the Lord Chief Justice. He is the keeper of all records of the Court of Chancery and of the rolls of all grants and patents that pass under the Great Seal. By the Supreme Court of Judicature Act of 1873, he was denied the privilege he formerly had of a seat in the House of Commons. 

MASTER AND SERVANT. See Family Law. 

MASTER SINGERS. See Meistersingers. 

Masters, Edgar Lee, American lawyer and writer: b. Garnett, Kan., 23 Aug 1868. He studied at Knox College, Illinois, and was admitted to the bar in 1891. His publications include 'A Book of Verses' (1898); 'Maximilian,' a drama in blank verse (1906); 'New Star Chamber and Other Essays' (1904); 'Blood of the Prophets' (1905); 'Althea,' a play (1907); 'The Trifer,' a play (1908); 'The Spoon River Anthology' (1915); 'The Great Valley' (1916). Mr. Masters writes his poems both in vers libre and in iambic pentameter. 'Spoon River Anthology' is the best known of his works. It is a unique collection of truthful epitaphs on the inhabitants of a middle Western village. It is marked by a biting vigorous satirical style, and is pervaded by a materialism.
that shocks and surprises. Despite its obvious limitations, its naïve force has won many readers and much favorable comment. Consult Lowell, Amy, 'Tendencies in Modern American Poetry' (New York 1917).

**MASTERWORT**, the rustic name of several umbelliferous plants, as those of the genus _Astragalus_ (for Durol, formerly much cultivated as pot-herbs, and held in great repute as a stomachic, sudorific, diuretic, etc.

**Mastic Gum**, or **Mastiche**, a resinous substance flowing from deep incisions made in the branches of the _Pistacia lentiscus_, a shrub of the terebinth family growing in the countries bordering on the eastern Mediterranean. This tree attains the height of 15 or 20 feet; the leaves are alternate and pinnate; the flowers are small, inconspicuous, disposed in axillary racemes, and are succeeded by an ovoid drupel containing an osseous nut. It forms one of the most important products of Scio, and other Aegean islands, where it has been cultivated from remote antiquity. Heat seems to exercise a great influence on the resinous product. Mastic is consumed as a chewing-gum in vast quantities throughout the Turkish Empire by women of all classes, for the purpose of cleansing the teeth and imparting an agreeable odor to the breath. It is related to myrrh, frankincense, etc., and was formerly in repute as a medicine throughout Europe, but at the present time is chiefly useful in the arts as a varnish for maps, drawings, etc. Dentists employ it as a filler for cavities.

**Mastication**, or **Chewing**, the thorough subdivision of the masticate in the mouth, so that it can be readily acted upon by the gastric juice and other digestive secretions. The tongue, cheeks and lips push the food material between the teeth, and by the lateral and upward motions of the lower jaw it is cut and torn by the incisor, canine and bicuspids teeth and bruised by the molar or grinding teeth. During these actions the food is softened by the saliva (insalivation), which exudes abundantly from the salivary glands by the action of mastication. Typical mastication is seen only in the higher vertebras. The amphibian bolts its fly, the bird its grain, and the fish its brother without the ceremony of chewing, but in man and the higher animals mastication is necessary for complete and comfortable digestion. Thrillcommunation in food by mastication is analogous to the pulverizing process employed by the chemist, but associated with mastication is insalivation, as it is almost impossible to swallow substances which are very dry. Imperfect mastication of food, either by reason of rapid swallowing (bolting), or because of the absence of sound and serviceable teeth, is very frequently the cause of the numerous ailments classified under the term indigestion. Exaggerated mastication which has been so highly recommended by certain persons as almost to constitute a panacea or complete prophylaxis is known to lessen the secretion of gastric juices which is started by sensations of taste, to protract beyond desirable limits its time of working and proper gastric digestion, to develop the salivary deposit in a proportion relatively too great when compared with the secretion of the pancreas. It is more over known that the teeth are likely to wear out too soon, if mastication is carried beyond a reasonable time.

Exaggerated mastication and the fancied advantages accruing from it are an illustration of an indulgence in a form of gratification of an unconscious desire. In infancy a great pleasure is derived merely from mouthing different objects, a pleasure originating in the mode of absorbing the early meals at the mother's breast. It has been discovered by the unconscious wishes of mankind that the sexual desire in the adult is a synthesis of different partial desires which in the infant are satisfied in different parts of the body, now here, now there, but which in the adult are assembled in the genital organs or are at least unified under the supremacy of the genitals. But it has been definitely proven that in some individuals this synthesis has never been successfully accomplished. Either the mouth pleasure zones of the sexual or the skin or some other zone which in infancy a quite absorbing sense of gratification has failed of appropriate subordination, and has persisted into adult life with some individuals, as a source of extraordinary pleasure. To this class of partially undeveloped minds belong not only the advocates of exaggerated mastication but all other persons who develop any other form of activity as a fad such that they are noticeably peculiar in that respect.

**Mastiff**, a breed of dogs of great size, recognized by the large head, the dependent lips, the broad, hanging ears, and by the general musculature of the form. The mastiff in general disposition is affectionate and gentle, extremely faithful and vigilant. In Rome and in classical ages these dogs were held in high estimation for their strength and courage. The most valued breeds were obtained from Great Britain, where these dogs originated, and were used to guard flocks and herds; and watching has become instinctive with them. Roman officers were appointed to breed them and to transmit them periodically to Rome, where they fought lions, etc., in the arenas of the Roman amphitheatres and were otherwise favorites. The dog now is highly valued, both as a watch-dog, and as a domestic companion. Fawn is the prevalent color, and the weight should be about 165 pounds.

**Mastigophora**, a class of Protozoa in which the flagellate form is prominent although the ameboid and encysted conditions frequently occur. Typical forms are contained in the order _Flagellata_ (q.v.).

**Mastodon**, a genus of fossil proboscids of the elephant family, whose remains are found in all parts of the world in Tertiary formations from Miocene time onward to the dawn of the present era. Although in size and external appearance the larger mastodons much resembled modern elephants, save that, like the mammoths, the northern species were probably clothed with long hair, they differed widely from other genera of the family in details of structure, especially those affecting dentition. Thus milk-molars were present and sometimes were persistent; and the teeth of the fossil molar teeth are not penetrated by deep partitions of cement, and their crowns are marked by few (3 to 5) transverse ridges,
Mastodons are often broken into nipple-like protruberances. This is, in short, the simplest form of tooth-structure in the family, of which the mastodons are the oldest and most primitive type, and nearest to the earlier Dinotheria. The tusks curved upward only slightly; and their length in Mastodon americanus, whose remains have been obtained nearly entirely from bog-deposits in various parts of the United States, was about nine feet, indicating, as do the measurements of the skeleton, an animal about equal in size and appearance to the modern Indian elephant, but with a rather more bulky body and a flatter forehead. Of this species, which was a belated survival of an ancient Old World type that became extinct in the Pliocene, several good skeletons are preserved in the museums of the United States and Canada, and certain European species are also well known. About 30 different kinds of mastodons have been described from bones found in almost every country in the world. In the Pliocene works of Texas, Nebraska, and Wyoming, remains of a proboscidian (Stegodon) which was a connecting link between the mastodons and the elephants. What brought this widespread group to an end is not clear. There was no diminution in their food, which consisted of herbage, bark and leaves, as is known from undigested stomach-contents found within the skeletons; and they survived the historic vicissitudes of climates until subsequently the present settled conditions arrived. There is good reason to believe that they lasted in America, at least, until after the advent of mankind, but indisputable evidence of this is lacking. See Elephants; Fossil.

Consult Woodward, 'Vertebrate Palaeontology' (1896); Lucas, 'Animals before Man in North America' (1902); Scott, 'End Mammals of the Western Hemisphere' (New York 1913).

Mastodonsaurus, a fossil labyrinthodont batrachian found in the Triassic formations of Wurttemberg and India. It is the type known as a tetrapod, having a length of four feet, a body extending to a length of 10 feet.

Masturbation. The limited, restricted dictionary definition is self-abuse, that is, genital manipulation by the hands, clothing, bed clothes, by riding, by hard objects and by pressure of things against the genitals, etc. Regarded in its broader aspect of an autoerotic reaction to external reality it covers a multitude of activities not ordinarily realized as masturbatory in nature and is one of the most important topics in the whole realm of psycho-pathology. Thus broadly defined it is anyogenous satisfaction through any and all modes of gratification carried on for their own pleasure and includes both somatic and psychic masturbation. Not regarded in antiquity as of very vital importance it was brought into prominence and called deleterious principally by Tissot, who wrote early in the 19th century, and is the sponsor of all the lurid literature which has spread over two centuries since his time. He taught that masturbation was a very vicious and depraved condition, and that it led to various forms of illness and insanity, statements for which modern medical science can find no satisfactory proofs. The most modern attitude toward masturbation is that the deleterious effects so often observed in those who practise it come not from any injury to the body but from the guilty feelings of those who abuse themselves and from the tendency it has to ramadoni and to more infantile levels and the discrepancy between the social value of the autoerotic behavior and the true adult behavior which is called for by the environment will result in some form of mental or bodily illness. The fate of Sodom and Gomorrah revealed its dangers, and the Greeks gave it a poetical conception in the myth of Narcissus (see Narcissus), the youth who fell in love with his image in a pool, a story which represents external reality reduced by autoeroticism to a mere reflection of self. Thus the forms of physical activity which may be regarded as essentially masturbatory in thought and action are very numerous. Any act which satisfies the unconscious desires through producing an effect upon the body instead of on the world of external reality is of this nature. And the body has various zones other than the genital in which this self-gratification is practised unconsciously. Variations are numerous in the forms of activity, the most prominent being the mouth, the intestines and different parts of the skin. The infant naturally puts everything into its mouth, and this habit is continued into adult life by persons who put things into their mouths for other reasons than that of satisfying or masticating them and swallowing them as food. In fact all objects, not food, that are mouthed serve this purpose, including tobacco, chewing gum, toothpicks, etc., and therefore are subject to the same reproaches as any other use of any part of the body through which no change, having a social value, is effected upon external reality. The skin as well as the muscles are used as sources of self-gratification, too, in massage; and such acts as stroking the skin, running, the hooves, scratching, tickling, etc., are other examples.

Constipation of the spastic type is the most common form of unconscious masturbation of the anal-erotic zone. Bodily masturbation, conscious as well as unconscious, is paralleled by a form of thinking that must be called mental masturbation, in which the individual, male or female, has acquired the habit, whether or not from practicing physical masturbation, of seeking pleasure from his own states of mind. Excessive day-dreaming, reading of light literature and attendance on light drama or moving picture shows, aimless driving about in automobiles and most other forms of solitary or unproductive mental activity may be classified as types of mental masturbation, and when carried beyond a certain degree generally result in a species of mental impotence, in which the individual is unable to carry out any activity to a productive conclusion. The treatment of both mental and physical masturbation is mental. The patient is to be shown through self-analysis just what he is doing, both in its physical and its psychological manner, and is to be led to a postural treatment, which represents an arrest of development at a very early level, which thus never permits him to act the true adult part in
life. Various wholesome and truly social activities should be encouraged, and the patient instruction of his entire libido (q.v.) in them, and the desire for solitary pleasure will gradually disappear.

SMITH ELY JELIFFE.

MASUDI (Abu-1 Hasan 'Ali ibn Husain ibn 'Ali ul-Masudi), Arabic geographer and historian: b. Bugdad, near the close of the 9th century; d. Forat, about 956 A.D. Receiving a good education he set out to study the history, manner of life, customs, etc., of every land at first hand. This quest took him to Persia and Kerman, in 915 to Istakhr, to Multan and Mavura in 916. From there he journeyed to Cambay, Saimur and Ceylon, to Madagascar and back via Oman. He also visited the shores of the Caspian; journeyed to Tiberias in Palestine. He visited Antioch in 943 and Damascus in 945. The last decade of his life was spent in Egypt and Syria. Of the Motaizalite sect, he was free from bigotry, studied Christianity and Judaism and was well versed in the history of the principal nations of both Orient and Occident. He wrote a universal history in 30 volumes, entitled 'Kitab akbar uz-Zaman', folio in length in 'Kitab ul-Ausat', chronology of general history. The two works were combined by the author in 'Muruj ud-Dhabah wa ma'adin ul-Jawahir' (Meadows of Gold and Mines of Precious Stones) in 947. Editions have been published at Bukh (1860) and at Cairo (1886). The original in French translation by C. B. de Maynard and P. de Courtelle has appeared (9 vols., Paris 1801-17; Vol. I, in English by A. Sprenger, London 1841). An enlarged edition of this work finished by Masudi in 956 appears to be now lost. Another work written in 956 is 'Kitab ut-Tanbih wal Iwhra' (Book of Indication and Revision) is a summary with corrections of his other writings. It was edited by M. J. de Goeje (Leiden 1894) and there is a French translation by C. de Vaux (Paris 1896) and a partial translation in De Saaj's memoir to Meynard's edition of 'Muruj'. Consult Brockelmann, Karl, 'Geschichte der arabischen Literatur' (Vol. I, Weimar 1899); Field, C. 'Talk of the Pharaohs' (1900); Nicholson, A. 'Literary History of the Arabs' (Cambridge 1907).

MASULIPATAM, or BANDAR, British India, capital of the district of Kistna, Madras, situated at the mouth of theKistna, on the Bay of Bengal. It was the earliest English settlement on the Coromandel coast, an agency being established there in 1611. Subsequently the town was held for some years by the French; it was taken by storm by Forme in 1759. A storm-wave inundated the town in 1864, and about 30,000 lives were lost. Weaving, bleaching and cloth printing are the principal industries, but do not enjoy their former importance. Noble College is the chief educational institution. The port is merely a roadstead in which vessels anchor five miles off shore. Masulipatam is reached by a branch of the Southern Mahatta Railway from Berwada. Pop. 42,100.

MASEURENLAND. East Prussia, a lake-dotted district around Lyck, Lötzen, Sensburg, Ortesburg, Neidenburg, Oletzka, Osterode, Rössel and Allanstein. It is marked by rolling hills, divided by hundreds of lakes, many of which are joined together by long narrow channels. Mauer and Spirden are the most important and largest of these bodies of water. A few years ago the imperial government entered into negotiations with a company which proposed to drain the greater part of the Masure region and sell the reclaimed land to settlers. Negotiations were proceeding and important sum when von Hindenburg heard of the project. For many years he had studied the region and was convinced that the lakes and surrounding marshes were the equivalent of several army corps in defending Germany against an invasion by Russia. He opposed the drainage scheme, went to Berlin, interviewed the emperor and as a result the project was abandoned. The view of Hindenburg was vindicated in 1914-15 after the battle of Tannenberg, when the aged general partly encircled the Russians with the lakes in their rear. Whole regiments were lost in the quagmires, and great quantities of stores fell to the Germans. See War. EUROPEAN—EASTERN FRONT.

MAT, the Egyptian goddess of justice and truth. She was usually represented wearing an ostrich feather on her head, with eyes bandaged as a sign of impartiality. Judges and kings were at all periods her worshippers. The father of the goddess was Ré, the sun god. Her Greek counterpart was Themis. Consult Budge, A. E. T. W., 'The Gods of the Egyptians' (Vol. I, London 1904) and Wiedemann, Alfred, 'Religion of the Ancient Egyptians' (New York 1897).

MATABELELAND, mā-tā-bē-lē-lánd, South Africa, the southeastern district of Rhodesia (q.v.) between the Limpopo and Zambezi, north of the Transvaal. In 1889 it came under the administration of the British South Africa Company, against whom the natives unsuccessfully rebelled in 1893 and 1896. The Matabeli are a war-like Kaffir race, who migrated from Natal in 1827 under their chief, Umslikaite. The country is traversed by ranges of hills—the Matoppo Hills being the chief—watered by numerous streams, has a climate believed to be rich in gold. It is now being rapidly settled and developed. Buluwayo is the capital. Other towns are Gierlo and Schuwwe. There are 11,000 whites and 249,000 natives. The Cape to Cairo Railroad passes through Buluwayo, which is 1,800 miles distant from Cape Town. Consult Baden-Powell, 'The Matabele Campaign' (2d ed., London 1901); Montague, 'Interior of Central Africa' (ib. 1886); Norris, 'Matabeland' (ib. 1895); Oates, Frank, 'Matabele Land and the Victoria Falls' (ib. 1881); Wills and Collingridge, 'The Downfall of Lobengula' (ib. 1894).

MATICHE, mā tā' chēn', or MATA-CHINE, 'the dance of fools,' a former well-known comic dance performed by maskers in mock-military guise. It was common in France and Italy. The dance itself was merely a display of tumbling or acrobatic feats.

MATACO, a South American Indian stock, including several tribes, whose habitat is in the Vermejo River Valley in the Gran Chaco, in northern Argentina. They are of medium size with wavy hair and subsist by hunting, fishing and cattle-raising. Their dress is made
MATADOR—MATCH INDUSTRY

of skins and they dwell in huts of brush. Consult 'Aneis de la Sociedad Científica Argentina' (Buenos Aires 1904); Brinton, D. G., 'Literary Life and Literature of the Chaco Region' (Philadelphia 1898); Schuller, 'Sobre el origen de los charruas' (Santiago 1906).

MATADOR, in Spanish bullfights the man appointed to administer the fatal stroke to the bull. See BULL-FIGHT.

MATAGALPA, mā-tā-gāl'pā, Nicaragua, town, capital of the department of Matagalpa, north of the central part of Nicaragua. It is situated in a fertile agricultural region, in which the chief products are tobacco, coffee and sugar. The lack of railroads has been a hindrance to the growth of the town, but plans are formed for connecting it with the Pacific and with Managua, the capital, and other cities. The inhabitants are mostly Indians. Pop. about 15,000.

MATAMATA, a large fresh-water turtle (Cymzmys anamurensis) of the Amazon and Orinoco valleys, which has a flat, weak, but heavily bossed shell, and lies in concealment among the weeds. Its neck is very long, the head is small, the nose is extended into a flat tubular proboscis and the jaws are so weak and soft that it is evident nothing can be forcibly seized with them. Hence it is believed that the frogs, small fishes and the like, upon which this turtle feeds, are sucked into the throat rather than bitten. To facilitate its concealment against both enemies and expected prey, the head and neck of this remarkable creature are covered with an outgrowth of fleshy fringes, which float about in the water, like tangled weeds, hiding its identity most effectively. Consult Gadow, Hans, 'Amphibia and Reptiles' (London 1901).

MATAMOROS, Mariano, mā-tā-mō'rsō, Mexican patriot: b. Mexico, about 1773; d. Valladolid, 3 Feb. 1814. He first appears in 1810 as substitute priest of the parish in Jantelolco, a village south of Mexico City. In 1811 he identified himself with the revolt of Hidalgo (q.v.), and became the principal commander under Morelos (q.v.). He attained the rank of lieutenant-general on 19 April 1813. On 14 Oct. 1813 he gained the victory of San Agustín del Palmar, and on 5 Jan. 1814 was captured at the defeat of Puruárán. He was executed in Valladolid market-place. The town of Matamoros, on the United States frontier, was named in memory of this sterling patriot.

MATAMOROS, Mexico, a frontier town and river port opposite Brownsville, Tex., in Tamaulipas, on the right bank of the Rio Grande del Norte, about 30 miles above its mouth in the Gulf of Mexico. It consists chiefly of brick houses; around the public square stand the church, town-house, custom-house and a number of elegant private dwellings. A considerable trade is carried on with the United States; horses, hides, wool, cotton-seeds, etc., are exported, and manufactured goods imported. In normal years its commerce is valued at about $4,000,000. During the Mexican War in 1846 the town was occupied by American troops under General Taylor, on 18 May. Pop. 10,000.

MATANE, mā'tān, Canada, town in Rémouski County, province of Quebec, on the Canada and Gulf Terminal and the Intercolonial railways, on the St. Lawrence River, midway between Montreal and Gaspé. The town has large saw mills and extensive timber interests. Pop. 2,056.

MATANUSKA RIVER, an affluent of Knik Arm, Cook Inlet, Alaska. The valley of this stream has extensive coal deposits which have been the subject of Federal legislation in recent years. See ALASKA, and consult Martin, 'Matanuska Coal Field' (in 'United States Geological Survey, Bulletin 239'), and 'Railway Routes in Alaska' (in 'Document 1346, House of Representatives, 62d Congress, 3d Session').

MATANZAS, mā-tān'zas (Sp. mā-tān'thás), Cuba, a seaport city on the north coast, capital of Matanzas province, 52 miles by rail east of Havana. It is situated on Matanzas Bay, one of the largest, safest and most convenient harbors of the western hemisphere. The city is well-built with wide, regular and paved streets, handsome public buildings and good railway communications. The caves of Bellamar and Yumuri Valley, in the neighborhood, are two popular natural resorts. Matanzas ranks in importance next to Havana in the export of sugar, molasses, rum and coffee, the exports of sugar alone averaging annually about $15,000,000. It has sugar mills, distilleries, oil refineries, tanneries, shoe factories, machine shops, etc. It was founded in 1693, and suffered from piratical incursions during the first century of its existence. The city was bombarded by the United States warships during the Spanish-American War in 1898, the only casualty, widely telegraphed, being an injury to a "Matanzas mule," which made the animal famous. Pop. 39,000.

MATAPAN, mā-tā-pān, Cape. See Cape Matapan.

MATAS, Rudolph, American surgeon: b. Bonne Carre, near New Orleans, La., 12 Sept. 1860. He was educated at Barcelona, Spain; Paris, France; Brownville, Tex.; Soule's College, New Orleans; Saint John's Literary Institute, Matamoros, Mex., and at Tulane University. Since his graduation he has practised in New Orleans, where since 1886 he has specialized in surgery. In the latter year also he was appointed to the chair of surgery at Tulane University. Dr. Matas is senior surgeon of Touro Infirmary and senior visiting surgeon at the Charity Hospital. In 1917 he was commissioned major in the medical reserve corps of the United States army, was president of the American Surgical Association in 1910; of the Southern Surgical and Gynaecological Association in 1911, and vice-president of the American Society of Clinical Surgery in 1908-10 and of the American College of Surgeons in 1913. From 1883 to 1895 he edited the New Orleans Medical and Surgical Journal. He is the author of many treatises and monographs on surgical subjects and a frequent contributor to medical journals and textbooks.

MATCH INDUSTRY. It was nearly 800 years after the discovery of phosphorus by an Arab, named Bechel, that it was found possible to obtain a light in a short time by the friction of phosphorus and sulphur. This discovery was
made and first applied commercially in the latter part of the 17th century by Godfrey Hawkwitz, of London, and, although the feasibility of producing a substance which, with a little rubbing, would ignite, was at once demonstrated, and, although it was proven that such a substance would be of immense commercial value, yet it was nearly a century and a quarter before a little box of matches was sufficiently put on the market. The method employed by Hawkwitz consisted of rubbing small particles of phosphorus between folds of brown paper and the flame produced lighted a sulphur match, but, as the phosphorus at that time was costly and considered dangerous, the match was not a success.

Among the earliest inventions was the "phosphorus bottle," containing a piece of phosphorus, stirred about by a hot wire, in order to coat the bottle with oxide of phosphorus, and when a light was desired a sulphur match was thrust into the bottle and thus ignited. This "phosphorus bottle" was followed in 1805 by the "oxyurniate match," the invention of Chancel, of Paris. These matches were, however, cumbersome and would be carried along with the phosphorus and magnesia was invented by Derepos, which was designed to do away with the danger attendant upon the use of the others.

One of the first forms of matches used was the brimstone match, and this consisted of small strips of resinous or very dry pine wood dipped in melted sulphur and lighted by means of a spark dropped from a flint and steel. This brimstone match was in almost universal use, despite the fact of later inventions, until the first part of the 19th century, and even as late as 1825, but with the general awakening at that time in all branches of industry the same progress was manifest in the invention of matches and of more ingenious machinery for making them. The first invention along this line came in the form of the "Instantaneous-Light Boxes," called the Eupyrions and Prometheans, the invention of a Mr. Jones of London. These light boxes retailed at a very high price and were made of small sticks of dry wood tipped with the linters and covered with phosphorus, which, when dipped into sulphuric acid, ignited. These were dangerous because of the acid and because of the liability of harm from the explosion when ignited and the cost was prohibitive to general use. This was followed in 1827 by the Congreve match, invented by a chemist, named Walker, of Stockton-on-Tees. This match was similar to the "Instantaneous-Light Box," but the mixture on the end consisted of gum, chloride of potash and sulphide of antimony, placed over a coat of sulphur. They were drawn between a fold of sandpaper to ignite them. These sold for a shilling per box, containing 84 matches. They did not become generally used because they did not readily ignite and the fumes created by the burning substances were very offensive.

In 1833 the lucifer friction match, the progenitor of the modern match, was put on the market and this differed materially from the "Instantaneous-Light Box," at first being tipped substantially the same as the Congreve, but later having phosphorus as the ingredient of the mixture. The manufacture of these phosphorus matches was commenced on a large scale in 1833 at Vienna, by an Austrian named Treschel, and gradually several factories began to produce matches of various kinds, Austria and southern Germany taking the lead in production. Red or amorphous phosphorus was discovered by Prof. Anton von Schröter, a German, in 1845, and was used as early as 1855 by Lundstrom, of Jönköping, the first manufacturer of the well-known "safety-match." In these matches the phosphorus is extracted from the composition placed on the tip of the match, but is placed on the side of the box, and thus the match will only ignite when rubbed on the box. On 24 Oct. 1835, Alonzo D. Phillips, of Springfield, Mass., was granted the first patent on friction matches given in the United States.

In the early days the greater portion of the matches made came from the poorer sections of London and various other large cities, and of course were made for the greater part in cellars and badly ventilated places. This often led to disease called necrosis of the bone, caused by the handling of phosphorus, or by inhaling its fumes. This disease in time became so prevalent among the match-makers that, for fear it would be encouraged by the manufacture of the factured articles itself, the local governments took a hand in the matter and forced the owners of these "cellars" to provide well- aired, ventilated and well-lighted places for the employees. With the improvement in surroundings also came improvements in the methods of manufacture. Until about 1842 the splints or sticks of wood were whittled out by hand entirely, but in that year a machine for cutting these splints was invented by Reuben Partridge and this practically revolutionized the trade by reducing the number of employees, producing a much better article in a shorter time and materially reducing the cost of manufacture. This will be seen to be true when it is stated that in the year 1856 there were but 40,000,000 matches made in England, while at the present time one factory alone in this country has facilities for making 100,000,000 matches per day.

The general size of the match now made is from one and seven-eighths to two and a half inches in length, the wood used being pine, thoroughly dried. After boiling and cross-grained parts, the blocks of pine are placed in the automatic feeder of a machine, run through and cut into splints. These splints are cut by knives or dies so arranged that when cut they are separated about a quarter of an inch and then set into cast-iron plates made into an endless chain by link attachments. The speed of this machine may be set according to the needs, from 175 to 250 revolutions per minute and as it cuts 44 matches at each revolution it is very rapid. After the splints have been cut the endless chain attachment carries them from the cutting end of the machine over a block which heats the heads to a temperature great enough to melt paraffine. After they have passed over the heating block the chain carries them along to the receptacle containing the paraffine and composition forming the head. The reason why the match is heated before reaching these composition rollers is that the paraffine may not be chilled by coming into contact with a cold surface and also the match takes more readily to the composition when heated. Having passed the composition rollers and received its head, the match is cooled off
by blasts of cold dry air for an hour and a half and then pushed off the iron plates or endless chain by a mechanical device into small paper or strawboard boxes. These boxes, containing 65 to 500 matches, are automatically fed into the machine and, after having received their quota of matches, are placed on a rotary of automatic machines, that cut the wood into combs, which are dipped, dried, packed and marketed in that form, for convenient carrying in the pocket. In the number of establishments making matches the effect of the modern machinery has made itself apparent also.

The statistics of the industry follows:

The importation is about 10 per cent of the manufacture, adding that much to the United States consumption. The match-making industry has assumed considerable proportions in Norway, Sweden, Germany, France and the United States; in France the industry being a government monopoly, in the United States being largely controlled by one corporation, the Diamond Match Company, which is credited with over 75 per cent of the production, having four very large factories. It is also an interesting fact for sociologists that in this industry the wage earners receive less than one-fourth of the value of the products they produce, furnishing the cost of materials.

**MATE**, an officer in the mercantile marine who acts as the assistant of the captain or master. There are four grades—first, second, third and fourth mate. The junior mate has usually the superintendence of the stowing of the vessel. The law recognizes only two classes of persons in charge of a trading vessel—the master and the mariners, the mates being included in the latter. In the navy, the term mate is now limited to the assistants of certain warrant officers, as boatswain's mate, gunner's mate, etc. See Petty Officer.

**MATÉ** (Port., *herba mate*; Sp., *yerba mate*), or PARAGUAY TEA, a beverage in general use in Brazil and also in general favor throughout South America, prepared from the leaves and shoots of *Ilex Paraguayensis*. The chief mate-producing state is that of Parana, from which are exported many millions pounds of this Brazilian *tea* annually. The mate tree (in appearance not unlike a small evergreen oak or *ilex* with a heavy and fleshy leaf) grows freely in the forest, entirely without cultivation; and in the forest the leaves undergo, as soon as they are plucked, a first preparation which both diminishes their weight before transportation and also keeps them from fermenting. They are dried at a fire, and then packed in sacks which are sent to the mills at Curitiba which reduces the leaves to powder and separate the various qualities. Aromatic properties retained in the dried and powdered leaves are extracted by means of infusion. As a stimulating and wholesome beverage habitually used throughout a large part—especially the southern part of the continent, mate might well be called, not by the competing names Brazilian or Paraguayan, but more simply the South American tea. The exportation of mate
MATEHUALA—MATÉRIA H Is to Paraná what the exportation of coffee is to the neighbor state of São Paulo: the basis, perhaps, of aonomic achievement. In a recent year mate was exported to the extent of 75,885 metric tons.

MATEHUALA, mà-tà-wàlà, Mexico, a southern town of the state of Nuevo Léon, with silver-melting establishments and important silver mines in the vicinity. Gold and copper are also found nearby in paying quantities. The city is well built, has several plazas and wide streets. Pop. 12,000.

MATERIA MEDICA (Lat. "medical matter"), that division or branch of medical science which treats of drugs, their origin, classification as natural products, preparation, purification, action on the animal economy, together with the mode of administering them for the relief and cure of disease. The action of the various agents in the materia medica upon the human family has been ascertained by experience, sometimes by experiment, especially by administering various drugs to some of the lower order of animals such as dogs, cats, rabbits, guinea pigs, rats and mice. Perhaps the best general classification of medicine is as stimulants, sedatives, narcotics, emetics, alteratives, tonics, anesthetics, antispasmodics, astringents, spinants, cathartics, diaphoretics, diuretics, blemorrhetics, emmenagogues, hematinics, antacids, irritants, demulcents, coloring agents and anthelmintics. This classification is based upon the direct effect of the different drugs upon the tissues of the human economy under the various headings which drugs may be conveniently grouped under four general sections, namely: 1. Those which have a special action on the brain, spinal cord and the general nervous system. 2. Those which have a special action on the secretions. 3. Those which change the blood. 4. Those which act locally, when applied to the surface of the body. Section (1) includes antispasmodics, anesthetics, astringents, narcotics, tonics, sedatives, spinants and stimulants. Section (2) includes the cathartics, blemorrhetics, diuretics, diaphoretics and cathartics. Section (3) includes alteratives, antacids and hematinics. Section (4) includes anthelmintics, coloring agents, demulcents and irritants. See PHARMACOPEIA; THERAPEUTICS.

MATERIALISM, the philosophical theory that everything which exists is ultimately material in nature, or that whatever is real can be derived and explained in accordance with the laws of material phenomena. This, of course, carries with it a denial of the reality of any finite or infinite spirit as an immaterial substance and a repudiation of all forms of idealism, which uses thought or intelligence as a principle of explanation. Materialism, however, may be more or less explicit and may maintain either absolutely, or with various modifications, the primary and all-embracing character of matter. Thorough-going materialism asserts that nothing exists but physical bodies and physical processes. What are called immaterial substances and processes it either declares to be unreal, or explains away as ultimately not different in nature from physical substances and processes. Moreover, for materialism of this consistent and uncompromising type, matter is dead and moved only by mechanical forces. It has no "psychic side," and the laws which it obeys are the expressions of a blind necessity. This extreme view is perhaps no longer maintained by any philosophical thinker of reputation, but in various modified forms it still exists as a tendency to subordinate mental phenomena to physical processes. The more important of these modifications and its mode of operation may be brought under the following heads. (1) The subordination of mental phenomena, while still acknowledging more or less explicitly their distinctive character, to physical, and especially to physiological processes as their determining causes. This position does not usually avoid any of the practical consequences of materialism, and always tends, when thought out, to revert to the strict ontological form of the theory. For it is an easy transition from the view that physical processes are able to cause mental modifications to the opinion that the mind is not fundamentally different in character from the matter which affects it. (2) The view that matter is not a dead lump or mass that moves only when acted upon by some external body, as the older physicists assumed, but that every particle of matter—every atom, or it may be every cell—is "conjoined with a soul," or has a "psychical side," or contains a certain element of mind-stuff. By thus introducing an element which is different in character and in mode of operation from matter, this theory seems to differentiate itself in principle from materialism. Nevertheless, it is usually assumed tacitly by representatives of this modern Hylozoism that within the atom or cell the material side is the primary and determining element, while the physical is secondary and subordinate. Moreover, the whole mode of conception usually remains at the mechanical stage, since the immaterial element never comes to its rights as an ideal principle, but is conceived as a mere moving force or instinct, and also since it is assumed that the complex mental life can be built up by the composition of psychic elements just as a material body is constituted by the combination of its parts. (3) The position of energism. Recently an attempt has been made to find in energy an ultimate reality of which both mental and material phenomena may be expressed. It cannot be maintained, however, that the conception of energy has yet been clearly defined, nor is everyone prepared to accept the assurance of Professor Ostwald, the chief representative of the theory, that energy is the concrete reality which we directly experience. To many it may appear to be merely an abstract conception built out of the data of experience. Apart from this difficulty, however, energism does not avoid materialism merely by dematerializing its fundamental principle. In Professor Ostwald's hands, it appears to remain essentially materialistic; since the conceptions employed and the laws which the transformations of energy obey are those of physical science.

If the period of the Middle Ages is excepted, when philosophical thought was determined mainly by theological conceptions, materialism may be said to have held a place throughout the whole history of philosophy. We have already noticed some of the forms in which this
mode of thought continues to appear at the present day, and may now refer briefly to its more important historical representatives. The system of the early Greek philosophers who founded the fundamental principle of things in some physical substance, such as water, air or fire, cannot properly be classed as materialism. For as yet there was no opposition between the material and the spiritual. Neither the conception of matter as lifeless and unintelligent substance, nor of mind as an immaterial directing principle, had yet been formed. Atomism, as developed by Democritus of Abdera, is the first thoroughly going system of materialism. Democritus taught that the soul, like everything else, is an aggregate composed of atoms. The soul-atoms differ from all the others in being the finest, smoothest and most mobile. When they are in isolation, they are insensible, but from their union arises. From sensation all the other processes of the mental life originate. The same conclusions were maintained by the Epicureans, who adopted without any essential modification the theory of atomism. In spite of the statement of the Stoics that whatever exists is corporeal, their system cannot properly be described as materialism. For the human soul and God, the all-embracing Logos of which the human reason is a spark of emanation, though constantly described in materialistic terms, yet function ideally as rational directing forces.

Materialism was revived in modern times by Gassendi (1592-1655) (q.v.) under the form of atomism. Modern materialism was, however, first worked out by Thomas Hobbes (q.v.), who based it upon the mechanical conceptions which in his day were being made the basis of all physical science. He did not deny the existence of immaterial things — God, angels, pure spirits — but shrewdly contented himself with showing that only that which is composed of parts, that is, bodies, can be the object of thought and so be known. All real phenomena must therefore be explained in accordance with the mechanical theory and in terms of the movement of bodies. Under the influence of the development of physical science and especially of the dominant conception of mechanism, materialistic tendencies played an important part in the thought of the 18th century. David Hartley (1704-57) and Joseph Priestley (1733-1804) (q.v.) definitely subordinated the mental life to the bodily processes, though the latter attempted to reconcile his materialism with Christianity and even to support it by appealing to the Bible. It is in France, however, in the systems of La Mettrie (1709-51), Baron d'Holbach (1723-89), and Chodiere (1758-1806) (q.v.) that we find in this century representatives of materialism who do not hesitate to draw the most extreme consequences of their doctrine, to deny the existence of God and to reduce man to a mere piece of physical mechanism. Again, in the middle of the 19th century, a revival of materialism occurred in Germany which had an important popular influence. The most important names connected with this movement are Carl Vogt, J. Moleschott, H. Czolbe and Gause, Büchner (whose book, 'Kraft und Stoff' — 'Force and Matter' — has been called the Bible of German materialism, and has passed through numerous editions in its English translation). The general adoption of the evolutionary point of view was in the beginning at least favorable to materialism. The philosophical problem seemed to be to derive from some such basis of existence, all the various modes of existence in accordance with the established laws of physical evolution. To this task Herbert Spencer (q.v.) devoted his life with a result that is variously estimated in different quarters. It can at least be said that at present thinkers are more inclined than formerly to question the adequacy of physical science to furnish a complete and final explanation of the nature of the evolutionary process.

MATHEMATICAL INDUCTION. See INDUCTION, Mathematical.

MATHEMATICAL SIGNS AND SYMBOLS, in mathematics, a symbol employed to denote an operation to be performed, to show the nature of a result of some previous operation, or to indicate the sense in which an indicated quantity is to be considered. The present mathematical symbolism is due to the labors of many men — men having different habits of thought, men living in different ages, men speaking different languages. A physicist will employ sine a and sine b to calculate the angle of refraction of light. Now certainly there is neither sine a nor sine b in reality; yet there are most certainly relations of reality which are accurately described in these expressions, sine a and sine b. Such is the function of all signs, symbols or characters. Whenever the eye can be brought to the aid of one's imaging faculty, a success in grasping a thought may often be gained which would otherwise be a failure. This is in particular true in mathematics where the subject matter, while objective and especially of the kind of the ideas, and symbols, stand for the emphatic presentation of mathematical ideas, often very subtle even when symbolized; and with such signs these ideas become thinkable, even very often to the whole complex train of ideas in which they occur.

One very important property for symbolism to possess is that it should be concise, so as to be visible at a glance of the eye and to be rapidly written. A sign should if possible always represent the same object, and the same object should always be represented by the same sign. If a new sign be devised, permanent or even temporarily, it should carry with it always some mark of the manner from that which is already in use, unless it be a demonstrable extension of the latter (De Morgan). The importance of notation is recognized when it is remembered, for example, how great an amount of the work on the famous problem of the three bodies was made when special attention was given to it, and a special symbolism chosen for it. And the invention of the sign ∑ by Gauss affords
a fine example of the advantage which may be
drawn from a good notation; it, without ex-
aggeration, marks an epoch in the development
of the science of arithmetic. The language
of analysis, says Laplace, being in itself a power-
ful instrument of discoveries, its notations,
especially when they are necessarily and happily
coupled to eminently new grounds of new calcu-
lus.

Nowadays we have a symbol for each mathe-
matical operation. Sometimes, even a choice of
symbols. And most of the letters of the Eng-
lish alphabet are now engaged for special mathe-
matical purposes. Thus:

- \( a \) signifies sometimes a finite quantity; at
  other times a known number, the side of a
  triangle opposite \( A \); also an intercept on
  the axis of \( x \), and, finally, altitude.
- \( b \) like \( a \) signifies a known number, and also
  a side of a triangle, the one opposite \( B \); it
  also stands for base; and lastly, for an inter-
  cept on the axis of \( y \).
- \( c \) signifies constant.
- \( e \) signifies the base of the Napierian loga-
  rithms.

A considerable inroad has been made, also,
into the Greek alphabet:
- \( \gamma \) signifies the inclination of the axis of \( x \);
- \( \pi \) stands for the ratio 3.14159;
- \( \mu \) is used for sum of tens similarly obtained;
  and
- \( \sigma \) indicates the standard deviation in the
  theory of measurements.

Some examples of reading notation may be
given:

\[
a + b, \quad a - b, \quad a + b, \quad a \times b, \quad a \sim b
\]

are read \( a \) plus \( b \), \( a \) minus \( b \), \( a \) multiplied
by \( b \), and \( a \) is similar to \( b \).

Further:

\[
a > b, \quad a < b, \quad a = b, \quad a \neq b
\]

are read \( a \) greater than \( b \), \( a \) less than \( b \),
\( a \) is equal to \( b \), \( a \) is not equal to \( b \).

Our present day symbols of operation, \( + \)
(plus) and \( - \) (minus), appear to be among
the oldest. Both are found in Widmann's
arithmetic published in 1489, at Leipzig. In
the time of Widmann, the symbols \( \times \), \( \div \),
\( > \) and \( < \) were unknown. Rudolf had already
been born, and the radical sign. But equals
had not yet appeared. In those days almost
everything was expressed by words, or mere abbrevi-
ations. Yet even then both cubic and biquad-
ratric equations had already been solved; the
methods even were published. Oughtred used
the term "separatrix" in sense of a mark be-
tween the integral and fractional parts of a
number written decimally. His symbol for a
separatrix was \( L \). Stevens had already
used a figure a circle over or under each
decimal place to indicate its order. And
of the various separatrixes that have been
employed by mathematicians, four are still em-
ployed:

- \( (a) \) A vertical line is still employed to
  separate cents from dollars in ledgers, etc.
- \( (b) \) A period, still employed as a separatrix, is
  so used as early as 1612 in the trigonometry of Piticus, a
  German.
- \( (c) \) The Greek colon, a dot above the line, was advocated as a
  separatrix by no one less than Sir Isaac
  Newton. His desire was to prevent it from being
  confounded with a period, or a mark of
  punctuation. This form of the decimal point
  is now commonly used in England; (d) Pi-
  ticus is the author of an Italian work on
  trigonometry. He, in this work, published in
  1608, uses a comma as a decimal point. Kep-
  ler, in 1610, seems to have introduced this mark,
  the comma, into Germany for the same purpose.
  Briggs likewise used a comma in his loga-
  rithmic tables, in 1624; and several other early
  English writers generally employed the comma
  as a decimal point. But to-day the comma
  is customary form of the decimal point, not in
  England, but in countries upon the mainland of
  the European continent.

For example: \( 1,5 \) would in America be
written decimally as 1.50; in England as 1·50;
and in Germany, France and in Italy as 1,50.

Symbols in general may now be mentioned:
The sign of cancellation is simply drawn across
the factors cancelled, like the one drawn across
the zeros above. These with the ordinary
Arabic and Roman numerals and the abbrevi-
ations for the names of things, like \( s, \) s, \( d, \)
\( g, \) c, \( s, \) \( g, \) \( c, \) \( s, \) \( g, \) \( c, \) \( s, \) \( g, \) \( c, \)
constitute the main symbols of
ordinary arithmetic. In algebra there are four
types of symbols: symbols of quantity, of
operation, of relation and of abbreviation.
Known quantities are represented by the first
letters of the alphabet; or by the final letters
with one or more accents, as \( x, \) \( y, \) \( z, \)
Besides letters of Greek and even of the Hebrew
alphabet are employed. Thus \( M \) stands for
"modulus" of any system of logarithms. \( \pi \)
has been spoken of.

Of symbols of operation, multiplication may
be indicated by placing a point between the
factors when both are expressed by letters, as
\( a \cdot b \). In a series multiplication between fac-
tors expressed even by numbers, may be ex-
pressed by a point between such factors. When
\( \sim \) is used between two quantities, it denotes
difference, but not which quantity is to be sub-
tracted from the other. Division has been
sometimes indicated thus: \( a \div b \). The radical
sign, \( \sqrt{} \), when placed over a quantity indicates
that its root is to be taken. Thus \( \sqrt{a} \) denotes
the square root of \( a \). In the same manner
\( \sqrt[3]{a} \) and \( \sqrt[n]{a} \) are read the cube root and the
nth root of \( a \), respectively. Here \( \sqrt{a} \) and \( \sqrt[n]{a} \)
give the index of the radical. A vinculum, \( \overline{} \), a bar [ ],
brackets [ ], and parentheses [ ] all indicate
that the quantities enclosed by them are to be
regarded together as wholes. In algebra, \( \Sigma \)
denotes that the algebraic sum of several quan-
tities of the same nature such that which the
sign is prefixed is to be taken. The letter \( f, \)
\( F \) and \( \phi \), written before any quantity, or quan-
tities, separated by commas, as

\[
F(x), \quad f(x, y), \quad \phi(x, y, z), \quad \text{et cetera,}
\]
denote quantities depending upon the quantities,
or the quantity, within the parenthesis, without
designating the nature of the relation. The
signs of proportion, \( \sim \), \( : \), when placed be-
tween quantities with show them in the proportion.
\( R \), \( r \) and \( p \), and other symbols, denote \( \nu \) of
circles. \( L, l \) and \( \lambda \) may denote latitude. The
leading letters of the Greek alphabet are also
sometimes used to denote known angles; and the final letters of the same alphabet to denote unknown angles. And when several quantities of the same kind are involved in an investigation, they may be designated by the same letter differently accented; thus: $a^a, a^b, a^c$, and $a_a$. An older usage of $o$ denotes an infinitely small quantity; and only sometimes absolute zero. Clearer thinking has impelled moderns to use $i$ (iota) or $i$ for an infinitesimal, and to denote by $o$, absolute zero, and that only. The symbol $\alpha$, first employed by Wallis in the 17th century, has long been used both for a variable increasing without limit and for absolute infinity. Taylor, in 1898, introduced the symbol $\alpha^b$, a contraction of $\alpha$ for an infinite, the reciprocal of an infinitesimal. The sign $\vdash$ denotes then or therefore; and the sign $\vdash$ since or because. The $y = f(x)$ is a general sign, indicating that there is a general relation between $y$ and $x$. In that is, $y$ and $x$ are so connected that $x$ cannot change without $y$ changing at the same time. The symbol $F(x, y, z) = 0$ implies that there is a general relation between $x$, $y$, and $z$, without specifying the relation. The symbols $\sin, \cos, \tan, \csc, \sec, \cot, \cotan$, etc., are abbreviations used, respectively, for the words $\sin$, $\cos$, $\tan$, $\csc$, $\sec$, $\cot$, $\cotan$, $\csc$, $\sec$, $\cotan$, $\csc$, and $\sec$. When the arc is supposed, as in trigonometry, to depend for its value upon any of the trigonometric lines, the function is called the inverse trigonometric function. The following symbols are used to denote this kind of a relation: $\sin^{-1}y, \cos^{-1}y, \tan^{-1}y, \cotan^{-1}y, \sec^{-1}y, \csc^{-1}y, \cos^{-1}y, \cotan^{-1}y, \cos^{-1}y, \cotan^{-1}y$. These stand, respectively, for the arc upon the sine, cosine, tangent, cotangent, secant, cosecant, versed-sine and co-versed-sine. The principle of notation has been extended to all inverse functions; thus:

$\log y, d^{-1}(x \times x), \text{etc.}$

These stand, respectively, for the quantity whose logarithm is $y$, and the quantity whose differential is $x \times x$, etc. The differential of a function, or independent variable, is denoted by $d$, thus:

$d(y^x) = 2dy$.

If we suppose the form of a function to vary, the symbol employed to denote the variable is $\delta$, thus:

$\delta u, \delta y, \delta x$.

If both the form of the function and the independent variable of the function vary together, the resulting variation is denoted by the symbol $D$, thus:

$D f(x, y) = \ldots \ldots$

The differential is the difference between two consecutive states of the quantity differentiated. If it is desired to represent the difference between two states of a function which are not consecutive, the symbol $\Delta$ is employed. Successive finite differences are represented by the symbols:

$\Delta u, \Delta^2u, \Delta^3u, \Delta^4u, \text{etc.}$

We have already spoken of $\Sigma$ as used in algebra, where it denotes an algebraical sum. Its use in the calculus is principally restricted to the denotation of the sum of the finite differences of a function. The symbol $f$ denotes an integration to be performed; while the symbol $\int f$ is used to denote a definite integral taken between the limits $a$ and $b$. The symbol $\Gamma (x + 1)$ stands for the integral $\int e^{-\gamma} \gamma^{-x} \text{d} \gamma$. The vector sign is $U$. $\Gamma beta$, in quaternions, should be read tensor of $B$.

In the foregoing list nearly all the symbols, commonly employed by American mathematicians, have been enumerated; as well as some used abroad.

MATHMATICAL SOCIETIES AND JOURNALS. The oldest of the sciences, mathematics has always been cultivated and fostered, often with a degree of preference over the later branches of the tree of knowledge, by the universities, the great academies and the other scientific bodies of a general scope throughout the civilized world. The indispensable condition for satisfactory progress, facility of publication, has been provided for mathematicians in a very large degree by the Transactions and Proceedings of learned societies representing a wide field. The specialist will usually prefer the mathematical journals proper, which indeed send out in a steady flow the finest product of the mathematical genius of the age. Theirs is the post of honor; it lies with them, by critical encouragement or repression, to maintain the standard of excellence of a great profession. But there remains another set of functions, which to-day are more and more efficiently performed by the mathematical societies. These include in their membership nearly every mathematician of standing in the four quarters of the globe. They provide a professional forum for the discussion of mathematical questions and of mathematical interests, and furnish the powerful stimulus of association and solidarity. Their activities cover a wide range, including the presentation and publication of papers and memoirs, the encouragement of bibliographic and encyclopedic undertakings, the organization of international congresses, special conferences and lectures, the exercise of a beneficial advisory influence on the mathematical curricula and equipment of the schools and universities, the diffusion of a better understanding of the science in the educated world, the formation of libraries, collections of models, etc., and the promotion of agreeable social and personal relations among mathematicians.

The following list comprises the principal mathematical societies of the world, arranged in chronological order of foundation, with mention of their several publications:

1900. Deutsche Mathematiker-Vereinigung. Jahresbericht. 1892—
A history of the Hamburg Society, prepared in connection with the celebration in 1890 of the 50th anniversary, may be found in volume II of the Mitteilungen. The 'Wiskundig Genootschap' renders an especially valuable service in the mathematical world by the publication of the Revue Sémestrielle, a condensed abstract of all the mathematical papers published in the various journals, constantly brought up to within a few months of the current date. The value to a productive mathematician of this great labor-saving device is quite inestimable.

The first president of the London Mathematical Society was the illustrious De Morgan, and the roll of members has included the names of Cayley, Sylvester, H. J. S. Smith, Clifford, Salmon, Stokes, Kelvin and most of the other eminent British mathematicians of the time. The full secretary's office was efficiently filled for the long period of 34 years (1857–1901) by the late Robert Tucker. The Proceedings, which is the leading British mathematical journal, has recently been enlarged in size. The membership of the society is about 300.

The Société Mathématique de France has about the same membership. The meetings are held twice a month at the Sorbonne. The president of the society for 1916 is M. Fouché, the secretaries are M. Lévy and Montel. The council includes Appell, Borel, Jordan, Painlevé, and Picard. The Bulletin is issued quarterly.

The Deutsche Mathematiker-Vereinigung represents in full measure the fruitfulness and vigor of German mathematics. Its organization had been foreshadowed for many years, but was actually brought about in 1890 by the initiative of members of the mathematical-astronomical section of the older Society of German Natural Scientists and Physicians, in affiliation with which the Vereinigung still continues to hold its meetings. The appearance of the Jahresbericht, whose volumes were originally issued in parts of book form, signalled the beginning of a series of invaluable reports on various branches of mathematics, beginning with the celebrated report by W. F. Meyer on 'The Present Status of the Theory of Invariants' (Vol. I, 1892). These reports and other undertakings of a bibliographical, critical and statistical character ultimately led to the plan of the 'Encyclopedia of Mathematics,' now in course of publication by Teubner, under the auspices of the academies of science of Munich, Vienna and Göttingen. The Vereinigung has also played an active part in the organization of the international congresses of mathematicians, notably those of Zürich (1897) and Heidelberg (1904). It has interested itself effectively in the questions concerning the teaching of mathematics in the schools, universities and technical institutes, the training of teachers, the correlation of instruction in pure and applied mathematics and other matters of reorganization and progress in education, some of which are phases of an international reform movement. A history of the Vereinigung by the former secretary and present editor of the Jahresbericht, Prof. A. Gutzmer of Jena, was issued on the occasion of the 50th anniversary. The society has at present about 650 members. Meetings are held annually. It recently received from B. G. Teubner the gift of a complete set of his extensive mathematical publications as the nucleus of a library. The Jahresbericht, now published monthly with occasional double bimonthly numbers, contains, beside the earlier reports mentioned above and a record of the society's activities, addresses, biographies and necrologies, original papers, criticisms, discussions and reviews and news of current events. More extensive papers are published as separate volumes.

The American Mathematical Society was originally organized as the New York Mathematical Society in 1888 and was reorganized under its present national title in 1894. Sylvester's work at Baltimore (1877–84) and the influence of young mathematicians returning from study in Germany had produced a tidal movement of which the society has since its early days been the foreb Bender and exemplar. Its membership, now about 2,700, is practically every mathematician in the United States, and a considerable number of foreign representatives. The Bulletin, published since 1891 in monthly numbers from October to July, is of the type later adopted by the Jahresbericht, but contains also the official reports of the frequent meetings of the society, with abstracts of the papers presented and a complete bibliography of recent mathematical publications. Another special feature of the Bulletin is the extensive 'Notes and News' section in the mathematical world. The Transactions, founded in 1900, is the official organ of the society for the publication of the more important papers read before it. The library of the society, now including 5,000 bound volumes, is deposited in the Columbia University Library.

Regular meetings are held four times a year in New York and twice a year in Chicago. Officers are elected at the annual meeting in December. A summer meeting is also held each year at some special chemical place at intervals of two or three years. The summer meetings are attended by colloquia, or courses of lectures by specialists on recent advances in their particular lines of work. The rapid growth of mathematical interest in the Central and Western sections of the country have led to the organization of a Chicago Section (1898), a San Francisco Section (1902) and a Southwestern Section (1907). The sections meet once or twice each year.

The presidents of the society have been J. H. Van Amringe, 1888–90; Emory McClintock, 1890–94; G. W. Hill, 1894–96; Simon Newcomb, 1896–98; R. S. Woodward, 1898–1900; E. H. Moore, 1900–02; Thomas S. Fiske, 1902–04; W. F. Osgood, 1904–06; Henry S. White, 1906–08; Maxime Bôcher, 1908–10; H. B. Fine, 1910–12; E. B. Van Vleck, 1912–14; E. W. Brown, 1914–16; L. E. Dickson, 1916–. The secretaries have been Thomas S. Fiske, 1888–95, and F. N. Cole, 1895–. The business of the society is transacted by a council composed of the officers, ex-presidents, editorial committee of the
reports the contents of some 250 journals; the 'Fortschritte' list is about 170.

The oldest journals in Müller's list are the 'Philosophical Transactions' and the 'Journal des Saviants,' both dating from the year 1665. Following these are the publications of the academies of Paris (1666) and Bologna (1669). From the 18th century there still survive, besides the journals of the academies (Berlin 1700; Petersburg, 1724; Göttingen, 1735; and others), also the 'Memorie di Matematica e di Fisica' (1782) of the Societé Italiana, the 'Bulletin' (1789) of the Société Philomathes of Paris, and the 'Journal de l'Ecole Polytechnique' (1794). Among the extinct journals may be mentioned the 'Ladies' Diary' (1704), 'Gentlemen's Diary' (1741), these two uniting in the 'Lady's and Gentlemens Diary' (1841-71); the 'Cambridge Mathematical Journal' (1835-45), the forerunner of 'Sylvester's Quarterly Journal'; George Peacock's 'Annales de Mathematique' (1810-31); Torroli's 'Annali' (1850-57), superseded by the present 'Annali di Matematica'; and the various journals (1788-1825) of Hindenburg, Breithaupt, Besel, Kreischnar. In America the ephemeral existences are chronicled in the 'Mathematical Correspondent' (1804-05), 'Adrain's Analyst' (1808) and 'Mathematical Diary' (1825-32), 'Mathematical Companion' (1828-31), 'Mathematical Miscellany' (1836-39), 'Cambridge Miscellany of Mathematics, Physics and Astronomy' (1842-43) 'Runkle's Mathematical Monthly' (1858-61). The publication of the 'Analytist' (1874-83) marked a substantial advance. Martin's 'Mathematical Visitor' (1877) and 'Mathematical Magazine' (1882), the 'Mathematical Magazine' (1882) and 'Mathematical Messenger' (1884) are extinct. The following list gives the date of foundation, the title and the present place of publication of the strictly mathematical journals now in existence and not already cited in connection with the list of mathematical societies above:

1826. 'Creul's Journal für die reinen und angewandten Mathematiken,' Berlin.
1835. 'L'Institut's Journal de Mathématiques pure et appliquées,' Paris.
1842. 'Annales de Mathématiques.'
1855. 'Quarterly Journal of Pure and Applied Mathematics.'
1858. 'Annali di Matematica pure ed applicata,' Milan.
1863. 'Gazette des Mathématiciens,' Paris.
1866. 'Mathematische Annalen,' Leipzig.
1871. 'Jahrbuch über die Fortschritte der Mathematik.'
1872. 'Messenger of Mathematics,' London.
1878. 'American Journal of Mathematics,' Baltimore.
1881. 'Mathesis,' Ghent.
1884. 'Annales de Mathématiques,' Cambridge, Mass.
1884. 'Bibliotheca Mathematica,' Leipzig.
1886. 'Periodico di Matematica' (Supplement 1880), Leghorn.
1890. 'Nyt Tidskrift for Matematik,' Copenhagen.
1891. 'Revue des Mathématiques pure et appliquées,' Paris.
1893. 'American Mathematical Monthly,' Springfield, Mo.
1894. 'L'Intermédiaire des Mathématiciens,' Paris.
1895. 'Gazeta Matematica,' Bucharest.
1896. 'Il Pitagora,' Palermo.
1896. 'Revue de Mathématiques,' Turin.
1897. 'Wiedemanns Matematische Annalen,' Warnew.
1898. 'Formulaires Mathématiques,' Turin.
1898. 'La Revue Mathématique,' Paris.
1898. 'Bollettino di Bibliografia e Storia delle Scienze Matematiche,' Turin.
1899. 'L'Enseignement Mathématique,' Paris.
1900. 'Bollettino di Matematica,' Bologna.
1902. 'Spitzes Oeuvre, Nancy.'
1909. 'Mathematics Teacher, Syracuse, N. Y.'
1912. 'Tohoku Mathematical Journal, Sondai, Japan.'
MATHEMATICAL SOCIETY — MATHEMATICS

MATHEMATICAL SOCIETY, The London, an association formed in the English capital in 1865 by a number of English professors of mathematics for the promotion of that science. It was incorporated in 1894. Since its formation it has regularly published "Proceedings" and papers on mathematical subjects. It has an excellent library of scientific works. The Society meets monthly from November to June, the anniversary meeting being held in November.

MATHEMATICS. The science of mathematics — what shall it be said to be? A question much discussed by philosophers and mathematicians in the course of more than 2,000 years, and especially with deepened interest and insight in our own times. Many have been the answers, but none has approved itself as final. All of them, by nature belonging to the literature of knowledge, fall under its law and tend to "perish by supersession." Naturally enough conception of the science has had to grow with the growth of the science itself. For it must not be inferred that mathematics, because it is so old, is dead. Old it is indeed, classic already in Euclid's day, being surpassed in point of antiquity by but one of the fine arts and by none of the "natural" sciences; but it is not only the oldest science, it is also as new as any, living and flourishing to-day as never before, advancing in a thousand directions by leaps and bounds. It is not merely as a giant tree throwing out and aboaf myriad branching arms in the upper regions of clearer light and plunging deeper and deeper root in the darker soil beneath. Rather is it an immense forest of such oaks, which, however, literarly grow into each other, so that, by the junction and intercrescence of limb with limb and root with root, the manifold work becomes a single living organic growing whole. A vast complex of interpenetrating theories — such the science now actually is, but it is more wondrous still potentially, component theories continuing more and more to grow and multiply beyond the comprehension and beyond the compass of any single genius, however gifted. What is this thing so marvelously vital? What does it undertake? What is its motive? How is it related to other modes and interests of the human spirit?

One of the oldest, at the same time the most familiar, of the definitions conceived mathematics to be the science of magnitude, where magnitude, including multitude as a special kind, signified whatever was "capable of increase and decrease and measurement." Capability of measurement was the essential thing. That was a most natural definition of the science, for magnitude is a singularly fundamental notion, not only inviting but demanding consideration at every stage and turn of life. It is a way of measuring not how much is there, but how much is the mother of counting and measurement and mathematics, first from necessity and then from joy, so busied itself with these things that they came to seem its whole employment. But now the ordinary notion of magnitude is that as the repeated application of a constant finite unit has been so refined and generalized, on the one hand through the creation of the so-called irrational and imaginary numbers (see Algebra; Complex Variable), and on the other by use of a scale, as in non-Euclidean geometry (see Non-Euclidean Geometry; Analytical Geometry), where the unit appears to suffer lawful change from step to step of its application, that to retain the old words and call mathematics the science of measurement seems quite inept as no longer telling either what the science has actually become or what its spirit is bent upon.

Moreover, the most striking measurements, as of the volume of a planet, the valency of atoms, the velocity of light or the distance of star from star, are not done by direct repeated application of a unit. They are all accomplished by indirection. Perception of this fact it was which led to the famous definition by the philosopher and mathematician, Auguste Comte, that mathematics is the "science of indirect measurement." Here doubtless we are in presence of a finer insight, a higher view, but the thought is not yet either wide enough or deep enough.

For it is obvious that there is much admittedly mathematical activity that is not in the least concerned with measurement whether direct or indirect. In projective geometry (which see), for example, it was observed that metric considerations were either absent or subordinate. The fact, to take a simplest example, that the two points determine a line uniquely, or that the intersection of a sphere and a plane is a circle, is not a metric fact; it is not a fact about size or quantity or magnitude. In this field it was position rather than size that to some seemed the centre of interest, and so it was proposed to call mathematics the science of magnitude or measurement and position.

Even as thus expanded, the definition yet excludes many a mathematical realm of vast, nay, infinite extent. Consider, for example, that immense class of things known as operations. These are limitless alike in number and in kind. Now it so happens that there are systems of operations such that any two operations of a given system, if thought as following one another, together thus produce the same effect as some other single operation of the system. For an illustration, think of all possible straight motions in space. The operation of going from a point A to a point B, followed by the operation of going from B to a point C, is equivalent to the single operation of going from A to C. Thus the system of such operations is a closed system: combination of any two operations yields a third not without but within the system. Now the theory of such closed systems — called groups (see Groups) of operations — is a mathematical theory of colossal proportions. But it is obvious that an abstract operation, though a very real thing, is neither a position nor a magnitude.

This way of trying to come at an adequate conception of mathematics, viz., by attempting to characterize in succession its distinct domains, or varieties of content, or modes of activity, is not likely to prove successful. For it demands an exhaustive enumeration, not only of the fields now occupied by the science, but also of those destined to be conquered by
it in the future, and such an achievement would require a prevision that none may claim. Fortunately, there are other paths of approach that seem more promising. Every one has observed that mathematics, whatever it may be, possesses a certain mark, namely, a degree of certainty not found elsewhere. So it is, probably, the exact science par excellence. Exactly not doubt, but in what sense? To this an excellent answer is found in a definition of the science given about one generation ago by a distinguished American mathematician, Prof. Benjamin Pierce: mathematics is the science which draws necessary conclusions—a formulation of like significance with the fine mot by Prof. William Benjamin Smith, to wit: mathematics is the universal art apodictic. These statements, though neither of them may be entirely adequate, are, both of them, tending approximations, at once shod- and neatly summarizing for popular use the conclusion reached by the creators of modern logic (see SYMBOLIC LOGIC), that mathematics is included in, and, in a profound sense, may be identical with, symbolic logic. Observe that the emphasis falls on the equality of being "necessary," or logically correct. Naught is said about the conclusions being true. That is another matter for subsequent consideration.

But why are mathematical conclusions correct? Is it that the mathematician has a reasoning faculty essentially different in kind from that of other men? By no means. What, then, is the secret? Reflect that conclusion implies premises, that premises involve terms, that terms stand for ideas or concepts or notions, and that these latter are the ultimate material with which the spiritual architect, called the reason, designs and builds. Here, then, one may expect to find light. The apodictic quality of mathematical thought, the correctness of its conclusions, are due, not to any special mode of rationalization, but to the character of the concepts with which it deals. What is that distinctive characteristic? The answer is precision, sharpness, completeness of determination. But how comes the mathematician by such completeness? There is no mysterious trick involved: some ideas admit of such precision and completeness of determination, others do not; and the mathematician is one who deals with those that do. Law, says Blackstone, is a rule of action prescribed by the supreme power of a state commanding what is right and prohibiting what is wrong. But what are a state, and supreme power, and right and wrong? If all such terms admitted of complete determination as do, for example, such terms as triangle and circle, then the science of law would be a branch of pure mathematics. And such, too, to take another example, would be psychology, were consciousness, mind, perception, imagination, and all kindred terms, as completely determinable as the notion sphere. It will be asked, does not the lawyer sometimes arrive at correct conclusions? It may be admitted that he does sometimes, and so, too, of the psychologist or historian. When this happens, however, when these students arrive, it is not meant at truth, for that may be by happy chance or by intuition, but when, strictly speaking, they arrive at conclusions that are correct, at conclusions, i.e., that follow logically from completely ascertained data or premises, is it not enough to have been for the time acting in all literalness the part of mathematician. That is not to aggrandize the science of mathematics. Rather is it for credit to all serious thinking that, in any considerable garment of thought, the may find here and there a really enough that have been a mathematic fiber, woven in some perhaps exceptional moment of precise conception and rigorous reason. To think aright is no characteristic striving of a class of men. It is a common aspiration. Only, as before said, the stuff of thought is mostly intractable, formless, nebulous, like some milky way awaiting analysis into distinct star forms of completely determinate ideas.

The mentioned aspiration and the tendency of all thought, of all science, to assume the character of mathematics admit of many illustrations, which at the same time serve to show clearly the ultimate distinction between that thought which is mathematical and that which is not. One or two such illustrations must suffice.

There is no more common or more important scientific notion than that of function. The term is applied to either of two variable things (including constants conceived as special variables, whose variation is zero in amount) so related that to any value or state of either there corresponds one (or more) value (values) or state (states) of the other. Any two corresponding values or states are said to constitute a function of state values, or states, and two functionally related variables may be called a function-pair. Examples of such function-pairs abound on every hand, as the radius and the area of a circle; the corresponding values of \(x\) and \(y\) in an equation, \(2x - 3y + 5 = 0\); elasticity of medium and velocity of sound or other undulation; the amount of sodium chloride formed and the time occupied by the reaction that generates it; the prosperity of a given community and, ceteris paribus, the intelligence of its patriotism. Indeed it may be that there is no thinking where is not in some form or other a function of every other. Be this as it may, one thing is very certain, namely, a very great part, if not the whole, of our thinking is primarily concerned with functional relationships, deals that is, immediately or mediately with pairs or systems of corresponding values or states or changes. Behold, for example, how the parallelistic psychology searches for correlations between psychical and physical phenomena. Witness, too, the sociologist seeking to determine a law of correspondence between the homogeneity of a population and its peacefulness; the anthropologist attempting to find a formula correlating mental power and brain-weight; the physicist's determinations of dependence between pressure and volume of a gas; and so on and so on. It is, then, here, in the immense and wondrously diversified domain of correspondences, the answering of value to value, of change to change, of condition to condition, of state to state, that the knowing activity, then, this happens. What is it precisely that we seek to do by means of a correlation? The answer is: when one or more facts are given or known, to pass with absolute certainty to the correlative fact or
facts. For example, if \( y = \sin x \), then, if a value be assigned to \( x \) or \( y \), the corresponding value or values of \( y \) or \( x \) are determined by the equation, or definition, of the functional correspondence between the assemblage of values which \( x \) may take and the assemblage that \( y \) may assume. To effect the desired transition from the given or known to the dependent ungiven or unknown obviously requires one or more formule or equations which shall serve to define precisely the manner of correspondence, the law of dependence. Where do such formule or equations exist? Strictly speaking, they are never found, they are always assumed, assumed immediately or else mediately, that is, in the latter case, derived by assumed logical processes from such as belong to the former case. This statement is valid in every field of logical thought. In every field it is true that from nothing assumed nothing can be derived. Now, nothing is easier than to write down a perfectly definite formula that does not tell how cheerfulness depends on climate or retentiveness on interest or the volume of a plum on its diameter. The mentioned inapplicability or "inutility" does not, however, at all tend to invalidate the formula regarded as defining a certain law of correlation. Indeed a given formula may be perfectly ineligible in itself; it, alone or joined with others in similar case, may state a perfectly intelligible law of correspondence, which, nevertheless, may have no validity whatever in the physical or in the sensuous universe. What is it, then, that guides in the choice of formula? For such determination of choice seems hardly referable to chance alone. The answer is that, broadly speaking, choice is determined by curiosity, and curiosity is itself not determined by choice, but is rather matter of native gift or predilection.

Just here we are in position where we have only to look steadily a little in order to perceive clearly the sharp and ultimate distinction between mathematics, on the one hand, and physical or other science, on the other. These sciences are the products of curiosity whence they spring. The mathematician is curious about definite abstract relationships, about logically possible modes of order, about varieties of abstract implications, both finite and determinable functional relationships considered solely in and of themselves, that is, without the slightest concern about the question whether or no they have external or sensuous or other sort of validity than that of being logically thinkable. It is the aggregate of logically thinkable relationships that constitutes the mathematician's universe, an indefinitely infinite universe, worlds in worlds of worlds in worlds of wonders, inconceivably richer in mathetic content than can be any outer world of sense. Immense indeed and marvelous is our own world of sense with its rolling seas and stellar fields and undulating ether. But compared, one need not say with the entire world of matheis, but only with the hyperspace (see HYPERSPACE). We are surrounded by the geometrician, the whole vast region of the sensuous universe is literally as a merest point of light in a shining sky.

Now this mere speck of a physical universe, in which the chemist, the physicist, the astrono-

mer, the biologist, the sociologist, and the rest of nature students, find their dear field, may be, as it somewhat seems to be, a realm of invariant uniformities or laws; it may be a mechanically organic aggregate, connected into an order whole by a tissue of completely definable functional relationships; and it may not. In other words, it may be that the universe eternally has been and is a genuine cosmos, that the external sea of things imressing us, although it is ever changing infinitely, changes only lawfully, in accordance with a system of invariants constituting an invariant (see INVARIANTS AND COVARIANTS) at once underrived and indestructible and securing everlasting harmony through and through; and it may not be such. The student of nature assumes, he rightly assumes, that it is, and moved and sustained by appropriate curiosity, he endeavors to find in the outer world what are the elements and relationships assumed to be valid there. "Natural science," said Bernhard Riemann, "is the attempt to comprehend nature by means of exact concepts." The mathematician, as one such, does not make that assumption and does not seek for relationships in the outer world.

Is the assumption correct? Undoubtedly it is admissible, and as a working hypothesis it is undoubtedly very useful or even indispensable to the student of external nature; but is it true? The mathematician, as man, does not know although he greatly cares. Man, as mathematician, neither knows nor cares. The mathematician does know, however, that, if the assumption be correct, the relationship that is valid in nature is, in abstracto, an element in his domain, a subject for his study. He knows, too, at least he strongly suspects, that, if the assumption be not correct, his domain remains the same absolutely. The two realms, of mathematics, of natural science, like the two attitudes, the mathematician's and that of the nature student, are fundamentally distinct and disparate. To think logically the logically thinkable—that is the mathematician's attitude; to find in nature is thus thinkable, an embodied rational logos, and to discover the thought supposed incarnate there—these are at once the principle and the hope of the student of nature.

Suppose the latter student in sight, suppose the outer universe really is an embodied logos of reason, an infinitely intricate garment ever weaving and ever woven, warp and weft, of logically determinate relationships, does that imply that all of the logically thinkable is incorporated in it? It seems not. A cosmos, a harmoniously ordered universe, one that through and through is self-compatible, can hardly be the whole of reason materialized and objectified. There appears to be many a rational logos. At any rate the mathematician has delight in the construction and production of divers systems that are inconsistent with one another, though each is composed of consistent relationships. He constructs in thought, as witness the geometry of hyperspaces, ordered worlds, worlds that are by the geometrician, the whole vast region of the sensuous universe is literally as a merest point of light in a shining sky.

Now these mere speck of a physical universe, in which the chemist, the physicist, the astrono-
regarded as "applied" mathematics, regarded, that is, as true descriptions of some one actual space, are incompatible. In our universe, to be specific, if it be, as Plato thought and nature science takes for granted, a geometrized or geometrizable affair, then one of these geometries may be objectively valid in it. But in the vaster world of thought, in the world of pure mathesis, all of them are valid; they coexist, and interlace among themselves and others as differing strains of a hypercosmic harmony.

In any case, indeed any mathematical theory, consists of a definite system of determinate compatible principles or assumptions or hypotheses or postulates (commonly called axioms) together with their implications, their logically deducible consequences. Accordingly, natural science, the term being broadly employed to signify knowledge that is ultimately dependent upon "observation and experiment," cannot be or become strictly mathematical. It aspires to the character, and appears, and is, that of a mathematical science, but it can never really attain either. Mathematics is concerned with implications, not applications. Such terms as "applied mathematics," "mathematical physics," and the like, in popular use, but the signification, rightly understood, is always that of a mixed doctrine, a doctrine that is thoroughly analyzable into two disparate parts: one of these consists of determinate concepts formally combined in accordance with the established canons of reasonation, i.e., it is pure mathematics and not natural science, the other is matter of observation and experiment, i.e., it is natural science and not mathematics. No fibre of either component is a filament of the other. Whether the behavior of natural phenomena is or is not exactly describable by mathematical formulae can never be ascertained, for the means to "natural knowledge," viz., observation and experiment, are fallible by nature, and, however refined or precise, are incapable of yielding absolute exactness or certainty. Of any so-called law of nature, the most, the last, the best that can be said is that its agreement with the facts is so nearly perfect that every discrepancy, if any there be, has escaped detection.

Cannot the like be said of mathematics? In the foregoing conception of mathematics it has indeed been tacitly assumed that some ideas are completely determinable, that there are possible systems of postulates absolutely free alike from obscurity and from interior contradiction, that the postulates of such a system import a perfectly definite body of ascertainable implications, and that there is a perfect standard of logic quite independent of time and place and of the defects and idiosyncrasies of individual reasoners. May not these assumptions, some or all of them, be incorrect? There are some grounds, historical and biological, for suspecting that such may be the case. Such an admission, however, whether tentative or unadvised, need not induce us to give up the study of the mind of the author.

mathematics would still rightly rank as highest. It would indeed be marked by a degree of uncertainty or indeterminateness or relativity or inexactness, viz., that degree of inexactness which by supposition would belong to all meanings and standards. Hence it would not be peculiar to mathematics, but would be common to it and every other science. But every such "other science" has an additional mark of indeterminateness, the characteristic inexactness of all possible observation and experiment. In any case, then, the observational and experimental sciences are, in respect to profound exactness, hopelessly inferior to mathematics.

But in all ages it has been the faith of the mathematician that complete determination of concepts and absolute rigor of demonstration are in fact attainable, not, however, in the realm of observation and experiment, but in the world of pure thought. It is, then, in that world, where all entia dwell, where is every type of order and every manner of correlation and every variety of relationship and every form of a thing, it is in this infinite ensemble of eternal verities whence, if there be one cosmos or many of them, each derives its character and mode of being,—it is there that the spirit of mathesis has its home and its life.

"Is it a familiar use, but the signification, rightly understood, is always that of a mixed doctrine, a doctrine that is thoroughly analyzable into two disparate parts: one of these consists of determinate concepts formally combined in accordance with the established canons of reasonation, i.e., it is pure mathematics and not natural science, the other is matter of observation and experiment, i.e., it is natural science and not mathematics. CASSIUS J. KEYSEY
Adrain Professor of Mathematics, Columbia University.

MATHER, mathematician, Cotton, American colonial clergyman, son of Increase Mather (q.v.): b. Boston, 12 Feb. 1663; d. there, 13 Feb. 1728. He entered Harvard College at 11, and at his graduation in 1678 President Oakes expressed his expectation that he would resemble his venerable grandfathers, John Cotton and Richard Mather, who should be united and flourish again in him. He was early distinguished for piety, and in his 14th year began a system of rigid and regular fasting and vigils which he continued through life. He was occupied after leaving college with teaching, in 1680 became the assistant of his father in the pastorate of the North Church, Boston, and in 1684 was ordained as his colleague. When, at the return of the Prince of Orange in England, Governor Andros was seized and imprisoned in Boston, Cotton Mather prepared the public declaration justifying the measure. But it is in connection with proceedings concerning witchcraft that he is most generally known. In 1685 he published his 'Memorable Providences relating to Witchcraft and Possessions,' narrating cases which had occurred at intervals in different parts of the country; and during the witchcraft excitement in Salem in 1692 his work was again investigated in the matter, publishing the next year his 'Wonders of the Invisible World,' in order to confirm believers in that kind of demoniac possession. In 1702 appeared his greatest work, 'Magna Christi Americana,' an ecclesiastical history of New England concerning witchcraft; he was admitted to know more particulars than any other man. Though strongly marked by his partialities and prejudices, its somewhat quaint and grotesque character, its admixture of superstition, learning and ingenuity, make it still a useful book. In 1713 his 'Cursus Americana' was read before the Royal Society of London, and he was elected a member of that body, being the first American to receive this distinction. In its 'Transactions' in 1721 appeared an account of the practice of inoculation for the smallpox, introduced by Lady Mary Wortley Montagu; and it was by the efforts of Mather in connection with Dr. Boylston, against both professional and popular prejudice, that the operation was first performed in Boston. His 'Essays to Do Good' (1710) was admitted by Dr. Franklin to have influenced some of the principal events of his life; and his 'Christian Philosopher' and 'Directions for a Candidate of the Ministry' enjoyed high repute. His 'Parens' (1724) is a life of his father, Inclined very pedantic as he was narrow and credulous as he showed himself to be in regard to witchcraft and other topics of his time, he was in many directions a useful, public-minded citizen who deserves to be regarded more leniently by posterity than has been customary. Consult 'Life' by Samuel Mather (Boston 1729); Pond, Enoch, 'The Mather Family' (ib. 1844); Marvin, A. B., 'Life and Times of Cotton Mather' (ib. 1892); Wendell, Barrett, 'Cotton Mather' (1891); Tyler, 'History of American Literature' (Vol. II, New York 1881).

MATHER, Frank Jewett, Jr., American professor of art: b. Deep River, Conn., 6 July 1868. In 1889 he was graduated from Williams College, and subsequently studied at Johns Hopkins (Ph.D. 1892), the University of Berlin and L'Ecole des Hautes Etudes, Paris. From 1893 to 1900 Dr. Mather was instructor and assistant professor of English and in the three languages at Williams College; was editorial writer on the New York Evening Post, assistant editor of The Nation in 1901–06; art critic of the Evening Post in 1905–06 and again in 1910–11; and American editor of the Burlington Magazine in 1904–06. In 1910 Dr. Mather became Marquand professor of art and archaeology at Princeton University. He is the author of 'Homer Martin, Poet in Landscape' (1912); 'The Collectors,' short stories (1912); 'Estimates in Art' (1916), also several literary and philosophical monographs. He is a contributor, chiefly on art, to The Nation, and other periodicals. In 1917 he served as chief boatswain's mate in the United States Naval Reserve Fleet (coast patrol).

MATHER, Increase, American colonial divine, son of Richard Mather (q.v.): b. Newchester, Mass., 21 June 1639; d. Boston, 23 Aug. 1723. He was graduated at Harvard College in 1656, and in 1658 at Trinity College, Dublin. He afterward preached in Devonshire and the island of Guernsey, and on the Restoration was urged to conform and settle in England; but he refused, and on his return to Boston was invited to preach to the North Church, of which he was ordained pastor in 1661. This office he held for 62 years. He was a member of the synod of 1679, and drew up the propositions which were adopted concerning the proper subjects of baptism. In 1681 he was elected president of Harvard College, but the reluctance of his church to relinquish him induced him to decline the position. In 1684 the office was again offered him, and he accepted it with a stipulation that he should retain his relations with his people. He continued in this station till 1701, when he retired in consequence of an act of the general court requiring the president to reside in Cambridge. He received the first diploma for the degree of D.D. that was granted in America. When in 1683 Charles II demanded that the charter of Massachusetts should be resigned into his hands, Mather was foremost in opposing the measure; and when that monarch annulled the charter in 1685, he was sent to England as agent for the colonies. He was in England during the revolution of 1688, and, having found it impossible to obtain a restoration of the old charter, accepted a new one, under which the appointment to all the offices reserved to the Crown was conferred on him. He returned in 1692, when the general court appointed a day of thanksgiving for his safety and for the settlement of the dispute. He is stated to have condemned the violent proceedings which followed relating to witchcraft. He was accustomed to spend 16 hours every day in his study, and always commissary. Consult 'Life' by Samuel Mather (Boston 1729); Pond, Enoch, 'The Mather Family' (ib. 1844); Marvin, A. B., 'Life and Times of Cotton Mather' (ib. 1892); Wendell, Barrett, 'Cotton Mather' (1891); Tyler, 'History of American Literature' (Vol. II, New York 1881).
Provincetown was republished in the 'Library of Old Authors' (1856), and other works by him are 'A Brief History of the War with the Indians in New England' (1676); 'Relation of Troubles of New England from the Indians' (1677; 1864); 'Cases of Conscience Concerning Witchcraft' (1693; 1862); 'Cometography, or a True Description of a Comet in 1643' (1863). Consult Pond, Enoch, 'The Mather Family' (Boston 1844); Walker, Williston, 'Ten New England Leaders' (New York 1901); Tyler, M. C., 'History of American Literature' (Vol. II, New York 1881); Shibley, 'Harvard Graduates' (Vol. I, Cambridge 1873).

MATHER, Richard, American colonial divine: b. Lowton, Lancashire, England, 1596; d. Dorchester, Mass., 22 April 1669. He became a schoolmaster at Tuxteth Park, near Liverpool, at the age of 15; studied at Brazenose College, Oxford, in 1618; was ordained in the English Church soon after, and became the minister of Tuxteth, in which position he remained 15 years. He was suspended for non-conformity to the ceremonies of the Established Church in 1633, and though soon restored by the influence of his brother and again silenced in the following year. He therefore decided to emigrate to New England, arriving in Boston in August 1635. The next year he became pastor of the church in Dorchester, and held that position till his death. He was one of the compilers of the 'Bay Psalm Books' and assisted to frame in 1648 a model of discipline known as the Cambridge Platform. He married for his second wife the widow of John Cotton (q.v.). His 'Journal, Life and Death' was issued by the Dorchester Historical Society in 1850. See CONGREGATIONALISM and consult Mather, Increase, 'Life and Death of Richard Mather' (Cambridge 1670); Tyler, M. C., 'History of American Literature' (Vol. II, New York 1881).

MATHER, Robert, American lawyer and railroad official: b. Salt Lake City, 1859; d. 1911. In 1889 he was graduated at Knox College, Illinois, and four years later was admitted to the bar at Chicago. He practised in that city in 1889-92; was local attorney in 1899-94, assistant general and general attorney in 1894-1902, and general counsel in 1902-09 of the Chicago and Northwestern Railroad Company. In 1909 he was elected chairman of the board of the Westinghouse Electric Company. Mr. Mather was interested, as officer or director, in several railroad and industrial companies.

MATHER, William Williams, American geologist: b. Brooklyn, Conn., 24 May 1804; d. Columbus, Ohio, 26 Feb. 1859. He was graduated from West Point in 1828 and was an assistant professor of chemistry and geology there, 1829-35. After a short period spent as professor of chemistry at the University of Louisiana (1836), he undertook the superintendence of a geological survey of the 1st district of New York State which included the Hudson River counties, a labor which lasted from 1836 to 1844. He was also State geologist of Ohio 1837-40, and of Kentucky 1838-39, and from 1840-45; professor of natural science in the Ohio University at Athens. He made a collection of about 22,000 mineralogical specimens. He contributed frequently to scientific journals, edited the Western Agriculturist for a time and published 'Geology of the 1st Geological District' (in 'Natural History of New York,' 1843); and 'Elements of Geology.'

MATHERSON, mār'son, Arthur James, Canadian statesman: b. Perth, Ontario, 1842; d. 1913. He received his education at Upper Canada College and Trinity College, Toronto; was called to the bar in 1870 and established a practice in his native town of which he was mayor in 1883-84. From 1894 to 1913 he was a member of the Conservative majority in the Ontario legislature and served as provincial treasurer in 1905-13 under Premier Sir James P. Whitney. In 1906 he was a member of the Ottawa Inter-provincial Conference and in the following year served on the national conference on Taxation. In 1910 he served as vice-president of the International Commission. Mr. Matheson was made K.C. in 1908. He served in the militia after 1866, saw service during the Fenian raids and in 1900 attained the rank of brigadier-general.

MATHERSON, George, Scottish Presbyterian clergyman: b. Glasgow, 27 March 1842; d. 28 Aug. 1906. He was educated at Glasgow University and although he had lost his sight in boyhood he entered the ministry of the Kirk of Scotland and was ordained in 1868. He was minister of Inverleith, minister of the First of Clyde 1868-86; and of Saint Bernard's Parish, Edinburgh (1886-97). He was the author of the famous hymn, 'O Love that Will Not Let Me Go,' which finds a place in nearly every modern hymnal. Among his published books are 'Aids to the Study of German Theology' (1874); 'Natural Elements of Revealed Theology' (1881); 'The Psalmist and the Scientist' (1887); 'Sidelights from Patmos' (1897); 'The Sceptre Without a Crown' (1901); 'Representative Men of the Bible' (three series); and 'Representative Women of the Bible' (1907).

MATHERSON, Samuel Pritchard, Canadian clergyman: b. Manitoba (then the Red River Settlement), 20 Sept. 1852. He received his education at Saint John's College School and Saint John's College, Winnipeg. He received deacon's orders in the Anglican Church in 1875 and those of priest in 1876. He became master at Saint John's College School; subsequently served as principal of the college; was excelled by Saint John's College, canon and dean of Saint John's Cathedral, deputy headmaster and headmaster of Saint John's College School. Subsequently he was warden and chancellor of Saint John's College. He became secretary of the Provincial Synod of Rupert's Land, and prolocutor of same and in 1902 became prolocutor of the General Synod of Canada. In 1903 he became coadjutor bishop of Rupert's Land, in 1905 he became bishop and in 1909 was made Primate of all Canada.

MATHER, Theobald, known as 'FATHER MATHews,' Irish temperance reformer: b. Thomastown Castle, County Tipperary, Ireland, 10 Oct. 1790; d. Queenstown, Ireland, 8 Dec. 1856. He was educated at Maynooth College and the Capuchin Convent, Cork, and was ordained to the Roman Catholic clergy at the Irish College and at 1814. In 1838 he inaugurated a temperance crusade and his labors in Great Britain and Ireland induced hundreds of thousands to sign the total abstinence pledge. The most conclusive evidence of the benefit of his preaching
was the reduction of nearly £600,000 on the duties of spirits imported in Ireland in five years. He made a tour of the United States in 1849–51 and was very successful. Though pensioned by the queen he was never entirely relieved from the burden of debt with which his extended tours had burdened him, and which caused his imprisonment for a time in 1847. Consult ‘Life’ by J. F. Maguire (London 1863; abridged ed., 1890); Matthew, F., ‘Father Mathew: his Life and Times’ (London 1890); Tynan, K., ‘Father Mathew’ (ib. 1908).

MATHEWS, mat’həz, Abert, ‘Paul Sieg-
volf,’ American lawyer and author: b. New
York, 8 Sept. 1820; d. there, Oct. 1903. He
was graduated from Yale in 1842 and after
studying law was admitted to the New York
bar in 1845. He soon acquired an extensive
practice and was especially skilled in chancery
practice. He found time for literary work de-
spite the claims of his profession, and under
the pseudonym ‘Paul Siegvolk’ published
‘Walter Ashwood,’ a once popular love story
(1860); ‘A Bundle of Papers’ (1879); ‘Thoughts on Codification of the Common
Law’ (1879); ‘Dissimulations: The Ideal
American Lady and Other Essays’ (1892); ‘A Few Verses’ (1893), etc. In the early part of
his career he was a close friend of N. P. Willis,
whom he aided in establishing ‘The Home
Journal.’

MATHEWS, Charles, English actor: b.
London, 28 June 1776; d. Plymouth, England,
28 June 1835. He made his début as an actor
in Richmond in 1793 and was subsequently
engaged for some years in Dublin and London.
In 1818 he made a hit as a professional enter-
tainer in his ‘At Home.’ He continued in this
class of work, making two successful trips to
the United States and, returning, presented in
England with great success ‘A Trip to America.’ In 1828 he became joint proprietor of the

MATHEWS, Charles James, English
actor: b. Liverpool, 26 Dec. 1803; d. Manches-
ter, England, 24 June 1878. He was the son of
Charles Mathews (q.v.) and was educated as an
architect, but abandoned that calling for the
stage. As a light comedian he was very suc-
cessful, but his attempts at managing Covent
Garden and the Lyceum Theatre in London
were failures. He made several trips to the
United States, Paris and Australia, presenting
an entertainment similar to his father’s famous
‘At Home.’ Consult Dickens, Charles, ‘Life of
Charles James Mathews’ (London 1879).

MATHEWS, Edward Bennett, American
geologist: b. Portland, Me., 16 Aug. 1869. In
1881 he was graduated at Colby College and in
1884 received the degree of D.Ph. at the Uni-
versity of Johns Hopkins. In 1891–94 he was
field assistant of the United States Geological
Survey; in 1894–95 was instructor in mineral-
ogy and petrography, in 1895–99 associate, in
1899–1904 associate professor and since 1904
professor of geology. He was convert in 1877.
In 1917 he has served as chairman of the geologi-
cal department. From 1898 to 1917 Dr. Mathews was assistant State geologist of Mary-
land and after 1917 was State geologist. He
published ‘Bibliography and Cartography of
Maryland’ (1897); ‘Maps and Map-Makers of
Maryland’ (1898); ‘Building Stones of Mary-
land’ (1898); ‘Limestones of Maryland’
(1910); ‘History of the Mason-Dixon Line’;
‘Physical Features of Maryland’; ‘Water Re-
sources of Maryland,’ and numerous geological
and historical papers.

MATHEWS, Ferdinand Schuyler, Ameri-
can artist and author: b. New Brighton, N. Y.,
30 May 1854. He was educated at Cooper In-
stitute, studied art in Italy and has made a spe-
cialty of decorative designing. He has con-
tributed extensively to the magazines both as
illustrator and writer, in the latter field dealing
chiefly with subjects which come within his own
profession and also those which belong to nat-
ural science. He has published ‘The Writing
Table of the 20th Century’ (1900); ‘The Field-
Book of American Wild Flowers’ (1902); ‘Field-Book of Wild Flowers and the Hun-
dred of Mushrooms’ (1904); ‘Field-Book of American Trees and Shrubs’ (1915), etc.

MATHEWS, Joseph McDowell, Ameri-
He was educated at the Newcastle Academy
and at the University of Louisville. He practi-
cised in Louisville and was appointed professor
of surgery at the Louisville Hospital College of
Medicine. He is president of the Kentucky State Board of Health and in 1898–99 was
president of the American Medical Association.
He published ‘Diseases of the Rectum, Anus
and Sigmoid Flexure’ (1893), 3d ed. (1897),
‘How to Treat and How to Succeed in the Practice of Medi-
cine’ (1902).

MATHEWS, Shailer, American educator: b.
Portland, Me., 26 May 1863. He was gradu-
ated from Newton Theological Institute in
1887 and studied in Berlin. In 1887 he was ap-
pointed assistant professor of rhetoric at Colby
University and in 1889 accepted the chair of
history and political economy, which he occu-
pied until 1894, when he was made associate
professor of New Testament history in the
University of Chicago. In 1896 he was made
professor, in 1899 junior dean, in 1905 profes-
sor of systematic theology, in 1906 professor
of history and comparative theology and in 1908
dean of the Divinity School. In 1911 he was
elected president of the Western Economic
Society, 1908 president of the Co-operative
Council of City Missions, in 1910 president of
the Chicago Baptist Executive Council, in 1912
president of the Federal Council of the
Churches of Christ in America and in 1915
president of the Northern Baptist Convention.
He is director of religious work in the Ma-
obian Institution, New York, and one of the
trustees of the Church Peace Union founded by Andrew
Carnegie. In 1915 he visited Japan as a repre-
sentative of the Federal Council of the
Churches of Christ in America. He gave the
Haverford Library Foundation Lectures in 1907,
the Earle Lectures, Berkeley, Calif., in 1913, and
the Merriam Lectures, Worcester, Mass., in
1914. He was editor of the World To-day from
1903 to 1911 and has been editor of The Biblical
World since 1913. He has prepared several
Testament handbooks, ‘The Bible for Home
and School,’ ‘Social Betterment,’ handbooks
of ethics and religion, Women Citizen’s Li-
brary and associate editor of the ‘Dictionary
of the Bible, 'American Journal of Theology, Constructive Quarterly. He is the author of 'Select Medieval Documents' (1891; 1900); 'The Patient, Jesus' (1897); 'A History of New Testament Times in Palestine' (1899); 'Constructive Studies in the Life of Christ', with E. D. Burton (1901); 'The French Revolution — A Sketch' (1901); 'Principles and Ideals for the Sunday School', with E. D. Burton (1903); 'The Messianic Hope in the New Testament' (1905); 'The Church and the Changing Order' (1907); 'The Social Gospel' (1909); 'The Gospel and the Modern Man' (1909); 'Scientific Management in the Churches' (1911); 'The Making of Tomorrow' (1913); 'The Individual and the Social Gospel' (1915); 'The Spiritual Interpretation of Modern History' (1916).

MATTHEWS, William, American author: b. Watertown, Me., 28 July 1818; d. Boston, Mass., 14 Feb. 1909. He studied law at Harvard and was admitted to the bar in 1838, practice for a time in Watertown, but abandoned law for journalism, establishing the Watervillian in 1841, which later he named the Yankee Blade. In 1859-62 he was engaged in journalism in Chicago. In 1862 he was appointed professor of English and rhetoric at the University of Chicago, but in 1875 resigned in order to devote himself exclusively to literature. Among his books are 'Getting on in the World' (1873); 'The Great Conversations' (1874); 'Words: Their Use and Abuse' (1876); 'Oratory' and 'Orators' (1879); 'Literary Style' (1881); 'Men, Places and Things' (1888); 'Wit and Humor: Their Use and Abuse' (1888); 'Nugae Literariae' (1896); 'Conquering Success' (1903), etc.

MATTHEWS, William Smythe Babcock, American musical writer and editor: b. London, N. H., 8 May 1837; d. 1912. He obtained his musical education in Boston and became a teacher in 1853; he was for a time engaged at the Wesleyan Female Seminary in Georgia, but in 1867 he removed to Chicago, where he was prominent as an organist and engaged in critical and editorial work on music on the leading Chicago papers. In 1891 he established the magazine, Music, and edited it until 1903, when it became a part of the Philharmonic. He is the author of 'Outlines of Musical Form' (1867); 'Emerson Organ Method' (1870); 'How to Understand Music' (1880-88); 'Music and Its Ideals' (1897); 'Dictionary of Musical Terms' (1895); 'Popular History of Music' (1901); 'The Great in Music' (1900-03), etc.

MATICO ('piper angustifolium'), a shrub of the natural order Piperaceae, native of Peru; remarkable for the strychnine property of its leaves and unripe fruit, used for stanching wounds.

MATIN, a large hound-like French dog, resembling the Great Dane, but having a rough coat. The head is elongated, the forehead flat, the ears pendulous toward the tips; color, yellowish-fawn or whitish. It is commonly employed in France as a sheep-dog and watch-dog.

MATINS, the daily office of morning prayer in the Anglican communion. It is composed in part of the pre-Reformation offices of Matins and Lauds. In the Roman Catholic Church, the first portion of the Divine Office, with which Lauds are usually associated. On Sundays and double feast days matins have three nocturns; on simple feasts and weekdays, one nocturn. Easter and Pentecost have each only one nocturn, with three psalms. After private prayer verses and responses are recited; the invitatory psalm follows. In the first nocturn are said three psalms on feast days, 12 when the office is of the Sunday and three lessons from Scripture; the other two nocturns have each three psalms and the lessons are chosen from the patristic writings for the second, and from some commentary on the Gospel of the day of the third nocturn.

MATRIARCHATE, position or power of a matriarch, a name formerly given to the wife of a patriarch. Among the Indians the mother is considered of superior importance in families, clans or tribes. Job's wife, Xantippe, and others in history have been called matriarchs. In certain primitive tribes the mother, in line of descent and inheritance, takes precedence of the father. In Turkey and Persia the father's name is kept, and this is inscribed in the tombstone; the mother's name is not. In the family of Consul Noguchi, 'Das Muttermrecht' (2d ed., Basel 1897); Dargan, 'Muttermutter und Raubehe' (Breslau 1883); Westermarck, E. A., 'History of Human Marriage' (3d ed., London 1903).

MATRIMONY VINE. See Lycium.

MATRONALIA, the 1st of March, the New Year's day of the Roman religious calendar, sacred to Juno, the deity of matrons. On this festival day wives exchanged presents from their husbands, and themselves gave entertainment to the household slaves. Consult Fowler, W. W., 'Roman Festivals' (London 1899).

MATSUAIIRA, mah-cta-sigh-rak, the generic name of 52 families of territorial nobles in feudal Japan, mostly, although not all, descended from an ancestor Mutsu Moto Chikae, of the 14th century, 11th in generation from Yoshiiye who, in the village of Matsudaira, in Mikawa, espoused the daughter of Matsudaira Nohushige and took his wife's name. When, in 1604, the Tokugawa line of shoguns was established, permission was given to the heads of allied or loyal clans to bear this name. Among the hundreds of feudal barons and others thus favored have been many of the most illustrious in the period 1604-1868. After the American connexion, the name of 'The Great' in Japan' (1809); 'Griffis, 'Th Mikado's Empire' (1912), and La Tourette, 'The Development of Japan' (1918).

MATSUAIIRA SHUNGAKU, mah-cta-sigh-rah shoon-gah-ku, champion, during Jajin's hermit days, of Western civilization and of French fashions. Born in Edo, 11 Oct. 1828; d. Tokio, 1880. Adopted at 10 years of age by Matsudaira, baron of Echizen, at 21 he began sweeping and con-
structive reforms, introducing modern military, economic and hygienic methods, abolishing archery in favor of fire arms, establishing cannon and rifle factories, sending young men as students to the Dutch at Nagasaki, establishing lectures on the Oyomé (q.v.) philosophy and writing manifestoes. He combated popular prejudices, showed the superiority of Western civilization and the reasonableness of Christianity, compelled the use by doctors of the Western methods of medical practice, opened up and secured the foreign literature department in the excellent clan school in Fukui. Opposed to opening the country prematurely, on unequal terms, as was done by Li Naosuke, he suffered domiciliary confinement but was later called to be virtual premier of the empire. With the assistance of Yokoi Héishiro he abolished the century-old custom of compelling the feudal barons to live half the year in Yedo, leaving their families as hostages when away. This made Kioto the centre of affairs. He later brought the first of the yalu to his domain, and here the first public schools beyond the treaty ports were organized, and one of the very first of the new regiments of the peasant national army was raised. Out of this regiment was raised the famous Ninin Division that took Port Arthur. High posthumous honors were awarded this pioneer of Western civilization. His biography and writings have been compiled by his son the marquis. Consult Griffis, 'The Mikado: Institution and Person' (1915), and 'The Mikado's Empire' (1912).

MATSUMATA, Masayoshi, mä-si-o'ši-mät-soo-kä'tä, MARQUIS, Japanese statesman: b. Satsuma 1835. He was son of a Samurai, but fell in with the Radical party; was made head of the prefecture (or ken) of Hida after the revolution; was prominent in the tax reform of 1875; represented Japan in several industrial exhibitions; was member of the Cabinet, in 1880 as Minister of Commerce, in 1881 as Minister of Finance, and, with the same post, the Minister from 1892 to 1893. His great work was in 1895-97, when he formed a new cabinet, carried through the gold standard, set Japanese credit on its feet, but he was forced to retire because of the ill-success of his scheme of taxation. He was Minister of Finance a second time in 1898-1900, became Privy Councillor in 1903, and received the title of marquis in 1906. He was also president of the Japanese section of the Red Cross.

MATSUMOTO, Japan, town, in the district of Nagano, in the island of Hondo, 100 miles north by west of Tokio. The town manufactures baskets, preserved fruits and silks and has an old daimyo castle. Pop. 35,000.

MATSUMURA, Ninzo, Japanese botanist: b. Ibaraki-Ken, 1856. In 1886-88 he studied at the universities of Wurzburg and Heidelberg, meanwhile holding the assistant professorship of botany in the University of Tokio to which he had been appointed in 1883. He became full professor in 1890 and seven years later was appointed director of the Botanical Gardens. He collaborated in British's 'Japanese-English Dictionary' (1896) and published 'Nomenclature of Japanese Plants in Latin, Japanese and Chinese' (1884); 'Names of Plants and their Products in English, Japanese and Chinese' (1892); 'Conspexitus of Leguminose' (1902); 'Index Plantarum Japonicarum: Cryptogamae' (1904); 'Phanerogamae' (1905); 'Tentamen Flore Lutchuensis,' with tfo (1899); 'Revisio Alni Specierum Japonicarum' (1902); 'Emmerato Plantarum in Insula Frumenti Sponte Crescentia' (1906); 'Chinese Names of Plants' (1915); 'Classified Etymological Vocabulary of the Japanese Language Ancient and Modern' (1915).

MATSUBISHIMA, Japan, village on the northeast coast of the island of Hondo, situated on the Bay of Sendai. In a lagoon opposite the village are 808 islets ranging in elevation from 30 to 300 feet and covered with pines. This beautiful natural garden is one of the wonders of Japan.

MATSUMURA, Japan, town and capital of the district of Ehime, on the island of Shikoku, five miles from Mitsu. It contains a great feudal castle, one of the few perfect specimens of its period in modern Japan. Pop. 44,166.

MATSUMURE, or Matususe, Japan, town and capital of the district of Shimane, on the island of Hondo, 140 miles north by west of Kioto. It has large paper manufactories and agate-polishing establishments and has numerous temples. It is well built and is one of the cleanest towns in Japan. Pop. 36,209.

MATSYS, mä-sis', or Massys, Quentin, Flemish painter; b. Antwerp or Louvain, about 1460; d. there, between 13 July and 16 Sept. 1530. A blacksmith until he was 20, legend says that he turned artist to win the love of a painter's daughter. He was acquainted with many of the notables of the day, including Dürer, Erasmus and Sir Thomas More. Much of his present fame is due to genre pictures, especially of misers and money-changers, which are not his work, but that of his school, among them his son Jan, whose 'Misers' is at Windsor Castle. Matsys' own work is styled a connecting link between Van Eyck and the latter Dutch realists; apart from such excellent portraits as those of Maximilian of Austria and Petrus Aegidius, it is mostly religious in theme. The 'Burial of Christ,' an altarpiece for the Antwerp Cathedral, now in the Antwerp Museum, and the 'Story of Saint Anthony' in the Brussels Gallery, are the best examples of his work. The Metropolitan Museum, New York, contains his 'Adoration of the Kings;' Consult Cohen, Walter, 'Studien zur Quentin Metsys' (Bonn 1904) and de Bosschere, Jean, 'Quentin Metsys' (Brussels 1907).

MATTAWA, or Mattawan, Canada, town in the Nipissing district of Ontario province, situated at the confluence of the Mattawa and Ottawa rivers at the east end of Lake Timiskaming, on the Canadian Pacific Railroad, 45 miles east of North Bay. Great quantities of mica are obtained in the neighborhood. The town has extensive lumber interests and is a distributing point for several great lumber companies. It is also famous as the starting-point of hunters and anglers. Pop. 1,524.

MATTAWA, a river of Ontario, the source of which is Trout Lake east of Lake Nipissing. It flows east a distance of about 45 miles and enters the Ottawa River at Mattawa, 308 miles from Montreal. This river forms part of an almost continuous water-way from the Ottawa
River to Lake Huron, and before the Canadian Pacific Railroad was built this water route was much used for transportation and travel.

MATTEAWAN, mät-tè-ə-wown, N. Y. See BEACON, N. Y.

MATTEI, mät-tä-ē, Tito, Italian musician and composer: b. Naples, 1841; d. 30 March 1914. He was educated in Naples. He received the degree of professor in Saint Cecilia’s Academy at Rome when he was 11 and was also elected a member of the Philharmonic Society in Florence and other cities. He gave his first concert when 15 and afterward made tours of Europe, but in 1863 settled in London, where he lived for 50 years, confining his concert tours to Great Britain, and in 1870 he conducted an Italian opera at the Lyceum Theatre. He was the composer of hundreds of songs and pianoforte pieces, many of which have become widely popular, and the operas ‘Maria di Gand,’ ‘La Prima Donna,’ etc.

MATTER, in physics, mechanics and chemistry, the tangible substance of which the world external to our minds is composed and which is characterized by the resistance which it opposes to the efforts exerted upon it. Since we can know it only through the mediation of our senses, its actual objective reality has often been questioned by philosophers and metaphysicians; and in order to avoid doubtful points of this sort it is frequently defined merely as a “physical concept,” without making any hypothesis as to its objective existence. (Consult Pearson, ‘The Grammar of Science’.) In physics and chemistry we think and speak of it as having a real existence, however, just as we do in common life. For scientific purposes it is highly important to be able to accurately compare the quantities of matter in two bodies; but the phrase “quantity of matter” is not commonly used in science, the word “mass” (or inertia) being substituted for it. The term “mass” is synonymous with “quantity of matter” so long as the bodies compared are identical in composition and in physical state; but by its use we avoid the uncertainty in the meaning of the longer phrase, when it is applied to bodies of dissimilar composition. Two bodies are said to have “equal masses” under the following conditions: Let the two bodies be conceived to be initially at rest, and free from the action of any external forces whatsoever. Let them then be exposed to the action of equal forces for an equal length of time. If, under these circumstances, the velocities that are produced in the two bodies are equal, the masses of the bodies are also equal, by definition. But if the velocities that are produced are unequal, then the masses are also unequal, and are (by definition) proportional to these velocities; the body which is moving the faster being the one whose mass is the less. It would be impossible to carry out an elaborate experiment of this kind every time we wished to compare the masses of two bodies; and it fortunately happens that masses can be compared with great accuracy by merely weighing the bodies against each other in a balance. For equality of weight means that the earth’s attractive force is the same upon both; and if (as we know) they are very commonly confused, because they are strictly proportional to each other, according to the most accurate experiments that have yet been made. Yet it is not at all impossible to imagine a state of things in which mass and weight would not be strictly proportional. It is only by experiment, for example, that we know that the earth attracts a body with precisely the same force, whether the body is hot or cold. The attraction between two permanent magnets varies with the temperature, and it may yet be found that gravitational attraction varies in the same way, though to a much smaller extent. Numerous experimenters have in fact fancied that they could detect an effect of this kind, though its reality is not yet admitted. But we can hardly admit that the mass of a body is a function of the temperature; and so we see that the apparently strict proportionality between mass and weight is not at all a necessity of thought, but merely an experimental fact, which may one day be shown to be a close approximation to the actual truth.

So far as we know, matter cannot neither be destroyed nor created by any experimental means at our command, nor by any process now operative in nature. This great fact is often called the “law of the conservation of matter,” and it appears to be rigorously true. As has been pointed out above, future experiment may show that the weight of a body depends to a slight extent upon its temperature, and it may also be found that the weight of a chemical compound is not always precisely equal to the sum of the weights of its constituents; but it is believed that any irregularities of this sort that may be discovered will hold true to the weight only, and will not affect the mass; and that the weight will also return to its original value when the substance that is weighed is brought back to the same chemical and physical condition again. The gravitational action of matter is one of its most singular attributes, and one which we are still far from understanding. It is apparently true that each particle of matter attracts every other particle with a force which is directly proportional to the product of the masses of the two particles and inversely proportional to the square of the distance between them; and independent of other circumstances. It is not certain that this law holds true, nor that the attraction exists at all, at distances comparable with the distance from the earth to the fixed stars, but it appears to hold rigorously at distances commensurate with the dimensions of the solar system. Electric and magnetic forces may be either attractive or repulsive; but gravitational action is probably always attractive, the only phenomena which would countenance the opposite view being the apparent repulsion that the sun exerts upon the tails of comets and upon the coronal streamers that are seen at the time of a total solar eclipse. Matter exists in three (or perhaps four) physical states. All ordinary bodies, for example, may be classified, roughly, either as solids or fluids; solids being further subdivided into liquids and gases. This classification is not all
that could be desired, since there are certain bodies (such as wax) which have certain characteristics of the solids and certain others of the liquids. A more complete and systematic classification is hardly practicable, however, in the present article. A solid body may be defined as a body capable of resisting a considerable shearing stress. (See Elasticity.) Solid bodies usually have a considerable tensile strength also. A solid does not yield continuously to a small deforming force; it resists deformation, and its resistance increases as the deformation increases. A fluid, on the other hand, is a substance having almost no shearing strength, and offering very little resistance to forces that tend to change its shape. A fluid yields continuously to a deforming force, and a force that will deform it at all will deform it indefinitely, so long as it is allowed to act. Considering the subdivision of fluids into gases and liquids, we may say that a gas is a fluid that presses continuously and in every direction upon the walls of the containing vessel or the object with which it comes in contact, if it will deform it indefinitely if they retreat. A gas, if left to itself, tends to expand indefinitely in all directions. A liquid is a fluid which does not follow the walls of the containing vessel if they retreat and is a liquid in the ordinary state of matter. (For the prevalent theories regarding the constitution of matter, see Gases, Kinetic Theory of; Molecular Theory.)

When a gas is rarefied very highly by a mercury vacuum pump, it exhibits properties which are different in many respects from those manifested by gases in the ordinary state of density. The pressure in such a rarefied gas, for example, may be different in different directions; so that in this respect, at least, the rarefied medium resembles a solid rather than a gas or liquid. Mechanical and electrical properties are also observed at high exhaustions which cannot be reproduced at ordinary pressures; and for these and other reasons Crookes considered that a gas, when under only 10 millionths of a atmosphere of pressure, may be fairly said to constitute a "fourth state of matter," which he considered to be as different from the gaseous state as the gaseous state is from the liquid state. The appearance of a gas in this state appears to be extreme and hardly a justifiable view; but it must be remembered that Andrews showed that the distinction between a liquid and the gas or vapor obtained from it by evaporation ceases to exist at temperatures higher than a certain critical value peculiar to each substance. (See Critical Point.)

This temperature is about 88° F. for carbon dioxide, and at temperatures progressively higher than this the isothermals of carbon dioxide approximate with increasing closeness to the hyperbolae of a perfect gas. It might be thought that a critical state exists with reference to the solid and liquid states; but this is still somewhat doubtful.

It appears probable that no such state exists between a solid and its liquid, unless the solid is crystalline; and its existence has not been established even for this case.

See Molecular Theory; Liquefied and Compressed Gases; Electron Theory; Solutions; Ether; Vacuum, etc.

Matterhorn, mät'tér-hörn, Mount. See Cervin, Mont.

Matten, mät'tén, Tompkins Harrison, American artist: b. Poughkeepsie, N. Y., 9 May 1813; d. Sherbourne, N. Y., 2 Feb. 1884. His early lessons in art were from an Indian; otherwise he was mostly self-taught, until the success of his 'Spirit of '76' when he settled in New York and studied in the National Academy. From 1851 until his death his home was Sherbourne. For a time he was a member of the New York legislature. His themes were historical or fanciful American country life, and his best-known pictures are 'The First Sabbath of the Pilgrims,' 'Examination of a Witch,' 'Eliot Preaching to the Indians,' 'Rip Van Winkle's Return from the Mountains,' 'At the Stile' and 'Foddering Cattle.'

Matthew, Matthew, the apostle of Jesus Christ, is with sufficient certainty identified with Levi, the son of Alphaeus, whose call by Jesus to discipleship is described in Mark and Luke in terms practically identical with a story of the call of Matthew, and was not uncommon among the Jews for a man to have two names and sometimes both names were of Hebrew, or Aramaic origin. The derivation and consequently the meaning of the name Matthew is uncertain, though it is commonly interpreted to mean 'Gift of God.' The mere mention of his father's name does not identify his family to us. He is first spoken of as being in his office as a publican, or collector of taxes, presumably near Capernaum on the great highway between Syria and the Mediterranean. While as such officer he would be in the service of the Tetrarch Herod, and not directly in Roman employ, yet he must have shared the obloquy which attached to this office among strict Jews, and it has accordingly been reckoned a mark of his humility that we find him designated as "the publican" in the Gospel which bears his name. After his call to discipleship he made a great feast of farewell, gathering his former friends and business associates to meet his new-found Master and the disciples attending him. The name of Matthew stands in all the lists of apostles, always the seventh or eighth in order, but of his activities as an apostle we have no record. No other name that his has ever been associated with the authorship of the first Gospel, and while this view has been discredited by many critics, because of the difficulty of considering the Gospel in its present form the work of an apostolic eyewitness, it is possible to conserve the historical value of this strongly confirmed tradition by holding that he was the author of the Discourse Document which constitutes such an important and characteristic element in Matthew. (See article Matthew, Gospel According to.) There are many variant traditions as to the missionary labors of Matthew, Macedonia, Egypt, Ethiopia and Parthia having been named as places where he worked. There is no sufficient reason for accepting any of these traditions, though perhaps the last is the most probable. Some traditions assert that he died as martyr and this has been accepted in the Western Church, but according to other
traditions perhaps no less reliable than a natural death.

David Foster Estes,
Professor of New Testament Interpretation,
Colgate University.

Matthew, George Frederick, Canadian geologist: b. Saint John, New Brunswick, 1837. He received his education at the University of New Brunswick; secured a civil service post in 1853 and in 1879 was appointed chief clerk of customs. He was made surveyor of customs in 1893. He collaborated with Bailey, in 1872, in preparing a report on the geology of southern New Brunswick and in the following year prepared a report on the Carboniferous system of that province. Subsequently he made several geological tours of exploration in the Maritime Provinces. He was a Fellow of the Royal Society of Canada and member of the New Brunswick Natural History Society. He published geological papers in various technical and scientific periodicals.

Matthew, Gospel According to. The Gospel with which the name of Matthew has uniformly been associated has with almost equal uniformity stood first in the gospel canon. It received this place both because it is the longest of the Gospels and many brief because of the apostolic authority which the name of Matthew gave to it, but the place is fitting also because it relates itself more closely to the Old Testament than does any other gospel.

Contents.—As respects the events recorded, they are much the same as those given in Mark and Luke, and are arranged in substantially the same order. The book may be briefly analyzed somewhat as follows: Introductory, genealogy, birth and infancy of Jesus, ministry of John the Baptist, baptism and temptation of Jesus, i, 1-11, 1. Early Galillean ministry (iv. 12-32, 50). II. Later ministry in Galilee and neighborhood, and the Peren journey (xii, 1-xx, 34). II. Entry of Jesus into Jerusalem and his teaching in the mainly controversial (xxi, 1-xxii, 39). IV. Eschatological discourse (xxiv, 1-xxv, 46). V. Closing scenes, anointing at Bethany, last supper, agony in Gethsemane, trial, crucifixion, death and resurrection (xxvi, 1-xxxi, 20). In addition to the story of events and many brief reports of sayings of Jesus, this Gospel is marked by a cycle of five long discourses, each followed by a uniform formula, "It came to pass when Jesus finished." These discourses are: the Sermon on the Mount (v, 1-7, 27); the Address to the Apostles (x, 5-42); the collection of Kingdom Parables (xiii, 1-52); the Discourse on Humility and Forgiveness (xviii, 1-35); and the Apocalyptic Discourse (xxiv, 4-xxv, 46). While it need not be doubted that Jesus made a large number of sayings of which these discourses are connected, it is commonly held, especially in view of the somewhat parallel reports in Luke, that the author has gathered sayings spoken at various times and grouped them to what may be called "bouquets" of discourse, uniting them, not on the ground that all were spoken on the same occasion, but rather according to a logical association of ideas. This Gospel is also characterized by an arrangement of material in groups of three, and it is likely to aid the memory. Some 40 triads have been named, e.g., the genealogy is arranged in three groups of 14 generations each, in chapters viii and ix there are three miracles of power, followed by three of restoration, there are given three prayers in Gethsemane, etc. Groupings by five and seven are not so common but occur often enough to deserve note as a striking characteristic of this book.

Purpose.—The purpose of the author plainly was to confirm Jewish Christians in their belief that Jesus of Nazareth was the Messiah long foretold by the Old Testament and expected by his nation. This is strikingly shown by the many references to the Old Testament which is cited no less than 40 times, often with the formal statement "that it might be fulfilled." The frequent use of the title "Son of David," as well as the genealogy, which is traced back to Abraham through the royal line of David, the declaration in the Sermon on the Mount of his right to legislate parallel to the original gift of the Divine law through Moses, the assertion that the kingdom is both near and far from the Jews and given to others and the grief over Jerusalem, the picture of himself as the judge at the Final Judgment, these claims in addition to the claims of Messiahship found in the other Gospels and culminating in the declaration of the risen Christ that all authority in heaven and earth alike is his, all this abundantly proves that the object of the author was to show that Jesus of Nazareth was the promised Messiah and that all the Divine promises were to be fulfilled, not for the nation at large which had rejected him, but for his followers, because they had accepted him.

Sources.—Careful comparison of the first Gospel with the second shows that the order of events is substantially the same in both and that almost every paragraph of Mark is reproduced in Matthew, the exceptions being only seven brief paragraphs of at most less than 35 verses. As the theory that Mark is an abbreviation of Matthew has proved untenable, it follows that Matthew must be in some fashion the basis of both, with the one being dependent not on the material of Mark: the resemblance is too close to permit the supposition that both drew from some independent document. But while the source of Matthew must have corresponded in general very closely to the present form of our Mark, it does not contain so much of picturesque detail which is not reproduced in Matthew that it cannot reasonably be held that Mark as we now have it was the source in question. How to account for this difference is still a problem of criticism. It is generally held that there may also be traced in Matthew a second main source, sometimes called the "Logia" document, sometimes "Q." (See article Gospels). In addition, there is some material which cannot reasonably be traced to either of the two main sources, as the genealogy and the infancy narratives, but it is impossible now to trace the origin and extent of these special sources. This fact need not, however, impair our sense of their trustworthiness. It may also be noted that it is not reasonable to hold that the author of this book was a mere copyist who kept slavishly to the exact form of any written sources which lay before him.

Authorship.—The author of this Gospel for Jewish readers must of course have been himself of Jewish descent. Nor is his use of the
MATTHEW TOWN — MATTHEWS

Greek language inconsistent with this, since the use of Greek was so widespread that in the 1st century Palestine must have been largely bilingual. That he was a Palestinian Jew is manifest from the whole tone of his work. The tone of his work is also such as to make it doubtful whether the behavior of the tradition as it now stands was himself an associate of Jesus in his ministry. While much of the material must go back to eyewitnesses, the author himself seems more remote. Accordingly the difficulty in the way of accepting the early and uncontaminated view that the Apostle Matthew was the responsible author is increasingly felt. It is also generally recognized that the book does not have the unavoidable marks of being a translation, but shows that it must have been originally composed in Greek; while the early tradition was that Matthew composed his work in the "Hebrew language," by which of course the Aramaic was meant, which had long before replaced Hebrew in common use. It will retain the substantial value of the tradition if it is held that Matthew was the author of "Q." When the Marcan source was reworked to include the collection of discourses and other material which was due to Matthew, it would not be surprising to find his name attached to the whole work. Accordingly the direct authorship by Matthew of the book in its present form is still very commonly held, there is a perhaps increasing tendency among critics to connect only the "Logia" document with the Apostle himself.

Date and Place of Composition.—There is little dissent at present from the view that this Gospel was composed late in the seventh decade of the 1st century, presumably 65–68. As to the place of composition there is less agreement. The material is Palestinian, but many feel a certain sense of detachment as if the author was not when he wrote amid the scenes which he describes. Of course this might be true if written in some place in Palestine remote from both Capernaum and Jerusalem; some Syrian city has been suggested, and even Alexandria has been thought not too remote, especially in view of its large Jewish and Jewish-Christian population.

Authenticity and Value.—If the common view of Matthew's direct authorship is still to be accepted, then this Gospel as the work of an apostolic associate of Jesus must be trustworthy and valuable in the highest degree. If, on the other hand, the book is referred to an unnamed author who worked mainly on the basis of the Marcan and Logia documents, its trustworthiness and value will be impaired less than might at first be supposed. We must assume the honesty of the compiler and editor, which indeed is everywhere manifest, and according to the theory he was working on documents which embodied the common Christian tradition approved by the many disciples who had seen Jesus face to face or which even had full apostolic authority. Such were presumably the Marcan source and most probably the Matthew Logia, while the genealogy could have been drawn from public sources, and the tone of the infancy narratives is such as conclusively to guarantee their very early date. When all these facts are taken into account, it will appear that the latest criticism really confirms the often quoted saying of Re-
MATTHEWS, John Hobson, English archivist: b. Croydon, near London, 1858; d. Ealing, 23 Jan. 1914. He was educated at the Proprietary School of Blackheath and at The Leys, Cambridge. In 1877 he entered the Roman Catholic Church and two years later was made a solicitor. From 1894 to 1903 he was employed as archivist to the corporation of Cardiff, Wales, and was also archivist to the county and urban councils of Monmouthshire. His various avocations included those of expert archivist, record searcher, genealogist, journalist, and local antiquary. In 1899 he discovered the text of the grant of Cardiff lands to Sir William Herbert, in 1550, the document being almost illegible. In the following year he brought to light the text of a charter to the borough of Newport. In 1903 and 1911 he was called as expert before the Royal Historical Manuscripts Commission. He published 'History of St. Ives, Cornwall'; 'History of the Hundred of Wromellow'; 'The Vaughans of Courtfield'; 'The Old Faith and the New'; 'Life and Memorials of St. Tello'; 'The Mass and its Folklore'; 'Continuity Reconsidered.' He continued Dumbcumb's 'Herefordshire,' edited 'Cardiff Records' (1898-1905) and contributed to 'The Catholic Encyclopedia,' the Tablet, Athenæum, etc.

MATTHEWS, Marmaduke Matthews, Canadian artist: b. Warwickehire, England, 1849; d. II. He received his education in Oxford and London; removed to Toronto 1860 and resided in New York from 1864 to 1869. In the latter year he returned to Toronto, was one of the founders of the Ontario Society of Artists, of which he was president in 1894. He excelled in woodland studies. His best-known works are 'The Canadian Wonder' and 'The Conquered Portal.'

MATTHEWS, Paul, American Protestant clergyman: b. Glendale, Ohio, 25 Dec. 1866. In 1887 he was graduated at Princeton University and three years later at the General Theological Seminary, New York. In 1891 he was ordained to the ministry of the Protestant Episcopal Church. He was assistant at the church of the Advent, Walnut Hills, Cincinnati, 1890-91; entered the Associate Mission, Omaha, and served as rector of Saint Luke's, Cincinnati, from 1891-95, from 1904 to 1913 he was dean of Saint Paul's Cathedral of the same city. In 1911-15 he was dean of the cathedral at Parihault, Minn., and professor at Seabury Divinity School. On 25 Jan. 1915 he was consecrated bishop of New Jersey.

MATTHEWS, Stanley, American jurist: b. Cincinnati, Ohio, 21 July 1824; d. Washington, D. C., 22 March 1889. He was graduated from Kenyon College in 1840, studied law and was admitted to the bar in 1842, when he established a practice in Maury County, Tenn., but returned to his native state, and practiced there. He was editor of the Cincinnati Herald, an anti-slavery journal, in 1846-49, and held various political offices, and in 1855-56 was a State senator. In 1858 he was appointed United States district attorney for the southern district of Ohio, but at the outbreak of the Civil War in 1861 entered the volunteer service and was commissioned lieutenant-colonel and was a colonel when in 1863 he resigned to accept the seat of judge of the Superior Court of Cincinnati. He was elected United States senator in 1877 after having acted as counsel before the Electoral Commission, and in 1881 he was appointed a justice of the Supreme Court of the United States.

MATTHEWS, Washington, American physician and etnologist: b. Killiney, Dublin County, Ireland, 1843; d. 1905. In 1864 he was graduated at the medical school of the University of Iowa. He was commissioned assistant surgeon in the United States army, from which he retired as surgeon in 1895. He made several anthropological studies of the Indians of North America. His published works include 'Dehrontology, or the Language of the Indians of the United States' (1873); 'Navaho Silversmiths' (1883); 'Navaho Weavers' (1884); 'The Mountaine Chant, a Navaho Ceremony' (1887); 'Navaho Legends' (1897); 'The Mystic Chant, a Navaho Ceremony' (1902); 'Navaho Myth, Prayers and Songs' (1907).

MATTHIAS, ma-thi'as, a disciple of Jesus, probably one of the 70, who was chosen by lot to take Judas Iscariot's place among the 12. Little is known of him. Even early legend confused him with Matthew, and an apocryphal gospel was attributed to him. In the Roman Catholic Church 24 February, in the Greek 9 August, is sacred to him. The Acts of Andrew and Matthias make him a missionary in Africa. Consult Eusebius, 'Ecclesiastical History' (Vol. I, 12; II, 1).

MATTHIAS (Ger. mät-tē'as), emperor of Germany: b. Vienna, 24 Feb. 1557; d. 20 March 1619. He was a younger son of Maximilian II. He was made governor of Austria in 1593 and two years later became heir to the imperial throne. He fought in the war against the Turks and in 1606 was made head of the House of Hapsburg. He became king of Bohemia in 1611 and had annexed Hungary and Moravia before the death of Rudolf II. In 1612-19 he was emperor of the Holy Roman Empire, having been elected on the death of his brother, Rudolf II (q.v.). His reign was an unsuccessful one owing to the divisions among the constituent parts of his empire. He attempted in vain to suppress by decree the Catholic League and Protestant Union. Consult Gindely, A., 'Rudolf II und seine Zeit' (Prague 1865) and Heling, J., 'Die Wahl des römischen Königs Matthias' (Berlin 1892).

MATTING

Vienna, 4 April 1490. The second son of John Hunyady, he was imprisoned in Bohemia by his father's enemies, who strongly but unsuccessfully opposed his candidacy for the crown of Hungary in 1438. Another party of opposition attempted to make the Emperor Frederick III king of Hungary; but Matthias brought them to terms, and was crowned by Frederick. By the Peace of Olmizt, 22 July 1479, he gained Silesia, Moravia and Lusatia, and the succession to the crown of Bohemia. In his wars with the Turks he was equally successful and a part of Bosnia was ceded to him by the Porte. War broke out again with the Austrian emperor; Matthias invaded his territory and captured and held Vienna. His court was a centre of scholarly men and his library, called the Corvinum, a famous collection.

The internal administration of Hungary was greatly improved under Matthias. Consult Fraknói, Vilmos, 'King Matthias Hunyadi' (Budapest 1890; German trans., Freiburg 1891) and Galeotti, Marzio, 'De egerie sapienti' (1525).

(VIENNA 1746).

MATING. While this term is usually employed to designate floor coverings made from reeds and fibrous grasses, it is a generic term which includes not only the commercial mattings for house floors, which are made in Eastern countries, but a much wider range of articles useful in the domestic economy and in other employments, such as screens and tatties, sleeping mats (used in India and the East), the matting employed by nurserymen for protecting hotbeds and cold frames, and even some forms of thatch. For the most part the mattings are hand-woven, in the finer varieties the warp being cotton or other yarns and the filling the culms of various sedges, reeds and grasses, an example being the familiar Japanese mattings of the house-furnishing stores. In the Russian bast mattings for nurserymen's use, bast of the linden tree is employed for both warp and filling, very coarsely woven or plaited. The roots of the Khus-Khus (Andropogon squarro-
sus), a perennial grass of India, are woven into frames for open windows and also for making awnings. The Taika rush mats of Lomros are famous as sleeping mats, and the best grades are said to be as fine and soft as cloth, resembling the best Panama hat weaving. Consult Davidson states that a mat of the highest grade, measuring 5 x 6 feet, requires the labor of a girl weaver 120 days, and such mats have sold for 60 to 70 yen (or about $40). The rush is an unidentified species, but sleeping mats are made from several species of Cyperus and Scirpus found in Asia, Africa and other countries.

The commercial mattings used for house decorations are for the most part of Chinese and Japanese manufacture. In Japan two species of Juncus effusus, the Bongo-i mat rush, which is always manufactured into the costly mats used by the higher classes (and known as Tatamimote) and Cyperus unions, which is employed for the cheaper grades. The largest importer of these mats is the United States, followed by England, Austria, and Germany, following in the order named. The qualities of the Bongo-i are named as follows: Kinkwanyen, manufactured at Okayama; first quality Aya-mushiro, second quality Aya-mushiro, Damask Aya-mushiro, common Aya-mushiro, manufactured at Bittiro. First quality Somewake-mushiro, common Somewake-mushiro, Damask Hana-mushiro, common Hana-mushiro, manufactured at Bungo; ordinary Hana-mushiro (best quality), manufactured at Chikugo. Cyperus unions produces the Shichito-i mats which are chiefly manufactured in the Oita prefecture. The plant is cultivated both on upland and irrigated lands. The varieties of mats from this species are known by names as follows: Kikatori Hana-mushiro, Damask Hana-mushiro, common Hana-mushiro (two forms). Seidaka Hana-mushiro, manufactured at Bungo. Matting made from the two species above have been exported in a single year to the value of 650,000 yen, or over $400,000.

The Chinese and Korean mat rush is Cyper-
us tegiformis, this species also being used for the manufacture of culms and sandals. The India commercial matting are made chiefly from Cyperus comolosus and tegum; the latter being known as the Indian mat rush, while the former is used for the Tinnerelly mats which are the finest made in India. They are also made at Palghat, but these are not so fine. In the manufacture of the India matting the culms are split into two or three parts and then woven into mats upon a warp of threads previously stretched across the floor of a room. The operator passes the culms with the hand alternately over and under the successive threads of the warp and presses them home.

It would be difficult to enumerate all of the mattings made in different countries, though mention should be made of the fine and highly prized Nihau mats of Hawaii, produced from Cyperus levisgatus. Matting is made in Spain and Morocco from Juncus maritimus, and in Italy from Juncus acutus. Two species of sword rush, Lepidocoma fluitans and L. flexu-
sum, are used by the natives of Australia not only for mats, but for baskets and other articles.

Lepironia macrona, found in Africa, and Polynesia, supplies the mats with which Chinese boats cover their cargoes.

In the United States, a handsome and utilitarian form of floor matting is largely manufactured from Slough grass, Juncus effusus. In normal years the imports of matting into the United States reach a total of $3,250,000.

The University of California has recently been experimenting with several species of matting rushes, chiefly Juncus effusus, and J. robustus, from which a fine sample of matting has been manufactured at a factory in Maine. There is a possibility therefore that rush matting may be produced in the United States, commercially, in the near future.

For matting fibres consult 'Dictionary Economic Products of India' (Descriptive Catalogue of Useful Fiber Plants of the World, and 'The Island of Formosa,' by Jas. W. Davidson. Consult also 'History and Manufacture of Floor Coverings' (New York 1898).

The leaves of many species of the different parts of the world, are used for native mats and matting, though few of these ever reach commercial importance. See PALMS.

CHARLES RICHARDS DODGE.
MATTING FIBRES—MAUBEUGE

MATTEPI, or FROG SNAKE, serpent (*Xenodon severus*) of northeastern South America. This poisonous variety, it is slow to bite. Its posterior teeth serve as fangs, but it has no venom sacks. The bite causes temporary swelling and soreness, but is seldom fatal.

MATTISON, Hiram, American Methodist Episcopal clergyman; b. Norway, Herkimer Co., N. Y., Jan. 6, 1811; d. 1868. After holding pastorates at Watertown and Rome, N. Y., he became pastor of the John Street Church, New York, in 1852. Subsequently he was made pastor of Trinity Methodist Episcopal Church in the same city. In the General Conference of 1860 Mattison tried to have action taken against all slave-holding members in the Church, and piqued at his failure he withdrew from the Church in 1861 and was made pastor of Saint John's Independent Methodist Church. Four years later he returned to his old denomination and was appointed to the pastorate of Trinity Methodist Episcopal Church, Jersey City. In 1888 Mr. Mattison was district secretary of the American and Foreign Christian Union. His published works include 'Tracts for the Times' (1843); an edition of Burritt's 'Geography of the Heavens' (1850); 'Spirit-Rapping Unveiled' (1854); 'Sacred Melodies' (1859); 'Impending Crisis' (1859); 'Immortality of the Soul' (1866); 'Resurrection of the Body' (1867); 'Defense of American Methodism' (1866); 'Popular Amusements' (1867), Consult Vansant, 'Life of Hiram Mattison' (New York 1870).

MATTO GROSSO, mā'to grō'sō, Brazil, a western central state bordering on Bolivia and Paraguay. It has an area of 532,683 square miles and an estimated population in 1917 of only 142,000 or 143,000, of whom 30,000 were in or near Corumbá (q.v.) and 20,000 were citizens of the capital, Cuiabá (q.v.). It appears, therefore, that in this vast political division of Brazil there is an average of one person to each three and two-thirds square miles, the estimates being based upon those given in the Pan-American Union handbook of Brazil. The only Brazilian state exceeding this in size is Amazonas (q.v.). The best recent descriptions of a portion of the interior from Paraguay up to the Amazon River are in the following books: Roosevelt, T., 'Through the Brazilian Wilderness' (New York 1914); Zahn, J. A. (H. J. Mozans), 'Through South America's Wildland' (New York and London 1916). The ex-President writes (p. 100): 'It is certain that this inland region of Brazil, including the state of Matto Grosso, which we were traversing, is a healthy region, excellently adapted to settlement; railroads will speedily penetrate it, and then it will witness an astonishing development.'

MATTOON, mā-'toon, Ill., city, in Coles County, on the Illinois Central and the Cleveland, Cincinnati, Chicago and Saint Louis railroads, about 75 miles east by south from Springfield. It was settled and incorporated in the year 1855. It is situated in an agricultural region in which broom corn is one of the principal products. Grain, fruit and livestock are also produced in large quantities. The chief manufacturing establishments are broom factories, flour mills, grain elevators, wagon and carriage factories, brick and tile yards, foundries, machine shops and repair shops for several railroads. It has a large trade in its manufactured articles, grain, fruit and livestock. Some of the prominent buildings are the Old Folks' Home (I. O. O. F.), the public and parish schools, the public library and reading-room and the churches. The electric-light plant is owned and operated by the city. The government is vested in a mayor, chosen for two years, and a council. Pop. 12,218.

MATURIN, Charles Robert, Irish dramatist and novelist; b. Dublin, 1782; d. 30 Oct. 1824. He received his education at Trinity College, Dublin, entered the ministry of the Church of Ireland and served successively as curate at Loughrea, County Galway, and at Saint Peter's, Dublin. He wrote the novels 'The Fatal Revenge;' or, the Family of Montorio' (1807); 'The Wild Irish Boy' (1808); 'The Mileian Chief' (1812), under the pseudonym of 'Dennis Jasper Murphy.' The novels were ridiculed by the critics, but at a later date attention was paid by Sir Walter Scott, who introduced Maturin to Lord Byron. These powerful friends secured the production of Maturin's tragedy 'Bertram' at Drury Lane in 1816, with Kean in the leading role. It ran for 22 nights, and a French version was produced soon afterward at the Théâtre Favart, Paris. His other tragedies 'Manuel' (1817) and 'Freddolfo' (1819) failed totally. Among his other works were the novels 'Women' (1818); 'Melmoth the Wanderer' (1820), and 'Angengenses' (1824). 'Melmoth' is his greatest work and was the most successful in his day. Balzac wrote a sequel to it entitled 'Melmoth Reconciled to the Church' (1835). Consult 'Melmoth,' edited with memoir of the author and bibliography (London 1892).

MATURIN, mā-too-rén, Venezuela, a town in the state of Monagas, formerly the capital of the state of Maturin. It is on the Guarapiche branch of the Orinoco Delta, 25 miles by rail above its port, Colorado, and 40 miles from the sea. A considerable trade in hides, principally in cattle and hides, is carried on. In the neighborhood are extensive plantations of cacao, sugar cane, fruits and cereals. Its industrial establishments turn out cigars, hammocks, boots, shoes and soaps. Pop. 4,400.

MATZOON, a milk food used in Armenia; prepared by exposing milk in open vessels to a heat of 90° F., and when coagulation takes place the curd is broken up by a churning process and a little salt is added. See KUMISS.

MATZOTH, the Hebrew name for a kind of unleavened bread or biscuit eaten by the Jews during the feast of the Passover.

MAUBEUGE, mō-'bē, France; fortress and manufacturing town in the department du Nord, occupying both banks of the Sambre, 140 miles by rail northeast from Paris, within two miles of the Belgian frontier. The origin of Maubeuge was in a double monastery for monks and nuns founded in the 7th century. Destroyed successively by the Normans, by Louis XI, by Francis I and by Henry II, it finally fell to France by the Treaty of Nimegen in 1678, and was fortified by Vauban. Pre-
vious to 1914 it was defended by nine forts. Besides its arsenal and several old convents Maubeuge has a variety of important industries, as iron foundries, tanneries and manufactories of firearms and iron and steel goods. It has also an active trade in coal, marble, slate, salt, petre, sugar and oil. In the Great War of 1914-18 Maubeuge and its forts held out almost a month against a heavy bombardment from German siege artillery. On 9 Sept. 1914 the Germans claimed the capture of the town, but the French on the 11th denied that it had fallen. On 18 September it became known that the town and forts had definitely fallen to the Germans. Pop. 23,200.

MAUCH CHUNK, māk chuck, Pa., a town and county-seat of Carbon County, on the Lehigh River, the Lehigh Coal and Navigation Company's Canal and on the Central of New Jersey and the Lehigh Valley railroads, 46 miles west by north of Easton. The town is picturesquely built on the side of a mountain rising 1,500 feet from the river, here winding through a narrow, deep ravine, and each of the 6,000 tourists attracted by the beauty of the surrounding natural scenery. The town has a county building, Young Men's Christian Association building, the Dimnick Memorial Library, the Asa Parker Park, is electrically lighted and has electric street railways. It has a number of foundries, shoe factories, car shops, silk mills, etc., but is best known as an important coal centre, marking the extreme boundary of the anthracite coal region of Pennsylvania; it was established by the Lehigh Coal and Navigation Company in 1818. The Summit Hill coal mines, nine miles southwest of the town, are among the best in the State. The coal is now carried through a tunnel, but was formerly transported to Mauch Chunk by a gravity railroad known as the Switchback, which has become famous as an exciting pleasure route for tourists. Mounts Pisgah and Jefferson, the summits of which are reached by the Switchback railroad; Prospect Rock, Flagstaff Peak and Glen Onoko are points of considerable interest, commanding a splendid view of the Lehigh Valley. The government is vested in a burgess and council, elected for terms of four years. Pop. 4,400.

MAUD. Tennyson called 'Maud' a "monodrama," a drama told in a series of lyric soliloquies. His explanation of its unique form is this: "The peculiarity of this poem is that different phases of passion in one person take the place of different characters." To tell the story of 'Maud' is to follow these phases of passion. The beginning shows the hero cut off from life by his heritage of love, his wrong, his crying for war to kill the greed and cruelty of peace. With the coming of Maud, the child of his enemies, begins his new life of love that embraces mankind. His joy is shattered at its climax; a hopeless exile, he seeks only escape from the world. In 1917, another long period of preparation followed, and on 28 Sept. 1917 General Maude attacked the Turks at Ramadie, carried the advanced positions and encircled them with his cavalry, compelling the whole division to surrender. On 6 November he captured Tekrit, the riverhead on three sides, and 150,000 of the Turkish forces withdrew from 30 to 50
MADUSSLY—MAUNOURY

Miles northward. Before he was able to achieve anything further, General Maude died, after a very brief sickness, at Bagdad on 18 Nov. 1917.

MAUDSLEY, mǎd'zli, Henry, English alienist: b. near Settle, Yorkshire, 6 Feb. 1835; d. 23 Jan. 1918. He was graduated in medicine from the University of London in 1857, was editor of the Journal of Mental Science in 1862-71, and in 1872 was professor of medical jurisprudence in University College, London. In 1913 he presented $150,000 to the London County Council for the erection of a Maudsley Hospital for the Insane. His works include 'Responsibility in Mental Disease' (1874); 'Physiology of Mind' (1876); 'Pathology of Mind' (1879); 'Natural Causes and Supernatural Seemings' (1886); 'Life in Mind and Conduct' (1902); 'Heredity, Variation and Genius' (1908).

MAULE, mów'le, Chile, a maritime province bounded north by the province of Talca, east by Linares and Talcahuano, south by Concepción and west by the Pacific Ocean. Area, 2,812 square miles. It takes its name from its principal river. The well wooded Coast Range, nearly 3,000 feet high, occupies the great part of the surface. Agriculture and its allied occupations constitute the principal industries. Cattle, hides, wheat and lumber are exported. The Maule and Stata are navigable and afford good means of communication. There is a branch of the government railroad from Cauquenes to Pitrufquén. Another line connects Constitución with Talca. Capital, Cauquenes (9,885); chief port, Constitución. Pop. of province 122,754.

MAULE, Chile, a river rising in the Andes and after a westerly course of about 150 miles, 52 of which are navigable for small vessels, flowing into the Pacific Ocean near the village of Constitución, 99 miles northeast of Concepcion. The Maule River is supposed to have been the southern boundary of the empire of the Incas. In its upper courses its waters supply extensive irrigation systems.

MAULMAIN, mól'mán, or MOULMEIN, mów'le-min, Burma, the capital of the Tenasserim division and a port near the mouth of the Salwin River, on the Gulf of Martaban 30 miles from the Bay of Bengal. The town, comparatively modern, dating from 1826, is regularly built on level ground between the river and a range of wooded hills, on whose heights are the gilded spires of numerous pagodas and elegant residences, commanding fine views of beautiful scenery. Maulmain has numerous public buildings, churches, chapels and missionary establishments, several charitable and educational institutions, barracks, a hospital, a jail, etc. A considerable trade is carried on with Indian ports, the chief exports being tea-kwood and rice, cotton, hides, horns, gums, ivory, copper, lead, wax, the imports, piece goods, hardware, provisions and general merchandise. Shipbuilding is a thriving industry because of the available supply of teakwood. The water supply system, gas plant and sewage system are the property of the municipality. Pop. about 60,000, besides native Burmese, comprising Hindus, Eurasians, Armenians, Chinese, Malays, Jews and Europeans.

MAUNEOE, mǎ-mě́, a river formed by the junction of Saint Mary's and Saint Joseph's rivers at Fort Wayne, Ind. It flows northeast across the northwest corner of the State of Ohio, and enters Lake Erie through Maumee Bay. Its affluents are the Auglaize and the Tiffin. Its basin is 6,700 square miles in extent. The river is 150 miles long and navigable 12 miles from its mouth to the Miami Rapids. The Miami and Erie Canal, which connects Lake Erie with the Ohio River, begins at the head of navigation on the Maumee, and follows the course of the river to Defiance, then turns south. The Maumee Bay, a shallow body of water, has been improved by deepening and straightening the channel. Toledo is at the mouth of the Maumee. The Maumee River was a part of one of the water routes much used by the early missionaries and explorers. The distance from the head waters to the Maumee to the Wabash River is only about 25 miles.

MAUNA KEA, mów'ná ke'á, Hawaii, an extinct volcano, the highest peak in the Pacific, 13,805 feet in altitude. Snow covers its upper slopes for the greater part of the year, and its sides are wooded. Coffee is cultivated on the lower slopes. See HAWAI'I.

MAUNA LOA, mów'ná ló'á, Hawaii, a volcano 13,760 feet high, with a crater nearly five miles in circumference, and vertical precipices on the inner side 500 to 600 feet high. Mauna Loa is situated in the central southern portion of Hawaii, and on its eastern slope is the site of a sugar mill. It is about 150 miles in circumference, but apparently having no communication with Mauna Loa, their periods of activity being independent of each other. Mauna Loa's last period of great activity was in 1861. See HAWAI'I; KILAUEA.

MAUNDY (mǎn'dē) THURSDAY, is the Thursday in the Passion week. Another popular old name of the day is Shrove Thursday, from the custom of shaving the hair which the priesthood used to observe. It used to be the custom in England and other countries, and still is in Austria, for the sovereign to wash the feet of a certain number of persons and to send them away with presents in the shape of food, clothing and money. This ceremony is in commemoration of the act of Christ, who washed his apostles' feet on the occasion of the last supper.

MAUNOURY, Michéi Joseph, French soldier; b. Maintenon, Eure-et-Loir, 17 Dec. 1847. He received his education at the École Polytechnique, Paris; first saw active service as second lieutenant in the Franco-Prussian War of 1870-71. In that conflict he was wounded at champigny. His professional studies were pursued at the École Supérieure de Guerre. From 1886 to 1888 Maunoury was artillery instructor at the famous military academy of Saint-Cyr. In 1897 he attained the rank of colonel, was made brigadier-general four years later and a general of division in 1903. In 1905 he had charge of the artillery of the Paris forts and soon after was made president of the commission of military schools. General Maunoury was commandant of the École Supérieure de Guerre in 1907; the following year of the 15th Army corps with headquarters at Marseille, and in 1909 of the 26th corps at Nancy.
He was made military governor of Paris in 1910 and a member of the Superior Council of War. In the War of 1914-18 Maunoury was placed in charge of the army of manoeuvre and was rushed north in an effort to turn the flank of Von Kluck's army then driving toward Paris. When the British discovered Maunoury on his right the drive was stopped and in the battle of the Marne the invader was driven back. Subsequently after the beginning of trench warfare Maunoury held a command at Soissons. He was severely wounded in March 1917 and in the same year received at the hands of the President of the Republic the médaille militaire, the highest military honor in the gift of France. He is also an officer of the Legion of Honor. In November 1915 Maunoury succeeded Gallieni as military governor of Paris. Consult Blanchon, G., *Le général Maunoury* (Paris 1916). See War, European.

MAUPASSANT, Henri René Albert Guy de, ōñ-rè ré-ňä ãl-bär gj dé mó-pô-sẫ̃n, French novelist: b. Château Miromesnil, Seine-Inferieure, France, 5 Aug. 1850; d. Paris, 6 July 1893. He began his career as a clerk in the Navy Department, and also served for a time in the French army during the Franco-Prussian War. The novelist Flaubert, a friend of his mother’s, was his godfather, and the youth took him as his model in the art of composition. After years of practice, during which he wrote a great number of manuscripts he allowed a short story, *Boule de Suif,* to appear in 1880, a work which displayed the greatest finish and at the same time allied him to the naturalistic school of fiction. In the same year he published a book of verse, *Des Vers,* and a drama, *Histoire du vieux Tems.* After this he continued to cultivate the short story and was very soon recognized as one of the greatest writers of short stories the 19th century had seen. In spite of the perfection of art displayed in their construction neither his brief tales nor his novels form pleasant reading. They compel admiration, but they are dominated by pessimism and in his later work the traces of an unbalanced mind may be plainly seen. In 1882 De Maupassant’s mental condition occasioned a cessation of literary occupation, two years later he became wholly insane and he died the next year in an asylum. His collections of short stories include *La Maison Tellier,* (1881); *Mlle Fifi,* (1883); *Les Soeurs Rondoli,* (1884); *Yvette,* (1884); *Contes du Jour et de la Nuit,* (1885); *Contes et Nouvelles,* (1885); *La Horla,* (1887); *La petite Roue,* (1888); *La Main gauche,* (1889); *Le Père Milon,* (1890); *L’inutile Beauté,* (1890), etc. The finest of his six novels is *Pierre et Jean,* (1888); the others are *Une vie,* (1885); *Bel Ami,* (1885); *Mont Oriel,* (1887); *Fort comme la Mort,* (1889); *Notre Cœur,* (1890). He also published several collections of travel sketches, such as *Au Soleil,* (1884); *Sur l’Eau,* (1888); *La Vie errante,* (1890). A collection of 13 of his short stories translated into English with the title, *The Odd Number,* represents him at his best, both in point of art and as regards the stories themselves. The absence of a moral sense is less apparent here than elsewhere and there is less gloom and animalism possible. Consult (Guhl)* Citations de phrases de Guy de Maupassant* (29 vols., Paris 1908-10); *Works of Guy de Maupassant* (9 vols., New York 1910); Brunetière, Ferdinand, *Le roman naturaliste* (Paris 1883); Doumic, René, *Ecrivains d’aujourd’hui* (ib. 1894); Bashkirtseff, Marie, *Further Memoirs* (London 1901); Symons, Arthur, *Studies in Prose and Verse* (New York 1899); *Le roman de Maupassant, sein Leben und seine Werke* (Berlin 1908); Matthews, Brander, *Inquiries and Opinions* (New York 1907).

MAUPERTUIS, Pierre Louis Moreau de, pê-är loö-mô-rô de mó-pêr-tü-e, French mathematician and philosopher: b. Saint Malo, France, 28 Sept. 1698; d. Basel, Switzerland, 27 July 1759. He was educated at the College of La Marche, Paris; entered the army in 1718 and after five years’ service resigned in order to become instructor in mathematics in the Academy of Sciences. He went to England in 1728, where he was made a member of the Royal Society and became a pupil of Newton. In 1736 he conducted a scientific expedition to Lapland for the purpose of measuring an arc of the meridian, the result of which was confirmed in Newton’s theory of the figure of the globe at the poles. In 1743 he was elected to the French Academy, in 1744 was summoned to Prussia by Frederick the Great and in 1746 was declared president of the Academy of Sciences at Berlin. A dispute with the philosopher König, regarding the discovery of the infinitesimal calculus shortened his days. Among his works are *Sur la figure de la terre,* (1738); *Discours sur la figure des astres,* (1742); *Lettre sur la comète de 1742,* (1742); *Astronomie nautique,* (1745; 1756); *Essai de cosmologique,* (1750); Maupertiana ou divers écrits,* (1753). Consult De la Baumelle, *Vie de Maupertuis* (Paris 1856); Damiron, J. P., *Mémoires sur Maupertuis,* (ib. 1858); id., *Mémoires pour servir à l’histoire de la philosophie du XVIIIe siècle,* (Vol. III, ib. 1864).

MAUREL, mô-rêl, Victor, French singer: b. Marseilles, 1848. He was educated at the Paris Conservatoire and made his début in Paris in 1869. His first appearance in Royal Italian Grand Opera was in 1873 and he achieved a signal success. He created Iago in Verdi’s *Otello,* Falstaff in the opera of that name, and has appeared in many operatic rôles in Europe and United States, being generally recognized as the leading acting baritone actor on the Italian stage. He has published *L’Art du chant,* (ib. 1880); *Le chant renoué par la science,* (ib. 1884); *Dix ans de carrière,* etc.

MAUREPAS, Jean Frédéric, zhôň frâ-är-dâr expecting mô-řô-pah, Phylépeaux, Comte de, French statesman: b. Versailles, 9 July 1701; d. there, 21 Nov. 1781. At 14 he succeeded to the office of Minister of State held by his father. In 1725 he became administrator of the navy, in which post he used the best knowledge then available to bring the navy to a high standard of perfection. He became Minister of State under Louis XV in 1738, but in 1749 was dismissed from the court for an attack on the same. Pompadour. In 1747 he was made Prime Minister by Louis XVI and became his principal adviser. The chief events of his administration were the restoration of the Parliament of Paris (12 Nov. 1774), and the alliance with and assistance of the American colonists in their struggle against Great Britain. He gathered
to the service of the state such men as Lamoignon-Malesherbes, Vergennes and Turgot. He intrigued against the latter and replaced him as Minister of Finance by Necker in 1776. Five years later Necker experienced the same fate. Consult Guyot, "Előlege historique de M. de Maupeou" (1782); the apocryphal "Mémoirs" edited by J. L. C. Soulavie (4 vols., Paris 1792) and a book of select corps (Paris 1896). On 14 May the Army Council placed Major-General Maurice on "retired pay." Though the letter had not been submitted to the Press Bureau before publication, in accordance with war-time regulations, no further steps were taken by the government. Major-General Maurice became military correspondent for the "Daily Chronicle." His writings are marked by lucidity and keen penetration. In a remarkable book, "Forty Days in 1914" (London and New York 1919), he traces the complicated and monumental campaign to the end of the battle of the Marne. His other publications include "The Russo-Turkish War 1877-78," a biography of his father, "Sir Frederick Maurice: A Record," and contributions to the "Cambridge Modern History." 

**MAURICE, NASSAU, Prince of**

Count and Count of Nassau: b. Dillenburg, Nassau, 13 Nov. 1567; d. The Hague, 23 April 1625. His father, William the Silent, was assassinated in 1584, and the 18-year-old boy was chosen stadtholder by the provinces of Holland and Zeeland, and later by the other provinces, the command of the army being entrusted to him in 1587 by the States-General. He captured Breda, Zutphen and Nimpeguen in 1590-91, and by 1597 had wrested the principal towns of the Netherlands from the Spanish. But Ostend was lost in 1604 and in 1609 a truce was made with Spain for 12 years. In 1618 he became Prince of Orange on the death of his brother Philip William. Internal dissensions followed and Olden Barneveldt, leader of the aristocratic Republicans and of the party of religious tolerance, was condemned to death (1619) on the charge of high treason, but actually because of his opposition to Maurice. The stadtholder renewed the war with Spain in 1621, immediately upon the declaration of a truce, and died at the very time he was negotiating an alliance with France and with England. The greatest general of his day he was personally cold and unscrupulous. See Holland and consult Kemp, C. M., "Maurits v. Nassau, prins v. Orange in zijn leven en verdiensten" (4 vols., Rotterdam 1843); Nutting, M. O., "The Days of Prince Maurice" (Boston 1894); van Prinsterer, G. Groen, "Archives ou corrspondance de la maison d'Orange-Nassau" (1 series, 9 vols., Leiden 1841-61). 

**MAURICE OF SAXONY, DUKE AND ELECTOR OF SAXONY, German soldier:** b. Freyberg, 21 March 1521; d. near Sievershausen, 11 July 1553. He succeeded his father, Henry the Pious, as Duke of Saxony, in 1541; and although a Protestant refused to join the Schmalkald League. In 1546, two years after a secret treaty with the Emperor Charles V, Maurice was made Elector of Saxony. But he soon broke with the emperor, fathoming his purpose of crushing the German princes, and by a sudden show of force made Charles sign the Treaty of Passau, 31 July 1552. On the 9th of
July in the following year he defeated Albert of Brandenburg-Kulmbach, who had refused to accept the Treaty of Passau, in the battle of Sievershausen, but died two days later of his wounds. Maurice was the foremost general and diplomat of his day in Germany, but he was entirely without scruple or principle, and played off one party against another until he was little trusted by either. Consult Brandenburg, E. (ed.), ‘Politische Korrespondenz’ of the Elector Maurice (Leipzig 1904); id., ‘Moritz von Sachsen’ (Leipzig 1898); von Ranke, L., ‘Deutsche Geschichte im Zeitalter der Reformaion’ (ib. 1882); ‘The Cambridge Modern History’ (Vol. II, Cambridge 1903).

MAURICIUS, mā-rish'-tūs, Flavius Tiberius, emperor of the East, 582-602 A.D.; b. Arabissus, Cappadocia, about 539 A.D.; d. Chalcedon, 27 Nov. 602 A.D. He served with distinction against the Persians, and for his abilities and character was made successor to Tiberius II by that emperor, whose daughter, Constantina, he had married. His reign was filled with wars. In 591 he restored Chosroes II to the throne of Persia, thus bringing to a close the long campaign against that country. He was, however, the last of the greatest of the Eastern emperors, a patron of the arts and sciences, and himself considerably learned. Phocas, one of his generals, commanding the army operating against the Avars, led a revolt against him, and he fled to Chalcedon, where he was murdered by Phocas' order. The Exarchate, a work on military affairs, published in a Latin version by Scheffer at Upsala in 1664 was long attributed to him, but is really by: some unknown contemporary. Consult Bury, J. B., ‘The Later Roman Empire’ (London 1889); Finlay, G., ‘History of Greece’ (Oxford 1877); Gibbon, E., ‘Decline and Fall of the Roman Empire’ (London 1896).

MAURISTS, mä'rīstz, the members of the Congregation of Saint Maur, to whom literature owes the stately tomes known as ‘Benedictine Editions.’ The Congregation had its origin in a group of monks who in the early part of the 17th century; it was supported by De Retz and afterward by Richelieu, and in 1720 possessed in France six provinces, containing 180 abbeys and priories, of which the principal was that of Saint-Mermain-des-Pres, Paris. Among the most celebrated of the Maurists are Mabillon, Martene, Montfaucon, the founder of the science of archaeology, Ruinart, Lami, Le Nourri and Martinay. Jansenism seems to have affected some of the convents, and, according to Badiache, a Masonic lodge was established at Glenfould in 1755, over which the priory of the monastery in that place presided. The Congregation was suppressed in 1792. The last superior-general with 40 members of his order perished by the guillotine. In their literary work they produced a great number of works of permanent value. Their complete bibliography comprises over 700 works by 220 authors. The Revolution put an end to the work, for which hundreds of volumes and literary documents were necessary for the establishment. The Société Nationale de Paris contains most of this material. Consult Helyot, ‘Histoire des ordres religieux’ (1718); McCarthy, ‘Principal Writers of the Congregation of Saint Maur’ (1888); Tassin, ‘Histoire littéraire de la con-

gregation de Saint-Maur’ (Paris 1770); de Lama, ‘Bibliothèque des écrivains de la congrégation de Saint-Maur’ (ib. 1882).

MAURITANIA, mā-ri-tā'nē-ə, West Africa, colony in the government-general of French West Africa. It consists of the districts of Trarza, Brakna, Gorgol, Guidimaka, Levrier Bay and Tagant. The total area is 344,967 square miles. The population in 1912 was about 22,051, of whom 22,897 were nomad Moors. In 1909 the French protectorate was extended over these districts; a provisional government with civil and military functionaries was formed under the name of Mauritania. Early in 1916 the region of Tibesti, recently occupied by the French, was attached administratively to French West Africa. The budget of Mauritania for 1916 was $334,000.

MAURITUS, mā-rish'-tūs, or ISLE OF FRANCE, an island colony of Great Britain, in the Indian Ocean, 500 miles east of Madagascar and 9,500 miles from England. It is of an oval form, about 40 miles in length, from northeast to southwest, and 25 miles in breadth; area, 720 square miles. There are numerous capes and bays along the shore and the island is surrounded by coral reefs. It is composed chiefly of rugged and irregular mountains, rising into points of considerable height; the highest are the Montagne de la Rivière Noire, 2,730 feet, and the singular isolated rock Peter Botte, 2,700 feet. Between the mountains, and along the coast, there are large and fertile plains and valleys, having a rich soil of black vegetable mould or still deeper watered by numerous streamlets, many of which become periodically dry. The climate is pleasant during the cool season, but oppressively hot in summer, and the island is occasionally visited by severe epidemics of fever. The rainy season is from January to April; between December and March the island is subject to hurricanes, occasionally of extraordinary violence. When discovered in 1505 the island was almost entirely covered with wood, the greater part of which has now been cleared down, although some extensive forests still remain. The fauna then included the dodo, but otherwise was in no way remarkable. Some of the trees are valuable, particularly the black ebony. The indigenous vegetation includes orchids, screw-pines, the traveler's-tree, bamboo, etc. Many plants introduced from Europe, Africa, Madagascar and India thrive well, and nearly every beautiful tropical tree or delicious fruit is met with. The principal item of cultivation is sugar-cane, and to a limited extent rice, maize, manioc, vanilla, coffee, spices, fruits and tea, the last introduced recently. The value of the exports of unrefined sugar, which is the staple, amounted in 1916 to $23,103,320. Other exports are rum, vanilla, coconut oil, aloes, fibre, spice. The total value of exports in 1916 was $24,770,015; of imports, $17,988,970. The imports consist of rice, wheat, cottons, haberdashery, machinery, manures, carriages and parts, coal, iron and steel, etc. Letters patent of 1885, 1901, 1904 and 1912 have established a partially representative form of government. The government of the island, with its dependencies, Diego Garcia, Rodrigues, etc., is vested in a governor, an executive council, comprising the commander of the forces, the colonial secretary, procurator-
general, receiver-general and other persons in the public service, whom the governor may designate as members of the council. The council of government consists of the governor and 27 members, nine of whom are named by the governor, eight are ex officio members and 10 are elected under a restricted franchise. The Indians are nearly all Hindus. The churches receive government aid — $50,880 in 1915-16.

The shipping on 1 Jan. 1916 comprised three steamers aggregating 1,080 tons and 28 sailing vessels aggregating 4,440 tons. In 1916 199 vessels of 438,960 tons entered and 197 vessels of 418,898 tons cleared the harbors of Mauritius. About 76 per cent of this tonnage was of British register. There are 621 miles of telegraph and 140 miles of telephone wires installed. Mauritius has cable connection with Australia, Madagascar, Reunion and Zanzibar. Consult the 'Mauritius Blue Book' (annual).)

MAURITIUS HEMP. See FIBRE.

MAUROCORDATO. See MAUROCORDATOS.

MAURY, Matthew Fontaine, American naval officer and hydrographer; b. in Spottsylvania County, Va., 14 Jan. 1806; d. Lexington, Va., 1 Feb. 1873. He studied at the Harpeth Academy in Tennessee, and entered the United States navy in 1825. During a voyage around the world in the Vincennes he began a taste for navigation, long used as a textbook in the navy. He was made lieutenant in 1836. In 1839, when he was lamed by an accident, disdained active sea-service for scientific work in the Naval Observatory. His powers of application were combined with rare gifts of imagination, and an elevated style. His 'Physical Geography of the Sea and Its Meteorology' (1859) has been considered a book of fascinating interest. In 1844 he published his views on the Gulf Stream, ocean currents and great-circle sailing. His 'Wind and Current Charts' have been of immense benefit to navigation. In 1853 he reached the rank of commander, and in that year projected the magnetic observation at Brussels, and also published 'Letters on the Amazon and the Atlantic Slopes of South America.' In 1861, when the Southern States seceded, he gave his services to the Confederate cause. For some time he attached himself to the fortunes of the Emperor Maximilian in Mexico; but for the last few years of his life he was professor of physics at the Virginia Military Institute. He was among the first to turn fresh attention to a branch of scientific inquiry which had been previously much neglected, the investigation of the depths of the sea, its currents, temperature, etc. He also published 'Lanes for Steamers Crossing the Atlantic' (1854). Consult Corbin, 'Life of Matthew Fontaine Maury' (London 1888).

MAUSBER, Paul von, pow mow'zer, German inventor and gun-maker; b. 1838; d. 29 May 1914. He worked as a boy in the royal armory at Oberndorf, and there with his brother Wilhelm (d. 13 Jan. 1882) patented several improvements on the small arms then in use, both new needle-guns and a model replacing the "needle" powerful percussion-pin. The introduction of the Prussian needle-gun into Württemberg after the Austro-Prussian War deprived the brothers of the patronage of the

2 By Carrere & Hastings, architects
3 By Dehli & Howard, architects
4 By Shickel & Ditmars, architects
government, and in 1867 he settled in Liège, where he was financed by an American capitalist. Paul invented the Mauser revolver in 1872 and the "Mauser" in 1878, the Belgian model in 1887, the Belgian rifle in 1889, the Argentinian model in 1891, the Spanish model in 1893 (adopted with slight change throughout South and Central America), and in 1896 a rifle for the Swedish army. Typical of his skills are the Belgian model of 1889 and the Argentinian of 1891, both magazine rifles with no cut-off, but capable of single fire by replacing the top cartridge in the magazine after each discharge. The magazine holds five cartridges, as in front of the trigger guard under the receiver, is fixed in type but can be easily cleaned. See SMALL ARMS.

MAUSOLEUM (Greek, mausoleion), a tomb or burial place, the name of which is derived from Mausolus, a king of Caria, to whom a sumptuous sepulchre was raised by his wife, Artemisia. Mausolus, King Mausolus died 353 B.C.; and his wife was so disconsolate that she perpetuated his memory by the erection of this magnificent monument which became so famous as to be esteemed the seventh wonder of the world and to give a generic name to all superb sepulchres. Its entire height was 140 feet, and the entire circuit 411 feet. It was overthrown, probably by an earthquake, between the 12th and 15th centuries; and when the Knights of Rhodes took possession of Halicarnassus in 1404 they availed themselves of the materials of the mausoleum to erect the fortress of San Pietro. Parts of the frieze were transported to the British Museum in 1846. Other famous mausoleums are that erected at Halicarnassus, in honor of Mausolus, and at Hephæstion, equally magnificent with that of Mausolus, though less refined; and the mausoleum of Augustus, built by him in the sixth century on the Campus Martius, between the Via Flaminia and the Tiber, the ruins of which are still seen near the church of Saint-Roch. One of the obelisks which stood before this superb building was found in the reign of Pope Sixtus V. This mausoleum contained the ashes of Augustus, Agrippa, Agrippina, and of some later emperors. The mausoleum of Hadrian at Rome is now the Castle of San Angelo. Consult Adler, 'Das Mausoleum zu Halikarnassos' (Berlin 1900); Newton, 'History of Discoveries at Halicarnassus, Chidus and Branchidae' (London 1883); id., 'Travels and Discoveries in the Levant' (ib. 1865); Smith, A. H., 'Catalogue of Sculptures in the British Museum' (Vol. II, ib. 1900).

MAUSTON, mås'ton, Wis., city, county-seat of Juneau County, on the Lamonier River, at the junction of the Milwaukee and Saint Paul Railroads, about 500 miles northwest of Milwaukee. The chief manufacturing establishments are lumber mills, machine shops and flour mills. Pop. 1,701.

MAUTHNER, mout'nèr, Fritz, German novelist and philologist: b. Hof, Bohemia, 29 Nov. 1848; d. Vienna, 20 Jan. 1932. He went to Prague at an early age, studied law there and became a contributor (1876) of the Berliner Tageblatt for which he continued writing in various departments (particularly dramatic criticism) until 1896. He retired from newspaper work and moved from Berlin (where most of his active life was spent) to Freiburg im Breisgau; he lived at Meersburg on Lake Constance from 1909. While he has written novels and satire, his greatest work is in the field of philosophical criticism of language as a means of expression; his position on this matter is best expressed in a large book: 'Beiträge zu einer Kritik der Sprache' (Vol. I, 'Sprache und Psychologie,' 1901; Vol. II, 'Zur Sprachwissenschaft,' 1901; Vol. III, 'Zur Grammatik und Logik,' 1902); and in an alphabetically arranged summary of the contents of this work, in dictionary form: 'Wörterbuch der Philosophie' (Munich and Leipzig 1910). His criticism is poetic and destructive rather than social in its import; his style smooth and brilliant. His most famous work before he undertook scholarly production was 'Nach verirrten Mustern' (Stuttgart 1878; 30th ed., 1902), a set of parodies of well-known German and foreign writers, in the manner of Bret Harte. In 1914 he published a collection of newspaper articles that had appeared in previous years, under the title, 'Gespräche im Himmel,' and in 1918 began the publication of an autobiographical work, the first volume of which deals with his school-days in Bohemia and is a rather bitter attack upon the educational system of the time. Among other works are 'Vom armen Franciszek' (Dresden 1879); 'Die Sonntage der Baronin' (Dresden 1881); 'Der neue Ahaver' (Dresden 1881); 'Kanthuppe' (Dresden 1884); 'Aturenbriefe' (Dresden 1885); 'Berlin W.' (a cycle of three novels, Dresden 1886–90); 'Die bunte Reich' (Munich 1896). There may be had, in English translation, Aristotle, An Unhistorical Essay' (New York 1906). On Mauthner's philosophical doctrine, consult Wells, H. G., 'A Criticism of the Instrument' (appendix to 'A Modern Utopia' 1905).

MAUVAS TERRES, mò-väz têr. See BAD LANDS.

MAUVE, mòv, an aniline purple coloring matter. See DYES.

MAVERICK, Peter, American engraver: b. New York, 29 Oct. 1780; d. there, 9 June 1831. He studied engraving in London, worked especially on bank-note designs and made famous engravings of Charles King's portrait of Henry Clay, of Waldo's portrait of Andrew Jackson and of Dunlap's portrait of Benjamin Moore. Maverick was one of the founders of the National Academy of Design in 1826. His most celebrated pupil was Asher B. Durand.

MAVERICK, an unbranded steer, especially one appropriated by a chance finder. This term, in common use in the cattle country of the United States, is said to be derived from the name of Samuel Maverick, a Texas lawyer and politician, who, having accepted a herd of 400 head of cattle in payment of a debt, left them in charge of one of his men. They were neglected and allowed to run wild and when the calves were born they were of course appropriated by other ranchers and branded with their marks, and so passed to their undisputable ownership. As the ownership of the cattle was determined by the brand, it may easily be seen why the name "Maverick" was given to all calves caught straying from the herd. From
MAVIS, the Scottish name for the British song thrush or thrrtle (q.v.), one of the favorite song-birds of western Europe.

MAVOR, James, English political economist; b. Stranraer, Scotland, 8 Dec. 1854. He was graduated at the University of Glasgow. He was for a time editor of the Scottish Art Review; in 1888 became professor of political economy at Saint Mungo's College, Glasgow, and in 1892 professor of political economy at the University of Toronto, Canada. He has written 'Wages, Theories and Statistics' (1888); 'Economic Theory and History Tables and Diagrams' (1890); 'Currency Reform' (1891); 'Economic Study and Public and Private Charity' (1892); 'English Railway Rate Question' (1894); 'Railway Transportation in America' (1909); 'Economic Survey of Canada' (1914); 'Applied Economics' (1914); 'A Short Economic History of Canada' (1915).

MAVROCORDATOΣ, māv-rō-kor-da-tōs, or MAUROCARDATOS, Alexander, modern Greek soldier and statesman: b. Constantinople, Turkey, 15 Feb. 1791; d. Εκαστα, 18 Aug. 1865. He was a skilful linguist and early schooled in diplomacy. On the outbreak of the Greek war for independence (1821), he devoted his entire fortune to the equipment of a ship and the arming of volunteers. He organized the insurrection in Ευλο and Acrarnania, was made president of the National Assembly at Epidauros, drew up the provisional constitution and signed the proclamation of independence of Greece (1822). He also became president of the executive council, but resigned in what he believed to be the interests of harmony. In 1833-34, 1841-43, 1844 and 1854-56, he was at the head of the Cabinet and in 1850-54 was Ambassador at Paris. He promoted public education and was a Liberal in politics, being of the British party and opposed to the Russian policy of Giovanni and Augustin Capo d'Istria. He is generally considered the most important leader in the Greek Revolution. Compil. Grecian, Oscar, History of the Modern World (Vol. I, New York 1912).

MAWSON, Sir Douglas, Australian geographer: b. Bradford, Yorkshire, 1882. He was educated at Sydney University, where he was graduated bachelor of mining engineer in 1901. In the following year he was demonstrator in chemistry there. In 1903 he made a geological exploration of the New Hebrides and lectured at Adelaide University in 1905. In 1908 he became a member of the scientific staff of Sir Ernest Shackleton's Antarctic Expedition and determined the position of the south magnetic pole on Victoria Land. In 1911-14 he was leader of the Australasian Antarctic Expedition to explore Antarctic lands and establish stations for scientific purposes. His discoveries were among the most important made so far. In 1911-13, 1913-14, 1914-15, he was awarded the founder's medal of the Royal Geographical Society and was knighted in 1914. He has published 'The Home of the Blizzard' (2 vols., Philadelphia 1915) and scientific papers in the transactions of learned societies. For a detailed account of the explorations directed by Mawson see ANTARCTIC REGIONS.
in Kentucky and Texas. He entered the Con-
 federate service as colonel of the 9th Texas
 Infantry and was engaged in the campaigns
east of the Hawn River under A. S. John-
 ston, Bragg and Joseph E. Johnston. In 1862
 he was made brigadier-general. In 1863 he
 was sent to command the Indian Territory. He
 raised and equipped numbers of troops, kept
 the Indians friendly to the Confederacy and in
 1864 he was given command of the Federal
 garrison at Steele, who was endeavoring to effect a
 junction with Banks in the Red River Valley. For
 this he was made major-general. After the
 war he was offered a Supreme Court judgeship
 in Texas but declined. From 1875 to 1887 he
 was in the United States Senate. Maxey was
 an able senator, a member of the prominent
 committees and an efficient advocate of Western
 interests.

**MAXIM**

**MAXIM, Sir Hiram Stevens, Anglo-
American inventor.** b. Sangerwile, Me., 5 Feb.
1840; d. London, England, 24 Nov. 1916. At a
boy he received his early education in the
country schools of Maine. What little spare
 time he had after attending to his work on
the farm and in his father's workshop was spent in
reading. When he was 14 years old he was sent as an
apprentice to a carriage builder at East Corinth, Me.
Later, while employed in a laboratory in Bos-
ton, he perfected his first invention, a method
of carbonating air and gas for lighting pur-
poses. His invention was used in many New
York hotels. Others of his inventions included
electrical devices, improvements on incandescent
lamps, self-registering current machines and
other similar contrivances. When he was 28
years old he was employed as a draughtsman in
a shipbuilding firm in New York City.
While there he invented a locomotive head-
light, which was used generally. In 1884
Maxim perfected the automatic rifle, or machine
gun, in which the recoil due to the explosion of
one cartridge was utilized to eject the empty
shell and at the same time reload the weapon.
The inventor was then in England. The gov-
ernment, interested at once in the possibilities
presented by the rifle, adopted it. It was the
Machine Gun of the British forces winning the
Egyptian campaign for the Eng-
lish. It is now used by the armies throughout
the world. Closely following came the "dis-
appearing gun," cordite and other smokeless
powders, a gun for hurling aerial torpedoes and the
"delayed action" fuse. For many years
Sir Hiram experimented with aeronautics.
In 1894 he succeeded in building a heavier-than-air
machine. At that time when aeroplanes were
only thought possible, Sir Hiram Maxim criti-
cised the British nation for lack of interest in
aeronautics and predicted that a bombardment of
the island from airships was possible. Sir
Hiram held membership in the American So-
ciety of Civil Engineers, the Royal Society
of Arts, the British Association for the Advance-
ment of Science and many other bodies. He
became a naturalized citizen of Great Britain
because of alleged unfair treatment of his
inventions by the American government. Sir
Hiram Stevens Maxim will be remembered as
one of the foremost inventors of his day. In
1881 President Greuv of France made him a
Chevalier of the Legion of Honor. This deco-
roration was followed in 1901 by recognition by
the British government, Queen Victoria elevat-
ing him to the knighthood.

**MAXIM, Hudson, American inventor and
engineer.** b. Orneville, Me., 3 Feb. 1853.
He received an academic education with especial
reference to the natural sciences and engineer-
ing, then took up the study of medicine; en-
tered the printing and subscription book pub-
lishing business at Pittsfield, Mass., in 1883,
gave up the publishing business in 1888
to take up business of ordinary and explosive
device. He was the first to make smokeless gunpowder
in the United States and was the first to sub-
mit samples to the government for trial. In
1890 he built a dynamite factory and smoke-
less powder mill at Maxim, N. J., named for
him. It was there that the multi-perforated
smokeless powder was developed and perfected
under his inventions and patents, which was
adopted by the United States government.
These patents were purchased by the E. I.
 du Pont de Nemours Powder Company, of
Wilmington, Del., in 1897. He invented the
process of making calcium carbide by incan-
descence of molten carbide conductor, now in
general use. In 1901 he sold United States
government the secrets of the high explosive
Maximite invented by him (see EXPLOSIONS);
invented United States service detonating fuse for
high explosive projectiles. He invented the
system of driving torpedoes by steam and
products of combustion of a self-combustible
compound called motorite, the steaming gen-
erated by the motorite. This system was pur-
chased by the United States navy. Since
1898 he has been consulting engineer for E. I.
 du Pont de Nemours Powder Company. He in-
vented stabilite (q.v.), a smokeless powder
made without volatile solvent, which con-
sequently requires no drying. He received the
degree of D.Sc. from Heidelberg University,
Ohio, in 1913. He is member of consulting
board of United States navy; of Albany Bur-
gesses Corps (rank, captain); of Military Ser-
vice Institution; of Society of Chemical Indus-
try; of Chemists Club; of Aeronautical Society;
Fellow A. A. A. S., of Society of Applied
Psychology; he is author of 'The Science of
Poetry and the Poet in the Poem' (1910); 'Defenseless America' (1915).

**MAXIMA AND MINIMA.** The maxima
and minima of a function \( f(x) \) are the points
of the curve \( y = f(x) \) where \( y \) is larger or
smaller, respectively, than for any value of \( x \)
differing from the value at that point by less
than some finite number. According to this
definition, a curve may have several maxima
or minima, and a maximum or minimum need
not be a point where \( y \) assumes the greatest or
least value, respectively, throughout the entire
curve. It is easy to see that a maximum is
a point where the curve ceases to go up and
begins to go down. At such a point, the slope
of the curve, or the differential coefficient \( \frac{dy}{dx} \)
changes sign. If \( \frac{dy}{dx} \) is continuous at a max-
imum, it can only be 0, and at any rate, on
an algebraic curve, it can only be 0 or ∞. Thus
the maxima — likewise the minima — are all to
be found among the points where \( \frac{dy}{dx} = 0 \) or ∞.
If \( \frac{dy}{dx} > 0 \), we have a minimum, of \( \frac{dy}{dx} < 0 \), a maximum. However, \( \frac{dy}{dx} \) may be 0 or \( \infty \) without their being a maximum or minimum at the point. In this case \( \frac{dy}{dx} \) will be 0. To determine whether we have a maximum, a minimum, or neither when \( \frac{dy}{dx} = 0 \), higher derivatives must be considered.

The definition of the maxima and minima of a function of two variables is obvious. It is clear that a necessary condition for a maximum or minimum of \( f(x, y) \), at a point where its partial derivatives are continuous, is that \( \frac{\partial f}{\partial x} = \frac{\partial f}{\partial y} = 0 \). A sufficient condition for a maximum is \( \left( \frac{\partial^2 f}{\partial x^2} \right) < 0 \) and \( \left( \frac{\partial^2 f}{\partial y^2} \right) < 0 \).

A sufficient condition for a minimum is \( \left( \frac{\partial^2 f}{\partial x^2} \right) > 0 \) and \( \left( \frac{\partial^2 f}{\partial y^2} \right) > 0 \).

Some important theorems in plane geometry having to do with maxima and minima are that of all polygons having a given perimeter and a given number of sides the regular one has the greatest area; that the circle has a greater area than any other figure with the same perimeter; that a right triangle is larger than any other with two sides equal to its legs, and that of all triangles with a given perimeter and a given base, the isosceles is the greatest. See CALCULUS, THE INFINITESIMAL; CALCULUS OF VARIATIONS.

MAXIMALISTS, or BOLSHEVIKI, the name applied to the adherents of the extreme Socialist party which, headed by Lenin and Trotsky, overthrew the provisional government and the Soviet leaders in Russia on 7 Nov. 1917. The words "Bolshevik" (sing.), "Bolshevik" (plural) and "Bolshevism" are not explanatory terms and have nothing to do with the policy or aims of the party. Their origin dates from the second conference of the Russian Social-Democratic party in 1903, at which the methods to be adopted in regard to revolutionary activity were under discussion. A sharp line of cleavage made itself evident; and when voting on the resolutions took place there was naturally a majority (bolshinstvo) and a minority (menshinstvo). From that moment the groups were called Bolshevik and Menshevik (maximalists and minimalists). The majority represented the extremists, the "whole-hoggers" of Socialism (bolšé — more), while those who got for the biggest things while the minority represented the "moderates" or "thin-end-of-wedge" theorists (menshi — lesser, smaller), or those whose aims are of smaller intent. There appears to be no evidence that the terms existed or were current before 1903, though the Russian Social-Democratic party was founded by Plekhanov and others in Switzerland in 1884. The abortive revolutionary movement of 1905–06, which opened with the Putilov ironworks strike and the Father Gapon episode, served to widened the breach between the two factions to the extent that in 1907 the party was definitely split into two independent groups — Bolshevik and Menshevik. The former, following in part the teachings of Karl Marx, were led by Lenin. The Marxian revolution was essentially a class revolution, to the realization of which nationalism was an obstacle. The European War and the aftermath of the Revolution of March 1917 revealed the wide divergence existing between the aims and methods of the two groups. The Bolsheviki contracted the class distinction to narrower dimensions and looked upon the educated classes, the bourgeoisie, and even the peasants as enemies. Their aim was radical internationalism; they sought not the re-creation of Russia, but the triumph of one class throughout the world — the proletariat; in other words, mob-rule. For the most part they were bitter and arid doctrinaires, reeling off strings of long, high-sounding words and phrases which few understood, and clinging to vague and abstract creed with fanatic devotion. Every problem was met with a reference to the letter of their law and interpreted accordingly. But whatever political, social or economic creed the Bolshevik professed on paper, their activity — and by that alone can they be judged — consisted in a wild orgy of crime, plunder and treason. No trace of practical ability was revealed by any of their leaders, but they had the driving force which even the shallowest fanaticism can give. They were opposed (on principle) as much as a German peace as to a peace dictated by the Allies: "No indemnity, no reparation and no annexation" became their ideal. The Menshevik were of a saner type; while claiming for the working classes the importance due to their numbers, they did not ignore other classes. Holding in view definite practical reforms, they were willing to utilize the existing machinery of the state for their purposes. They accepted the war and its necessities as a part of their program and realized that nationalism must precede internationalism. They recognized that the cause of the Allies was also their cause, and in this belief they were undoubtedly supported by a majority of Russian Social-Democrats. To the Bolshevik the fate of their country mattered nothing, provided only that their own crude ideas of social reconstruction survived the ordeal. They were eager for peace on any terms in order that they might proceed with their own program, that class war which recognized no political frontiers nor national consciousness. After the fall of Kerensky the Bolshevik began their career as rulers by the wilful and systematic destruction of the Russian army and navy. Their leaders posed before the world as the elect champions of a new ideology which was to redeem mankind. They proposed to teach other democracies the true and saving doctrine of the real revolutionary creed. Of exercising good government, as that term is understood among civilized peoples, they proved themselves utterly incapable; government, in fact, holds no place in their system, of which the sole principle is civil war or, as they term it, "class war." The doctrine of Socialism (from which it is really far removed), Bolshevism may be described as a com-
ound of anarchism, syndicalism, hatred and blind fanaticism. Needless to say, ingredients of this type cannot fail to attract all the purely criminal elements which, in normal times, are held in check by the forces of law and order. With the removal or breakdown of that salutary check and the absence of an efficient substitute, a free rein is given to unbridled passions by which a society in transition is thrown into a mere carnival of terrorism. This was what happened in Russia in 1917. The Bolsheviks had nothing whatever to do with bringing about the revolution which swept away the autocracy in March of that year. That revolution was neither engineered nor organized; it sprang not from the burning inspiration of a new faith, but succeeded almost automatically from sheer weariness: tired in mind and body, Russia had lost nerve and heart. The provisional government that was formed on 16 March consisted of honest, patriotic and intelligent men—Prince Lvov, Guchkov, Millyukov, Terestchenko, Nekrasov, Shingarev and Kerensky, who was the only Socialist in the group. Of all these, Kerensky was the most prominent. He was a man with sufficient magnetism to compel a following. Their first energies were devoted to maintaining discipline in the army and to carry the war to a successful conclusion. But already in September 1915 Lenin had issued the Zimmerwald manifesto, signed by himself and the Swiss Socialist, Robert Grimm, calling for "peace without annexations or indemnities." German agents had sedulously spread this doctrine among the Russian rank and file. With the result that the idea of 'peace' soon won a large number of converts. It was easy for German propagandists to convert the working classes to this view. The people were told what they wanted to hear—that it was folly to fight longer and that their Western Allies were the true foes of Russia, since they sought to force her to remain in the war. Not only did demoralization of the army set in, but there also grew up a spirit of hostility against the Allies, especially Great Britain. Thus, while the provisional government and later Kerensky alone struggled to maintain order and national unity, Bolsheviks and German agents were undermining the structure with glowing promises and sedition. On 16 July 1917, the Bolsheviks in Petrograd, led by Lenin and Trotsky, attempted to seize the reins of government and failed. Lenin disappeared when warrants were issued for the arrest of the Bolshevik leaders. At the last moment Kerensky weakened; he countermanded the order for their arrest. Up to this time the Russian armies were still fighting in the field; their offensive in Galicia was nearing its disastrous climax and Bolsheviks—the foe of the revolution and an enemy of the people—were growing in momentum. Confusion spread; Kerensky denounced the counter-revolutionists and those who unwittingly encouraged anarchy (Moscow, 25 Aug. 1917), which caused a wider split among the Provisional Cabinet and gave the Bolsheviks the opportunity. The retreating Russian armies gave themselves up to pillaging their own people and the sailors of the Baltic fleet murdered their own officers. Lenin crept out of hiding and raised his voice afresh in Kronstadt—the worst nest of anarchy. Kerensky once more fulminated against the Bolsheviks and then informed the United States that Russia was worn out. The dark forces waiting in the shadows quickly observed the change and made their preparations. The apathy and despair of Russia made her an easy victim to a body of determined men. Trotsky, then president of the Petrograd Soviet, summoned the proletariat of all nations to do what had been done in Germany and to raise his party to the supreme power. On 5 Nov. 1917 the Military Revolutionary Committee ordered the Petrograd garrison to place itself under their instructions. Kerensky suppressed the chief Bolshevik paper and called on the loyal troops to defend the government. On the 6th the military cadets occupied stations, bridges and telegraph offices and threw a cordon around Kerensky's residence, the Winter Palace. Lenin arrived the following day with his leading spirits and took over the Smolny Institute (a girls' school) the Bolshevik headquarters. He issued a proclamation announcing the fall of the government. The majority of the troops went over to the Bolsheviks. Kerensky fled on the 7th, leaving a guard of cadets and some women at the Palace. The Bolsheviks troops (Red Guards) captured the palace, committed many brutalities on the inmates and in a few hours the whole of Petrograd was in their hands. The "new government" was placed in the control of a "Council of People's Commissioners," of which Lenin was appointed president, Trotsky Foreign Minister and Ensign Krylenko as commander-in-chief of what was left of the army. Only the comparatively weak Bolsheviks overthrew the provisional government was due mainly to the passive attitude of the troops. Had Kerensky had at his disposal a few brigades of reliable troops he might as easily have crushed Bolshevism on the same day. On 8 November Lenin telegraphed to all the belligerent governments a proposal for a three months' armistice. On the 10th a series of decrees began to emanate from the Smolny Institute, their principal features being the spoliation of one class and the transference of its property to another. Municipalities were empowered to sequestrate all houses, whether inhabited or not, and to instal in them citizens possessing no abode or occupying crowded or insanitary dwellings. All factories were passed to the possession of the operatives (syndicalism), and a moratorium was proclaimed for the payment of rent for small houses and lodgings. The most important decree threatened civil war in the rural districts by declaring all private ownership in land to be annulled without com-
pensation to the owners. The land was to be nationalized and handed over to the cultivators, while for the present all lands belonging to the state, to the Church and to monasteries, etc., with all appurtenances — flocks, herds, machines, etc., were to be placed at the disposal of the local agrarian committees until the meeting of the Constituent Assembly. The local boards were authorized to preserve order during the process of confiscation. All mines, forests and waterways were acquired by the state, and the smaller woods, rivers and lakes were to be the property of the village commons. The gloom of Bolshevism had settled over Russia. Missionaries of that cult were dispatched to all European countries and to the United States to spread the faith and incite proletarian uprisings, though with negligible success. During 1918 the dread of Bolshevism became a haunting specter to not a few governments. Everywhere outside of Russia it was denounced by public men and its slightest symptoms rigorously suppressed. It is a remarkable fact that, while Jews formed a large percentage of the leading Bolsheviki, over 90 percent of Russian Jews were hostile to them. Many of them had lived in America, Switzerland, Great Britain, France, Germany and the Scandinavian countries. They returned to Russia after the Revolution, where their ranks were swelled by large numbers of exiles from Siberia—not all political offenders, but also some of the most dangerous criminals. The further adventures of the Bolsheviki régime are told under Russia—History; see also Russian Revolution of 1917; War, European; Kerensky; Korniloff; Trotsky; Lenin. Consult Trotzky, L., 'The Bolsheviki and World Peace' (New York 1918); The World's Work (New York, October 1918); Current History (New York, November–December 1918).

MAXIMIANUS I, māk-sim-in'əs, Marcus Aurelius Valerian, Roman emperor: February 310 A.D. He so approved himself by his services in the army that Diocletian selected him for his colleague, creating him first Caesar (285), then Augustus (286) and at the same time conferred on him the honorific appellation of Maximianus. Maximianus had the care of the Eastern Empire, while Diocletian undertook that of the Western. In 287 he was consul with Diocletian, and in the same year conducted a campaign in Gaul. After conducting several wars, in 303-304 he was for the seventh time made consul, having for his colleague Diocletian for the fifth time, with whom he abdicated 1 May 305. In the following year he was again invested with the imperial title by his son Maxentius, to whom his services against Severus and Galerius were of the most important kind. His son shortly after expelled him from Rome, and repairing to Gaul, in 306 caused himself to be proclaimed Augustus at Marsileles, but Constantine easily deposed him. See Constantine; Diocletian.

MAXIMILIAN I, māk-sil-mil'yan (Ger. Mäximilian), emperor of Germany: b. Neustadt, near Vienna, 22 March 1459; d. Wiener Neustadt, in Upper Austria, 12 Jan. 1519. He first became an independent prince by his marriage with Mary of Burgundy, the daughter of Charles the Bold, who died in 1477. This match involved him in a war with Louis XI, King of France, in which he was successful, though he was defeated at a later period by the Milanese. At Frankfort in 1486 he was chosen, but not invested as emperor, and was imprisoned by the Flemings at Bruges. He secured the Tyrol in 1490 and in the same year made war against Charles VIII of France. In 1493 he became Holy Roman emperor on the death of his father. He was involved in war with Venice, France and the Turks for the greater part of his reign. He was succeeded by his grandson, Charles V. Consult 'Cambridge Modern History' (Vol. I, 1903), and Heyck, 'Kaiser Maximilian I' (Bielefeld 1898).

MAXIMILIAN, emperor of Mexico, known in earlier life as Ferdinand Maximilian Joseph, Archduke of Austria: b. Vienna, 1 July 1832; d. Queretaro, Mexico, 19 June 1867. He was the younger brother of Francis Joseph I, emperor of Austria (q.v.). He entered the Austrian navy in 1846, and in 1854 obtained the rank of rear-admiral and was placed at the head of the Austrian marine on the Adriatic. In 1857 he became the regent of the Lombardo-Venetian kingdom in 1857–59, and in 1857 married Princess Charlotte of Belgium, daughter of King Leopold I. On his return from a voyage made to Brazil for scientific purposes he fixed his residence at Miramar in the vicinity of Trieste, in 1863, received a deputation from the Mexican Assembly of Notables, who offered him the crown of their country. He officially announced his acceptance 10 April 1864. He landed at Vera Cruz on 28 May and entered Mexico at 12 June. He set himself energetically to consolidate and develop his dominions, granted an amnesty to political offenders and exhibited great interest in religious worship and education. But he failed to conciliate the Republican party, and as he did not restore to the clergy their confiscated estates they pronounced him a traitor. Meanwhile there were incessant conflicts between the partisans of President Juarez and the allied French and imperial troops; and the decree of 2 Oct. 1865, by which the members of the Juarist bands and those who abetted them were to be regarded as bandits and shot, alienated the party of the Liberals. Juarez raised the standard of independence. Complications and misfortunes thickening around Maximilian rendered his position critical in the extreme. The empress in vain undertook a mission to Europe to enlist support for her husband, and grief and disappointment overthrew her reason. The French troops, largely by reason of the representations of the United States government, were withdrawn by Napoleon in March 1867; but Maximilian decided to remain in the hope of being able to maintain the empire. While bravely defending Queretaro against a Liberal force under Escobedo, he was bayed down by General Lopez on the night of 14 May 1867. Tried by court-martial, he was sentenced, with his principal officers, to be shot. The sentence was carried into effect on the morning of 19 July. Maximilian’s body was after some delay surrendered to his relatives, and his funeral was celebrated with great pomp in the cathedral of Vienna on 18 Jan. 1868. Maximilian was a man of eminent abilities and high and varied culture. His collected writings are contained in a posthumous publication entitled
MAXIMILIAN — MAXIMS 489

'Aus meinem Leben: Reizeskizzen, Aphorismen, Marinebilder' (1807), which gives ample testimony to the vigor of his intellect and the variety of his attainments. (See Mexico, History). Consult Bancroft, H. H., 'History of Mexico' (6 vols., San Francisco 1883-88); 'Cambridge Modern History' (Vol. II, New York 1909); Kemper, E., 'Maximilian in Mexico' (Chicago 1911); Martin, P. F., 'Maximilian in Mexico' (London 1914).

MAXIMILIAN, Joseph, 1st king of Bavaria: b. Schwetzingen, Baden, 27 May 1756; d. Nymphenburg, near Munich, 13 Oct. 1825. He succeeded his uncle, Charles Theodore, as elector in 1799. He was a supporter of Napoleon, and gave his daughter in marriage to Eugene Beauharnais in 1806. In the same year his duchy was erected into a kingdom. In 1813, however, he was member of the league against the emperor, and thus retained his throne after the fall of Napoleon. His reign is distinguished by the introduction of many administrative reforms, especially the constitution of 1818.

MAXIMINUS, māk-sī-mī-nūs, Caius Julius Verus, Roman emperor: d. Aquileia, 238 A.D. He was at first a shepherd in Thrace and when of age became a soldier in the Roman armies, where he was distinguished by his gigantic stature. His capacity for fighting procured him rapid advancement, and under Alexander Severus he had the command of a legion on the Rhine. In 235 A.D. he took part in a conspiracy against Alexander, and after his murder of the latter by the soldiers was proclaimed emperor. The Gordiani having been proclaimed in Africa, Maximinus hastened to Italy and laid siege to Aquileia. He was there killed by his soldiers.

MAXIMITE, a high explosive employed as a bursting charge for projectiles, invented by Hudson Maxim (q.v.) of New York City. The secret of the invention and the exclusive right to the use of the explosive was purchased by the United States government in 1901, after very exhaustive trials at Sandy Hook proving grounds. Maximite was the first high explosive to be successfully employed as a bursting charge for armor-piercing projectiles. This explosive, while it is claimed to be 50 per cent more powerful than ordinary dynamite, is so insensitive that it will not only safely withstand the shock of discharge from the gun, but will also stand the far greater shock of penetrating armor-plate as thick as the projectile containing it is capable of passing through, the projectile being then exploded immediately behind the plate with a delay action detonating fuse.

Ignited in the open, maximite simply burns like pitch. Projectiles are charged with it by the simple process of melting and pouring, the explosive solidifying on cooling and adhering firmly to the walls of the shell. Maximite is known to be a picric acid compound. See Explosives; Projectiles.

MAXIMS. The 'Maxims' of La Rochefoucauld furnish the most famous body of examples of that polished and studied condensation of the explosive solidifying on cooling and adhering firmly which the French so delight in and so excel, and of which the 'Pensées' of Pascal, the 'Caractères' of La Bruyère and the 'Réflexions' of Vauvenargues are other specimens. They are precisely what their fuller official title proclaims them: Reflections, or Sentences and Moral Maxims ('Réflexions, ou Sentences et Maximes morales'). They are exactly what the sense that they are concerned with the facts of human conduct and motive, but not at all in the sense of serving a didactic purpose or in proposing an incentive or a guide to virtuous living; and they are reflections rather than maxims in the ordinary meaning of the word, since what they give us is not practical precept and counsel, but an analysis of moral facts. In this analysis the sharp distinction and opposition between vice and virtue disappears. His moral philosophy is summed up in the maxim that stands as epigraph at the head of the collection: 'Our virtues are most frequently but vices disguised.' The idea is restated a little more specifically in the first reflection: 'What we term virtue is often but a mass of various actions and divers accidents which fortune, or our own industry, manage to arrange, and it is not always from valor or from chastity that men are brave, and women chaste.' The root of all our actions, mask it as we will, is selfishness. This view of virtue and vice as expressions of its bitterness and pessimism to the personal temper of La Rochefoucauld, soured by disappointment after playing a restless and unsuccessful part in political and private intrigue. But it owed much also to his penetrative observation of the life of court and salon, and even those who wanted to think more generously of human nature admitted sadly the accuracy of his analysis, while all were captivated by the concision and elegance of his style. To this he gave unending care, polishing and refining his sentences, rejecting some and adding others in successive editions (1665, 1666, 1675, 1678). The standard edition is that prepared by M. Gilbert (Paris 1868). The Maxims have had many admirers among English writers, as Addison, Swift, Dr. Johnson and Lord Chesterfield. They have often tempted to translation. A late and complete English version is by J. W. Willis Bund and J. Hain Friswell (London 1871).

ARTHUR G. CANFIELD.

MAXIMS, Legal, epigrammatic statements of established principles in law, as 'Ignorance of the law excuses no one' ('Ignorantia legis neminem excusat'). They are of historic and practical value, and are common in both law and equity. Usually they are given in Latin or in English, but occasionally they appear in French. The following are some of the most important which appear generally in English: 'Equity treats asdone which ought to b done'; 'He who comes into equity must come with clean hands'; 'Who seeks equity must do equity'; 'Acts indicate the intention'; 'Where there is equal equity, the law must prevail'. The following usually appear in Latin: Qui facit per alium facit per se ('He who acts through another acts himself important in the law of agency'); Affirmavit est probare ('He who affirms must prove'); Causa proxima non remota spectatur ('The immediate and not the remote cause is to be considered important in the law of torts'). While maxims are of importance in the law to-day, it is nevertheless true that some of them, through legal changes, are practically obsolete. Due
allowance also must be made for the fact that they do not contain exceptions and amplifications of the principles they state; otherwise there is little to be misleading.

MAXIMUM DUTIES. See Duty.

MAXIMUS MAGNUS, Roman emperor: b. in Spain; d. 388. In 383, while commanding the Roman army in Britain, he proclaimed himself emperor. Gratian marched against him, but was defeated and assassinated, and Maximus, having made himself master of Gaul, Britain and Spain, fixed the seat of his empire at Trier. He then advanced into Italy and was besieged in Aquileia by the Emperor Theodosius, who caused him to be beheaded.

MAXWELL, Sir Herbert Bustace, 7th Baronet of Monreith, Scottish author: b. Edinburgh, 8 Jan. 1845. He was educated at Oxford, was Conservative member of Parliament for Wigtownshire, 1880-1906, and president of the Society of Antiquaries of Scotland, 1900-13. Among his many publications are 'Noontide Essays' (1892); 'Scottish Land Names' (1894); 'Rainy Days in a Library' (1897); 'Duke of Wellington' (1889); 'Memories of the Month's' five series (1900-09); 'The House of Douglas' (1901); 'Memoirs of George Romney' (1902); 'The Crewe Papers' (1903); 'A Century of Empire' (1900-11); 'The Making of Scotland' (1911); 'Fishing at Home and Abroad' (1914); 'Trees, A Woodland Notebook' (1914).

MAXWELL, James Clerk, Scottish natural philosopher: b. Edinburgh, 13 Nov. 1831; d. Cambridge, England, 5 Nov. 1879. He was educated at Edinburgh and at Trinity College, Cambridge, and in 1856 was appointed professor of natural philosophy in the Marischal College, Aberdeen, and held that office till its amalgamation with King's College to form the University of Aberdeen in 1860, when he was appointed to a similar chair in King's College, London. In 1857 he obtained the Adams prize at Cambridge for an essay 'On the Stability of Motion of Saturn's Rings.' From 1855 to 1872 he published his investigations on 'Perception of Color, and Color Blindness,' which obtained for him the Rumford medal and his election as F.R.S. He resigned his chair in 1865 and in 1871 was appointed to the newly founded chair of experimental physics at Cambridge. He directed the formation of the Cavendish laboratory founded by the Duke of Devonshire and opened in 1874. In 1871 he published his 'Theory of Heat,' which has gone through several editions. In 1873 appeared his great work, 'Electricity and Magnetism.' Maxwell's fame will rest on his being the one who took the first grand step toward the discovery of the true nature of electrical phenomena. He rejected the theory of electrical "action at a distance," and sought to explain all electrical and magnetic phenomena as the results of local strains and motions in a medium whose contiguous parts only act on one another by means of translation. His scientific papers have been collected by W. D. Niven (1890). Consult Campbell and Garnett, 'James Clerk Maxwell' (London 1882); Glazebrook, R. T. 'James Clerk Maxwell and Modern Physics' (1896).

MAXWELL, William Henry, Irish-American educator: b. Stewartstown, Tyrone, Ireland, 5 March 1832. He was graduated at Galway Queen's College in 1872, and two years later received the degree of A.M. In 1874 he came to the United States. After eight years as teacher in Brooklyn he became assistant superintendent of schools in that city in 1882 and superintendent from 1887 to 1898. Since 1898 Dr. Maxwell has been superintendent of public schools of Greater New York. In this position he often came into conflict with the board of education. He advocated a college training for teachers and raised the requirements for teachers' examinations in New York. He was president of the National Education Association in 1908. Dr. Maxwell has always been deeply interested in the promotion of the study of English. He published 'Elementary English Grammar'; 'School Grammar' and other educational works.

MAY, Phil, English illustrator: b. Leeds, 22 April 1864; d. Saint John's Wood, London, 5 Aug. 1903. He was son of an engineer; had his schooling in Leeds; was apprenticed there to a lawyer, whom he soon left to join a company of players; for them he designed posters; married at the age of 19; and in 1884 and 1885 began drawing for Society and Saint Stephen's Review. He went out to Sydney, Australia, in 1885, where he gained some fame as artist of the Bulletin, and was forced by the exigencies of newspaper illustration to a very scanty use of line and a complete omission of anything else; went to Paris; returned to his work on Saint Stephen's Review; then began to draw for the Daily Graphic; in 1888 returned to England; thereafter traveling through America; and shortly after Du Maurier's death was taken on the staff of Punch. He must rank with Leech, Tenniel and the other great British caricaturists. His art was remarkably simple and telling, his method, it is said, being to reduce an elaborate and detailed drawing to the fewest possible lines. He was particularly happy in his portrait sketches of London street-life, which are full of humor and sympathy; his Parliament sketches are less felicitous and a misapplication of his talent. His own hatching face, banded hair and ever-present cigar figure in many of his caricatures. From 1892 to his death he published 'Phil May's Annual.' His other collected drawings are 'Parson and Painter' (1891); 'Phil May's Sketch Book' (1895) and 'Phil May's Gutter-Snipes' (1896); 'Phil May's Graphic Pictures' (1897).

MAY, Samuel Joseph, American reformer and abolitionist: b. Boston, Mass., 12 Sept. 1797; d. Syracuse, N. Y., 1 July 1871. He graduated at Harvard in the class of 1817, and after studying theology under Dr. Ware at the Harvard Divinity School became a Unitarian clergyman and in 1822 accepted a call to a church at Brooklyn, Conn. He was interested in the anti-slavery cause and preached as well as wrote in favor of it, advocating immediate emancipation, for which he was mobbed and burned in effigy at Syracuse in 1830. He was a member of the first New England Anti-Slavery Society, formed in Boston in 1831, and actively championed Prudence Crandall, when she was persecuted and arrested for receiving colored girls into her school at Canterbury, Conn. Mr. May was also a member of the Philadelphia convention of 1833 which formed the American
Anti-Slavery Society, and was one of the signers of the Declaration of Sentiments, the author of which was William Lloyd Garrison. For 18 years he was the general agent of the Massachusetts Anti-Slavery Society, and as such lectured and traveled extensively. He was five timesmobbed while on a lecture tour in Vermont, New Hampshire, and Massachusetts. In the capitol at Montpelier. He had charge of the Unitarian church at South Scituate, Mass., from 1836 to 1842, becoming in the latter year, at the request of Horace Mann, the principal of the Girls' Normal School at Lexington, Mass. In 1845 he became pastor of the Unitarian Society at Syracuse, N. Y., which position he retained until 1868. Mr. May assisted in the rescue of Jerry, the slave, in 1851, and with several others was arrested for this offense against the Fugitive Slave Law. May and his associates issued a declaration in which they admitted the fact of their being implicated in the rescue, but claimed that the Fugitive Slave Law was unconstitutional and wicked. Realizing the changing sentiment in the North the authorities never brought the case to trial. May's life, like that of many another Abolitionist, was often in danger. He was among the most conservative anti-slavery leaders in his methods and was prominent also in many educational and charitable enterprises, and did a great deal toward improving the public-school system of Syracuse. By his associates May was termed the Saint John Apostle of the Gospel of Freedom, on account of his gentle voice and manner. He was both gentle and firm, courageous, unwearied and unfailing in the anti-slavery cause. He published 'Education of the Faculties' (1846); 'Revival of Education' (1855); 'Recollections of the Anti-Slavery Conflict' (1868). Consult Mulford, 'Memoir of Samuel Joseph May' (Boston 1873; new ed., 1882).

MAY, Thomas, English dramatist and historian: b. Mayfield, Sussex, 1594; d. London, 13 Nov. 1650. He was educated at Cambridge, became a member of Gray's Inn, but never practised, and figured brilliantly at court. He published 'Antigone,' 'Cleopatra,' and other plays and a translation of the 'Georgics' and Lucan's 'Pharsalia.' He was an intimate of Charles I and at the latter's behest wrote histories of Edward III and Henry II in verse. He espoused the cause of Parliament in the Civil War, was made secretary and historiographer to Parliament and wrote 'History of the Parliament of England, 1640-43' (1650; several times republished), and a 'Breviary' of the same history (1650). Until the Restoration his body reposed in Westminster Abbey, but as in the case of other Parliamentarians, it was then dishonored and thrown into a neighboring pit.

MAY, Thomas Erskine, Baron Farnborough, English historian: b. London, 8 Feb. 1815; d. Westminster, 17 May 1886. He was educated at Bedford Grammar School, became assistant librarian to the House of Commons in 1831 and was called to the bar in 1838. He was appointed examiner of petitions for private bills in 1846 and clerk to the House of Commons in 1871. He was knighted in 1866, and just prior to his death in 1886, he was raised to the peerage. He is best known as an antiquarian and historian. His chief works are 'A Practical Treatise on the Law, Privileges, Proceedings, and Usages of Parliament' (1844; 10th ed., much enlarged, 1893), a model of its kind, which has been translated into most modern languages; 'Constitutional History of England since the Accession of George III, 1760-1860' (1861-63; republished with supplementary chapters, 1877); 'Democracy and Reform; a History' (1877). In 1854 he collected and reduced to writing the 'Rules, Orders, and Forms of Procedure of the House of Commons.'

MAY, the fifth month of the year, having 31 days. It was second in the order of Roman calendar, third in that of Romulus and fifth in that of Numa Pompilius. The etymology of the word is doubtful. It was called Maius by Romulus, in respect to the senators and nobles of his city, who were called Maiores, as the month following was called Junius, in honor of the youth of Rome who served him in war and were named Juniores. Some etymologists hold the opinion that it was called Maia, from the goddess of that name, the mother of Mercury, to whom they offered sacrifices on the first day of the month. The sun enters Gemini during May and the plants of the earth generally begin to flower. See CALENDAR.

MAY APPLE. See MANDRAKE.

MAY BEETLE, or JUNE BUG, popular names for the clumsy brown beetles of the genus Lachnosterna (family Scarabaeida) common throughout the United States. The adults fly by night during late spring and often are troublesome upon the young foliage of trees and shrubs. They are attracted by light and may be trapped in this way. The larvae are large, brown-headed, white-bodied grubs which feed upon the roots of grass, etc., passing one or more years in the ground. For this reason strawberries and other crops which they attack should not be planted upon freshly-turned sod land. Late fall plowing is often practised to destroy them.

MAY-BIRD, a gunner's name for various shore birds which return from the South in the month of May, especially the oyster-catcher. In New England the black-belled plover, and in the South a curlew, are called May-birds or May-cocks.

MAY CHERRY, a local name for the service-berry bush. See AMELANCHIER.

MAY DAY, popular name of the first day of the month of May, on which from a very early period general festivities took place. May has generally been regarded as a time for gladness. The outbreak into new life and beauty which marks nature instinctively excites. The first emotion is a desire to seize some part of that profusion of flower or blossom which spreads around, to set it up in decorative fashion and to let the pleasure which it excites find expression in dance and song; and among pagans the tendency has been to render to this vegetative trophy a sort of homage. Among the Romans, the feeling of the time found vent in their Flora, or Flora Games, which began on 28 April and lasted to 3 May. Among the old Celtic peoples, a festival called Beltain (Bal's fire) also was held on this day, but it does not seem to have been connected with flowers, but rather with sun-worship. In Christian times in the Celtic countries the Church
Christianized this celebration by transferring it to 24 June, the feast of Saint John, which is still celebrated with bonfires. In England, as we learn from Chaucer and other writers, it was customary, during the Middle Ages, for all, both high and low—even the court itself—to go on the first May morning at an early hour "to fetch the flowers fresh." Hawthorn branches also were gathered; these were brought home about sunrise, with accompaniments of horn and tarlet, and all "to meren". The people then proceeded to decorate the doors and windows of their houses with the spoils. By a natural transition of ideas, they gave the hawthorn bloom the name "the May"; they called the ceremony "the bringing home the May"; they spoke of the expedition to the woods as "going a-Maying." The fairest maid of the village was crowned with flowers as the "Queen of the May"; placed in a little bower or arbor, where she sat in state, receiving the homage and admiration of the young revelers, who danced and sang around her. This custom of having a May queen seems a relic of the old Roman celebration of the day when the goddess Flora was specially worshiped. How thoroughly recognized the custom had become in England may be illustrated by the fact that in the reign of Henry VIII the heads of the corporation of London went out into the high grounds of Kent to gather the May—the king and his queen, Catharine of Aragon, coming from their palace of Greenwich, and meeting these respected dignitaries on Shooter's Hill. But perhaps the most conspicuous feature of these festive proceedings was the erection in every town and village of a fixed pole—the May-pole—as high as the mast of a vessel of 100 tons, on which, on May morning, they suspended wreaths of flowers, and round which the people danced in rings nearly the whole day. A severe blow was given to these merry and often wild revels, by the Puritans, who, in their campaign of taking the joy out of life, caused May-poles to be uprooted and a stop put to all their jollities. They were, however, revived after the Restoration and long held their ground, but the celebration is now confined to school children, their elders now being, so much has our modern industrial feudalism absorbed the leisure time of all but the parasite classes. In France, Germany and other countries, May-poles were common and festive sports are even yet observed. The Roman Catholic Church, in order to counteract the evils too often incident to the celebration of May Day, appears to have instituted the feast known in France as La Fête-Dieu, celebrated with processions and offerings. In America May Day celebrations have come into favor in the present century and in nearly all public parks of great cities games and processions are held. Consult Strutt, J., 'Sports and Pastimes of the People of England' (London 1801).

MAY-FLY, SHAD-FLY, or DAY-FLY, members of the order Ephemera. The species of which about 300 have been described nearly one-third of which are North American, and of which winged females are large fore-wings, small or wanting hind-wings, short antennæ, atrophied mouth parts and two or three thread-like abdominal filaments. Being greatly attracted to lights, the adults are often a source of annoyance in lakesides and riverside towns, and are sometimes especially troublesome in obscuring the lights from lighthouses. The eggs are laid in fresh water either upon the surface or upon the bottom, the female diving for this purpose. The larval stage is the most remarkable part of the matter, are active creatures with strong legs, abdominal tracheal gills and anal appendages. They live upon the bottom, under stones, covered with mud, or in burrows. After molting about one or two times they increase with each molt until the last, which may be number 20. This occurs in the open air, the one previous to which occurs at the surface of the water, the insect escaping from its subterranean cell rather suddenly. One striking difference the adults exhibit is the development of paired sexual organs, which do not appear in other orders of insects. The larvae may take three years to develop; the adults live only a few days, lay their eggs and die. Both adults and larvae are important food for fishes, and consequently they form a favorite bait with anglers, and are imitated in making artificial flies.

MAYA, mà' ya", the ruling race of Yucata at the time of the discovery of America and for many years previous. Where they came from is uncertain; but that they invaded the peninsula from two different directions is asserted in various of their traditions. This probably means that the people are of distinct races, one of which came by way of the Gulf of Mexico and the other from the west southwest by land. The Maya, or descendants of the inhabitants to Yucatan recorded in the traditions was led by the great culture hero Zamán ñ (or) who became the first temporal and ecclesiastical ruler of the land, a sort of Moses, a giver of laws and a solidifier of traditions. Tradition says he lived to be quite old and then divided the country into districts which he gave to his followers of noble birth. At the time of his death the Mayas were in secure and peaceable possession of the peninsula of Yucatan, throughout the length and breadth of which they had extended their culture. These early Mayas seem to have been closely connected with the other great cultured peoples of Chiapas, Honduras and Guatemala, in language, customs and religious institutions.

The second inroad of foreigners into Yucatan was, according to traditions, headed by Quetzalcoatl. This probably means that the newcomers were followers of the Toltec religion and probably possessors of Nahuan culture. Whether, on their arrival in Yucatan they spoke the same language as the first Mayas is not known; but it seems probable that they did, since they are called, by various early writers, "the Itzas," a name generally conceded to mean the followers of Zamán ñ or Itzamná, the culture god of one of the early Mayas. Yucatan now had two governing races which seem to have lived on more or less friendly terms with one another, and to have had no trouble in communicating with one another. It is certain that, at the time of the conquest of Yucatan, Yucatan had about 300 years later, only one language existed in the country. Yet the style of the various ruins of Yucatan show that there must have been a blending of cultures and religious ideas, and indicates the
influence of Nahuan civilization in the peninsula. It is probable and there are intimations in Mayan and Quiché traditions, that not only one but numerous migrations took place over considerable periods of time from the southwest into Yucatan.

Both the original followers of Zamna and the immigrants from the southwest, Chiapas and Guatemala, may have come, as tradition pictures them, great builders for Yucatan is literally covered with ruins whose forms, decorations and peculiar characteristics show that at least two races of considerably different cultures built them. Yet however different may have been the cultures of these two peoples they appear to have become pretty well blended by the time of the conquest, and the two races had merged into one, which the Spaniards named Maya or sometimes Itza. Under the Tutul Xiu at Uxmal (q.v.) the Mayas built a civilization noted for its splendor among all the neighboring nations. Uxmal became the greatest, most powerful, wealthy and artistic city in Yucatan and as such flourished for many years; but it was finally conquered; and Maya power was transferred to Mayapan, which in its turn fell into the hands of people from the mountains near the end of the 13th century. This was followed by a century and a half of civil war in the peninsula, which led finally to the destruction of Mayapán (q.v.) about 1460. In this war the Xius and their power greatly reduced and themselves driven to take refuge in Mani, a city which they still inhabited at the time of the Spanish conquest during the first half of the 16th century. With all these influxes of foreigners who evidently remained in the country, into which they appear to have continued to flood up to the time of the discovery of America, the language of Yucatan remained a unit, in which the dialects were so slightly marked that the people of the whole peninsula conversed with one another without any difficulty. This would seem to indicate that the Maya race was fundamentally the same as that which erected the great historic buildings now in ruins throughout the Quiché country, in the Yucatan and the Mexican state of Chiapas. Their culture seems also to have been related to that of Oaxaca, Tabasco, Campeche and Guerrero. The territory of the Maya race proper stretched southward covering all the peninsula of Yucatan and reaching to the Pacific Ocean.

The Mayas had made a very great advance in civilization at the time of the discovery of America; though, owing to the long and bloody civil wars through which they had just passed, this civilization had lost much of its splendor. This was completely destroyed during the Spanish conquest, which lasted 16 years. Then many of the Mayas retreated to the hilly country and the deeply wooded coast-land to the west where they continued to maintain their independence during the 300 years of Spanish rule. Numerous military expeditions were sent against them and it was not until the administration of Porfirio Diaz that they were reduced to comparative quiet, from which they have again more or less freed themselves. The Maya tongue is still spoken by about 300,000 persons of whom about 100,000 are of mixed descent. See Mexican Mythology and Ethnology.

CHICEN-ITZA. See also bibliography under Yucatan.

MAYAPÁN, má-pa-gwás'. Porto Rico, a seaport city on the Mayaguez River near the west coast, the capital of Mayaguez department and third city of the island in size, 72 miles southwest of San Juan. The city was founded in 1752 and has a modern appearance, with wide streets, public plazas, fine buildings, electric lights and a street railway. A railroad brings it into communication with the interior. It has a large but shallow harbor, and its port is three miles distant at Mayaguez Playa, where a considerable export trade in coffee, sugar and Yacuán is carried on chiefly with the United States. In the vicinity is the Porto Rico Agricultural Experiment Station, which dates from 1902. Pop. about 20,000.

MAYAPÁN, the ancient capital of the Maya kingdom in Yucatan. According to tradition it was founded by Zamna, the ancient highpriest, ruler and culture hero of the Mayas. Zamna divided the Maya kingdom among his leaders whose descendants formed the Maya nobility of Yucatan. In later days the Tutul Xiu, high nobles, became the ruling power under the sovereign, who was chosen from among them. Many years later Kukulcan, another traditional semi-god, according to traditional history, became king and high priest of Mayapán. As this name is a literal translation of the word Quetzelcoatl (q.v.), the name of the Nahua god of culture, and as the story of the latter and that told of Kukulcan are almost identical, it is probable that this tradition records the conquest of Mayapán by the Toltecs or some Nahua tribe who introduced into Yucatan the worship of Quetzalcoatl. According to the Maya traditional history this Kukulcan formed a confederacy of the rulers of Mayapán and Chichen Itzá, the latter the ruling party among the Itzas. Of this confederacy he seems to have been the pontifical head and the ruling spirit; though with him the other sovereigns were legally joint rulers with equal powers. On his departure from Mayapán, which seems to be mythical, Kukulcan left the kingdom to princes known afterward as the Cocomes, under whose several descendants Mayapán enjoyed a period of wonderful prosperity during which many cities throughout the country subject to this capital are supposed to have been built. The ruins of these ancient cities are still found in the vicinity of Mayapán.

In the meantime, the city of Uxmal (q.v.) rose to power in another part of the isthmus. In a sanguinary war with this latter Mayapán was finally defeated and destroyed. Uxmal became the head of a new confederacy, with the Tutul Xiu the ruling royal family. The latter ruled wisely and well at first and rebuilt Mayapán, which continued to flourish for several centuries. It was, however, finally razed to the ground about the middle of the 15th century, or shortly before the discovery of America, in a civil war in which the vassal lords fought against and finally overthrew the power of the Tutul Xiu dynasty. Thus finally disappeared Mayapán, the first of the known great and populous cities of ancient Mexico.

The ruins of the city of Mayapán are situated about 25 miles south of Merida. The condition of these ruins to-day seems to bear
MAYBRICK — MAYER

out the traditional history that this old capital of the Mayas was completely destroyed, for little of its past magnificence now remains. But Everywhere, irracésed and pyramids, badly ruined edifices and huge quantities of stone, sculptured blocks and foundations of buildings scattered over a considerable extent of territory are evidence of the existence of a vast population and a place of some magnitude. One great mound or pyramid over 69 feet high has a stairway 20 feet wide on each of its sides leading from the ground to the truncated summit, a stone-paved platform considerably wider than the stairway. Sculptured stone blocks lie scattered over an area of three miles, attesting the great extent of this ancient Maya capital which tradition says was once surrounded by a thick and high stone wall, but that this wall was razed to the ground at the time of the final destruction of the city about 100 years before the conquest of Yucatán by the Spaniards. Along the line of this wall runs an old ditch, now filled up with débris, and on both sides of the remains of stone supposed to have once formed part of this ancient rampart. See UXMAL; CHICHEN ITZÁ; YUCATÁN.

JOHN HUBERT CORYN.

MAYBRICK, Michael ('Stephen Adams'), English composer: b. Liverpool, about 1845; d. 26 Aug. 1913. He studied music in London and Germany and was for many years a leading baritone vocalist in concerts and English opera. As a writer of songs over the signature "Stephen Adams," he was widely popular in this country and England. Among the best known of his many songs are 'The Midshipman,' 'Nancy Lee,' 'Alsatian Mountains,' 'The Holy City,' 'A Warrior Bold.'

MAYENCE, mä-yänс. See MAINZ.

MAYER, Alfred Goldborough, American zoologist: b. Frederick, Md., 16 April 1868. In 1889 he was graduated at the Stevens Institute of Technology and at Harvard in 1897. From 1892 to 1900 he was assistant to Dr. Alexander Agassiz and had charge of radiates in the Harvard Museum of Comparative Zoology from 1895 to 1900. In 1900-04 Dr. Mayer was curator of natural sciences and curator-in-chief of the Brooklyn Institute Museum; in 1904-05 he was director of the marine laboratory of the Carnegie Institution, Tortugas, Fla., and since 1915 has been director of the department of marine biology at the Carnegie Institution, Washington. Dr. Mayer took part in several scientific expeditions in many parts of the world. Since 1913 he has been lecturer in biology in the University of Chicago, where he lectured on "Medusa of the World" (3 vols., 1910); and contributions to zoological publications, especially on the insects and medusae and on chemical causes of animal movements; effects of ions upon rate of nerve conduction; studies of coral reefs of Samoa, etc.

MAYER, mä'tcr, Alfred Marshall, American physicist: b. Baltimore, 13 Nov. 1836; d. Maplewood, N. J., 13 July 1897. He studied at Saint Mary's College, Baltimore; spent two years in a machine-shop and draughting-room; specialized in chemistry and physics; became professor of these branches in the University of Maryland (1856) and in Westminster College, Fulton, Mo. (1859); after two years of study in Paris was appointed to a chair in Pennsylvania College, Gettysburg (1865); went thence to Lehigh University in 1867, and from 1871 to his death was professor of physics in Stevens Institute, Hoboken, N. J. There he made important researches in acoustics; invented the topophone, an apparatus to detect the phases of sound vibration; discovered five methods of analysis of compound sounds into their elementary tones; and stated the law of tuning-fork vibration. He became a member of the National Academy of Sciences in 1872. He wrote many papers for the American Journal of Science, notably a series entitled Researches in Acoustics and was at one time a member of the editorial staff; several contributions to the Scientific American Supplement; in; The Earth a Great Magnet (1872); 'Light' (1877); and 'Sound' (1878). Consult Science (issue of 20 Aug. 1897).

MAYER, Brantz, American author: b. Baltimore, 27 Sept. 1809; d. there, 21 March 1879. He was educated at Saint Mary's College, Baltimore, studied law by himself during an Oriental voyage in 1827-28 and then at the University of Maryland; was admitted to the bar in 1829; and after a year in Mexico as secretary of legation wrote 'Mexico as it Was, and as it Is' (1844). In the same year he founded the Maryland Historical Society. In the Civil War he sympathized with the Union was president of the Union State General Committee, and from 1863 to 1871 was a member in the United States army. His best book was 'Captain Canot,' a story of the slave trade founded on fact. He wrote also 'Mexico, Aztec, Spanish, and Republican' (1851); Observations of Mexican History and Archaeology (1856); 'Mexican Antiquities' (1858); Memoir of Jared Sparks' (1867); and 'Baltimore as it Was, and as it Is' (1871).

MAYER, Constant, American artist: b. Besançon, France, 4 Oct. 1832; d. 1901. A student at the School of Fine Arts in Paris, he left his studies in 1857 and settled in New York where his sketches and portraits won immediate success. His portraits of Grant and Sherman and his life-sized genre paintings, such as 'Maud Müller'; 'The Song of the Shirt'; 'Evangeline,' gained favor. From 1866 he was an associate of the National Academy of Design and exhibited frequently at the Salon.
MAYER, Frank Blackwell, American artist, brother of Alfred Marshall Mayer (q.v.) and nephew of Brantz Mayer (q.v.): b. Baltimore, 27 Dec. 1827; d. 1908. He studied art there under A. J. Müller, and under Gleyre and Brion in Paris and then settled in Annapolis. He made a special study of Dakota Indian types and contributed to Harper's and Century various articles with his own illustrations; and exhibited in the Paris Salon and at the Centennial Exhibition of 1876, where he received a medal for two pictures, 'The Continents' and 'Attic Philosopher'. Among his other canvases are 'Feast of Mondawmin'; 'The King's Fool'; 'The Trappist'; 'Maryland in 1750'; 'Crowning a Troubadour'; 'The Treaty of Traverse des Sioux'; 'Minnesota' (1886); 'The Washington Cockade'; 'Founders of the Baltimore and Ohio Railroad' (1891); and 'The Burning of the Peggy Stuart'.

MAYER, Henry, American caricaturist: b. Worksop, England, 18 July 1868. Educated in Germany and England, he at first followed a business career in the latter country, but emigrating to the United States in 1887 soon won for himself a distinct place as caricaturist, by his designs and illustrations for American and European papers. Since 1893 he has resided in New York. His works are 'Autobiography of a Monkey' (1896); 'In Laughland' (1899); 'Fantasies in Ha-Ha' (1899); 'A Trip to Toyland' (1900); 'Adventures of a Japanese Doll' (1901); 'Alphabet of Little People' (1901). He is the creator of 'Impressions of the Passing Show' for 10 years in the New York Times. He received a personal gift of two cloissonné vases with imperial crest from the late Mikado for his cartoons during the Russo-Japanese War. He is editor of Puck since 1914.

MAYER, mîtér, Julius Robert von, German physicist: b. Heilbronn, Württemberg, 25 Nov. 1814; d. there, 20 March 1878. He was educated at the gymnasiurn in Heilbronn, studied medicine at Tübingen and finished his university studies at Munich and Paris. In 1837 he went to Java as a ship's surgeon, and while there turned his attention to studies of the blood, extending his work to exhaustive investigations of animal heat, to which he applied the mechanical theory. Returning in 1841 to Heilbronn, where for some years he practised his profession, he became deeply engrossed with his scientific labors, and in 1842 published in Liebig's Annalen der Chemie und Pharmacie a preliminary statement of his revolutionary theory of heat, together with his views on the conservation and correlation of energy. Three years later he restated his results in 'Die organische Bewegung in ihrem Zusammenhange mit dem Stoffwechsel', at the same time giving a forecast of his theory of the meteoric origin of the sun's heat. Contemporaneously with Mayer the mechanical theory of heat was worked out independently by J. P. Joule (q.v.) in England, and a controversy arose regarding the priority of discovery. The Royal Society gave Mayer the Copley medal in 1871, and two years later his coffin was placed on the king's throne at Württemberg. His collected works appeared in 1867 under the title 'Die Mechanik der Wärme' (3d ed., by J. S. Weyrauch 1893). Consult Weyrauch, 'Robert Mayer' (Stuttgart 1890); id., 'Kleine Schriften und Briefe von Robert Mayer' (Stuttgart 1893); Gross, 'Robert Mayer and Hermann von Helmholtz' (Berlin 1898); Jeutzh, E., 'Julius Robert Mayer; seine Krankheitgeschichte und die Geschichte seiner Entdeckung' (Berlin 1914).

MAYFAIR, London, England, a fashionable neighborhood in the West End adjoined Belgravia, east of Hyde Park, and bounded by Park lane and Bond street. See LONDON.

MAYFIELD, Ky., city, county-seat of Graves County, on the Illinois Central Railroad, about 30 miles from the Mississippi River and 25 miles from the Ohio at the mouth of the Tennessee. It was settled about 1820 and incorporated in 1850. It is in a fertile agricultural region in which the chief product is tobacco and in which the city has extensive interests. Mayfield has large tobacco warehouses and factories, clothing factories, woolen mills, fire-clay works, flour and lumber mills. It has an extensive trade in tobacco. The mayor is elected once in four years; the council acts upon the appointments of the executive. Pop. 5,916.

MAYFIELD, Pa., borough of Lackawanna County, 15 miles northeast of Scranton, on the New York, Ontario and Western and the Delaware and Hudson railroads. It has extensive interests in coal, the mining of which is the leading industry. There is also a silk mill. Pop. 3,660.

MAYFLOWER, The, the name of the vessel in which the Pilgrim Fathers, or first colonists in New England, sailed to this country in 1620. The Mayflower was a vessel of 180 tons. She set sail from Southampton, England, on 5 Aug. 1620, in company with her sister ship, the Speedwell, but the courage of the captain and the crew of the latter vessel failing, both ships put back to port. Finally on 6/17 September the Mayflower again spread her sails from Plymouth, having on board as passengers 41 men and their families, 102 persons in all. They succeeded in crossing the Atlantic after a stormy voyage of 63 days. They intended to go to the mouth of the Hudson River but the captain of the Mayflower took them to Cape Cod. They landed at Plymouth, Mass., at a point where Plymouth Rock, a huge granite boulder, stands at the water's edge. A complete and authentic list of the male passengers who landed from the Mayflower is as follows:

The Mayflower Passengers:

Alston, Isaac
Allen, John
Allerton, John
Ballington, John
Bradford, Wm.
Brewster, Wm.
Brittenage, Richard
Brown, Peter
Carr, John
Chilton, James
Clarke, Richard
Cook, Francis
Crackston, John
Dyer, Edward
Eaton, Francis
English, Thos.
Petcher, Moses
Puller, Edward
Puller, Samuel
Gardiner, Richard
Goode, John

Vol. 18—30
With these 41 male passengers and heads of families came 15 male servants, whose names were as follows:

**SERVANTS ON THE MAYFLOWER.**

Carter, Langemore, Sampson,
Coper, Latham, Story,
Bay, Minter, Thompson,
Holbeck, Moore, Trevore,
Hook, Prower, Wilder.

The following is a copy of the covenant agreed upon by these first settlers of Massachusetts, signed and subscribed on board the *Mayflower* at Cape Cod, 10/21 Nov. 1620, two days after the ship came to anchor.

**THE MAYFLOWER COMPACT.**

In the name of God Amen! We whose names are underwritten, the loyal subjects of our dread sovereign Lord, King James, by the grace of God, of Great Britain, France and Ireland, King, Defender of the Faith, etc., have undertaken for the glory of God and the advancement of the Christian faith and for the glory of our King and Country to undertake,奋斗 to plant the first colony in the northern parts of Virginia; do by these presents, alienate and mutually, in the presence of God and of one another covenant and combine ourselves together into a civil body politic, by the name of The Virginia Company of London, and by virtue hereof to enact, constitute and frame just and equal laws, ordinances, acts, constitutions and offices, from time to time, as shall be thought requisite and convenient for the general good of the colony; and we promise all due submission and obedience. In witness whereof we have hereunto subscribed our names, at Cape Cod, the 11th of November, in the year of our Lord one thousand six hundred and twenty. Anno Domini 1620.

**MAYFLOWER DESCENDANTS, SOCIETY OF,** an American patriotic society founded in New York City, 22 Dec. 1894. Its membership is limited to lineal descendants of passengers on the *Mayflower*, the voyage of which terminated at Plymouth Rock, Mass., in November 1620. There are also numerous State societies of a similar character. There are more than 2,000 members of the society.

**MAYHEM, mā'hēm,** 1. Guilt, criminality, the destroying or disabling of an arm, leg, hand or foot, putting out an eye, etc. Mayhem renders the perpetrator liable to a civil action for damages, and also to a criminal prosecution.

**MAYHEW, Henry,** English journalist and author: b. London, 25 Nov. 1812; d. 25 July 1857. In 1831 he started, with Gilbert A'Beckett, a periodical called *Figaro* in London; in 1841 produced, with A'Beckett, the farce of the 'Wondering Minstrel'; and not long after formed a literary partnership with his brother Augustus, the *Brothers Mayhew,* as they came to be familiarly known. Among a number of most successful works of amusing fiction. Among these may be mentioned 'The Greatest Plague of Life, or the Adventures of a Lady in Search of a Good Servant' (1847); 'The Image of His Father, or One Boy is More Trouble than a Dozen Girls' (1850); 'Loving for Appearance' (1855). In 1851 appeared the first volume of his most important work, 'London Labor and the London Poor.' He was one of the founders of *Punch* (1841) and its first editor. Other works of his are 'The Wonders of Science, or Young Humphry Davy'; 'Young Benjamin Franklin'; 'The Boyhood of Martin Luther'; 'German Life and Manners, as Seen in Saxony at the Present Day'; 'The Criminal Prisons of London and Scenes of Prison Life' with Binny. His brothers Horace, Thomas and Edward also assisted Henry and Augustus in their enterprises, besides publishing independently.

**MAYHEW, Jonathan,** American clergyman: b. Martha's Vineyard, Mass., 8 Oct. 1735; d. Boston, 9 July 1766. He entered Harvard in 1744, and from 1747 until his death was minister of the West Church in Boston. In a day of theological controversy he was prominent for his tracts. His views were so liberal as to cause him to be expelled from the Boston Association of Congregational Ministers. He opposed the measures of the British society for the propagation of the Gospel in foreign parts, and got into a dispute about it with Secker, archbishop of Canterbury. In both pulpits he press he was an earnest partaker of the measures of the Church of England. He was the author of 'Discourse concerning Unlimited Submission and Non-Resistance to the Higher Powers' (1753), and 'Sermons and Discourses.' He was the 'Memoir' by Bradford (Boston 1838); Tyler, 'History of American Literature.'

**MAYHEW, Thomas,** American colonial governor: b. England, 1592; d. Martha's Vineyard, Mass., 25 March 1682. Prior to his emigration to New England in 1651 he had been a merchant in Southampton and settled first at Watertown, Mass., and in 1641 secured from the agent of Lord Stirling a grant of the larger part of the island of Martha's Vineyard and the title of governor. With his son Thomas he labored to convert the Indians of the island so successfully that during King Philip's War the island Indians protected the white settlers. He founded Edgartown in 1647, and after the death of his son and grandson continued their ministry and organized an Indian church. Consult Banks, C. E., *History of Martha's Vineyard* (Boston 1911).

**MAYNARD, mā'nard,** Charles Johnson, American naturalist: b. West Newton, Mass., 6 May 1845. He had a common school education, worked on a farm and devoted himself to natural history in his spare time. As an ornithologist, discovered the bittern's vocal organs and in 1875 was elected vice-president of the Nuttall Ornithological Club, in connec-

**MAYNARD, Edward**, American inventor:
b. Madison, N. J., 26 April 1813; d. Washington, D. C., 4 May 1891. He entered West Point in 1831; resigned because of ill-health in 1832; studied dentistry and practised in Washington from 1836 to 1890. He invented new dental tools, discovered in 1846 the diversity of the maxillary antra, introduced the method of filling cavities with gold foil, taught dentistry in the Baltimore College of Dental Surgery and in the Massachusetts University at Washington, and practised successfully in Europe. His great fame was due to his invention of small arms and new priming methods which superseded percussion caps. He patented a breech-loading rifle in 1851; a method of converting muzzle-loaders to breech-loaders in 1860; a plan to join two barrels so that contraction and expansion in either would be independent of the other, in 1868, and in 1886 a registering device showing the number of cartridges in a magazine rifle. His rifle was adopted by the United States, and brought him decorations from the governments of Belgium, Prussia and Sweden.

**MAYNARD, George Willoughby**, American artist: b. Washington, D. C., 5 March 1843. He studied at the New York Academy of Design and later became a pupil of Van Terins and De Keyser at the Belgian Royal Academy, Antwerp. He had a studio in Paris in 1878, but later located in New York. He is a National Academician and librarian of the National Academy of Design, member of the Society of American Artists, the American Water Color Society and ex-president and honorary member of the Salmagundi Club. Maynard's decorative work may be seen in the Congressional Library, Washington, D. C., the Bijou Theatre, Boston, the ceilings of the Metropolitan Opera House, New York, the Essex County Courthouse, Newark, N. J., and the Appellate Court, New York. His principal canvases are *Vespers at Antwerp* (1876); *Vendome Court, Courtenay*; *Fine Art* (1894); *Strange Gods* (1904); *Old and Rare*; *Grandfatherly Advice*; *A Musician*; *Rocks at Ogunquit* (1912); *Flood Tide* (1912). He is represented in the Metropolitan Museum, New York, the Providence Museum, the Corcoran Gallery, Washington, and the Pennsylvania Academy.

**MAYNARD, Horace**, American politician:
b. Westboro, Mass., 30 Aug. 1815; d. Knoxville, Tenn., 3 May 1882. He was graduated from Amherst College in 1838; and became instructor, and later professor, in East Tennessee College, Knoxville, Tenn. He studied law, was admitted to the bar in 1844 and built up a successful practice. In 1857 he was nominated for member of Congress by the Know-Nothing party, and elected. On the outbreak of the Civil War he declared his loyalty to the Union and took an active part in the unsuccessful attempt to keep Tennessee from seceding; on this account he suffered persecution and heavy loss of property during the war. When the Union forces occupied his State in 1864 he was made attorney-general. In 1866-75 he was again member of Congress, being representative-at-large for his State in the last two years. In 1875-80 he was appointed Minister to Turkey, and in 1880 Postmaster-General in President Hayes' Cabinet, holding the office till 4 March 1881.

**MAYNARD, Mass., town of Middlesex County, 25 miles northwest of Boston, on the Boston and Maine Railroad and the Assabet River. It contains woolen mills. The town owns the water-supply system. Pop. 6,390.**

**MAYNOOT, mä-noot', Ireland, a market-town of County Kildare, 15 miles west by north of Dublin. Its modern celebrity is derived from the well-known Roman Catholic college of Saint Patrick (q.v.). Maynooth is of historic interest as the seat of the powerful Geraldines, and has ruins of their castle, built 1176 and enlarged in 1426. Several battles with the English occurred here, including the rebellion of Silken Thomas in the reign of Henry VIII, and the war of the Confederates (1641-50). Pop. about 886.**

**MAYNOOTH COLLEGE.** See SAINT PATRICK'S COLLEGE.

**MAYO, ma-ö, Amory Dwight**, American Unitarian clergyman and educator: b. Westwick, Franklin County, Mass., 31 Jan. 1823; d. 8 April 1907. He was graduated from Amherst, and taught in the public schools in Massachusetts 1839-44. In 1846 he became the minister of the Universalist Church at Winchester, Mass., and later held Universalist pastorates at Cleveland, Ohio (1854-56), and at Albany, N. Y. (1856-63). He then entered the Unitarian ministry, and was pastor at Cincinnati, Ohio (1863-72), and at Springfield, Mass. (1872-80). He was long prominent as an educator, was an efficient and active member of the boards of education, in Cincinnati and Springfield, and was connected with the Meadville (Pa.) Theological School as lecturer and professor from 1868-98. After 1880 he devoted his attention chiefly to the advancement of education in the South, lecturing frequently in many different States. He was the chief editorial writer for the *New England and National Journal of Education*, and published *The Moral Argument for Universalism*; *Graces and Conditions of the Christiant Life* (1852); *Biography and Collected Writings of Mrs. S. C. E. Mayo*; *Symbols of the Capitol, of Civilization in New York* (1859); *Talks with Teachers* (1885); *Southern Woman in the Recent Educational Move-

---

The document contains biographical information about several people, including Edward Maynard, George Willoughby Maynard, Horace Maynard, and Amory Dwight Mayo. It also mentions various inventions, artistic works, and educational institutions. The text is structured in a way that each individual's life and achievements are highlighted, providing a comprehensive overview of their contributions.
ment in the South' (1892), and 'History of the American Common School.'

MAYO, Charles Horace. American surgeon; b. Rochester, Minn., 19 July 1865. He was educated at the Rochester High School, Northwestern University, and in 1888 was graduated in medicine at the Chicago Medical College. In the same year he entered on the practice of medicine at Rochester, where he has since resided. He has received the following honorary degrees: A.M., Northwestern University, 1902; LL.D., University of Maryland, 1909; F.A.C.S., American College of Surgeons, 1913; LL.D., Kenyon College, 1916; D.Sc., Princeton University, 1917. Dr. Mayo is surgeon to the Mayo Clinic of Saint Mary's Hospital, Rochester, Minn.; to the Mayo Foundation, University of Minnesota, where he has been professor of surgery since 1915. In 1913 he was commissioned first lieutenant in the Medical Reserve Corps, United States Army; was appointed major in 1917, and colonel in the same corps in 1918. In the same year he was made associate chief professor of the United States Army Medical Department for Surgical Services. He is also consulting surgeon of the Chicago and Northwestern Railway and of the Chicago Great Western Railway. Dr. Mayo is a member of the American Medical Association, of which he was president in 1916-17 and chairman of the section on surgery in 1910; of the American Surgical Association; of the Association of Military Surgeons of the United States; of the Clinical Congress of the American College of Surgeons (president in 1914-15); of the Minnesota State Medical Society, of which he was president in 1905; of the Society of Clinical Surgeons; of the Southern Surgical and Gynecological Society; of the Western Surgical and Gynecological Society, of which he was president in 1904-05; of the Council of National Defense Medical Board; of the National Medical Museum; of the Minnesota Pathological Society; of the American Association of Railway Surgeons; of the American Association for the Advancement of Science; etc.; etc. In 1908-09 he was president of the section on surgery of the International Congress on Tuberculosis. In 1915, with his brother, W. J. Mayo, LL.D., he donated $1,500,000 to establish the Mayo Foundation for Medical Education and Research at Rochester, in affiliation with the University of Minnesota.

MAYO, Frank. American actor; b. Boston, 19 April 1839; d. 8 June 1896. His first appearance on the stage was at the American Theatre in San Francisco, and he was for several years the leading actor on the Pacific coast. In August 1865 he appeared in Boston as Badger in 'The Streets of New York' with great success, and though he played Shakespearean and other rôles acceptably, notably Othello, Hamlet and Ferdinand, became best known in his character of Davy Crockett, first played by him in Rochester, N.Y., in 1872, and thereafter almost exclusively by him till 1884. In later years he played in his own drama, 'Nordeck' and in a stage version of 'Pudd'nhead Wilson.'

MAYO, Henry Thomas. American naval officer; b. Burlington, Vt., 8 Dec. 1856. In 1876 he was graduated at the United States Naval Academy; was advanced through various grades and promoted rear-admiral 15 June 1913. In 1915 he was made vice-admiral and in 1917 was promoted admiral. He served on various vessels of the United States navy, also on both naval and coast survey; was commandant of the Mare Island navy yard in 1911-13; served as aide for personnel at the Navy Department, Washington, in 1913, and in that year was made commandant of the fourth division of the Atlantic fleet. In 1915 he commanded the battleship squadrons of the Atlantic fleet and two years later became command-in-chief of that fleet and hoisted his flag on the Pennsylvania. Admiral Mayo demanded an apology from the Mexican commander at Tampico and the firing of a national salute of 21 guns to the United States flag, to make amends for arrest of paymaster and crew of the dispatch boat 'Dolphin.' He was a member of the Michigan. University, 1889; LL.D., University of Toronto (1906), University of Maryland (1907), University of Pennsylvania (1912); D.Sc., University of Michigan (1908) and Columbia University (1911). He is a fellow of the Royal College of Surgeons of England since 1912, of Scotland since 1905 and of the American College of Surgeons since 1913. He is widely known for his numerous successful operations in cases of gallstones, cancer and diseases of the intestinal tract.

MAYO, William Starbuck. American novelist; b. Ogdensburg, N.Y., 20 April 1812; d. New York, 22 Nov. 1895. His parents had removed to Ogdensburg in the year of his birth. He studied in his native place and in Potsdam Academy and in 1833 was graduated at the College of Physicians and Surgeons, New York. After practising his profession for several years in Ogdenburs he was forced to abandon it owing to ill health. He visited Spain, made a tour in the Barbary States and
then took up his residence in New York City, where he gave his entire attention to literature. He is the author of 'Flood and Field, or Tales of Krooladak and Land' (1844); 'Kaloedah or Journeys to the Djebel Kumri,' purporting to be the autobiography of Jonathan Romer and describing his marvelous adventures in Africa (1849); 'The Berber, or the Mountain of the Atlas,' similar to the preceding (1850); 'Rouches Dust from the Historie Places,' a collection of short tales, founded on historical incidents (1851); 'Never Again,' a novel (1872).

MAYO, mō'ō, a tribe of Mexican Indians of the Piman family, located on the banks of the Mayo River in southern Sonora. Their allies and northern neighbors are the Yaquis and their habits and language, the latter known as Cahita, are almost identical. They are a peaceful, agricultural people and are thoroughly Mexicanized. They number perhaps 6,000.

MAYO-SMITH, mā'ō-smith', Richmond, American political economist; b. Troy, Ohio, 9 Feb. 1854; d. New York City, 11 Nov. 1901. He was graduated from Amherst College in 1876; graduated from the universities of Berlin and Heidelberg. From 1877 he was connected with Columbia University, first as assistant in history and political science, then as adjunct professor (1878-83) and professor of political economy and social science (1883-1901). He was also one of the faculty of the graduate School of Political Science, established in 1880, and his chief work as teacher was done in this school. His specialty was statistics, on which he was a recognized authority. He was an honorary Fellow of the Royal Statistical Society of Great Britain, a member of the International Statistical Institution and of the American Statistical Association, being vice-president of the latter; he was also a member of the National Academy of Sciences and of the American Economic Association, of which he was one of the founders. He was editor of the Political Science Quarterly from 1886, and published 'Emigration and Immigration' (1890); 'Statistics and Sociology' (1895); and 'Statistics and Economics' (1899).

MAYON, mā-yō'n, a volcano of the Philippines situated in the northern part of the province of Albay, Luzon, height, 8,274 feet. It rises from a broad plain about six miles from Albay Gulf and forms a perfect cone; its summit is surrounded by vapor, which at night has a fiery glow. Its sides, almost at the top, are covered with grass or moss, and the ascent, though it has been made, is difficult. Near the summit there are fissures which emit sulphurous gases and steam, and there were several eruptions during the 19th century, the town of Cagsaua at the foot of the mountain being entirely destroyed in 1814. Great quantities of lava and ashes were belched forth in the last eruption (1897).

MAYONNAISE, mā-ōn'āz', a thick cold dressing for salads, cold meat, poultry, fish, vegetables, etc., made of the yolks of eggs, salad oil and vinegar, with a little salt and pepper; it is sometimes colored red with powdered lobster shell or green with spinach or parsley.

MAYOR. See Cities, American, Government of; City Manager Plan of Government; Executive.

MAYOR OF ZALAMEA, The ('El Alcalde de Zalamea'). Two Spanish plays bear this title, the first by Lope de Vega (1562-1635), the second, an adaptation, by Calderón de la Barca (1600-81). The superiority of the adaptation over the original is admitted by all critics. A comparison of the two works is somewhat unfair to Lope de Vega, because his play is one of his least worthy at the last degree. He reveals, indeed, his characteristic spontaneity, but fails to seize resolutely upon the dramatic possibilities of his story, preferring for some reason to narrate events in their chronological sequence. Calderón studies the dramatic situations more carefully and by discarding irrelevancies, reducing the number of personages and sharpening the features of those retained, produces a masterpiece. To his predecessor he owes his plot, the dramatic conflict, the principal personages and a few touches, Lope's transfers to his play unaltered. The most striking difference between the two pieces is the character of Isabella, daughter of the mayor (or magistrate). In Lope's play there are two daughters, both flirtatious to the last degree. So little control has the father over them, that when he is appointed magistrate, he asks pathetically, 'How can a father who fails to rule at home, govern a town?' The fate of the daughters at the hands of dissolute soldiers does not surprise the spectator, and the penalty of death imposed upon the seducers hardly seems justified. Calderón corrects this defect, and in Isabella, who replaces Leonora and Agnes, he presents a modest young woman, the unhappy victim of a crime which she strives in vain to prevent. Her soliloquy after she has been wronged is pathetic and poignant, and is one of the best passages in the play (Act II, scene i). Among other excellent scenes may be noted the magistrate's farewell to his daughter, in which shrewd advice and good feeling are happily blended (Act II, scene xxi), and the prolonged struggle between the magistrate and the gouty, blustering, irascible, old soldier, Lope de Figueroa (Act III, scene xv). King Philip II, who appears suddenly at the close of the play, sets his seal of approval upon the action of the father-magistrate in avenging the wrong done to his daughter and thus vindicates the triumph of justice and local autonomy (a precious privilege to Spaniards) over the lawlessness of undisciplined soldiery. The events narrated by the two dramatists are so circumstantial that it is assumed that they are based on a real incident in the march of Philip II into Portugal (1580), when the Tecio de Flandes, a famous regiment commanded by Lope de Figueroa, passed through Zalamea, a small town in Estremadura. Krenkel published both plays with valuable notes in 'Klassische Bühnendichtungen der Spanier' (Vol. III, Leipzig 1887). Consult also Meméndez y Pelayo's edition in 'Obras de Lope de Vega' (Vol. XII, 1902), and 'Select Plays of Calderón' (ed. MacColl, London and New York 1888).

MAYORUNA, South American Indian tribe of Panoan stock. Their country lies south of the Marañon and between the Ucayali and

MILTON A. BUCHANAN.
Javari rivers, in eastern Peru. They are nomadic, are tall and well formed, go entirely naked and live by hunting. The hair is cut away from the forehead but is allowed to fall down the back. Some have fair skin and beard attributed with some degree of probability to an admixture of white blood through Spanish contact. They fight a constant war with the whites and with other Indian tribes. Spears, clubs and blowpipes are their war weapons. The blowpipe, from which a poisoned dart is thrown a considerable distance, is their most formidable and dangerous weapons.

MAYOTTA, mā-yōt'tä, or MAYOTTE, mā-yōt'. See COMORO ISLANDS.

MAYOW, mā'ō, or MAYO, John, English physiologist and chemist, the first to attack the theory of phlogiston: b. London, May 1643; d. there, October 1679. He was of a Cornish family; entered Wadham College, Oxford, in 1658; became a scholar there in 1659; and was elected a fellow of all Souls in 1660. He was graduated in 1665; studied medicine; practised in Bath; and in 1678 was elected to the Royal Society. His Latin tract on the respiration appeared in 1668; it urged that the heart was a mere muscle, that breathing is simply to give the nitroaerian constituent (oxygen) to the blood and that this constituent is necessary to life. In 1674 he published 'Tractatus Quinque,' summarizing and completing his theory; in this work he showed that 'fire-air,' 'fire-oxygen,' or 'eart air,' as he styled oxygen, is contained in all acids and is necessary to combustion and respiration, which are therefore analogous. The 'Tractatus Quinque' was republished in 1681 as 'Opera Omnia Medica Physica.' In 1684 a Dutch translation appeared; in 1799 a German, and French and English translations in 1840 and 1907, respectively.

MAYOYOAS, mā-yō-yā'ōs, a native tribe of the island of Luzon, Philippines, living in the southwestern part of the province of Isabela and in the northwestern angle of the province of Nueva Vizcaya. They are a head-hunting tribe of Malay race; and of the Ifugao linguistic stock.

MAYSVILLE, māz'vıl, Ky., city and county-seat of Mason County, on the Ohio River and on the Louisville and Nashville and the Chesapeake and Ohio railroads, about 63 miles southeast of Cincinnati. The first settlement was made about 1782, and in 1787 it was incorporated by the legislature of Virginia. In 1833 it was granted a city charter and in 1848 became the county-seat. It is in a rich agricultural region and its facilities for transportation give it considerable commercial importance. Its chief manufacturing establishments are flour and lumber mills, foundries, distilleries, cotton mills, plow and pulley works, boot and shoe factories, tobacco, furniture and pressed brick. Some of the prominent buildings are the Masonic Temple, the Odd Fellows' Temple, the Methodist Church, the Hospital, the County Historical Association Building and the Maysville and Mason County Public Library. The library organization was established in 1878. The government of the city is vested in a mayor, who holds office four years, and a council. Pop. 6,141.

MAYWOOD, Ill., village in Cook County, 10 miles west of Chicago, situated on the Des Plaines River and on the Chicago Great Western, the Chicago and Northwestern and other railroads. It is the seat of the Chicago Theological Seminary, the German Lutheran Theological Seminary, the Logen Home, the Baptist Home, the Smith Home for Crippled Children and Library Hall. Maywood's industrial establishments manufacture tin plate, cans, etc., and lithograph products. The village owns the water-supply system. Pop. 9,780.

MAZARIN, Jules, or GIULIO MAZARIN, French cardinal and minister of Louis XIII, Anne of Austria and Louis XIV: b. Piacenza, in the Abruzzi, Italy, 14 July 1602; d. Vincennes, 9 March 1661. He came of a Sicilian family, his father being intendant of Philip Colonna. The first part of his life was spent in reaching out for power and the second part in maintaining that power. Young Mazarin first attempted fortune in a military career. After brilliant studies under the direction of the Jesuits at Rome and afterward at the universities of Alcalá and Madrid, he entered the papal military service as an infantryman in 1625. His talents, however, lay in diplomacy to which he soon turned and wherein he distinguished himself by his ability. He was rewarded for his services by being made viceregent to Avignon, in 1634, and as such at Paris, in 1634–36. At Paris he gained the favor of Richelieu, who persuaded him to enter the service of France, which he did in 1640. He became a naturalized citizen of France; was made a cardinal (although not a priest) in recognition of his diplomatic services in Savoy; and in 1642 was designated by Richelieu as his successor. On the death of Louis XIII the queen, Anne of Austria, became regent for her young son, Louis XIV, and it was thought that Mazarin would be dismissed, but instead he gained over the queen-regent, to whom he became bound by mutual ties of affection, and perhaps by a secret marriage. By her he was confirmed in the office of Prime Minister, in May 1643, and this office he continued to occupy, with the exception of two brief periods of exile, until his death. His activities were first directed toward theCabale des Importants, which he so suppressed, and to the prosecution of the Thirty Years' War. The war was carried on with success due mostly to the soldiery qualities and ability of Turenne and Condé. The victories of Rocroi, Fribourg, Nordlingen and Lens and the revolt at Naples forced the German emperor to terms and obliged him to cede Alsace to France by the Treaty of Westphalia, in 1648. While prosecuting these enterprises abroad, Mazarin had unfortunately neglected home affairs and financial embarrassments resulted in a general revolt and civil war known to history as the Fronde. The Parliament of Paris denounced the increasing taxation, while the nobility dreaded the supremacy of Mazarin. At the Hôtel de Hospitalet, County Historical Association Building and the Maysville and Mason County Public Library. The library organization was established in 1878. The government of the city is vested in a mayor, who holds office four years, and a council. Pop. 6,141.
particular from Condé, who had hitherto remained faithful to the royal authority. With the support of the parliamentarians, Mazarin was enabled to put down the Fronde des princes, imprisoned Condé at Vincennes and crushed the revolt of the latter's friends at Rethel and Guyenne, in 1659. Mazarin's ingratitude to his old allies, boded ill for the future. All his adversaries unite to against him and in February 1651 he was obliged to go into exile near Cologne. His activity, however, was nowise at an end. He continued to direct the policy of Ang, and when in 1653, he was exiled, Mazarin resumed the direction of affairs. In September, he re-entered the court at Poitiers, and soon afterward was about to enter Paris with it when he saw that his presence was an obstacle to the young king's entry to the capital. He again went into exile, in October 1652, but returned to Paris on 13 Feb. 1653, and through means of intrigue formed a powerful royal party in the state, gained General Turenne to his cause and returned to his position at court. Untroubled now with troubles from within, Mazarin set about winding up the war with Spain. The outcome of this conflict remained in doubt until 1655, when French victory became assured through the alliance with Cromwell and the help of English soldiers. The Spanish king, threatened in the Netherlands and menaced at home by the capture of Barcelona, were obliged to sue for peace. By the Treaty of the Pyrenees (1659) the Spaniards lost to France Roussillon, Artois and parts of the duchy of Luxembourg and of Hainaut. Not satisfied with this splendid result, Mazarin formed, in 1658, the League of the Rhine against Austria and diverted the succession to the throne of Spain by bringing about the marriage of Louis XIV with the Infanta Maria Theresa. With the completion of these projects his career ended. Mazarin was very avaricious, and through every kind of financial dealing amassed the huge fortune of over 50,000,000 livres. To the Royal Library he bequeathed his magnificent collection of books. He founded the Collège de Quatre-Nations, later known by his name as the Collège Mazarin. He has been blamed for the favors shown his family and the project, once entertained by him, of marrying his daughter Marie Mancini, by his son-in-law Louis XIV. These, however, are but the smaller side of a great character. They cannot make one forget the great political genius who extended the territories of France from the Pyrenees to the Rhine and which he dedicated from a dangerous external crisis. Consult Chérue, 'Lettres du cardinal Mazarin pendant son ministère' (in 'Collection de documents inédits sur l'histoire de France,' Paris 1872-94); id., 'Histoire de l'ambassade de Louis XIV' (1879-80); id., 'Histoire de France sous le ministère de Mazarin' (1883); Chantelauze, 'Portraits historiques' (1886); Cousin, V., 'La jeunesse de Mazarin' (1865); Hassell, A., 'Mazarin' (1903); Perkins, J. B., 'France under Mazarin' (New York 1915).

MAZARRÓN, Spain, town, in the province of Murcia, 18 miles west of Cartagena and about three miles from the Mediterranean coast, with which it is connected by rail. It has flouring mills, soap works and metallurgical factories, and there are copper, iron and lead mines in the nearby mountains. A custom-house, barracks, lighthouse and lead works are situated on the coast. The town has a large trade in coal, lead and other ores. Pop. 22,660.

MAZATLAN, má-sát-lán', Mexico, a town and seaport of Sinaloa, about 183 miles southeast of the city of Sinaloa, at the entrance to the Gulf of California, on the Mexican Southern Pacific Railroad. It is built on a hilly crest and has a pleasing appearance. It has a municipal gas system and a street railway. Mazatlan is the chief Pacific port of Mexico and the outlet for the products of the mining district of Saint Sebastian; it has a considerable import and export trade. Silver, copper, lead, pearls and hides are exported. In 1914, the town was besieged by the Constitutionalists and taken after many months. A consul of the United States is located here. In normal times the exports amount annually to about $4,250,000 and the imports to $2,500,000.

MAZDAK, máz dák, Persian religious leader: b. Persepolis, about 470 A.D.; d. Nahrawan, between 530 and 540. He was a chief priest at Nishapur, and in 500 proclaimed himself a prophet. He preached the equality of man, the abolition of property rights and from love, abstinence from animal foods, the simple life generally. He converted King Kobad to his views, which forthwith became law, but a rising of the nobles ousted Kobad for three years, and on his return he abjured Mazdak and his doctrine. Khsru Nasarvan put him to death. Consult Browne, E. G., 'Literary History of Persia' (London 1909).

MAZE, Hippolyte, é-pó-lét máz', French historian: b. Arras, 5 Nov. 1839; d. Paris, 25 Oct. 1891. He studied at the École Normale Supérieure; taught there and at the Lycée Impérial; was elected prefect of Landes in 1870, deputy in 1879 and 1881 and senator in 1888. He wrote 'The Republic of the United States: Its Foundation' (1869); 'The End of the Revolution' (1872); 'Hoch in Vendée' (1882); 'The Struggle Against Want' (1883); 'The General Marceau' (1889), and 'The Generals of the Republic' (1889).

MAZEPPA, má-zép pá, Ivan Stepanovitch, or John, hetman of the Cossacks: b. Podolia, about 1645; d. Bender, Bessarabia, 1710. He was page to John Casimir, king of Poland, who was a patron of the arts and literature, and he had therefore an opportunity of acquiring various useful accomplishments. A Polish nobleman having surprised Mazepa with his wife bound him naked upon his own horse and committed him to his fate. The horse carried him to his own residence. Shame made him flee to the Ukraine and join the Cossacks, whose warlike roving life suited his disposition. He made himself conspicuous by his dexterity, bodily strength and courage. His knowledge and sagacity procured him the post of secretary to the hetman Samilovitch, and in 1699 he overthrew Samilovitch and himself became hetman. He gained the confidence of Peter the Great, who loaded him with honors and he was finally made Prince of Poland. In 1706 he opened negotiations with Charles XII (q.v.) of Sweden for the purpose of freeing himself from Russian dominion, but his treachery was finally revealed to Peter, and he was obliged openly to declare for Charles. After the defeat of Pultowa in 1709 Mazepa
fled to Bender. Peter tried to have the sultan extradite him, but failed despite an offer of 300,000 ducats for the favor. Lord Byron has made Mazeppa the hero of a poem (1818) and Liszt of a symphony.

MAZURKA, a lively Polish national dance, popular also in the United States. The movements are of a grotesque character. The term is applied to the music which accompanies the dance, sometimes in three-eighths time, but for the most part in three-fourths. The Mazurka is danced by four or eight couples. Augustus III brought the mazurka to Germany, whence it was learned by the French and finally about the middle of the 19th century it acquired considerable popularity in England. The music of the dance has taken its modern form from Chopin.

MAZZINI, Giuseppe, Italian patriot: b. Genoa, 22 June 1805; d. Pisa, 10 March 1872. He studied law at the University of Genoa and practiced it for a time, but the strong Liberal opinions he had imbibed as a child and his conviction that the oppressed condition of his country under Austrian rule called for men of action and public spirit, and that a noble course lay open before anyone who would give himself up to the useful task of the work of reforming her, led him to devote himself to a political career. In his ardent aspirations for the national unity of Italy, it seemed to him that her deliverance from foreign tyranny was to be achieved only by a return to the republican glories of ancient times. His patriotic enthusiasm in this direction was fostered by his early studies, which developed in him a passionate interest in the glories of a republic, and by the successes which he had achieved in literature while still little more than a youth. In 1827 appeared his maiden essay, 'Dell' Amor Patrio di Dante,' which was published in a Liberal journal, the Subalpino. This led him to contribute under the mask of literary critics other historical, philosophical, and critical papers to the Antologia of Florence and the Indicatore Genovese. But the authorities, perceiving that the periodical literature of Italy was becoming far too strongly tainted with advanced Liberal opinions and journals, and hoped, no doubt, thereby to have silenced their writers also. About 1830 Mazzini became an active member of the Carbonari, and this affiliation was the introductory step to his subsequent political life; he was active, able, bold and impetuous, and he soon rose into a position which gave him great influence in the councils of that secret society. While on a mission for the society he was betrayed by a Piedmontese spy, arrested and detained for six months as a prisoner in the fortress of Savona. On his release he went to Marseilles, France, to escape the police surveillance imposed on him in Italy. Here he organized the society of La Giovine Italia (Young Italy), and established under that same title a journal to advocate his views; the purpose of the society was to liberate Italy and establish a national government, Mazzini desiring a republic. It was about this time, too, that he addressed to Charles Albert of Sardinia the celebrated letter which so impressed the sovereign that he ordered the arrest of the distinguished person of perpetual banishment from his native country. He took active part in the organization of an insurrection of which Genoa was to be the centre, but the plot was discovered and failed. For his share in it Mazzini was sentenced to death in the Sardinian courts. He then went to Switzerland, where he organized another conspiracy for the invasion of Savoy (1834), which also failed. In 1837 he quitted Switzerland and took up his abode in London, where he kept in correspondence with the revolutionary leaders on the Continent, was recognized as the head of the Young Italy party, and instigated several insurrections, which were unsuccessful. After the insurrection in Milan in 1848 he again went to Italy, was chosen a member of the Tuscan provisional government in February 1849, and in the following month, when Rome was proclaimed a republic, he was chosen first of the triumvirs. He was the main spring of the defense of Rome against the French, and on the surrender of that city in June Mazzini escaped to Lausanne, Switzerland. At this time he addressed to M. de Tocqueville a letter in which he declared his most bitter and reproachful letters on the hithand policy pursued by France. Finding his continental residence too hot for him he returned to London, not, however, with any idea of abandoning his longcherished hopes for Italian unity. Later he had a hand in successful uprisings at Mantua (1852), in Milan (1853) and in Piedmont (1857), being in Italy for a short time in 1857. He assisted also in organizing the expeditions led by Garibaldi in 1860, 1862 and 1867. An ardent Republican, he refused to take his seat in the Italian Parliament under the monarchy, though repeatedly elected from Messina, as a protest against the uncanceled sentence of death against him. In 1866 this sentence was formally rescinded; in 1868 he suffered from a serious illness, the effects of which left him in impaired health. In 1870 he was arrested at Gaeta under charge of conspiracy with Garibaldi and imprisoned for two months, being released after the occupation of Rome by the Italians. He was accorded a public funeral by the Italian government.

Mazzini was a copious writer. A perfect master not only of Italian, but of French and of English, he expressed these journals and arguments of his own in a style that gave him great influence in the councils of that secret society. While on a mission for the society he was betrayed by a Piedmontese spy, arrested and detained for six months as a prisoner in the fortress of Savona. On his release he went to Marseilles, France, to escape the police surveillance imposed on him in Italy. Here he organized the society of La Giovine Italia (Young Italy), and established under that same title a journal to advocate his views; the purpose of the society was to liberate Italy and establish a national government, Mazzini desiring a republic. It was about this time, too, that he addressed to Charles Albert of Sardinia the celebrated letter which so impressed the sovereign that he ordered the arrest of the distinguished person of perpetual banishment from his native country. He took active part in the organization of an insurrection of which Genoa was to be the centre, but the plot was discovered and failed. For his share in it Mazzini was sentenced to death in the Sardinian courts. He then went to Switzerland, where he organized another conspiracy for the invasion of Savoy (1834), which also failed. In 1837 he quitted Switzerland and took up his abode in London, where he kept in correspondence with the revolutionary leaders on the Continent, was recognized as the head of the Young Italy party, and instigated several insurrections, which were unsuccessful. After the insurrection in Milan in 1848 he again went to Italy, was chosen a member of the Tuscan provisional government in February 1849, and in the following month, when Rome was proclaimed a republic, he was chosen first of the triumvirs. He was the main spring of the defense of Rome against the French, and on the surrender of that city in June Mazzini escaped to Lausanne, Switzerland. At this time he addressed to M. de Tocqueville a letter in which he declared his most bitter and reproachful letters on the high-handed policy pursued by France. Finding his continental residence too hot for him he returned to London, not, however, with any idea of abandoning his longcherished hopes for Italian unity. Later he had a hand in successful uprisings at Mantua (1852), in Milan (1853) and in Piedmont (1857), being in Italy for a short time in 1857. He assisted also in organizing the expeditions led by Garibaldi in 1860, 1862 and 1867. An ardent Republican, he refused to take his seat in the Italian Parliament under the monarchy, though repeatedly elected from Messina, as a protest against the uncanceled sentence of death against him. In 1866 this sentence was formally rescinded; in 1868 he suffered from a serious illness, the effects of which left him in impaired health. In 1870 he was arrested at Gaeta under charge of conspiracy with Garibaldi and imprisoned for two months, being released after the occupation of Rome by the Italians. He was accorded a public funeral by the Italian government.

He was accorded a public funeral by the Italian government.
MAZZOLA — MEAD

few friends. There was hardly a human being whom long familiarity had not estranged from Mazzini. With manners consummately affable and courteous he combined an overweening conceit and a narrowness and bigotry of view which hardly tolerated independent minds. He was a lonely genius, all apart from the common ways of other mortals, spurting the suggestions of the plainest common sense, philosophy, or health, without anything with them or by their aid. He gave up the idea of ever being a prophet in his own country in his own age; his only trust was in a coming generation, where the germ of his idea could alone attain full development. The best edition of his works is 'Scritti Editi ed Inediti' (18 vols., Milan 1861-91); a partial collection is published under the title 'Life and Writings of Joseph Mazzini' (1891). His letters have been published in English (6 vols., London 1890-91), Consult 'Memoir of Joseph Mazzini' (1877) containing his two essays 'Thoughts on Democracy in Europe,' and 'On the Duties of Man'; Linton, W. J., 'Recollections of Mazzini' (1892); Marriott, 'Makers of Modern Italy' (London 1889); 'Six Radicals Thinkers' (London 1907); Holland, R. S., 'Builders of United Italy' (New York 1908); 'Cambridge Modern History' (Vol. XI, 8vo. 1909); King, Bolton, 'Life of Mazzini' (new ed., 8vo. 1912); King, H. E. B., 'Letters and Recollections of Mazzini' (London 1912); Thayer, 'The Dawn of Italian Independence' (1893); Martinengo-Cesaresco, 'Italian Characters.'

MAZZOLA, mat-so'la, or MAZZOLI, mat-so-o'-lä, Francesco, Italian painter, known from his birthplace as Fr. PARMIGIANO: b. Parma, 11 Jan. 1599; d. Casalmaggiore, 24 Aug. 1540. His father and two uncles were painters, and to them and to Correggio, who was in Parma in 1521, he owed his earlier training. Correggio's manner he caught so well that his 'Cupid Fashioning a Bow' was long and generally attributed to Correggio; then 20 he went to Rome and there imitated Raphael and Michelangelo. In 1527, upon the capture of Rome by Charles V, his losses were great and he had to escape from the city. He returned to Parma, lost his health, was imprisoned by the city authorities for failure to complete a commission which had been paid for in advance, and upon his release fled to Casalmaggiore, failing to live up to his promise to repay. His paintings are to be found in most of the galleries of Europe; mention should be made of the 'Madonna with St. Margaret,' in the Bologna Gallery; 'Madonna del Collo Lungo,' Pitti Palace, Florence; 'Annunciation,' Ambrosian Library, Milan; various portraits, the Nièvre Museum; several sacred subjects, notably 'Madonna' in the Dresden Gallery and in the Louvre; and the great frescoes in the church of Saint John, Parma. More important, though less well known, are Mazzola's etchings, since he introduced etching into Italy. His drawing is correct, and his work bold, fiery and graceful.

MAZZONI, Guido, gwëd'dô mat-so'ne, Italian scholar and poet: b. Florence, 12 June 1859. He was educated at Florence, Leghorn and Bologna, in 1881 became instructor in Italian secondary schools and in 1887 professor of Italian literature at Padua. After 1894 he was professor of the Italian language and literature at the Institute of Florence. His poetic work has been to a great extent influenced by his familiarity with English literature and largely by his countryman Car- ducci. Besides contributions to reviews, he wrote 'Epigrammi di Meleagro da Cadoro' (1880); 'In Biblioteca' (1882); 'Esperimenti metrici' (1882); 'Un canto, with nothing with them or by their aid. He gave up the idea of ever being a prophet in his own country in his own age; his only trust was in a coming generation, where the germ of his idea could alone attain full development. The best edition of his works is 'Scritti Editi ed Inediti' (18 vols., Milan 1861-91); a partial collection is published under the title 'Life and Writings of Joseph Mazzini' (1891). His letters have been published in English (6 vols., London 1890-91), Consult 'Memoir of Joseph Mazzini' (1877) containing his two essays 'Thoughts on Democracy in Europe,' and 'On the Duties of Man'; Linton, W. J., 'Recollections of Mazzini' (1892); Marriott, 'Makers of Modern Italy' (London 1889); 'Six Radicals Thinkers' (London 1907); Holland, R. S., 'Builders of United Italy' (New York 1908); 'Cambridge Modern History' (Vol. XI, 8vo. 1909); King, Bolton, 'Life of Mazzini' (new ed., 8vo. 1912); King, H. E. B., 'Letters and Recollections of Mazzini' (London 1912); Thayer, 'The Dawn of Italian Independence' (1893); Martinengo-Cesaresco, 'Italian Characters.'

MAZZOLA, mat-so'la, or MAZZOLI, mat-so-o'-lä, Francesco, Italian painter, known from his birthplace as Fr. PARMIGIANO: b. Parma, 11 Jan. 1599; d. Casalmaggiore, 24 Aug. 1540. More important, though less well known, are Mazzola's etchings, since he introduced etching into Italy. His drawing is correct, and his work bold, fiery and graceful.

MAZZONI, Guido, gwëd'dô mat-so'ne, Italian scholar and poet: b. Florence, 12 June 1859. He was educated at Florence, Leghorn and Bologna, in 1881 became instructor in Italian secondary schools and in
sell Sturgis and in Europe, and upon his return to the United States became a member of the prominent New York firm of McKim, Mead and White, which has had charge of many of the most important public and private buildings in the country. In 1902 he was made a Fellow of the American Institute of Architects, and is a member of the American Academy of Arts and Letters and president of the American Academy, Rome. In 1910 he was chosen member of the National Academy of Design and was awarded a gold medal of honor by the National Institute of Arts and Letters. He is a brother of L. G. Mead (q.v.).

**MEAD, or METH, a vinous liquor, used in northern Europe and made of honey and water by means of digestion and fermentation. It also receives an addition of fruit, spices and simples to give it a richer flavor. When new, mead has always a strong taste of honey, but this diminishes as it becomes older. Mead is mixed with the must of apples or with wine, beer and even vinegar, and then takes the name of wine-mead, beer-mead, etc. It is one of the oldest of beverages, being known all over Europe even in historic times.**

**MEADE, George Gordon, American soldier:** b. Cadiz, Spain, 31 Dec. 1815; d. Philadelphia, 6 Nov. 1872. In 1835 he was graduated from the United States Military Academy and assigned to the 3d Artillery, in 1835-36 served in the Seminole War in Florida, on 26 Oct. 1836 resigned from the army, and in 1836-37 was assistant engineer in the construction of the Alabama, Florida and Georgia Railway. He was later employed in various works of engineering, including surveys of the mouths of the Mississippi and of the northeastern boundary between the United States and British North America. On 19 May 1842 re-entered the army as second lieutenant of topographical engineers. He joined Scott's staff at Corpus Christi, Tex., 14 Sept. 1845, and during the Mexican War participated in the battles of Palo Alto, Monterrey, the battle of Resaca de la Palma and the siege of Vera Cruz. After the war he was occupied in lighthouse construction and in the geodetic survey of the Great Lakes (1857-61). He became captain in the corps of engineers in 1856. On 31 Jan. 1861 he was commissioner brigadier-general of volunteers and assigned to the command of the 2d brigade of the Pennsylvania reserve corps of the Army of the Potomac, stationed on the right of the lines before Washington. He served in the Virginia peninsula campaign and took part in the actions at Mechanicsville (26 June), Gaines' Mill (27 June) and Frayser's Farm (30 June). On 18 June he was promoted major of engineers. At Manassas (second Bull Run) he commanded the 1st brigade of Reynolds' division, and later he took a distinguished part at South Mountain (14 September) and Antietam (17 September). In the latter battle, when Hooker was wounded, he was placed in command of the First Corps. For his services he was promoted major general of volunteers on 29 Nov. 1862; and at Fredericksburg (13 December) commanded the 3d division of the First Corps, with which he broke through Lee's right and penetrated to the position occupied by the Confederate reserves, but for want of support was compelled to fall back. At Chancellorsville (2-4 May 1863) he commanded the Fifth Corps. On 28 June 1863 he was appointed commander of the Army of the Potomac, to succeed Hooker. His command was then scattered, and on the march through Pennsylvania in pursuit of the Confederate invaders, Meade had everything yet to learn of both his own force and the enemy. At Gettysburg on 1-3 July he won the great and decisive battle with which his name is generally associated. (See GETTYSBURG, BATTLE OF.) He received the thanks of Congress and was made brigadier-general of the United States army, 3 July 1863. During the remainder of the war he commanded the Army of the Potomac with conspicuous ability, and on 18 Aug. 1864 became major-general in the regular army. From 1 July 1865 until his death he was commander of the military division of the Atlantic, with the exception of the period January 1868-March 1869, when he was in command successively of the Third Military District and the Department of the South. He was a Fellow of the American Academy of Arts and Sciences, and a member of the American Philosophical Society. He was purchased for him by the citizens of Philadelphia, and after his death $100,000 were collected and given to his heirs. There is an equestrian statue of him by Calden in Fairmount Park, Philadelphia, and one by Bush-Brown on the field of Gettysburg. Bache, R. M., 'Life of General G. G. Meade' (Philadelphia 1897); Pennypacker, I. R., 'General Meade' (New York 1901).

**MEADE, Richard Kidder, American soldier:** b. Nansendom County, Va., 14 July 1746; d. Frederic, now Clarke, County, after 1800. He was educated in England at Harrow and in private schools. He had returned from England some years before the outbreak of the Revolution, and in 1775 entered the service of the struggling colonies, and distinguished himself in his first battle, that of Great Bridge. Recognition came speedily with an appointment to the staff of General Washington, with whom he remained until the close of the war. The supervision of the execution of Major Andre fell to his lot, a duty which while recognizing the necessity for it, he performed with deep regret. At the conclusion of the war he returned to Virginia to engage in the quiet life of the plantation.

**MEADE, Richard Worsam, American naval officer:** b. New York, 9 Oct. 1837; d. Washington, D. C., 4 May 1897. He was a nephew of Gen. G. G. Meade (q.v.). He entered the navy as midshipman 2 Oct. 1850. His promotions were lieutenant, 23 Jan. 1858; lieutenant-commander, 16 July 1862; commander, 20 Sept. 1868; captain, 13 March 1880; commodore, 5 May 1892, and rear-admiral, 7 Sept. 1894. On 20 May 1895 he was retired from the service. In 1862-63 as commander of a division he cooperated with the land forces of Sherman in subduing the Confederates on the Mississippi. In 1863 he was in command of the marines during the Natchez campaign; in 1866 he was in charge of a department at the naval academy; in 1868 was sent to Alaska and in 1871-73 commanded the Narragansett on the Pacific station. In 1894 he was placed in command of the North Atlantic squadron. He was naval representative at the St. Louis Exposition and at the World's Columbian Exposition, Chicago.
1893. He published 'A Treatise on Naval Architecture and Ship-building' (1809).

**MEADE, William, American Protestant Episcopalian.** b. near Millwood, Va., 11 Nov. 1789; d. Richmond, Va., 14 March 1862. He was a son of R. K. Meade (q.v.), and was graduated from Princeton College in 1808, studied theology and took orders in the Episcopal ministry in 1811. His first charge was his home parish which he served gratuitously, and in 1829 he was elected assistant to Bishop Moore. He was in charge of Christ Church in Norfolk, Va., in 1834-36, and in 1841 succeeded Bishop Moore as head of the diocese of Virginia. He was one of the founders in 1847 of the 'Evangelical Knowledge Society.' He tried to keep Virginia in the Union in 1861, but later entered into the spirit and aims of the Confederacy. He was the author of several works, among which are 'Family Prayers' (1834); 'Reasons for Lowering Episcopal Church' (1852); 'Old Churches, Ministers and Families of Virginia' (1857); 'The Bible and the Classics' (1861). Consult the memoir by his coadjutor, John Johns (Baltimore 1867).

**MEADOW, Making and Care of.** Meadows may be divided into general groups which will depend upon location, duration and purpose, and their treatment will vary with each of these factors. Meadows located upon low ground, which may be inundated, or which is constantly moist, usually consist of grasses and other plants which do not thrive so well upon upland fields. Because of their dampness they cannot be treated like dry soils and they are therefore more frequently permanent than temporary. Further, they are generally better adapted for haying than for grazing, because the grasses that naturally grow upon them are ranker, taller growing species and generally have grown to a considerable height before the land becomes dry enough to turn stock upon it. Except as to season the preparation of lowland meadows is not necessarily different from that of upland.

For best results the land should be deeply plowed as early in the season as soil conditions will permit, and harrowed at intervals of 10 days and after each rain that forms a crust until late summer. The practice will not only destroy weeds and weed seeds, but ensure the quick germination of grass seed sown even in dry weather, the soil being moist close to the surface. The soil may be anything, but preferably not sand or clay. If mucky, as in a reclaimed swamp, rolling is frequently advisable, otherwise generally not. Prior to plowing liberal applications of good manure or commercial fertilizers should be made and light annual dressings should also be given, preferably in autumn or early spring. Temporary pastures which are intended to last only three or four years should constitute part of a general rotation scheme (see Rotation of Crops) and should be followed by some crop such as corn or potatoes, which can best utilize their products of decomposition. Permanent meadows should be inspected each spring and the spots which appear to be failing given special attention, such as fertilizing, liming, seeding, etc., to maintain a general good average. When the annual yield of hay falls below two tons the meadow may be considered unprofitable and should be plowed up and given a change of crop for three or four years.

In general, timothy or "hert's-grass" is the most popular grass in America, because it is hardy, long-lived, large, easily cured and its seed inexpensive and likely to be free from weed seed. Orchard grass, tall meadow fescue, red-top, rye-grass and cat-grass are also often used, but are secondary. Big bluestem, which generally appears as a volunteer grass in permanent meadows, is rarely profitable as a hay grass, but is unequaled in the north as a pasture grass. These grasses may all be sown with a sparsely planted cereal which acts as a "nurse crop." But this practice is generally considered inexpedient. The admixture of clover, however, is generally highly desirable, since the clovers supply nitrogenous food to the grasses. Alsike clover is considered best for mixing with timothy since it is somewhat later in ripening than the other clovers, and open rich before the timothy can be profitably cut. Consult Wing, Joseph E., 'Meadows and Pastures' (Chicago 1911).

**MEADOW-GRASS.** See Blue-Grass.

**MEADOW-HEN, the American coot.** See Coot.

**MEADOW-LARK, or MEMLARK, a beautiful American starling (Sturnella magna), numerous in eastern United States as far west as the high central plains, where it is replaced by a variety (S. neglecta) remarkably different in song and some habits. It is about 11 inches long and tail five inches. The body is thick and stout, the legs large, the bill long and straight and the flight powerful. The upper parts are brown, marked with brownish-white, and the exposed portions of the wings and tail with transverse dark-brown bars; the under parts yellow, with a black crescent upon the breast, which is very distinctive as well as a handsome ornament. These birds receive their popular name "lark" from their terrestrial habits and way of singing in the air, uttering a loud sweet double call while circling upon fluttering wings above the meadow or grain-field where the nest is carefully concealed among the roots of the grasses. The eggs are white, profusely speckled with light red. The western variety has a longer, more vivacious and tuneful song than the eastern bird, and is justly accounted the finest song-bird of the region of the interior. These birds are migratory in the northern parts of their range, but most of them remain during the winter in the middle parts of the United States and southward, and in the autumn are often shot for market, although in most States such shooting is now prohibited by law. In the Southern States it is commonly called "old-field lark." The meadow-lark subsists both on insects and on seeds. In winter they often form groups, but in the fine seasons seldom more than two are seen together. Consult "Birds of the Northwest." (Washington 1874).

**MEADOW-MOUSE.** See Field-mice.
MEADOW-PINK, or MEADOW-CAMPION, the common cuckoo-flower (q.v.), or ragged robin (Lychnis flos-cuculi). See LYCHNIS.

MEADOW-RUE, a plant of the crowfoot family and of the genus Thalictrum. These plants are erect perennial herbs, with much divided leaves and small flowers, usually in loose panicles. The genus contains about 75 species, scattered about the north temperate zone, of which the United States and Canada possess about 13 species. The early meadow-rue (T. dioicum) is a slender, leafy species, of rocky woods, a foot or two in height, whose flowers, purplish and greenish with yellowish anthers, appear in April or May. The purple meadow-rue (T. dasytum), common in New England woods, is distinguishable by its size (two to four feet tall), large bright-green, waxy leaves and purplish stem; the flowers form a greenish fleecy bloom. A third large species is the thick-leaved (T. coriaceum) of the Southern States, whose flowers are of different hues, the staminate flowers being white and showy, while the pistillate flowers, borne on separate plants, are purplish. The tall meadow-rue (T. polygonum) towers to a height of 10 feet in favorable situations. All are fertilized mainly by the wind.

MEADOW-SNIPE. See JACK-SNIPE.

MEADOWSWEET, a well-known handsome European plant (Ulmarius ulmarus) of the rose family. It grows by the sides of streams and in damp places, has pinnate leaves and stems two feet high bearing corymbs of white fragrant flowers. A decoction of it with copper is used for dyeing black, and the root has been used as a tonic. It is also called queen of the meadow.

MEADOWVILLE, med’vil, Pa., city and county-seat of Crawford County, on French Creek and on the Erie and a branch of the Pittsburgh, Bessemer and Lake Erie railroads, about 90 miles north of Pittsburgh and 30 miles south of Erie. The first settlement was made in 1806 by David Mead and others. It became a borough in 1823 and in 1866 was chartered as a city. It is in a fertile agricultural region, in the vicinity of extensive oil fields and in the part of the State noted for its iron and steel industries. The chief manufacturing establishments are the Erie Railroad shops, the Phexin iron works and the Meadville malleable iron works, the Keystone vise works, chocolate chips factory, Barbour silk mills, shoe-button fastener works, silk mills, printing works, confectionery factories, engine works, tool, casting and brass works, chemical works, corset factories and other manufactories. The city has many churches, an academy of music, courthouse, three parks, the county fair grounds, a race-track, iron bridges and several fine wholesale and retail buildings. Its educational institutions are the public and parish schools, a high school, the Meadville Theological School, opened in 1844 by the Unitarians; Allegheny College, opened in 1815 by the Marquis of Eaton; East High School of Music, Meadville Business College and a public library. There are the City Hospital and Saint Joseph’s Hospital. The three banks have a combined capital of over $350,000. The government, according to the commission plan adopted in 1913, is vested in a mayor and four councilmen. The electric-light plant and the waterworks are owned and operated by the city. Pop. 12,780.

MEAFORD, Canada, lake port in Gray County, Ontario, situated on an inlet of Georgian Bay, Lake Huron, on the Grand Trunk Railway, 20 miles west-northwest of Collingwood. It has brick yards, grain elevators, fruit evaporating works, flouring mills, tannery, furniture factory, textile works, foundries, box works, etc. It has a good harbor with a depth of 20 feet. Pop. 3,200.

MEAGHER, mä’ther, Thomas Francis, Irish-American soldier; b. Waterford, Ireland, 3 Aug., 1823; d. near Fort Benton, Mont., 1 July 1867. He was educated at the Jesuit College, Clongowes Wood, Kildare, and at Stonyhurst College (near Preston), England; became one of the principal orators of the Young Ireland party, which aimed at independence through armed revolution; in 1848 was sent on a mission by the Irish Confederation to the French provisional government, and on 21 March was arrested on a charge of sedition. He was released but on the passage of the Treason-Felony Act rearrested; and in October sentenced to death for treason. The sentence having been commuted to life banishment, he was removed to Tasmania (9 July 1849); but in 1852 escaped to the United States, where he was admitted to the bar in 1856 and practised in New York in 1856-61. For some time also after 1856 he edited the Irish News of New York. In 1861 he organized a company of zouaves for the Federal army, with which he joined the 69th New York Volunteers, under command of Col. Michael Corcoran. After three months’ service, he recruited the Irish brigade (1861-62), and was elected colonel of the 1st regiment. On 3 Feb., 1862, he became brigadier-general and took command of the brigade. He fought bravely at Richmond, the second Bull Run, Fredericksburg and Antietam and after Chancellorsville found his command so reduced in numbers that he resigned. He was brigadier-general of volunteers and was assigned to the command of the military district of Etowah. He resigned 15 May 1865, was appointed secretary of Montana Territory and in the following year acted at one time as governor pro tem. At Fort Benton, Mont., on 1 July 1867 he boarded a steamer for a trip down the Missouri and thereafter was never seen. It is supposed that he fell overboard unperceived during the night. He wrote ‘Speeches on the Legislative Independence of Ireland’ (1852). Consult Cavanagh, ‘Life, Writings and Speeches’ (Worces- ter, Mass., 1892).

MEAGRE. A fish. See MAIGRE.

MEAKIN, me’kin, Budgett, English author and writer; b. Ealing Park, England, 8 Aug. 1866; d. London, 26 June 1906. He was educated at the Regiate Grammar School, became associate editor of Times of Morocco and was editor 1884-93. He lectured extensively on industrial history. Among his works are ‘The Moorish Empire’ (1899); ‘The Land of the Moors’ (1901); ‘The Moors’ (1902); ‘Model Factories and Villages,’ etc.
MEAL-MOTH, or MEAL-WORM. See FLOUR and MEAL INSECTS.

MEAL-TUB PLOT, in English history, an alleged conspiracy, concocted in 1679 by an informer, Dangerfield, with the view of cutting off those who were opposed to the succession of James II after he had embraced Roman Catholicism. The false charges to which Dangerfield was prepared to swear were found in the meal-tub belonging to a Mrs. Cellier, one of his friends. Ultimately he confessed his crime, was whipped and condemned to stand in the pillory.

MEALY-BUG, a scaleless scale insect of the genus Dactylopius and family Cocicidae. These insects are covered with a mealy or waxy substance which they secrete for protective purposes. Like their relatives, the true scale insects, they also secrete honey-dew and are attended and transported by ants; unlike these relatives they do not lose the power of locomotion. The species are most numerous in tropical and sub-tropical countries; one species (D. citri) being the best-known outdoor species in the United States, feeding upon citrus trees in Florida. In greenhouses another species (D. destructor) is often troublesome. Owing to the protective covering difficulty has been met in ridding plants of these creatures, but fumigation and caustic solutions have been tried with most satisfactory results, a kerosene and soap emulsion being particularly effective in destroying them. (See INSECTICIDE). Consult Comstock, J. H. and A. B. *Manual for the Study of Insects* (8th ed., New York 1908); Comstock, J. H. 'Report of the United States Department of Agriculture' (Washington 1880).

MEALY WING, a minute bug of the family Aleurodidae, whose species (about 150 in number) have the wings covered with a white meal-like secretion. They are allied to the coccids, but differ in development and structural peculiarities; and throng upon the leaves of plants which they injure by sucking away the sap and also by attracting a growth of smut fungus by their secretion of honey-dew. In this manner they blacken and harm orange and lemon trees in parts of Florida and Louisiana, where they are prevalent. Consult Howard, *Insect Book* (1901).

MEAN VALUE. If n quantities are commensurable, the sum of their units divided by n, the number of the quantities, is the arithmetical mean and is the mean value of the n quantities when their number is finite. For example, if the number of units in three quantities are respectively 4, 8 and 15, the mean value is \( \frac{4 + 8 + 15}{3} = 9 \); and in general, if the number of units in n quantities is denoted by \( X_1, X_2, X_3, \ldots, X_n \), the mean value is

\[
M = \frac{1}{n} \sum_{i=1}^{n} X_i
\]

But if a quantity vary continuously in accordance with some law, thereby assuming every possible value between two extremes, the number of different quantities is infinite, and the mean value in such a case requires a new definition. For example, assume that at every point in the diameter of a semi-circle a perpendicular to the diameter is drawn to meet the semi-circle. The lengths of these lines form a continuous series of values represented by every number from zero to r, where r is the length of the radius. In such a case if n values of the perpendiculars are obtained and their sum is divided by n, the ratio should approximate to the mean value. It is easy to see, however, that this ratio will approximate to \( \frac{2}{n} \) of the radius of the circle if the n perpendiculars are evenly spaced on the circle, to \( \frac{\pi}{4} \) of the radius if they are evenly spaced on the diameter. It follows that the mean value of a continuously varying quantity is not definite until the law is known by which the "weight" of each portion of the scope of variation is determined. The several forms of the theorem that pass under the name of the mean value theorem involve the principles of the infinitesimal calculus. The first theorem of the mean value is the following: Let \( f(x) \) denote any finite and continuous function of x in the interval between \( x = x_0 \) and \( x = X \); let dx denote the increment and retain the same sign in this interval; and assume that m and M are respectively the least and the greatest values of \( f(x) \) in this interval:

then the definite integral \( \int_{x_0}^{X} f(x) \, dx \) has a definite value that is greater than \( m(X - x_0) \) and less than \( M(X - x_0) \); that is,

\[
m \int_{x_0}^{X} dx < \int_{x_0}^{X} f(x) \, dx < M \int_{x_0}^{X} dx.
\]

Since \( f(x) \) is continuous in the interval \( X - x_0 \), there must be a value \( x = \xi \), where \( x_0 < \xi < X \) such that \( \int_{x_0}^{X} f(x) \, dx = f(\xi) \cdot \int_{x_0}^{X} dx \).

The value, \( f(\xi) = \frac{1}{X - x_0} \int_{x_0}^{X} f(x) \, dx \), is called the mean value of \( f(x) \) in the interval \( X - x_0 \). If we assume \( F(x) \) to be the primitive or indefinite integral of \( f(x) \), then \( F(X) - F(x_0) = (X - x_0) f(\xi) = (X - x_0) F'(\xi) \) which is the familiar form of the law of the mean in the differential calculus.

The theorem of mean value is of importance in establishing Taylor's series. It follows immediately from the theorem of mean value that if \( F(X) = F(x_0) = 0 \), for some \( \xi \) between \( X \) and \( x_0 \), \( F'(\xi) = 0 \), if \( F \) is continuous between \( X \) and \( x_0 \). Let \( \phi \) be a function of \( X \) with derivatives of every order at every point between \( x_0 \) and \( x = b \). Construct the function

\[
\psi(x) = \phi(x) - \phi(x_0) - (x - x_0) \frac{\phi'(x)}{2!} - \frac{(x - x_0)^2}{3!} \frac{\phi'''(x)}{3!} - \cdots
\]

where \( x_0 \) is of the form \( x_0 + k \), and \( x \) and \( x_0 \) lie between \( a \) and \( b \). \( \psi \) will be of the form

\[
\psi(x) = \psi(x_0) - \frac{(x - x_0)^2}{2!} \phi''(x_0) - \frac{(x - x_0)^3}{3!} \phi'''(x_0) - \cdots
\]

Furthermore, \( \psi(x) \) is identically 0, and by properly choosing \( P, \psi(x_0) \) can be made 0.
MEANDER — MEANING

Therefore, by the theorem just stated \( \psi'(x) = \frac{(X-\epsilon)^n}{n!} \left[ \phi(\psi\nu(\nu+1)) \right] \) vanishes for some value of \( \nu \) between \( \nu_0 \) and \( x \). As it can be shown that this value need not be \( X \) itself, we have \( \psi'(X) = 0 \) for some value of \( \nu \) between \( \nu_0 \) and \( X \), and since \( \psi(X) = 0 \), if we let \( X = x_0 + h \), we have \( \psi(x_0 + h) = \psi(x_0) + \psi'(x_0) h + \cdots + \frac{\psi^{(n)}(x_0) h^n}{n!} \).

\[
\phi^{(n+1)}(x_0 + \theta h) = \frac{1}{(n+1)!} \sum_{k=0}^{n+1} \binom{n+1}{k} \phi^{(k)}(x_0) h^k,
\]

where \( 0 < \theta < 1 \). Therefore, \( \psi^{(n+1)}(x_0 + \theta h) \) can be made as small as \( n! \) can be under the limit, \( n = 0 \).

MEANDERS, mé-án’der, in art, an ornamental design, in which the lines interlace; it is often used in the decorative vase. The lines usually advance in one direction and pass one another at right angles. The design is so named from the river Meander, well known for its numerous windings.

MEANING, broad swinging curves made by a river on its flood plain. A river in its early history may have accidental curves, but it is only when it has cut its course as deeply as it can, and has begun to widen its valley notably, in other words when it has passed its maturity and is progressing toward old age, that it characteristically develops meanders. These frequently become almost perfect loops many miles around and but a few rods across the neck. When a meander cuts off and is occupied by stagnant water only, ox-bow lakes are formed. If a region in this stage is uplifted the river will again begin to deepen its valley, and the meander curves will cut down anew, forming deep valleys or gorges. They are then said to be entrenched or incised meanders. Sometimes the neck of an incised meander may be cut through at river level, by undermining the neck, a natural bridge. See NATURAL BRIDGES, and the section on WORK OF RUNNING WATER in the article on GEOLOGY.

MEANING, the object of a symbolization, considered from the standpoint of the symbol. Thus the meaning of the figure 2 is the number two, the meaning of the formula \( (x + y) \frac{x^2 + 2xy + y^2}{2} \) is the law that formula represents, and so on indefinitely. The experiences which we undergo possess besides their presented content a represented content, and this represented content bears toward them the relation of meaning. One of the cardinal problems of modern psychology is the determination of the psychical concomitants of this meaning. In accordance with the general nominalistic and associationistic trend of experimental psychology, those who approach the question of meaning from this angle have usually considered that the meaning of an image is conveyed in consciousness by a group of such accompanying substantive states as images, sensations and feelings. They held, that, that the meaning of "bear" read into a noise in the woods is "carried by a verbal image and an organic shudder," and that every experience is surrounded by a fringe of vaguer meaningful states. They would consider that the vehicle of the law is a visual or auditory or interpretative verbal image, together with certain organic and kinesthetic sensations.

All this psychology of meaning suffers from the lack of an antecedent logical analysis. The logical situation best adapted and most significant is that of the relation of a set of mathematical symbols to the theory they represent. The theory is obviously the meaning of the symbols, but it is only to the very slightest extent carried by the individual symbols themselves. Only the elementary constituents of the system, together with certain of the simpler general notions, are represented by special characters. The structural relations are signified, and must be signified, by the arrangement—that is, the structural relations of the symbolism on the paper. The essence of the conventional system of algebraic notation lies, not in the use of letters for numbers, but in the symbolizing of addition by + and of multiplication by X, but in the one agreeing use of the relation of the symbols and the laws of number. Symbolization is primarily the relation toward a system of entities of a similarly ordered system of arbitrary marks, and only in a derived sense the relation between a mark and the corresponding entity. The symbol is a symbol only within a symbolism. It is precisely as a symbolism that our verbal images, kinesthetic sensations and other mental states convey a meaning.

When the mathematician is developing a new theorem, his mental content may be inventoried as a verbal image or two, his sensation of the paper and pencil in front of him, and a few organic sensations. Somehow or other he puts these into an entirely extraneous correlation with the entities which he is examining. This strain behind the eyeballs acquires a temporary association with the unknown function for which he is seeking; that fragmentary visual image of a formula represents a mathematical law; and so on. In his trained mind the symbolism of his states shapes itself into the desired conclusion, which he symbolizes anew in the conventional algebraic notation on the paper lying before him. No enumeration of his substantive states can ever disclose how the meaning of the conclusion and the procedure is carried in his mind, for it is not these states themselves, but their arrangements, that are the vehicles of meaning.

This structural nature of the vehicle of meaning is intimately connected with our power to communicate with others. My sensation of red is something that as far as I know may be peculiarly mine. If there were a man who from his birth had seen red where I see green and green where I see red, it would be a matter of the utmost difficulty for me to express his anomaly. He would learn the name "red" from hearing it applied to the things which appear red to me but green to him, so that his speech would not disclose his peculiarity. But by observing that green objects excite in him the expression of the emotions which we consider appropriate to red, or by some similar peculiarity in the associations of his experience of red and green objects, that the interchange of his red and green sensations could even be sus-
MEASLES, méz, John, English navigator: b. England, 1756; d. London, 1809. He entered upon a seafaring life at an early age and in 1771 he entered the navy and served in the war with the French until peace was declared in 1783, when he became a captain in the merchant service. In 1786 he explored the coast of Alaska and made in 1789 a second tour of exploration on the discoveries of which the British government based its claim to the possession of British Columbia and Oregon. Three ships sent by him to Nootka Sound in 1789 were captured by the Spaniards and this act caused England to fit out an expedition in the following year, upon which reparation was made by Spain. He was the author of 'Voyages in the Years 1788-89, from China to the Northwest Coast of America' (1790).

MEARIM RIVER, Brazil, rises in the Sierra do Negro, and after a northerly course of about 360 miles in the state of Maranhão flows into the Bay of São Marcos near the city of Maranhão. It has numerous affluent streams and is navigable, but the sudden tidal bores are dangerous.

MEARS, Helen Farnsworth, American sculptor: b. Oshkosh, Wis., 1878; d. 17 Feb. 1916. Her early years were passed in Oshkosh, Wis., where she began her art work as a child by carving a life-size portrait of her sister from a block of solid plaster. She studied under Saint-Gaudens, who recommended her as one of the strongest pupils he had ever had when he sent her to Frederick Macmonnies in Paris. She was particularly known for her portrait busts. Her memorial statue to Frances E. Willard in the capitol at Washington (1905) was the first statue of a woman by a woman placed in that building. In 1911 her design was accepted for a statue for the new Wisconsin State house. Before that she had done much work of note, including the MacDowell bas-reliefs, familiar to visitors at the Metropolitan Museum, New York, and the National Cow Club; a 'Fountain of Life,' which won a prize at the Saint Louis exposition. Other works are the portrait relief of Augustus Saint-Gaudens and the portrait busts of George Rogers Clark and William L. G. McRostie, M.D., in the Smithsonian Institution, Washington.

MEARS, James Ewing, American surgeon: b. Indianapolis, Ind., 1838. He was graduated at Trinity College, Conn., in 1864, and at Jefferson Medical College, Philadelphia, in 1865. He served in the Civil War and in 1865 established his practice in Philadelphia. He held the chair of anatomy and surgery at the Pennsylvania College of Dental Surgery from 1870 to 1898 and for many years was surgeon-in-chief of the Pennsylvania National Guard. He published 'Practical Surgery' (1878; 2d ed., 1885), and numerous contributions to surgical journals.

MEASLES (also called Rubella and Morbilli), a highly contagious eruptive disease, frequently epidemic, and sometimes dangerous because of its debilitating effects and tendency to end in inflammation of mucous membranes, such as pneumonia and enteritis. So-called black or malignant measles, occurring mostly in persons

pected. If the interchange were his sole peculiarity, he would always consider himself, and be considered by others, in the light of a normal human being. Accordingly, we have no reason to believe that the sensory qualities or sense-data of normal human beings agree with our intuitions. The qualities and sense-data, and there is no way of conveying these qualities and data by language. On the other hand, language is the vehicle of meaning and of nothing else. This alone is enough to prove that the meanings do not reside in any special data or qualities in our minds. What language does is to order the mind of the hearer or reader in a manner similar to that of the speaker or writer. In reading a story we pass through a sequence of mental states which has been designed for us by the author. The verbal idiosyncrasies in the minds is for the author to follow. It is one that this relational context, which is all that language can convey, is identically the meaning conveyed by language.

The situation when we hear a noise in the bushes and interpret it as "bear" can now be analyzed. The meaning is not carried in the first instance by the verbal image and the shudder. It is true that there is a possible state of consciousness in which the rustle in the bushes, the verbal image, and the shudder are all that is present, but at this stage meaning has not yet appeared. Meaning first appears when we think, not "bear," but "That's a bear." In this case, the rustle in the bushes stands for "that," the shudder or verbal image for "bear," and the juxtaposition of the shudder or image with the verbal image for the relation expressed in the sentence. The meaning of "bear" is derived from the meaning of the sentence. In other words, the meaning of the sound in the bushes resides, not in its correlates, but in its function (See TROUGHTON). Consult James, W. 'Principles of Psychology' (New York 1899); Stout, G. F. 'Manual of Psychology' (London 1913); Titchener, E. B. 'Experimental Psychology of the Thought Processes' (New York 1900).
of very poor health, is usually fatal. Where frequently epidemic it is less likely to be severe, and where it attacks a community for the first time it has a high mortality. For instance, it was taken to the Fiji Islands by a British ship from Australia and swept away 40,000 out of 150,000 inhabitants. Although measles is a disease of childhood, adults are not exempt from it. As a rule it attacks an individual but once. The contagious principle exists in the breath and in exhalations from the skin, the tears, the nasal and bronchial secretions and the urine. Cloth, in dry air, the rain, and even the air of an infected atmosphere is liable to spread the disease. How long the contagium remains in infected articles is not known. The disease may be divided into four stages, beginning with the stage of incubation, or the interval (varying from 7 to 21 days) between the date of infection and the outbreak of symptoms, that is, the stage of invasion. The symptoms are chilliness, fever, pain in head, back and limbs, bloodshot eyes, with intolerance of light, running of the nose and sneezing, and a troublesome cough. About the fourth day an eruption or rash appears (stage of eruption), first in the throat, then upon the face, trunk and extremities, as minute pinkish red spots, which coalesce into larger ones with time, and at the same time scaly in shape, raised above the surface of the skin. The eruption usually lasts about three or four days. Gradually disappearing (stage of decline), fever and catarrhal symptoms abate, and appetite returns. The cough may remain for days. The patient should be kept in a warm, well-ventilated and fairly lighted room, should be given easily digested food and plenty of water. Treatment should also regulate the bowels with saline medicines, and allay the severity of the cough with simple remedies. Severe symptoms require the attendance of the physician. Complications may ensue in the shape of chronic inflammation of the tonsils, of laryngitis, of chronic Bright’s disease and of ophthalmia; but the most serious complication is that of broncho-pneumonia, which occurs in about 25 per cent of cases of measles. Measles is contagious until the eruption has disappeared and all dead particles of skin have come away of themselves or have been washed off by tepid baths.

MEASURE, a definite unit of capacity or extent, fixed by law or custom, by which relative sizes and capacities are ascertained and expressed; as, a yard, a measure of length; a gallon, a measure of capacity; a square foot, a measure of area; a cubic foot, a measure of volume, etc. See WEIGHTS AND MEASURES.

Lineal Measure.—The measure of lines or distances; the standard unit of lineal measure in the United States is the yard. The system is based on the law of nature that the force of gravity is constant at the same point of the earth; and, consequently, that a length of a pendulum which oscillates a certain number of times in a given period is also constant.

Unit of Measure.—A given quantity, used as a standard of comparison, in which is contained a quantity of the same kind. Every kind of quantity has its own unit of measure, and under different circumstances the same kind of quantity may have different units of measure.

Line of Measures.—The line of intersection of the primitive plane, with a plane passing through the axis of the primitive circle and the axis of the circle to be projected.

Measure of Angles.—The right angle being taken as the angular unit, its subdivisions are degrees, minutes and seconds. The right angle contains 90 degrees, the degree 60 minutes and the minute 60 seconds. All subdivisions are expressed decimally in terms of the second.

Measure of Magnification.—The measure of magnification, or magnifying power of any optical instrument, is the ratio of the magnitude of the image to the magnitude of the object, or, more in the modern sense, of the apparent diameter of the image to that of the object.

Measure of a Ratio.—Its logarithm, in any system of logarithms, or the exponent of the power to which the ratio is equal, the exponent of some given ratio being assumed as unity.

In Music.—The quantity of notes which are placed in the bar, and which is generally called the time, of which there are but two kinds, namely, common time, containing an equal quantity of notes in the bar, and triple-time containing an unequal quantity. Common time is generally marked with a & at the beginning, which means that every bar contains four crotchets, or their value in other notes. There are also other kinds of common time which are marked 3, 4, 6, 8, 9, 10, 12, and 13.

MEASURE FOR MEASURE is the most characteristic of the group of so-called "dark comedies" produced in Shakespeare's middle period. Modern critics are agreed that 'Measure for Measure,' first printed in the 1623 folio, must have been composed about 1603, and the critics' opinion, based almost solely upon evidence of style, can now be confidently supported by a piece of external evidence lately redeemed from suspicion of forgery; namely, a memorandum in the accounts of the royal Revels Office which records that 'Measure for Measure' by Shakspere was performed before King James by His Majesty's Players on Saint Stephen's night, 26 Dec. 1604. Few Shakespeare's greater works are so unequal in quality or have evoked such critical enthusiasm. In certain details of form it is one of the most careless of the plays. The subject is intrinsically displeasing to modern taste (though vastly more refined here than in the original story); several of the characters (notably the goody-goody Duke and the unmanly Claudio) repel the reader; and many of the devices of plot, especially in the perfunctory closing act, are frankly clap-trap. On the other hand, Shakespeare's moral beauty and dramatic brilliance are nowhere more loftily exemplified than in the best scenes — those, namely, in which Isabella's gracious figure appears. In a word, this play marks, and is the first to mark, the complete ascendency of spirit over form so notable in the last plays of 8 or 10 years later; it is the earliest to make conspicuous Shakespeare's utter heedlessness of rules and details and his uncanny splendor in silhouetting moral beauty against an all-encompassing mundane vulgarity. This is a play as full of genius as it is of wisdom. It may not enchant, and notable appreciation calls it "one of the greatest works of the greatest English mind." There is no evidence that 'Measure for Measure' has ever been much performed (except in Germany), though an injudicious attempt to blend it with 'Much Ado about Nothing' ('The
MEASUREMENT OF SHIPS — MEASURING WORM

Law against Lovers, by Sir William Davenant) was popular in the latter half of the 17th century. Yet two English revivals in 1907 and 1908 (one by the company of Oscar Ashe and Lily Brayton, the other by the Oxford University Dramatic Society) were so successful that the piece seemed to have come up for a second performance. Shakespeare's source was a long, fictitious prophecy made by a soothsayer named Cassandra by George Whetstone (1578), which in its turn is derived from an Italian tale in Cinthio's 'Hecatommithi.'

TUCKER BROOKE.

MEASUREMENT OF SHIPS FOR TONNAGE, or BUILDER'S MEASUREMENT, a method of computing the tonnage of merchant vessels, in use among shipbuilders. Its results are nearly double the legal or registered tonnage. See Tonnage.

MEASUREMENT OF STREAMS. One of the many useful works of art conducted by the United States Geological Survey; the measurement of streams having an industrial value. Wherever water is likely to be employed for power or irrigation the amount available is ascertained by that bureau. The volume varies greatly from season to season, and sometimes from year to year. Any calculation by the manufacturer or farmer which does not take this variability into account would be misleading. Moreover, it is common for streams to lose their straightness, the character of their beds and other particulars. Accurate measurement is still further complicated by the lack of uniformity in the movement in a given cross section. What might be true for one point would not be true for other points to the right or left of it, or at a higher or lower level.

The first step in the work is to place a gauge in a permanent position, and employ a suitable observer to read it every day. The gauge is graduated to feet and tenths. Usually it is up right. It may be laid over slanting, however. In that case, the spacing is widened, so as to give accurate results. One observation a day is made, and its results transmitted on a postal card, or on telegram. The hydrographer's computation is the velocity of the stream, at different heights. To ascertain this only occasional measurements are necessary. These are made by experts, but with their aid it is possible to prepare tables showing the total discharge of that particular stream for all the different gauge readings. After such tabulation is effected the maximum, minimum and mean flow for any month in the year can be told at a glance.

Velocity is ascertained with a meter lowered into the water. The instrument contains a tiny screw propeller, the number of whose rotations under the pressure of the fluid is automatically registered. Many types of meter have been devised. The kind which the bureau prefers has an electric wire leading up to a buzzer in the operator's pocket. There a click or other audible sound indicates to him the speed of the screw. He counts the number of revolutions for some definite period, usually fifty seconds, records it in his notebook and moves along a short distance to make another observation.

If measurements are made at various depths along a vertical line, the results will not be equal. For this reason hydrographers have studied to find, if possible, a level that would fairly represent the average velocity for any vertical. In this way the observer can simplify the labor. It has been found that such an average can be secured by taking the speed at a depth of from six-tenths to two-thirds of the way down from the surface. To obtain a correct idea for the whole stream, though, these tests must be made at a number of points on one shore and the other. No measurement at a single point can be trusted to be fairly representative.

MEASURING WORM, INCH WORM, LOOPER, or SPAN-WORM, a caterpillar of any species of moth of the superfamly Geometridae. The creatures are characterized by the presence of only two pairs of abdominal legs, one upon the ninth, the other upon the anal segment, and by their peculiar form of locomotion, the rear of the body being brought forward toward the front legs while forming a loop at right angles to the surface upon which the insects walk. Nearly all the numerous species feed upon foliage, a few upon seeds in which they bore. Some are considered serious pests in orchards and upon shade trees; for instance, the canker worm (see Agrotis), the lime-tree moth (Hybernia tilia), and Cymatophora pampinaria, which sometimes devastates cranberry plantations. The duration of the larva state is variable; from their great voracity they grow rapidly and shed their skins several times before attaining maturity; when arrived at this state they seek some sheltered spot in which to undergo the change to pupa form, some clinging to the lower surfaces of leaves while others bury themselves in the earth, those remaining in the air suspending themselves in various ways by means of their silky secretions, others enclosing themselves in silky cocoons. Those burying themselves also build cocoons around them, but many of these only line their cavity with a little silk threads to keep the wall from falling in. One of the European species, Fidonia Plumistaria, is distinguished by curious feathery antennae. The caterpillars of this species are very injurious to fruit trees, especially those in the European species, Agrades, A. grosclariata, which inhabit gooseberry bushes, often entirely stripping them of their foliage. The caterpillar of the American canker worm moth, A. nitiperta pectinaria, also belongs to this species of worm, the eggs being hatched in the spring; when grown they are about an inch long and of various colors, and are also dangerous to orchards. Most of the species, however, are of small economic importance. The caterpillars usually resemble twigs when at rest, their protective coloring and their attitudes serving to deceive their enemies. The caterpillars of a few species of the owlet moths, family Noctuidae, walk in this way, since they also lack prolegs upon the middle abdominal segments. They are not, however, considered true measuring worms. The geometrid moths are usually of small size and inconspicuous but delicate and beautiful coloration. Consult Holland, 'The Moth Book' (New York 1903); and Packard's 'Monograph of the Geometridae,' with colored plates, published by the United States Geological Survey (Washington-
MEAT, Inspection of. The purpose of meat inspection is to eliminate diseased or otherwise bad meat from the general food supply, to see that the preparation of the meats and products passed for human consumption is clean; to guard against the use of harmful dyes, preservatives, chemicals or other deleterious ingredients; and to prevent the use of false or misleading names or statements on labels, in short to protect the rights and health of the consumers of meat and meat food products to the fullest extent possible. In the United States the meat inspection service is administered through the Bureau of Animal Industry of the Department of Agriculture.

In 1890, 1891 and 1895 Congress passed legislation empowering the Secretary of Agriculture to take measures to ensure a wholesome export trade in all meats in the country, and to protect the home consumer against diseased or unsound meat. Under the provisions of these laws great dependence was placed on the ante-mortem examination of all animals for export of the parts designated, but the provisions for the post-mortem examination of carcasses were inadequate. The great defect of this early legislation was that it did not make a ruling for the disposal of carcasses and animal products which upon examination had been found unfit for use as food. During the war with Spain in 1898 the prevalence of sickness among the enlisted men drew the attention of the public to the laws relating to meat inspection. A report was made that "emblamed beef" was being supplied the army by the great packing-houses. Investigation failed to establish this, however, and the public was apathetic in the matter until the publication of Sinclair's "The Jungle," in 1906, in which it was charged that the condition of the slaughter-houses in Chicago, the packing center of the country, was filthy and that the menace to the public health as a result was very great. The nation was aroused and the Pure Food and Drugs Act of 30 June 1906 was enacted after the investigations of a government committee which disclosed the astonishing fact that a large part of the meat placed upon the market was far from clean; and that, in fact, the methods of handling and preparing these food products were dangerous to health.

Federal inspection is now maintained under the act of 30 June 1906, and supplementary legislation in the Tariff Act of 3 Oct. 1913. The food animals to which the act refers are cattle, sheep, swine and goats. The slaughtering, packing, rendering and meat-preparing establishments to which it applies are those which sell or ship their products in whole or in part in interstate or foreign commerce. The Meat-Inspection Law does not apply to those establishments the meats and products of which are neither sold nor shipped outside the confines of the State in which the plant is operated. A qualified exemption from inspection is granted under the law to retail dealers supplying their customers, and a similar exemption is granted in the case of meat from farm-slaughtered animals. The legislation of 1913 provided for the inspection of imported meats and products.

The requirements as to sanitation in the establishments that operate under inspection occupy an important place in the meat-inspection regulations. Prior to 1906 the Secretary of Agriculture was without authority to enforce such requirements but when it was conferred in the act of that year the department proceeded to enforce sanitation in all establishments operated under Federal inspection. The first step taken was to require strict cleanliness in the rooms and equipment and in respect to the conduct of operations and the handling of products, and the second was to adopt rules governing plant and equipment construction.

In new plants the use of non-absorbent materials was demanded and natural light supplemented artificial as far as possible. Improved drainage, plumbing and sanitation were demanded as also proper facilities for the conduct of inspection.

Each establishment is given an official number, which must appear in every instance as a part of the mark of inspection, that is, the mark or statement used on meats and products or the containers thereof, to show that they have been inspected and passed under the Federal regulations.

Ante-Mortem Inspection.—Under the Federal system not less than two examinations are made of the animals slaughtered in official establishments. The first is the ante-mortem inspection or examination of the live animal, the second the post-mortem examination of the carcass and the various organs and parts at the time of slaughter. The post-mortem is the more valuable of the two inspections, but both are necessary if it is to be determined with certainty in every instance that the flesh of the animal is sound, wholesome and fit for human food. The ante-mortem examination is performed in the pens and alleys of the establishments, except that at most of the large slaughtering centres it is found more convenient to conduct it in the public stockyards. The animals are carefully observed for evidence of disease or abnormal condition while at rest in the pens or as they move from the scales after weighing. If any of a lot show symptoms, then the entire lot is subjected to further and individual inspection. If the animals are swine and the symptoms indicate cholera, they are driven to a special pen for further examination and in certain cases to ascertain their temperature and to make a record of the same. Other diseases or conditions in which the question of temperature is important are Texas fever, anthrax, blackleg, pneumonia, septicemia and severe injuries. When its appearance is such as to lead the inspector to suspect that an animal is affected with a disease or condition that may cause its condemnation in whole or in part on the post-mortem inspection, it is marked for identification by means of a serially numbered metal tag bearing the phrase "U. S. Suspect" affixed to the ear. A record of the case is made and sent to the inspector who is to conduct the post-mortem examination. Such suspect animals are kept apart and slaughtered separately from those which were passed on the ante-mortem inspection.

Animals which show symptoms of rabies, tetanus, milk fever or railroad sickness, and hogs which are plainly sick with hog cholera,
INSPECTION OF MEAT

1 Products Inspection
2 Dry Salt Curing Cellar
3 Sealed Rendering Tank
are condemned on the ante-mortem inspection. Such animals are marked by means of a serially numbered "U. S. Condemned" metal tag affixed to the ear. Animals so tagged may not be taken into the slaughter-room, but must be destroyed and disposed of as required for condemned carcasses to prevent their use for food. Animals found dead or in a dying condition on the premises are condemned and disposed of in the same manner.

**Post-Mortem Inspection.**—The post-mortem inspection is made at the time of slaughter and includes a careful examination of the carcass and all its parts. Where the number of animals dressed per hour does not exceed a certain general limit, one inspector, constantly present, performs all the inspections. Where the number of inspections per hour exceeds certain general limits, the inspectors are increased accordingly and the work so arranged and coordinated that each inspector gives his entire attention to some particular part of it. Thus the work is in a sense specialized with the result that a high individual and collective proficiency is maintained, and the inspector is assured regardless of the rate of slaughter. An important requirement in the conduct of this inspection is that the identity of the carcass and of each of its severed parts be carefully maintained until the inspection is completed, so that if there is a disease in any one organ or part, all the other parts and the carcass may be brought together for additional examination. Facilities for maintaining such identity are provided in the slaughter departments.

The different steps of the post-mortem inspection are: Head inspection, viscera inspection, carcass inspection, final inspection, disposition, and marking. In cattle heads the different pairs of lymphatic glands are cut into and examined, particularly for tuberculosis. The tongue is also examined. The presence in the flesh of cattle of a certain cyst capable of producing tapeworm in man can usually be determined by examining the inner and outer cheek muscles. A careful survey is made of the head as a whole for acanthomycosis, deformities, etc. In the heads of swine certain lymphatic glands, which are favorite seats of tuberculosis, are incised and examined.

In the inspection of viscera, the several organs as they are removed from the carcass are placed before the inspector, on a table, in pans or other suitable metal receptacles for examination. Facilities for promptly cleansing such equipment in the event of contamination through the contact of diseased viscera are at hand. The various organs and parts are carefully viewed and certain of them cut into while others are subjected to manual as well as visual examination.

The carcass inspection embraces a careful viewing of all surfaces and parts of the carcass, with particular attention given to the condition of the serous membranes of the thoracic and abdominal cavities. Further, certain parts which more frequently than others are seats of disease are subjected to a manual as well as a visual examination. The head and carcass examinations together constitute the regular post-mortem inspection. The animals found to be free from disease or any doubtful condition are marked "Inspected and Passed," while those in which any disease or doubtful condition is found are retained for the final inspection, which takes place in a special room, where another inspector with special facilities at his command subjects them to a searching examination. Since the animals held for final inspection are tagged or retained for cause, only veterinary inspectors who have become skilled through training and experience in the work are detailed to make such examinations and to determine the final dispositions.

As soon as the several examinations have been made and the dispositions determined, there remain two important acts to complete the post-mortem inspection. They are the marking of each carcass to show plainly to every beholder the disposition made of it and to see that those carcasses and parts which are condemned are disposed of as required by the regulations to prevent the sale or use of the same as human food. In regard to the disposal of condemned articles it is required that every condemned carcass, part of carcass, meat or product be plainly marked to show that it is condemned, and that parts or products too small to be so marked be placed in appropriately marked containers. All condemned articles remain in the custody of an inspector from the time they are condemned until properly disposed of, and if not disposed of on the day they are condemned they are locked in the "U. S. Condemned" compartments, the locks of which are selected and supplied by the department and the keys of which remain in the custody of the inspector. The required destruction or denaturing of the condemned articles must be done in the presence of an inspector, who renders a report on the transaction. The usual method is to convert condemned parts into grease and fertilizer by rendering in a steam-pressure tank.

**Inspection of Products.**—Because meat or other edible portion of an animal which was entirely sound at the time of slaughter may become unsound or contaminated through improper care or handling, and because healthful products may be made unwholesome through adulteration or the addition of deleterious ingredients, and for the purpose of protecting the purchaser against false and misleading labels, a proper measure of control of the various operations of processing, preparing and labeling meats and products becomes necessary and such control is exercised by the Federal Inspection Service. All meats and products, therefore, notwithstanding that they were previously inspected and passed, are reinspected as often as may be necessary to ascertain whether they remain sound and wholesome. The materials added to products are examined to see that the regulations relating to prohibited ingredients are absorbed and that the requirements as to correctness of labeling are complied with. Samples of the different kinds of products are taken and referred to the meat inspection laboratories for chemical or other technical examination. If upon reinspection of an article it is found to have become unfit for food from any cause, the original inspection mark or label thereon is removed or defaced and the article condemned.

**Imported Meats and Meat Food Products.**—The regulations governing the admission of meat and meat food products from foreign countries require that every importation shall
be accompanied by a certificate signed by an official of the national government of the country of origin; stating that the animals from which the meat or meat food product was derived received an ante-mortem and a post-mortem veterinary inspection, and that at the time of slaughter the meats and products were sound, healthful, wholesome and otherwise fit for human food. Further, that they had not been treated with and contain no ingredient prohibited by the regulations of the United States Department of Agriculture. Meat or meat food product not accompanied by the required certificate is refused entry, and that from a country which does not maintain a system of meat inspection satisfactory to the Secretary of Agriculture is also refused.

Upon arrival every consignment of imported meat or product is checked with the foreign inspection certificate and is subjected to a thorough physical examination, and in most cases samples thereof undergo a laboratory examination. The meat or product is then admitted, refused entry or condemned according to the findings.

Statistics.—The Federal system of meat inspection reaches about 60 per cent of the animals slaughtered in the United States and all imported meats. This leaves approximately 40 per cent of the domestic meat supply outside of Federal control. Much of the latter, it is known, receives no adequate inspection. The number of establishments at which inspection is regularly maintained varies somewhat; however, for several years it has approximated 850. The total of cattle, sheep, swine and goats given both the ante-mortem and post-mortem inspections is in excess of an average of 58,500,000 per year. The average number of whole carcasses of such animals condemned during that period was more than 262,000 per year, while the number of parts of carcasses condemned per year was very much greater. The records of the inspection and reinspections of meats and products subsequent to the slaughter inspection show totals running into billions of pounds annually, while the amount condemned on reinspection account of having become tainted, rancid or otherwise unfit for human food approximates 18,000,000 pounds per year. In 1915 Congress appropriated $3,375,000 for meat inspection, of which the cost was less than six cents for each of the 58,500,000 animals slaughtered. Consult Ditewig, George, 'The Meat-Inspection Service of the United States Department of Agriculture' (in the 'Yearbook for 1916' of the Department, Washington 1917).

MEAT, Market Classes and Grades.—The kinds of meat considered in this article are beef, veal, pork, mutton and lamb. Each kind is classified according to certain general distinctions, such as the sex of the carcass or the part from which the cut is taken. The classes, in turn, are graded with respect to quality, covering, weight or other factors which determine the value of the individual cut or carcass.

Beef.

Beef products are marketed either chilled, frozen or cured. Fresh chilled and fresh frozen beef include the carcasses, quarters and the various commercial cuts of beef. Cured beef includes pickled or corned beef, dried or smoked beef and canned beef. About one-half of the fresh beef sold on wholesale markets consists of beef carcasses (split into halves or sides; each side in turn is divided into fore and hind quarters). The rest is sold in the form of commercial cuts such as ribs, loins, rounds, chuck, plate, brisket, flanks, shanks and skirt. "Block" beef refers to all side beef which is sufficiently thick fleshed and fat to be sold readily over the butcher's block. "Cutters" are the carcasses of thinly fleshed or poorly finished cattle from which only certain commercial cuts such as loins and ribs are suitable for block purposes, the other portions being adapted only to conversion into boneless cuts and cured meat products. "Canners" are those carcasses of beef no portion of which is suitable for block purposes. Such carcasses generally are divided into smaller cuts, such as boneless fresh meats, sausage trimmings, canned and cured beef products.

Classes and Grades of Carcass Beef.—The classes of carcass beef are steers, heifers, cows, bulls and stags. This classification is based not merely upon differences in sex, but also upon the general uses to which the different classes are adapted. Steer carcasses are identified by the cod fat and generally by their full, fleshy rounds and loins, heavier, coarser bones and short, thick necks as compared with cows. They show more quality and finish and are sold as carcass beef more extensively than any other class. The grades are prime, choice, good, medium and common. Heifer carcasses are distinguished from steers by the shape of the udders, which should show no evidence of lactation or a development of the sinuses usual in the udders of cows. As a rule they have smaller bones, slightly more angular rumps, less development of lean flesh and are of an average lighter weight than steers. The grades are prime, choice, good, medium and common. The angular form, long neck, hard white bones, more cavernous interior and lack of thickness of the flesh of the majority of cow carcasses make them easy to distinguish from other classes of beef. They should not split as smoothly as in heifers or young steers. The flesh is seldom well marbled by fat deposits between the muscle structure as in heifer or steer carcasses. A large percentage of the carcasses of cows are sold and canners with a correspondingly smaller proportion suitable for "block beef." The grades are choice, good, medium, common and canners. Dressed bulls are easily recognized by the short and thickly muscled, prominent neck, heavy shoulders, thick rounds, dark and coarse-grained flesh and the absence of cod fat. Rough conformation and hard bones are also common characteristics of bull sides. Many stags approach steers in form, quality and finish, while others are difficult to distinguish from bulls. "Yearlings" are carcasses of young steers and heifers with sufficient quality and finish to be used as block beef. "Butcher" cattle, as the term is applied to carcass beef, are those which are suited to the cheaper butcher shop trade. They are medium and common grades of all classes of beef cattle. "Kosher" cattle are dressed beves that have been slaughtered, inspected, cleansed and labeled in accordance with Jewish rites; "Kosher" being the Hebrew word for "clean"
They include all classes and grades of beef cattle. *Distillers* steers, bulls and stags that have been fed on distillery wastes and have soft, flabby, *wasywashy* flesh together with the *straight cuts* and the characteristic of cattle fattened on such feed.

**Beef Cuts.**—Beef cuts are sold both as *straight cuts* and as subdivisions thereof.

The method of dividing carcasses into cuts differs in the various cities and sections of the country. The straight cuts handled in Chicago markets are loins, ribs, rounds, chucks, plates, flanks and shanks. The standard grades of straight cuts are No. 1, No. 2 and No. 3, according to their weight, quality and thickness. Cuts that are too deficient in thickness and quality to be used on the butcher's block, and which consequently are made into boneless cuts, cured beef products, sausage, etc., are called *stripers*.

**Cured Beef Products.**—The plates, flanks and rumps of all grades of cattle are, at times, used in making cured beef, and in the lower grades of beef the rounds and chucks are quite commonly cut up and cured before marketing. Barreled or corned beef is packed in brine. The cured beef products are extra India mess beef, extra plate or extra family beef, regular plate or family beef, packet beef, common plate beef, rolled boneless beef, prime mess beef, extra mess beef, rump butts beef, mess chuck beef, beef hams and Scotch butocks. Smoked or dried beef consists almost entirely of beef hams, made from the rounds which, after curing in sweet pickle, are dried and smoked. Canned beef is hermetically sealed in tins or glass jars, usually after curing and processing. It consists principally of chopped beef, beef loaf, corned beef and roast beef. Roast beef is not cured but is cooked and processed in about the same manner as corned beef products.

**Factors in Grading Beef.**—The grade to which a carcass, side or quarter belongs depends upon its form, thickness, finish, quality, soundness and weight. The factors that determine the grade of a wholesale cut of beef are its form, texture, covering, quality and weight. By *form* is meant the *build* of the side, its general outlines and the proportions of its different parts. Thickness of a carcass or cut refers to the amount and depth of lean flesh it carries. It is a factor of self-evident importance in selecting wholesale cuts. *Finish* refers to the amount and distribution of fat with reference to the covering of the carcass or cut, to the fat deposits around the muscle structure and to the quality of the flesh insofar as it depends upon the degree of fatness. Quality in beef is so closely associated with form, thickness and finish that the term often is used loosely to cover all three points. It refers more particularly to size, color and softness of bone, smoothness and grain of flesh, color and general appearance of the carcass or cut and an absence of coarseness in general. Soundness refers to freedom from disease and bruises, and from any other conditions which injure the appearance or keeping qualities of the flesh. Weight It is the most important factor of a beef to the extent that the heavier carcasses generally are better in form, thickness, finish and quality than lighter ones; but weight has lost much of its former significance as a grade factor owing to the development of earlier maturing beef types, the increasing practice of finishing and marketing beef cattle as yearlings and two-year olds, and the growing tendency of the consumer to prefer steaks, roasts and other cuts from relatively lighter weight carcasses of good quality and finish.

**Veal.**

Calf carcasses weighing less than 300 pounds with comparatively light-colored, fine grained flesh are classed as veal, and the trade is essentially a fresh meat trade. In dressing calves the skin generally is left on in order to preserve the color and moisture of the flesh. The carcasses from heavy calves are skinned and split and are known as *split veal*.

**Carcass Veal.**—The grade and value of a calf carcass depend upon its form, quality, finish and weight. The weights of dressed veal vary greatly with the season, being highest in April and May and gradually becoming heavier until the next annual veal season. The grades of carcass veal, the extreme weights and the usual weights of each grade are as follows:

<table>
<thead>
<tr>
<th>GRADE</th>
<th>Extremes of Weight</th>
</tr>
</thead>
<tbody>
<tr>
<td>Choice</td>
<td>80-120 lbs.</td>
</tr>
<tr>
<td>Good</td>
<td>70-130</td>
</tr>
<tr>
<td>Medium</td>
<td>60-150</td>
</tr>
<tr>
<td>Light in Common</td>
<td>50-75</td>
</tr>
<tr>
<td>Heavy in Split</td>
<td>150-350</td>
</tr>
</tbody>
</table>

**Veal Cuts.**—Only 10 to 20 per cent of the supply of dressed calves are cut up in the wholesale trade, and this is done largely to supply a few retail markets with choice cuts and to take care of the Kosher trade which uses only the forequarters. The cuts usually made are saddles and racks, both of which grade choice, good, medium and common.

**Pork Products.**

Hog products may be described under two heads: dressed hogs and pork cuts.

**Dressed Hogs.**—The classification of hog carcasses is based on the uses to which they are adapted, or the products into which they may be converted. Smooth heavy or heavy loin hogs are prime smooth hogs, either barrows or good clear (not seedy) sows, weighing 240 to 400 pounds dressed. Butcher or light loin hogs are composed of barrows and smooth, clear sows, weighing from 200 to 220 pounds dressed. Packing hogs include mixed hogs of all weights which are too coarse in quality, rough in shape or soft and uneven in finish to be suitable primarily for fresh pork products or smoked meats, and which therefore are packed principally in such forms as bacon and clear pork. The grading of this class of hogs is based on weight, the grades being heavy, medium and light. Bacon hogs are those which are suitable primarily for sugar-cured breakfast bacon and English meats. The hams from this class of hogs are preferred by the trade to the heavier varieties. The grades are choice, good and common and are determined by the degree of quality and finish. *Shippers* are similar to butter hogs in shape and quality but are lighter in weight and generally are not as highly finished, having only a moderate covering of fat and a comparatively small amount of leaf fat. Pigs are carcasses of light, young swine that are comparatively lean and light-colored in
flesh, with thin, soft skin, soft, red bones, weighing from 20 to 100 pounds.

**Pork Cuts.** The various cuts made from pork may be divided into the following general classes: hams, sides, bellies, backs, loins, shoulders, butts, plates and miscellaneous. These products are referred to according to the manner in which they are handled, prepared or packed; viz., fresh pork cuts, dry-salt and bacon meats, barreled or plain-packed pork, sweet-pickled meats, smoked meats, "English" meats and boiled meats. Fresh pork cuts are sold either chilled or frozen. The bulk of the uncured product is disposed of within a few days after slaughter, during which time it is chilled at temperatures slightly above the freezing point. Fresh pork cuts are taken more or less from all classes of hogs, but light loin hogs are used more extensively for fresh pork than any other class. The loin is the leading fresh pork cut. Tenderloins and spareribs also are used primarily as fresh cuts. Shoulders, plain and skinned, shoulder butts, hams, bellies, fat backs and raw leaf fat are sold fresh to a small extent.

Dry-salt meats are domestic cuts made from heavy, fat packing and loin hogs, cured and shipped in coarse salt. They generally are pumped with a strong brine to hasten the cure and make it more certain. The cuts which are sold in this form are heavy sides, bellies, shoulders, fat backs, plates and jowls. Barreled or plain pickled pork is packed in plain salt brine in tight barrels, and is made largely from sides of packing and heavy loin hogs. It consists principally of mess, fat back and belly pork of various grades. A much smaller proportion of the pork supply is barreled than formerly. Sweet-pickled meats are cured in brine, to which sugar or molasses has been added to aid in curing, to improve the taste and to give the product a better color effect when smoked. Most of these products are smoked before they reach the consumer. The cuts which are quoted as sweet-pickled meats are hams, picnics, New York style and skinned shouldered bonnet butts and light bally. This class of meats is cut principally from butcher hogs and from medium and light packing hogs. Hams and picnics from all classes of hogs generally are sweet-pickled. Smoked meats are pork products which have been cured in brine, sweet pickle or dry salt before smoking. "English" meats is a term applied to cuts that are dry-cured in English salt and salt petre; borax being added when required by the foreign purchaser. They are primarily adapted to English trade, being given a milder taste than domestic meats. The leading cuts of this class are "English" bacon sides, long-cut hams, clear backs and bellies and square-cut shoulders. Boiled and cooked meats consist of bonnet hams, picnic shoulders and loins which have been cured in sweet pickle and cooked by steam or in water. They are sometimes given a light smoke.

Hams are of two general kinds, short-cut and long-cut. The former are made from comparatively fat, plump side and back, cut round at the butt, with the foot cut off generally above the hock joint. Long-cut hams are lean, long hams, with the but left full and the foot taken off at the first joint below the hook. Sides include various grades and cuts of short ribs, short clears and "English" bacon sides. Short rib sides include regular short ribs, jobbing or rough short ribs, hard short ribs, extra short ribs, *extra* ribs, *extra* short ribs or "English" short ribs. Short clear sides include regular short clear sides and extra short clear sides or "extra clears." "English" bacon sides, comprising both the side and shoulder, and in one instance the ham also, include Wiltshire, Cumberland, Dublin, long rib, long clear, York- shire and Staffordshire sides.

Bellies include dry-salt, sweet-pickle, breakfast bacon and English bellies. Backs include the short rib backs, short clear backs, short fat backs and long fat backs. Loins consisting of the back with the fat trimmed off are sold either as regular pork loins or as loin rolls.

The standard grades of shoulders are rough, regular, picnic, New York style, skinned, square, New Orleans style and boneless rolled shoulders. Shoulder butts are cut from muscular parts of the ends of tops of the shoulders. Jowl butts are made from the jowl (neck and face). The various grades of shoulder butts are boneless Boston style, Milwaukee style, Buffalo style, New York style, picnic, dry-salt and square-cut butts. Plates are made from the heavy fat which covers the ends or tops of the shoulders. They are known to the trade as regular plates and clear plates.

The so-called back plates are made from fat backs.

**Miscellaneous Cuts.**—The miscellaneous cuts of pork may be grouped as mess pork, belly pork, shoulder pork, spareribs and trimmings. Mess-pork includes regular mess pork, light mess pork, prime mess pork, extra clear pork and loin clear pork. Belly pork includes regular belly pork, brisket pork and rib and lean belly pork. Back pork includes regular back pork (short cut mess or family back pork), clear back pork, fat back and short cut clear pork and ham butt pork (loin end or rump pork).

Shoulder pork consists of extra prime pork and Boston style butt pork. Bean pork or clear butt pork is made from the jowl. Spareribs are termed "full-sheet," "half-sheet" and "backbone" spare ribs. Neck bones including the shoulder ribs come within this general class. Trimmings are of two grades: special lean or "A" and regular or "B" grade. The standard grades of lard are keistle refined, prime steam, refined and compound lard. They differ as to the kinds of fats from which they are made, methods of rendering, color, flavor and grain. Lard compounds are composed of a mixture of pork fats with other animal or vegetable fats or oils. Lard substitutes or vegetable shortening contain no pork fats or oils, being composed wholly of vegetable fats, or of vegetable fats with beef fats added.

**Mutton and Lamb.**

Mutton and lamb are sold almost entirely in a fresh or frozen state. The bulk of supplies, except those frozen, are disposed of within a week or 10 days after slaughter. Approximately two-thirds to three-fourths of the wholesale supply of mutton and lamb consists of lamb.

**Classes and Grades of Carcass Mutton and Lamb.**—The classes of dressed sheep and lamb are wethers, ewes, bucks, yearlings and lambs. This classification is based on differences
in sex and degree of maturity. The grades of
carcasses in the different classes are designated
by the terms choice, good, medium, common
and culled or cutters. The grade and value of
a lamb or mutton carcass depend chiefly upon
its form, quality, covering and weight. The
method of grading is the same in principle as
the grading of beef.

Wether carcasses are distinguished from
ewes by the cod fat; from bucks by their
smaller necks and shoulders and finer quality,
and from yearlings and wether lambs by
*round* joints on the fore-legs. The *bae*
(udder) and a comparatively large *bung
(pelvic cavity) are characteristic of ewe car-
casses. They also are distinguished from
wethers as a rule by their more angular forms,
longer necks, smaller bones and less abundant
flesh, especially over the loin, back and ribs.
Bucks constitute only a very small percentage
of the dressed mutton supply. They may be
identified by their thick, heavy necks, shoulders
and briskets, large bones, coarse, dark colored
flesh and fat and thick, oily *skin* or *fell.*
Yearlings may be defined as carcasses of that
size that show by their general development by the *break-
joint* that they are not mature sheep, but are
too old and generally too heavy to be classed as
lambs. Carcasses of sheep that are more in-
mature than yearlings are classed as lambs.

Like yearlings, they have the fore-legs removed
at the *break-joint* or *lamb-joint,* which has
a tooth-shaped surface.

**Mutton Cuts.**—About one-half the supply of
dressed wethers, ewes and yearlings in large
wholesale markets is sold as mutton cuts. The
feet and parts sold as mutton cuts are:

1. Prime品质的里脊肉
2. Cuts sold as mutton cuts.  
   - **Prime rib of beef (first cut).**
   - **Prime rib of beef (last cut).**
   - **Shoulder block roast.**
   - **Chuck Rib roast.**
   - **Loin of beef.**
   - **Ham (smoked).**
   - **Pork shoulder.**
   - **Backbones and neck bones.**

Retail cuts of mutton are classified according
to several different standards. Some are satis-

The purpose for which each retail cut from
beef, veal, lamb and mutton, and pork may be
used is indicated below. The number of pounds
usually found in each cut is shown by the
figures opposite the cuts named.

LOUIS D. HALL,
Specialist in Marketing Livestock and Meats, Bureau of Markets, United States Department of Agriculture.

MEAT EXTRACT, or juice of meat, has become since its introduction by Liebig (q.v.), a subject of great importance in medicine, dietetics and commerce. The chemical constituents of meat juice are not clearly established, although creatine, sarcine and inosinic acid are among the substances intelligently investigated. Phosphoric and hydrochloric acids and inorganic salts, with some coagulable ingredients are among the constituents. Beef tea while of value does not furnish complete food either for sickness or health. Other preparations under this name are now on the market. Some are merely the juice of meat pressed out or dried and pulverized meat; others are the so-called predigested foods. In the true extract of meat fats and albumens are absent; therefore, while of use as a stimulant, such a preparation is not a true food and cannot take the place of meat in this respect.

MEAT INSPECTION ACTS. See Pure Food Acts.

MEAT-PACKING. Meat-packing may appropriately be considered under three heads, namely, preparation and disposal of fresh (unsalted) meats; curing and preservation of meats by salting, smoking and the like, as is usually practised with hog hams, bacon, etc., and preservation of meats by hermetically sealing in tin cans, glass jars, etc., including the final sterilization necessary to complete the process.

The preparation and disposal of fresh meats is perhaps the most important branch of the packing industry and in its development is the newest. Fresh meat has been, of course, an article of commerce from the earliest times; but it is only within recent years that the art of refrigeration has been perfected to an extent enabling fresh meat to be shipped thousands of miles and its condition and quality so conserved that it is more desirable and palatable after arrival at destination than when first slaughtered. Fresh beef, particularly, is much more juicy and tender if well refrigerated and kept two weeks or more after slaughter. Fresh meats will keep best if held in a temperature slightly above the freezing point but in practice a temperature of 35° F. gives good results, except for long shipments such as from United States ports to Europe, in which cases approximately the freezing point should be maintained; and it may herein be observed that lean meat freezes at about 1½° lower temperature than water.

Freezing is slightly injurious to the palatable quality of fresh meat, but by freezing hard and holding at a temperature of 10° F. it may be kept without taint for many months. When beeves are in good supply and cheap, the choice cuts, such as ribs and loins, are frozen and held in large quantities until the winter and spring season, when they usually meet with a more favorable market. Fresh pork and lamb are sometimes frozen and carried from season of surplus to season of scarcity, but the volume of this trade in the United States is not great, comparatively. This carrying from the season of over-supply to the season of under-supply by means of freezing has a doubly beneficial effect on the market, increasing the demand for live stock during time of glut, and increasing the supply during the time of scarcity.

The dressed carcasses are, immediately after slaughter, still being suspended from the trolley hooks on which the latter part of the dressing operation is done, run into refrigerated rooms and chilled, usually for two days. The cattle carcasses, and usually the hog carcasses, are split through the back bone into "sides." After cutting, the sides are cut, the beef usually into quarters and the pork into smaller pieces. The quarters of beef are shipped hanging on hooks in refrigerator cars, and the smaller pieces intended for sale fresh are usually boxed and shipped also in refrigerator cars. Many of the lamb are shipped in the same way, usually in whole carcasses. The refrigerator cars used depend upon ice for their temperatures, and the most successful cars use the ice crushed and with from 6 to 12 per cent of rock salt.

The development of the fresh meat branch of the packing industry received its first important impulse from George H. Hammond, who, in the summer of 1869, began at Hammond, Ind. (a suburb of Chicago), the business of shipping fresh beef in refrigerator cars to Boston. The first year the business was not successful, but it was courageously continued, the difficulties were gradually overcome, and the second year found it more satisfactory, and the volume amounted to about 600 quarters per week. During the following two years this volume was doubled and it continued to grow moderately until, in 1887, Gustavus F. Swift established at the Union Stock Yards, Chicago, a similar business. Under the stimulus of this competition the trade increased rapidly, consignments were made to other cities in New England and New York, other houses entered the trade, and by 1885 it became apparent that this new method of slaughtering cattle near their native pastures and shipping the carcasses thus prepared to supersede, largely, the older method of shipping them on
the hoof and slaughtering near the place of consumption. To-day a large portion of the fresh beef used in the principal cities east of Chicago and a part of that in the West is delivered at destination in refrigerating cars. What is true of fresh beef is true also of fresh mutton and pork.

In the early days of the fresh meat branch of the packing industry, it became apparent that new and improved methods and equipment was necessary; obviously, fresh meat could not be received in carloads and distributed to the retail dealer, through an ordinary, unrefrigerated warehouse, as had been the custom with cured meats. To meet the necessities of the case, refrigerated rooms were built, with systems of overhead tracking, on which quarters of beef and carcasses of small stock were stored and handled, suspended from trolley hooks. In connection with these refrigerated rooms, or meat coolers, as they came to be known in the trade, there were built suitable shipping rooms, offices, etc. These distributing houses were, as a rule, built adjacent to railroad tracks, enabling the direct discharge of meats from the cars. As the time came for consolidation of the packing industry, it became evident to the packers that great care in the construction, maintenance and operation of these distributing houses was of the utmost importance; it was therefore desirable that a packer own and operate his own fresh meat preserving plant, rather than to continue the operation of the older type of family business. As a result, many of the early large houses were converted into preserving plants, with the curing processes used by the packers of earlier days.

Curing and Preservation by Salting, Smoking, etc.—The preservation of meat by salting, smoking, etc., was the first method extensively practised, and the term “curing,” now applied to the whole business, formerly had a narrower meaning and was used in connection with this branch exclusively. In fact this was, in the early days, the only branch.

From the earliest times meats have been cured by salting and smoking and in principle there is nothing essentially different in the practice of the modern packer from the curing processes used by the packers of earlier days. The business is now conducted on a much larger scale, and with more care as to conditions, particularly as to refrigeration and sterilization, so that meats are now cured with less salt than formerly, or to use the trade expression, mild cured.

The two methods of curing with salt are known as “pickling” and “dry salting.” These terms are relatively descriptive. In pickling, the meat, after being cut into hams, shoulders, etc., is submerged in pickle or brine and kept under the surface with weights or other devices, so the salt in the pickle is diffused through the meat. This causes the strength of the pickle to decline and the meat to become soft. In dry salting, the meat is placed on a fresh hoghead with restrengthened pickle. The usual time of cure varies with the size of the joints or pieces of meat, but ranges usually between 30 and 45 days. The pickle is made of various strengths for various cuts of meats, but is generally 40" to 50" salometer, and for hams, bacon and the finer cuts of meat contains sugar as well as salt and a small percentage of saltpetre. Meats for consumption in the United States are generally cured in sweet pickle.

The process of dry-salting is to pile the joints or cuts of meat closely in layers on the curing floor, first rubbing them thoroughly with salt, and sprinkling salt freely between the layers and on top. The piles are made three or more feet in height, and the refrigerating car, as used to-day by practically all of the packing companies, has reached its present state of development by a steady growth of improvements made from time to time. This matter of preservation of the refrigerator car has been one in which there has been great rivalry among the various packers, and to this competition is due the high efficiency of the present refrigerator car for carrying fresh meat. The building, maintenance and care of these refrigerator cars is the field of one of the most important departments in connection with the various packing companies. These cars must not only be kept in first-class running order so as to make them suitable for operating on fast trains, but they must be kept in a high state of cleanliness. The icing of the cars is also a very important feature and has to be done with the utmost care. Before loading, the cars must be iced at least 24 hours in advance, so as to be thoroughly cooled. They are then re-iced at the time of shipment and are re-iced in transit as necessary, depending upon the length of the journey. Immediately after unloading, the car is scrubbed with soap and hot water, all hooks are wiped clean and the car is ventilated so that it will return home in a sweet, clean condition.

The two methods of curing with salt are known as “pickling” and “dry salting,” and these terms are relatively descriptive. In pickling, the meat, after being cut into hams, shoulders, etc., is submerged in pickle or brine and kept under the surface with weights or other devices, so the salt in the pickle is diffused through the meat. This causes the strength of the pickle to decline and the meat to become soft. In dry salting, the meat is placed on a fresh hoghead with restrengthened pickle. The usual time of cure varies with the size of the joints or pieces of meat, but ranges usually between 30 and 45 days. The pickle is made of various strengths for various cuts of meats, but is generally 40" to 50" salometer, and for hams, bacon and the finer cuts of meat contains sugar as well as salt and a small percentage of saltpetre. Meats for consumption in the United States are generally cured in sweet pickle.

The process of dry-salting is to pile the joints or cuts of meat closely in layers on the curing floor, first rubbing them thoroughly with salt, and sprinkling salt freely between the layers and on top. The piles are made three or more feet in height, and the refrigerating car, as used to-day by practically all of the packing companies, has reached its present state of development by a steady growth of improvements made from time to time. This matter of preservation of the refrigerator car has been one in which there has been great rivalry among the various packers, and to this competition is due the high efficiency of the present refrigerator car for carrying fresh meat. The
Hams, shoulders, bacon and side meats are, after curing, generally smoked. The process of smoking is also quite old and its origin unknown. The meats are hung in brick houses or compartments in tiers, as closely together as practicable without touching, a slow fire of wood is built beneath, and the meats kept in the resulting smoke for 12 to 48 hours. They are then cooled, wrapped, boxed and made ready for shipment. The hams and bacon, also the meats, generally have a brand burned in the skin before wrapping. For shipment to hot climates the pieces, after wrapping in paper, are also “canvased,” or sewn up in cotton sheeting, and coated with a thick pasty solution of China clay, bayries or the like, and then dried. This forms an air-tight, vermin-proof covering. Hickory and sugar maple are the best woods for smoking.

The preceding paragraphs relating to the curing of meats by salting, smoking, etc., describe the process as applied to meats of the hog. Beef is cured in like manner by pickling and is generally shipped to destination and kept in the pickle until removed for consumption. An exception is “dried beef,” being the suitable lean pieces, which, after curing in pickle, are smoked slowly for several days so as to dry them to a firm condition.

**Preservation by Hermetically Sealed Cans, etc.**—The method of preserving meat by packing in hermetically sealed tin cans and the like was introduced commercially into the United States about the year 1873 at Chicago, Ill., by William Wilson and John Wilson. In the following year Libby, McNeil and Libby also entered this trade, and during succeeding years other houses followed. The business grew rapidly from the beginning, and has reached great magnitude.

The process in brief is as follows: The meat after being trimmed from the bones and cut into small pieces is put into a curing pickle composed of common salt and a little sugar in solution. It is left in this pickle any length of time from a few days to 20 days, depending upon the degree of saltness desired. It is then taken out of the pickle and cooked in hot water until thoroughly done. After this the gristle is trimmed out, the surplus fat is removed, and the pieces are cut into small and comparatively even sized bits, usually not exceeding four cubic inches. In this condition, and while still hot, it is stuffed by an automatic machine into tin cans which have previously been prepared and thoroughly washed. Each can is then weighed so as to get the correct quantity of meat in it, and is “capped,” that is, a small tin disc is soldered over the hole through which the meat is introduced into the can. The further steps of the process embrace the sterilization, or so-called “processing,” which consists in heating the cans for a number of hours up to a temperature of 250° to 350° F., depending upon the size of the can and the kind of meat. The object in heating is sterilization, being the same process as is pursued by the housewife in canning fruit, etc. The cans are then washed, cooled, labeled and the exposed surfaces are coated with a varnish to prevent rust. They are then ready for shipment, and shipped to all parts of the world, and will keep for years without deterioration.

**By-products.**—The business of meat packing as practised in Chicago and the other large packing centres of the United States involves not alone meat preserving, but the entire range of slaughtering, preparation of the fleshy and other edible parts, and preparation of the by-products, such as hides, hoofs, horns, bones, hair, fats, intestines, blood and viscera. In many of the most prominent establishments these by-products are manufactured into glue, buttons, combs, curled hair, soap, candles, oils, glycerin, etc. All the modern establishments manufacture the blood and residual solids from their fat rendering apparatus into fertilizers, in some cases the blood-albumen being first separated and dried independently.

The accompanying diagram will illustrate graphically the disposition usually made of the different parts of beef cattle.

Corresponding parts of other animals are put to similar uses. The stomachs of hogs are utilized for peptic manufacture. Some of the glands of hogs, sheep and cattle, notably thyroid and pancreatic, are used in the production of pharmaceutical preparations. Sheep skins first have the wool pulled from them and are then utilized for leather, the cuttings being made into glue. Hog hair also is made into curled hair and brushes. Curled hair is sold for mattress making. All scraps and parts not put to some other important use, are cooked, desiccated and used in many valuable products and as fertilizing material, the chief property of which is nitrogen.

**General.**—By the careful study of economy in utilization of by-products large values are now derived from parts formerly wasted. To-day there is practically nothing wasted. This close study of economy in saving everything enables the packing business to be done on an unprecedentedly small margin of profit. For a series of years, during 1911, the financial reports, made by some of the largest and most successful packing corporations to their stockholders, show that their profits ranged from 2 to 2½ per cent of their distributive sales.

It must occur to all thoughtful persons in a business of such large volume the securing of steady and sufficient supplies of fat animals is of prime importance, and how this comes to be how this is done. Almost the entire supply of live stock is purchased from day to day, as needed by the various packing companies, at central markets in the large cities, such as the Union Stock Yards of Chicago, Kansas City Stock Yards of Kansas City, National Stock Yards of East Saint Louis, South Omaha, Neb., South Saint Joseph, Mo., South Saint Paul, Minn., National Stock Yards, Ill, Fort Worth, Tex., Sioux City, Iowa, Oklahoma City, Okla., Denver, Colo., etc. These stock yards are equipped to receive live stock in train loads—unload, pen, feed, water and otherwise care for the comfort and health of the animals.

Live stock raisers most frequently sell their animals at home to a dealer, who, in turn, consigns to a commission salesman at some central market, where the buyers for the various packing companies meet in competition and bid for each lot or car-load. The bidding is not by public outcry or auction, but by each buyer independently. There is no public system of grading, but each purchase is made on individual inspection and judgment of the buyer and salesman.

The development of these stock yards has

kept pace with the growth of the packing industry. Indeed, these large central markets for live stock and the packing plants are interdependent and mutually helpful. Together they constitute one of the modern wonders of our commercial development. The benefits to the raiser of live stock, the live stock dealers, the transportation companies, the retail dealer, and to the consumer, of an organized business that affords the producer an every-day cash market for any number of animals, the carrier a reliable and steady freight volume, and the retailer—and through him the consumer—a constant supply of the widest variety of kind and quality of animal food products, can hardly be exaggerated. To appreciate these benefits, let the reader try to imagine a return to the conditions of a generation ago. Within the memory of many still engaged in the business, the farmer had only a local and very uncertain market for his live stock. He could sell in limited numbers, must find his customer by inquiry and frequently had to wait for weeks after his stock was typed and right for slaughter. The business depended on local supply, and must needs ride through the countryside and inquire, and frequently felt compelled to buy and use stock of a quality not suited to the demands of his business. He had to drive the animals to his little, unsanitary, slaughterhouse, slaughter them himself in the cool hours of the night, and hurry the sale of the fresh meat before incipient decomposition. He was constantly oversupplied or undersupplied, had too much of one grade and too little of another, and so frequently met with losses that his margin of profit must needs be large. The consumer, of course, could fare but ill under these conditions. He might whet his appetite with the thoughts of a juicy porterhouse or a prime rib roast, and find his butcher could furnish only veal or pork chops, and was compelled constantly to choose from a narrow and unattractive variety, and to pay an excessive price. Values were unstable and varied greatly, and producer, dealer and consumer alike suffered.

The day the modern packing-house, with the central market for live stock which it has built upon one hand, and its system of refrigeration and distribution on the other hand, brings the producer and consumer into such near touch that the one can market his animals in any town or village of the country having railroad connections, any desired quantity and quality of so wide a variety of animal food products that his slightest whim or necessity can be satisfied. This bringing together of the producer and the consumer the modern packer, with the aid of our railroads, stock yards and refrigeration, has accomplished, to the enormous benefit of both; and to-day the actual producer gets a much larger part of the total price paid by the actual consumer than ever before. Investigations by the United States Department of Agriculture showed that the producer received about two-thirds of the price paid by the consumer for meat and by-products.

In this age of engineering and mechanical advancement, the use of machinery, of course, played a prominent part in the development of the business of meat-packing. The modern packing plant is divided into many departments, so related with reference to each other that the whole, in reality, constitutes a vast machine. The invention and perfection of machines to do the various kinds of work has been given a great deal of attention, and the practical men in connection with the different packing companies have vied with each other in that improvement has followed improvement, in many cases one machine being improved by another before fairly having the newness worn off. To-day, in the most up-to-date packing plants, the vast majority of the operations carried on are done by machinery. Such plants are operated entirely by electric power, are lighted by electricity, supplied with water by electric pumps, refrigerated with cold brine circulated by electric pumps, and in some cases the live animals themselves are hoisted from the ground to the top floor of the slaughter-house by enormous electric elevators, carrying a car-load at a time. They are hoisted by means of electrically-driven hoists. Hogs are scalded, scraped, cleaned and delivered to the chill-rooms by machinery, hand work being reduced to less than half what it formerly was. The meats are cut by machinery, also sprinkled and rubbed with salt and packed. Hams are branded by machinery, and are carried by mechanical means to the loading platforms, ready to go into the cars.

In the handling of by-products, various machines do all of the most important work. Fer-tilizing materials are cooked, pressed, dried, ground, sifted and packed in bags and weighed by machinery. Bones are dried, sawn, made into knives, and hung on hooks, etc., largely by automatic machinery. Glue is evaporated, jelly sliced, jarred, broken, ground, bolted and packed into barrels by machinery. Soap is cut into bars, stamped, wrapped, packed into boxes, and the boxes nailed and printed by machinery. Soap powder is mixed, ground, sifted, packed into cartons, labeled, pasted and delivered to the boxes by machinery. So on, throughout the various departments, great attention has been given to the introduction and perfection of machines, so that the modern packing plant, volume considered, uses no more than half the hand labor that would have been required 20 years ago to do the same amount and variety of work.

The packing business is one of the largest industries of the country in the value of its output. For 1910 the census report shows 1,641 establishments employing 108,716 persons, with a capital of $383,249,000; value of output $1,370,568,101. This industry returns to the producers of the raw material 87.8 per cent of the total value of the products. Statistics of slaughter for the year 1909, are as follows:

MEATS AND MEAT PRODUCTION

The packing business is notable for furnishing a spot cash market for any quantity of live stock that the producer chooses to send to the market. It is notable for its ability to distribute products of live stock throughout the world, where the demand is greatest. For the enormous volume of business done by the large firms and for their very small margin of profit per cent of sales.

LOUIS F. SWIFT,
President, Swift and Company, Chicago.

MEATS AND MEAT PRODUCTION.
The discussion of the subject will be confined to a consideration of the properties, use and production of the flesh of cattle, sheep and swine for human food. All animal tissues are made up of dry substance, or solid material, and water. The per cent of water in meats varies from 10 to 78. The two things which appear to have the greatest influence upon the percentage of water in meat are the age and condition, or degree of fatness, of the animal. Other things being equal, the younger the animal the more water its flesh as well as other tissues contains; while the higher the percentage of fat in the meat the lower the percentage of water.
The extreme variation in the water content of different cuts and varieties of meats is due largely to an extreme variation in fat content. The lean meat consists approximately of 75 per cent of water and 25 per cent of solid material. While the water in meats aids in their digestion and absorption in the alimentary tract, the nutritive value of meats rests largely on the quantity and character of the dry substance or solid material they contain. From 50 to 65 per cent of the fat steer is meat. In other words, the dressed carcass of a steer represents from 50 to 65 per cent of the weight of the live animal. The remainder is made up of by-products, in general, such as hides, fat, offal, etc., less valuable than beef. A physical examination of meats shows them to be made up of muscular tissue or lean meat, fatty tissue or fats, cartilaginous tissue or the gristle, and bone. From the standpoint of the nutritive value of meat, gristle and bone are practically refuse.

Composition.—Chemically, meat is composed of protein, fats, water, ash and carbohydrates, which are the necessary food constituents for the production of energy and repair of the animal body. The amount of carbohydrates is so small as to make it almost a negligible factor. Extractives are also present in meats which are believed to be responsible for meat flavors. While differences in the chemical composition of two cuts of meat are not necessarily an indication of their relative food value, yet the composition of meats in general is important as indicating their place in the diet of man. Lean meat contains from 15 to 21 per cent protein; whole eggs, 12.5 per cent; fresh fish, 25 per cent; and dry peas, 30 per cent. Fresh vegetables, other than peas and beans, contain 0.5 to 3 per cent protein; fresh peas and beans, 2 to 7 per cent; wheat flour, 10 to 12 per cent; and dry peas and beans, 18 to 25 per cent.

It will be seen that meat contains a relatively high per cent of protein as compared with other staple foods. The mineral matter comprising the ash of meats is made up chiefly of potassium phosphate, with small amounts of magnesium, sodium, calcium, phosphates and chlorides. The percentage of ash in fresh edible meats varies from 0.5 to 1.3 per cent. The organic extractives of meat consist mainly of creatine, certain basic nitrogenous substances including the purine bases, and small amounts of lactic acid, glycogen or animal starch and glucose in traces. Glycogen and glucose are the only carbohydrates in meat and occur normally in very small quantities. The percentage of organic extractives in meat varies widely with the kind of meat and the location of the cut, from 0.7 to 2 or 3 per cent.

Dietetic Value.—Meat is a staple food in the American dietary, chiefly as a source of protein and fat. In the average American dietary, 28 per cent of the protein and 58 per cent of the fat is represented by the consumption of meat from cattle, sheep and swine. Protein is essential for the growth and repair of body tissue, and while the actual bodily requirement for protein may be relatively small, it seems probable that a fairly liberal protein intake is essential for optimum conditions of health and vigor. Meat is essentially a factory source of protein in the diet, first, because it is so readily and completely digestible as compared with the vegetable proteins, and, second, because it is better adapted to the body's requirements and thus possesses a higher physiological value. Illustrative of the latter point, in a recent experiment on a human subject it was shown that the following minimal amounts of the various proteins indicated were required to cover the protein requirements of the body and to protect body protein from loss:

- Meat protein: 30 grams per day.
- Milk: 31 grams.
- Rice: 28 grams.
- Potato: 54 grams.
- Beans: 36 grams.
- Bread: 102 grams.

The value of meat as a food is also enhanced by its content of organic extractives. These substances are among the water-soluble constituents of meat and give to meat its characteristic flavor. Thus, it may be shown that the greater palatability of the higher priced cuts of beef is associated with a higher percentage of organic extractives in the lean meat. While the organic extractives have practically no food value, as the term is ordinarily used, yielding but little energy or structural material to the body, they are known to be potent in stimulating the digestive glands, especially the gastric glands, and thus probably play an important rôle in digestion.

From one-tenth to one-third the cost of food in the average family is paid out for meats. Some facts are given therefore which throw some light on the question as to the desirable qualities of beef. Beef is used to illustrate the matter of quality because it is pre-eminently the most popular flesh food and because quality means more in beef than in mutton or pork, especially the latter. If all the desirable qualities of beef could be secured in one cut it would be palatable, nutritious and easy to digest. This is practically impossible, however; there are wider differences in cuts of meat as to palatability and cost than as to food value, while the less-
pensive cuts may be rendered more palatable by proper methods of cooking. Palatability of beef depends upon tenderness, juiciness, quality and flavor. Tenderness, juiciness and flavor depend upon the age of the animal, the location of the cut, the condition of the animal as to ripeness, the degree of ripeness of the meat and the method of cooking. As a rule the younger the animal the more tender the meat. Perhaps nothing, however, has more influence upon tenderness than cooking,—different cuts requiring different treatment. The flesh of young animals invariably lacks that fine marbled appearance, or distribution of fat throughout the muscular tissue that is so characteristic of beef of high quality taken from mature bullocks that are in a finished or well-fatted condition. The beef of young cattle is also more or less lacking in flavor. Satisfactory flavor in beef is of course largely a matter of individual preference, but a reasonable state of maturity and development is required to give beef its most characteristic flavor. It is significant that the more tender cuts of beef, such as the tenderloin, lack noticeably in flavor. Good judges agree that the best dressed beef for export is that which are frequently used during the life of the animal. This exercise renders these muscles tougher, but of distinctly higher flavor. Beef cut from cattle of rather advanced age, or for that matter from cattle of any age, is rendered relatively more tender by the ripening process. Fresh beef that has not hung in the cooler for 10 days to two weeks lacks both in tenderness and flavor. Even a longer time in cold storage is desirable with higher grade beef. The beef cut from well-fattened steers of good quality or containing a high percentage of beef blood can be much more satisfactorily ripened in cold storage than that cut from mongrel bred steers which have been slaughtered in an indifferent condition. Carcasses of prime steers possess a characteristic coating of surface fat which protects the lean beef from too much exposure and gives it an opportunity to fully ripen. In the case of the carcass from the medium and common grades the beef frequently lacks that surface fat which seems to serve such a useful office during the ripening process. Low grade beef will literally rot before it will ripen. Juiciness in beef is largely dependent upon the percentage and distribution of fat, and the method of cooking. While an abundance of fat anywhere on a cut of beef adds materially to its apparent juiciness, an even distribution of fat throughout the muscular tissue, a condition which gives to the meat when carved (especially when cold) that beautifully marbled appearance, is the leading factor in contributing ideal juiciness to the beef. Juiciness may be easily destroyed by too prolonged roasting or broiling. The marbled quality in beef is seldom seen except in reasonably mature well-fatted cattle.

Prime condition in the live animal is essential for producing high quality in beef and other meats as well. In order to secure the highest quality in meats the consumer must pay a relatively high price for meat considerably more fat than can be agreeably eaten along with the lean of the cut, thus making it necessary to utilize the superfluous fat for other purposes or consider it as waste or refuse. In either instance it renders the edible meat of high quality relatively high priced as compared with low grade meat. On the other hand, meat of high quality need not necessarily be the product of a large and fat carcass, for, when properly cooked, it is so delightfully tender and juicy that all of it is edible, save possibly a small amount of superfluous fat. However, this extra fat is of such quality that it can be readily rendered and used for cooking purposes to supplement or in some instances satisfactorily take the place of more expensive shortening. Another fact which should not be overlooked is that the cheaper, and as generally considered, less palatable cuts taken from a carcass of beef possessing high quality are often fully as desirable as the best cuts from low grade carcasses.

Packers.—The packer or slaughterer of meats is willing to pay a premium for animals in prime or well-fatted condition because when slaughtered they yield a higher percentage of dressed meat, fat, and, in the case of cattle, hides. Not only is this true, but the packer understands that prime condition in the live animal is a strong indication of high quality in the carcass. Poor carcass condition is a prime requisite for producing high quality. It has a greater influence undoubtedly than high breeding. Again, the packer pays a premium for cattle prime in condition and prime in quality, or good breeding, because in well-bred animals the percentage of high priced cuts is greater than in mongrel or indifferently bred stock. Undoubtedly, the tendency of the meat trade is to concentrate in larger part the slaughtering of the country at leading market centers like Chicago. In other words, gigantic and powerful packing companies have developed from small beginnings until they have within their combined power the ability to practically regulate the market for live cattle, hogs and sheep and meats the world over. Chicago is the greatest live stock and meat market in the world. A large majority of local meat markets in the cities and villages throughout the United States are supplied through the medium of the packing-houses located at our leading livestock markets. Packing-houses can furnish any grade of meat desired. For example, in beef they can supply all grades from No. 1 to canning stock at prices corresponding with the quality. So economically is the business of the packing-house administered and so well organized are the various industries growing out of the wholesale slaughter of meats that it is possible for them to sell practically all grades of beef in cities and villages remote from their central plant at prices which successfully compete with local competition. The local purveyor of meats can buy whatever grade of meat he can dispose of to advantage. As a rule in the smaller cities and villages the retailer buys a medium to low grade carcass, because his trade is not willing to pay prices which of necessity must be paid to secure meat of high quality. It is safe to say that the beef offered at such markets is seldom above No. 2 in grade, no matter whether the market is supplied by packers or local slaughterers.

It is impossible to predict the ultimate effect upon the meat trade of the change from local to packing-house slaughtering. On the one hand a packing-house trust can control the price of
meats and meat production

The following table shows the annual per capita consumption of meat, including beef, mutton and pork, for different countries:

MEATS AND MEAT PRODUCTION

Per capita consumption of meat in all countries for which the information is obtainable, probably of dressed weight is expressed in pounds, unless otherwise stated. For Germany, some parts are included in addition to dressed weight in the preceding table.

From this table it is evident that the per capita meat consumption for the different countries reported varies within wide limits, Italy ranking lowest and the Australian Commonwealth highest. The high figure for the latter country is largely fictitious, due to the excessive waste of meat and meat products for which the Australian is noted. The low figure of 40.5 pounds of meat as the per capita consumption in Italy is the result of a thorough investigation of the slaughter of meat animals in every commune in Italy, made by the Director-General of Public Health. The per capita figure for the United States ranks third in the list. Of the estimates given in the table of the meat consumption in this country, those of the Bureau of Statistics are undoubtedly the most accurate; and of the three figures given, the last, representing the per capita consumption of edible dressed meat and of other edible portions of the carcass, is undoubtedly the most significant as indicative of the actual consumption of meat.

As a nation the United States leads all others in the production of meat. The table presented on p. 495 shows that the United States produces one-third of the world's supply of beef. The United States also produces more than one-half the pork and one-seventh of the mutton of the world.

The accompanying tables are interesting as showing the relative amounts of beef, mutton and pork consumed in a few of the principal countries:

* Vols. 65 and 67, Royal Statistical Society.

Williams has conclusively shown that the importation of American and other foreign beef and mutton has materially reduced the London wholesale price of these meats. His statement is here reproduced:

Average wholesale price of beef in London markets:
1876-80 from 5s. to 8 d. per pound.
1895 from 2d. to 6d. per pound.

Average wholesale price of mutton in London markets:
1876-80 from 7d. to 9 d. per pound.
1895 from 2d. to 7d. per pound.

The total amount of meat products exported from the United States in 1915 was $25,243,600, valued at over $90,000,000. In 1916 $50,416,690 pounds valued at $780,000,000 were exported. Meat production is one of the leading industries of the farms in Iowa, Illinois, Missouri, Indiana and Ohio. In fact wherever corn thrives there we find meat production an important industry. Corn is undoubtedly more largely used in meat production than any other feed. The problem of economic meat production in the United States is largely a question of the best method of utilizing corn and its by-products. There is a gradual and apparently necessary and certain change, just beginning, which will have an important bearing upon beef production in the United States. With the closing of many ranges in the range country which have hitherto furnished a high percentage of stockers and feeders which have been finished on the corn belt, or at any rate upon corn grown in the corn belt, the problem presents itself, where are cattle feeders to look for their future supply of feeding cattle? Everything points toward the utilization of more of the cattle fattled for the market on the high-priced lands in the corn belt will be bred and reared there. In other words the entire process of beef production will necessarily be
carried on by the majority of cattle men. As it is, about 85 per cent of the native beef cattle marketed in Chicago have been previously bought as feeders and finished by cattle feeders who do not breed or rear the cattle they feed. The tendency in meat production at present is to put live-stock in marketable condition and market them at an earlier age. This system involves the feeding of ruminants, the feeding and a large use of nutritious foods.

MECCA, měk’ə, or MAKKA, Arabia, the holy city of Arabia, the Mecca of the Muslims, the capital of the province of Hejaz, about 49 miles east of Jiddah, its port on the Red Sea, with which it has telegraphic communication. The Mohammedans call it Umm-al-Kora, 'Mother of Cities,' and it derives its sanctity from having been the birthplace of Mohammed. The city stands in a narrow, sandy valley, enclosed by barren hills from 200 to 500 feet high, and is supplied with water from the mountains to the east by an aqueduct built in the 9th century, by Zu- baidah, wife of Haroun-al-Raschid. The great mosque of the Umm-al-Kora, or Umm-al-Haram (The Invincible), enclosing the Kaaba (q.v.), the Moslem 'holy of holies,' occupies a central square which divides the city into the northern upper and the southern lower towns. The unpaved streets are wider than is usual in Oriental towns, and the houses of stone, often three stories high, are lighted with windows looking on the street, giving them an Occidental appearance. The stationary population is about 60,000, but the city is large enough for smokes that number, and is usually filled at the time of the Hajd or pilgrimage to the Kaaba, when apartments in almost every house are rented to strangers. This pilgrimage customary among the Arabs in early and idolatrous ages, and subsequently enjoined by Mohammed on all his followers, is the foundation of Mecca's fame, and the only source of the inhabitants' wealth and occupation.

The Meccaw, or inhabitants of Mecca, are, with the exception of a few Hejaz Bedouins, all strangers by birth or parentage. They are, in fact, settlers or children of settlers, attracted hither by the love of gain, and as they care nothing for learning, the colleges of Mecca have fallen to decay, and the libraries, once rich, have disappeared. Mecca during the pilgrimage becomes for three or four months in the year the greatest market in the East.

The pilgrims converge upon the holy city from three directions; those coming from the south are Mohammedans from Oceania, Java, Sumatra, Indo-China, India, Turkestan and southern Persia, who pass into the Red Sea through the Strait of Bab-el-Mandeb and on to Jiddah, the port of Mecca; the northern branch of the pilgrims, north Persians, Turcomans and people from Asia Minor and European Turkey, go southward to the holy city both by the land and sea routes; the third stream is from the west, Egyptians, Moroccans, Algerians, Tunisians and Turks, who reach Jiddah through the Suez Canal. For years past the average number of pilgrims passing through the Suez Canal to Jiddah has been 16,000, but this number is sometimes greatly exceeded; the number in 1901 was 26,000, and in 1902 was over 40,000. The northern pilgrims, however, are only a small part of those who came to Mecca, in which the total number every year exceeds 100,000, practically all of whom are present at the fête of Bairam. The Sheriffs of Mecca, direct descendants of Mohammed, are now a numerous and widely spread body. They all wear the same costume, priding themselves on a green robe which marks their descent. These nobles, as they may be called, elect the Sheriff of Mecca, and their choice is formally confirmed by the Ottoman sultan. Ptolemy mentions Mecca under the designation of ‘Dumah’; it had a chequered history. According to Arab legend Ishmael dwelt there, and his descendants were driven out by the Banu Jurhum, who were themselves ousted in turn by the Khurra about 210 A.D. Mohammed was born here, but for eight years was opposed by the city’s nobles. In 692 Al Hajjaj laid siege to the city and on taking it slew the pretender Abdullah Ben Zobeir. From 1517 to 1916 the Sheriffs of Mecca derived their authority from the Sultan of Turkey. The Wahabees took it in 1803; but in 1833 it was given up to Neemeh at, who, son Ibrahim was made Sheik el Haram. Upon the establishment of the kingdom of Hejaz in 1916 Mecca came under the new régime. Consult Kahn and Sparrow. ‘With the Pilgrims to Mecca’ (New York 1905) and Wavell, A. J. B., ‘Modern Pilgrim in Mecca’ (1912).

MÉCHAIN, Pierre François André, pé-ar frân swã, ma-shàn, French astronomer: b. Lamon, France, 16 Aug. 1744; d. Castillon, Spain, 20 Sept. 1805. He became a mathematical tutor and devoted himself to the study of astronomy in his spare moments. In Paris he gained the interest of the astronomer Lalande who assisted him to his professorship. In 1780 he was engaged in the survey of the French coast and in astronomical observations. The Academy of Sciences elected him a member in 1782, and in 1785 he was editor of Connaissances des Temps, in which appear some of his most valuable scientific papers. He was commissioned by the National Convention in 1791, in company with Delambre, to measure the arc of the meridian between Dunkirk and Barcelona. The results of the calculations made failed to satisfy him because of a slight discrepancy and though now appointed a director of the conservatory at Paris he persuaded the board of longitude to commission him to measure the arc between Dunkirk and the Balearic Isles, but died of fever in Spain while on his mission. Consult Delambre, Histoire de l'Astronomie au dix-huitième Siècle.3

MECHANICAL DRAWING. See DRAWING, MECHANICAL.
MECHANICAL ENGINEERING is that branch of the science and art of engineering which relates specially to machinery. It is closely allied to other classes of engineering with which it has much in common. So much as there is hardly an occupation or industry in which machines of some sort are not directly or indirectly concerned, and it is often, for this reason, difficult to draw the line clearly between one class and the other. The civil engineer who plans and supervises the building of a railroad calls to his aid the machinery used in excavating, blasting, building masonry and numberless other mechanical processes required in the work, all of which are the result of mechanical engineering. Electrical engineering would accomplish comparatively little in the production of light and transmission of power were it not for the dynamo and other machinery on which dependence is placed for the manufacture and use of electric current. Mining engineering would be of little use in devising means for extracting the coal and mineral treasures buried in the earth if suitable machinery planned by mechanical engineers could not be employed to assist the labor of men. In marine engineering it is the mechanical engineer who plans and produces the motive power for the propulsion of the steamship, and without his assistance there would be no such a thing as a steamship. In dealing with problems relating to waterworks, the hydraulic engineer would be powerless if he could not make use of the pumps and hydraulic machinery which the mechanical engineer has devised. In every kind of industry where power is required, whether it be connected with engineering, architecture, chemistry, agriculture or any other subject, the mechanical operations involved are based on the continuous operation of the machine constituting the motive power, whether it be a steam engine or water wheel or other motor, and these are the products of mechanical engineering. When we come to fully analyze the subject, therefore, it appears that mechanical engineering so far underlies engineering of every class, and all kinds of industrial operations, that it can almost he said to sustain the whole fabric of modern civilization. The mechanical engineer's work, in the broad sense, relates simply to the design of machinery. In its common application it has for its scope both the design and construction of machines required for performing certain desired operations, and in addition the design and operation of the complete industrial plant, of which the individual machines form a part, and the construction of the plant in such a manner as to secure a successful working whole for whatever purposes the plant is built. A large part of the mechanical engineering required at the present day consists in the assembling of machinery to produce certain desired ends, rather than in the design of the machinery itself. In many cases, the machinery has already been designed and constructed by engineers of the past and the perfected machines can be had by purchase in the market. This class of mechanical engineering covers a wide field. Perhaps its scope in this field can best be shown by referring in some detail to a familiar example. Take the case of the engineering required in a large modern hotel. The mechanical plant of such an establishment embraces a great variety of machinery, among the most important of which are the machines and appliances required for power, heating, ventilation, lighting, elevator service, distribution of hot and cold water, fire protection, refrigeration, ice-making, laundry work and cooking. The buildings and systems which are the auxiliary to the mechanical plant, must, at the very outset, be directed to the building itself. The building, no doubt, accords with the modern ideas of construction which call for a framework made of iron, in the design and construction of which the architect must have the assistance of the mechanical engineer. Not only this, but there must be, at the outset, a careful consideration of the required location of the various mechanical appliances, so that in working out the details of thus relating to the building the architect may provide the necessary amount of room. He must leave a place for the boilers, engines, steam turbines, dynamos, pumps, etc., which make up the steam plant, and room also for the supply and storage of fuel for the steam plant which is to receive of flues, ducts, pipes and wiring, which pass up through the building and which are distributed here and there to the different rooms. The character of the structures which may be needed for supporting the machinery, and the location of such structures, must also be planned at the outset so that the building may be prepared for them before it is too late. In the design of the mechanical apparatus, one of the first questions for the engineer to consider is the size and character of the steam plant. In dealing with this matter he ascertains all the uses to which steam is applied embracing the generation of power, the pumping of water, the supply of steam for all kinds of heating and cooking, and that required for ventilating. With this data, he determines the total amount of steam required for all purposes and then calculates the boiler capacity needed to furnish the steam. For the next step he decides upon the type of boiler best suited for the purpose, whether fire-tube or water-tube, in its structural or in its method of heating, whether it be internally or externally fired, and fixes upon the number and size of the units as well as their location. He then makes a plan showing the location of the boilers in the building; the style of the brick setting, if externally fired; the arrangement and location of the smoke flues and of the stack or chimney to which they connect. Having done this and settled all matters relating to the accessories which form a part of the boiler plant, he takes up, in due course of time, the remaining portion of the work relating to the boiler plant, which may be described at this point because it is representative of much of the work which requires to be done in relation to the other departments of the plant. He draws up specifications describing in full detail the character of the boiler plant desired and what is expected of it as regards capacity and economy. These specifications are submitted to boiler manufacturers who are asked to furnish proposals for the construction of the plant in the manner described. When the proposals of the different
bidders have all been received, the engineer examines them, and after consulting with the owner of the property, selects one of the parties with whom to contract for doing the work. Next follows the work to be done in the process of construction in the shop and erection in the building, the object in view being to determine if all the terms of the specifications are complied with. Finally, when the plant is completed and the contractor sets it to work, the engineer proceeds to work over the plant and test it with reference to the boiler plant and other parts of the building. At the same time there must be laid out on the plan a system of steam-piping connecting the boiler to the engines or turbines, and this must be arranged with a view to supplying steam to all other points of use, including the heating of the building. Next in order, the pumping machinery requires attention. This embraces the boiler feed pump, the various pumps used for the different classes of hotel work, the elevator pump, if the hydraulic system is employed, and the fire pump. The engineer must determine the proper size of each one according to the amount of water to be pumped, and he must select the type of pump, fix its location, show it on the plan and extend the system of steam-piping to furnish each with the proper supply. He must also plan the exhaust piping required for each engine, turbine and pump, the necessary vent pipe for carrying the waste steam, and so forth. If steam is used for heating, the required connection of the exhaust pipe to the main supply of the building. There must be a heater provided in the exhaust pipe system for heating the feed water before it is pumped to the boilers, and another heater for the supply of hot water to the building, and both of these, in their selection, location and connection, require the careful attention of the engineer. They must be properly laid out and shown on the plan. A complete system of water-piping is required, connecting boilers, pumps, hydrants and elevators, to say nothing of the hot and cold water supply pipes which extend to the various rooms of the hotel, and the location of these must likewise be shown by means of a suitable plan. Not the least important part of the mechanical engineering for the building is the design and construction of the heating and ventilating apparatus. Calculations of the amount of heat and radiating surface needed, the capacity of air required to be changed in a given time and the size of the motors and returns are involved in this work. Here, also, the kind of the system to be employed, the location and type of the heating and ventilating apparatus, including all the necessary details, are questions which the engineer must consider and decide, and the results must be indicated by proper plans. These various parts of the work are made the subject of detailed specifications, in the manner already referred to, and, likewise, proposals for the installation of the work are obtained, contracts awarded, inspection carried on during construction and the work tested for acceptance when parts are completed, all of which is done under the jurisdiction of the mechanical engineer. In much the same manner, the selection, location, construction and installation of the remaining parts of the mechanical plant, embracing elevator machinery, laundry machinery, refrigerating machinery, ice-making machines and the many other appliances concerned in the work of the hotel are carried out under his supervision.

The same class of mechanical engineering as that referred to in the above example is that involved in the design and construction of industrial plants of various kinds, such as cotton- and woolen-mills, bleacheries, paper-mills, rubber-mills, machine shops and foundries, this branch of the profession being commonly known as mill engineering. In all of these cases the elementary parts consist of the power plant, which is sometimes operated by steam, sometimes by water and often by both, the machines in the mill or manufactory and the pulleys, shafting and belting required to transmit the power from the one to the other. The work of the mechanical engineer in these plants consists in properly assembling the various machines so as to perform their functions, the selection of an appropriate power plant and the proper design and arrangement of the transmitting apparatus required for operating them.

The work of the mechanical engineer is of paramount importance in the construction of steamships. Not only does the design of the boilers and engines on which the whole operation of the ship depends originate with him, but he is also concerned in the design, location and connection of the auxiliary steam appliances which abound throughout the vessel and which contribute so much to the comfort of the passengers. The modern steamship is required to contain all the accommodations of a first-class hotel. The services of a mechanical engineer are many times more needed in its design and construction than in that of a hotel, for the reason of the contracted space in which the machinery is necessarily enclosed.

One of the most important industries in which the mechanical engineer is a leading figure is that of the steel-rail-mill. Here the plant, which is distributed over many acres of land, embraces immense blast furnaces where the pig iron is made, elevators by which the raw material is lifted to the top of the furnaces, blowing engines which produce the airblast required at the base of the furnace, converters in which the iron is changed to steel, hydraulic lifts by which the converters are manipulated and the steel blooms moved to cars, trains of rolls with their powerful direct-connected driving engines where the rails are rolled from the masses of white-hot metal,
together with their reheating furnaces and, in
addition to all these, the extensive boiler plants
and the system of piping and other apparatus
required for conveying and supplying the boilers
with waste furnace gases, on which they
largely depend for fuel. The mechanical
engineer who lays out and assembles the parts
of which such a plant is composed has a task
the magnitude of which is commensurate
only with the importance of the interests
involved.

Since mechanical engineering includes in its
scope not only the proper design and con-
struction of machinery, but also its satisfactory
performance, one branch of the profession re-
lates to the determination, by means of suit-
able tests, whether the desired performance
has been realized. This has especially to do
with boilers, engines, turbo-generators and
other apparatus using steam, which the engi-
neer requires to be installed under specific
guarantees of performance. The performance
of boilers in the matter of economy may be
specified in terms of the number of pounds of
water evaporated per pound of coal, and, in
that of capacity, in terms of the number of
horse power developed, while that of the en-
gine or turbo-generator may be specified as the
number of pounds of feed water or dry steam
consumed per unit of power per hour. The
performance tests require the determination of
the quantities stipulated, by actual measurement
of the coal, water, steam and power under
working conditions. Another branch of me-
chanical engineering, in a similar line, relates
to the testing of materials used in construc-
tion, the object being to determine whether
they have the requisite strength and physical char-
acteristics. A sample or specimen of the ma-
terial is placed in a testing machine and sub-
mitted to an actual breaking force and the
amount of strain ascertained by measurement.

Having now given some explanation re-
garding the character of the profession of me-
chanical engineering, the question naturally
arises as to the qualifications needed to make
a success of such a profession. It hardly needs
to be said of this profession more than of
another that the one who adopts it should do
so merely as a means of livelihood, but be-
cause his tastes lie in the direction of mechan-
ical pursuits, if, indeed, he does not love the
profession for its own sake. No one should
enter the profession who is not fond of
machines, who is not a "born mechanic" as the
saying is, or who is not deeply interested, to
say the least, in every kind of machine. But
apart from natural inclinations there are qual-
ifications that especially fit one for the work
of a mechanical engineer. He should have a
technical education so as to be thoroughly
grounded in the principles of mechanics. He
should not only understand these principles but
he should know them by heart. He may or
he may not remember the formula derived
from the principle, but the principle itself
should ever be at his finger's end. He should
be familiar with mathematics, geometry and
trigonometry. He should know the strength of
materials and be able to calculate the strains
occurring in structures and in machines, both
at rest and in motion, so as to be thoroughly
versed in the proper amount of strength, or,
if already designed, that he may be able to
prove that they are of sufficient strength for
any purpose he may desire to use them. He
should know their behavior under varying con-
ditions and should be able to detect their points
of weakness and know the best methods of
strengthening them when they have been
made and of what is necessary
for the draughtsman and, what is the draugh-
tman's next neighbor, an inventor. He should
know the processes involved in the work of
the patternmaker, founder, blacksmith and
machinist. He should know how to prepare
machinery and how to operate it after
erection. He should know the practices of the
trade and he should know the various articles
concerned in mechanical operations which can
be bought in the market, and, in a general way,
their cost. He should be familiar with the dif-
ferent kinds of boilers, engines, turbines,
pumps, water wheels, etc., in the market and
their relative advantages. Not the least in im-
portance should he be grounded in the prin-
ciples of steam engineering and the laws which
determine the generation and use of steam, not
only for the operation of engines of various
kinds, but for the various kinds of steam heat-
ing. He should be familiar with the steam
engine indicator and be able to test a boiler or
engine for capacity and economy. He should
be well versed in hydraulic, pneumatic and elec-
trical machinery. He should know about the
construction and operation of the various ma-
chines of the plant he has assembled, so as to
be able to judge of the correctness of their de-
sign and construction and whether they per-
form their functions in a proper manner and
according to the specified requirements. He
should be able to prepare detailed specifica-
tions of the work he plans, and he should pos-
sess sufficient literary ability to draw up a suit-
able report upon any question that may arise
regarding the work he is called upon to per-
form and pass judgment upon the comparative
merits of different makes of machines required
for a given purpose or of the different modes
of carrying on given processes. In a word, the
mechanical engineer must be skilled by observa-
tion, by study and by experience in the science
and art of the profession from beginning to
end.

One of the leading problems confronting the
mechanical engineer, whatever the special line
in which he is engaged, is the fluctuation in the
cost of production, and, what is allied to it, the
attainment of the maximum result from machin-
ery with the least expenditure of money, time
and labor. As machines and processes are in
a continual state of improvement, and almost all
lines of business are in a continual state of
growth, it does not require many years to elapse
after a piece of engineering work has been com-
pleted before it must be remodeled or enlarged
to meet the demands of the times. This problem
of reducing the cost of production is, therefore,
one which is continually before him. In the de-
sign of an individual machine, the highest aim is
to reduce the number of parts and quantity of
material used to the smallest amount consistent
with proper operation, and to run it at the high-
est speed which can be safely and successfully
maintained. In arranging a plant for carrying
on some industrial process, the aim must be to
employ that which makes it possible to save the
labor of men, and assemble the machines so that
the least number of hands and
the least expense is required to change the raw material into the finished product. Following in the commercial scale and will use the necessary waste of fuel or energy required in operating the machinery, whatever the class of work and in whatever department of the work such waste may occur.

There are many notables problems of a more specific nature than the one just named which absorb the attention of mechanical engineers and await their solution. One of these is the reduction in cost of steam power. Owing to the great amount of heat which passes to waste through the escape of exhaust steam to the atmosphere or to the condenser, amounting in the most economical engines to some three-fourths of that required in the original generation of the steam, there is a wide field for improvement in steam engine economy. Efforts have been made to reduce this waste by employing a part of the heat thus lost for evaporating some other liquid having a sufficiently low temperature of evaporation, and using the vapor thus produced to act on the cylinder, thereby adding to the total power developed by the engine, and reducing in a corresponding degree the cost of the power per horse power. Another problem of the same kind is the substitution of some other motive power for the steam plant, which would be practically impossible if reciprocating engines were used.

The development of the steam turbine and its substitution for reciprocating engines is one of the recent problems which mechanical engineers have worked out with most efficient results. One of the most notable features in this work has been the enormous capacity of single units which have been installed in electric power plants, which would be practically impossible if reciprocating engines were used.

Another problem of mechanical engineering which is important to all business interests is that of rapid transportation by railroad. The great increase in speed on street car lines which has already been obtained makes it seem probable that the further adaptation of electricity in railroad work, not only on short lines, but on trunk lines, will meet all the requirements.

The great problem of aerial navigation, which naturally lies in the domain of mechanical engineering, seems in a fair way to be solved. Aeroplanes of sufficient power to carry the operator and one or two passengers are in successful use by expert aviators, and long flights are made with aeroplane in the air a number of hours. The skill and adaptability necessary for an aeroplane in connection with operations of war has been demonstrated beyond question, and government provision of aeroplane fleets has become a recognized necessity the same as that of armies and navies. That part of the problem which remains to be solved is the adaptation of the aeroplane, and of the airship as well, to the transportation of passengers and freight on a commercial scale and in such a manner as to be safe and reliable, whatever the condition of air currents or state of weather.

There are other great problems of mechanical engineering, yet unsolved, which relate to the production of power by the employment of the forces of nature not heretofore utilized. One of these has for its object the utilization of the sun's heat. It has been worked out in a small way in California. A concave mirror having 1,000 square feet of surface has been employed for converging the rays of the sun upon a steam boiler which lies at its focus, and suitable mechanism is arranged for keeping the mirror always turned in the proper direction toward the sun. It is said that in full sunshine this apparatus has developed 10 horse power. Wind power is widely and successfully employed on a small scale, but there remains the problem of overcoming its variable nature by providing means for storing it, and of applying the power thus obtained to useful work. The development of tidal power, like that of wind power, is largely a problem of the storage of energy, and no success in this field has been realized.

What the future offers to a young man choosing the profession of mechanical engineering depends very much upon the ability of the man himself. The broad scope of the profession, already referred to, furnishes ample indication that there is a wide field of work for him. That there are positions awaiting the young engineer may be seen by examining the catalogues of prominent technical colleges, which record the names of graduates and their occupations. For example, in one of these catalogues the class graduated last had a total of 44 men in the department of mechanical engineering. Of this number only three are put down without employment, and one of the three is in reality employed, being a graduate student. Of the 41 holding positions, 18 are engaged in various engineering occupations connected with the manufacture of machinery, three are employed in textile mills, eight are engaged in steel works, three are connected with railroads and the remaining nine are variously occupied in engineering pursuits. If the young engineer becomes connected with the business of sufficient size and importance to warrant the steady employment of a mechanical engineer, and he shows the necessary ability, the prospect is that he will in time push forward to a position of responsibility which will command a good salary and satisfy any ordinary ambition. If his desire is to establish an engineering business of his own, he can make the emoluments greater than in a salaried position, provided he is able to secure the necessary clientele, and conduct such business to advantage. If this is his choice, the most promising course for him to pursue is to first enter the office of a successful engineer, and spend a few years in learning the business. Then, if he has the acquaintance and good name necessary for getting business for himself, he can set up his own establishment, and by careful attention to the execution of his work strive for the success he seeks. In mechanical engineering, as in other professions, large emoluments await the men who rise to the top, for these are the engineers who are called
MECHANICAL MOVEMENTS, POWERS AND APPLIANCES

upon by individuals and corporations for consultation.

The profession of mechanical engineering offers as many attractions to those entering it as any other profession, for in it, as in others, there is always room for those who excel, and no professional man meets with success unless his work commands it.

GEORGE H. BARRUS,
Expert and Consulting Steam Engineer, Boston.

MECHANICAL MOVEMENTS, POWERS AND APPLIANCES. The primary, fundamental mechanical contrivances are termed the mechanical powers or engines, seven in number and all based on the principles of either the lever or the inclined plane. The common classification is the lever, wheel and axle, cord and pulley, toothed wheels (these four operating on the lever principle), and the inclined plane, wheel and screw (operating on the principle of the inclined plane). What are known as the mechanical movements (sometimes called mechanical motions) include about 750 of the more or less simple and common combinations, covering practically all the fundamental arrangements of the mechanical powers for machine building and engineering work. They constitute the groundwork which the machinist or student of engineering must master before he can make much headway in understanding the complex problems which arise in practice.

Taking first the simple lever, it is found to be of three classes: (1) those in which the fulcrum is situated between the power and the weight; (2) those in which the fulcrum is at one end of the lever arm with the weight nearer to it than the power; and (3) those in which the fulcrum is at the end with the power nearer to it than the weight.

In the first, if the weight W is nearer to the fulcrum, there is a mechanical advantage — illustrated by the crowbar, which on account of the great difference in the length of its arms is advantageously used to overcome great resistance. Scissors and nippers are double levers of this class. If the power P is nearer to the fulcrum, there is a mechanical disadvantage, and if the weight and the power are at an equal distance on either side of the fulcrum, the power is equal to the weight and gives an arrangement similar to the ordinary balance.

The distinction between the gain of power

\[ y = \frac{x}{z} \]

and the loss of velocity, and the reverse of these conditions, as depending upon the position of the fulcrum, is exemplified by the shears used for cutting metal and those used for cutting cloth, respectively. In the former, short blades with long handles overcome a great resistance slowly; while in the latter, long blades operated by short handles, move quickly.

In the second class there is always a mechanical advantage. The wheelbarrow is an example of the simple lever. The fulcrum is at the centre of the wheel, the weight acts downward at the centre of gravity of the load and the power is applied at the ends of the handles. A hinged nut-cracker is an example of a double level of this kind.

In the third class there is always a mechanical disadvantage; but great rapidity of movement is obtained. The human forearm is an example of a simple lever of this class. The fulcrum is at the elbow-joint, the weight acts downward at the hand and the power is applied obliquely by a tendon from the biceps muscle attached near the elbow. A pair of tongs is an example of a double lever of this class.

The wheel and axle consists of two cylinders of different sizes rigidly connected together and turning about a common axis. The larger cylinder is called the wheel and the smaller the axle. The power is applied to the end of a rope wound around the wheel and the weight is raised by a rope wound around the axle:
The diameter of the larger cylinder or wheel being twice that of the smaller cylinder, or axle, a power of one pound at \( P \) will balance a weight of two pounds at \( W \). This is essentially a form of lever, and the power is to the weight lifted as the radius of the axle is to the radius of the wheel. The principle is applicable to all forms of hoisting machines, steering gear of ships, fusee clock and watch movements, etc. If the axle be fixed and the wheel be loosely mounted to revolve on it, we have the ordinary machinist's loose pulley, and a variety of uses suggest themselves. If the axle be fixed to the body of a carriage and the wheel allowed to rest on level ground, we find that the carriage can be drawn along with slight effort, requiring a push or pull representing only a small fraction of its weight.

The cord and pulley shows the further uses of the wheel as a lever. In the arrangement shown in Fig. 5 the upper points \( F \) are fixed, being virtually fulcrums; a downward pull of one pound one foot on the cord \( P \) will raise the weight \( W \), which may weigh nearly two pounds, a half foot; it would balance two pounds but for the loss by friction.

In Fig. 6 a movable pulley is shown in combination with the wheel \( a \) and axle \( b \) and a crank \( R \) is added. If the crank is one foot long, the wheel one foot in diameter and the axle six inches in diameter, one turn of the crank may draw up the right hand cord about three feet, and lengthen the left hand cord about 18 inches, resulting in raising the pulley and attached weight \( W' 9 \) inches. As the crank handle has traveled about six feet, or eight times as far as the weight is raised, the leverage is 8 to 1, and a boy who can put 50 pounds of effort on the crank can raise nearly 400 pounds at every turn, and in eight turns he will raise it six feet, the distance of travel of the crank at one turn.

A very common arrangement of pulleys, called stepped pulleys, is shown in Fig. 7, as positioned for driving a lathe. The steps of the pulleys on the lathe are supposed to be 3, 6, 9 and 12 inches diameter, respectively. The belt is shown on the 12-inch power pulley and 3-inch lathe pulley, and obviously, if the power shaft is making 100 revolutions per minute, the lathe shaft will make 400. If the belt be shifted to the next step, where the proportions are 9 to 6, the 100 revolutions of the power shaft will give 150 revolutions of the lathe shaft. On the third step 6 to 9 is the proportion and the lathe will rotate at a speed of 66⅔ revolutions; on the fourth step it is 3 to 12, and the 100 revolutions of the power shaft will give but 25 of the lathe shaft. See Pulley.

Toothed wheels, now commonly called spur gears, illustrate another type of wheel leverage. Spur gears are shown in Fig. 8; here the smaller gear-wheel rotates twice to cause one revolution of the large wheel; thus a small wheel secures increased power at reduced speed.

In Fig. 9, the large wheel, being the driver, turns both the small wheels in the same direction, but oppositely to itself, and gives the shafts of the small wheels two revolutions to one of the large wheel. In Fig. 10 are shown bevel gears, which work at right angles. It is apparent that almost infinite combinations of such gears are possible. See Wheel Gearing.

The inclined plane is simply an expedient for lifting weight above the level on which it lies, by giving it a longer distance. The lever the inclined plane itself, and when the plane is long enough, the effort is small compared to the weight raised. In this respect it resembles a wheel and axle, but the latter is more compact, being able to lift a greater weight for equal effort.

Plane inclined to the horizon at an angle, and upon which a weight tends to slide down by gravity, or up the slope of which a weight may be pushed or rolled by a force usually horizontal in its action. In Fig. 11 the sliding weight would fall back if the power was withdrawn; it also shows power applied horizontally to move a rolling weight up the plane. In this latter case a continuing power of less than a pound will push a pound roller up the incline because the power has a distance greater than the height overcome in which to exert itself.
The inclined plane principle is used in rolling barrels up on a wagon, in loading logs on a sled, in the operation of a mountain railway and in the cam, which is described later. The employment of the principle does not reduce the work of lifting to the top of the plane, but extends the time of the lift, so that a smaller force used for a longer time does the work.

The wedge (Fig. 11a) is a double plane and gives power at the expense of speed. It is sometimes considered as a combination of two inclined planes placed base to base. The mechanical advantage increases as the angle of the wedge decreases — "the power being equal to twice the resistance into the sine of the angle of the wedge." The relation, however, has but little practical value since the resistance due to the friction is very great. The principle is used in many forms of cutting tools such as the knife, the chisel, axe and plane. For working in comparatively soft materials, the angle is kept small and the edge sharp; but for harder materials the angle is increased. Metal planting tools have very large angles, ranging from 60 degrees to 80 degrees. When the wedge is employed for cleaving wood, the cohesion and friction combined produces so great a resistance that the force is applied in the form of a blow from a heavy body, and the resulting strain is equal to the force of the blow multiplied by the length of the wedge divided by its width. See Wedge.

The screw is essentially an inclined plane wound spirally around a cylinder, in the form of an advancing groove, known as the screw-thread. A cylinder having such grooves cut interiorly like the inside of a nut is termed a female screw. The screw shown in Fig. 12 has two grooves spiraling around and is therefore double-threaded. There being eight threads to the inch, the pitch of this screw may be regarded as one-eighth of an inch, the distance between threads; or as one-fourth of an inch, the distance between one spiral and the next turn of the same spiral. The principle of the screw is used in the screw propeller (q.v.), and the lifting jack or jackscrew. See Screw.

A mechanical movement is some simple combination of the elementary powers described above. Perhaps the simplest are the familiar crank (q.v.), cam (q.v.) and cylinder and piston. (See Steam and Steam-Engines.) A few of the more familiar movements are here grouped and illustrated. If fully mastered and understood they will be of great assistance to the student of mechanics in understanding the more difficult and complicated descriptions and drawings of modern machinery.

Fig. 13 is a rack and pinion, for converting rotary motion into linear motion, or the reverse, according to whether the rack or pinion is the driver.

Fig. 14 shows a pinion between two racks. If the lower rack be fixed and the pinion rolled one foot the upper rack will move two feet. In this way the stroke of a piston can be doubled.
Fig. 15 is a gear-wheel and worm, for changing a rapid rotary motion into a very slow rotary motion. One rotation of the worm turns the gear-wheel the distance of one tooth.

Fig. 16 is a group of bevel gears, positioned as in the differential on the rear axle of an automobile. Either of the large bevel-gears may drive the other through the small bevel-gear.

Fig. 17 is a mangle wheel and pinion. The pinion $P$ drives, traveling around the long C-shaped rack, rotating the mangle first into one direction then in the reverse direction.

Fig. 18 is a pair of eccentric gear-wheels, either of which may be the driver. The rotation of the driven wheel is alternately slow and rapid.

Fig. 19 shows a couple of pump-cams. As they touch at every point of their rotation they may be used to raise a column of water by lifting.

Fig. 20 is a diagram of a crank and piston movement. It will be noticed that the spot $x$ on the centre of the piston rod describes an oval. The nearer this spot is placed to the piston the more elongated is the oval. If the student will make a pattern of this in cardboard and test it in various positions he will get a far better understanding of why a crank motion is so generally preferred in machinery.

Fig. 21 for altering rotary into reciprocating motion — the change is so gradual that jar is obliterated.

Fig. 22 is a combined bell-crank and wheel-crank for altering rotary motion into reciprocating. The wheel drives and as the pin $P$

travels in the slot it raises and lowers the rod $r$, rapidly in one direction, more slowly in the other.

Fig. 23 is a parallel motion. To whatever distance the bars are moved they are held parallel by the slanting connections.

Fig. 24 is a shears for cutting metal. The wheel $w$ and pin $p$ operate the upper blade, giving a long leverage for increased shearing power.

Fig. 25 is a toggle joint. Only a slight force is required to throw the two levers into line exerting a vastly multiplied energy over a short distance. It is used in many machines to apply a sudden pressure.

Fig. 26 is a universal joint, permitting a rotating shaft to be bent to a slight angle as necessary, without interfering with its working.

Fig. 27 is a three-throw cam. The three-pointed wheel measures the same at every point of its diameter, and as it rotates gives a reciprocating motion to the rod, moving it back and forth three times to each revolution.

Fig. 28 is a heart-cam for giving irregular reciprocation to the rod.

Fig. 29 is an ore-stamp. The cam shaped like a long $x$ raises the stamp twice during each revolution and leaves it free to drop by gravity.

Fig. 30 shows a drum-shaped cam $C$ whose groove moves the shaft $S$ of the large wheel $W$ alternately to the right and left.

Fig. 31 is an eccentric, or wheel mounted out of centre, so that through the encircling straps it gives a reciprocating motion to the rod. It is much used on steam-engines.

Fig. 32 is a pair of pulleys connected by a twisted belt for reversing the direction of rotation of one of the shafts.

Fig. 33 is a two-speed gear. The pulley $a$
being the driver, the upper large pulley is driven on one speed; when the belt is shifted to $b$, which is a loose pulley there is no driving; when the belt is shifted to $c$, the other drive at a different speed is effective.

Fig. 34 is the steering gear of a sailing vessel, showing how the turning of the hand-wheel $w$ is made to shift the ropes $rr$ and throw the tiller $t$ of the rudder to right or left.

Fig. 35 is a positive "silent" chain drive. Either the chain or gear-wheel may drive. It is used on auto-trucks and a variety of heavy machinery where belts are inadequate.

Fig. 36 is an intermittent motion given the toothed wheel by the rotation of the notched pinion. Every time the notch comes around it advances the wheel one tooth.

Fig. 37 is an escapement. The levers are connected with a pendulum or the like and at every swing allow the wheel to turn one notch.

Fig. 38 is a ball governor as used on steam engines. When a certain speed is exceeded the balls are thrown out by centrifugal force, and rise, opening a valve or adjusting a cut-off and thus reducing the speed back to the normal.

"Compound motions" are obtained by combining any two or more of the simple motions, and machines are built up by combining the simple motions harmoniously.

"Pendulum motion" is the oscillatory motion of a body in the arc of a circle, the body being attached to a rod which vibrates to and fro from a fixed axis. In the ideal simple pendulum, consisting of a body attached to a string without weight and vibrating from the point of suspension without resistance of any kind whatever, a material body once set in motion would continue to swing to and fro forever.

Under these conditions it has been noted (1) that the time of vibrations of a pendulum through short arcs is independent of the lengths of the arcs and that when the length of the arc is constant, as in the case of clock devices, the times of vibration are equal; (2) that when the force of gravity is constant, as is the case of any given point on the surface of the earth, the time of vibration varies directly as the square root of the length of the pendulum, so that if a pendulum of a given length vibrates in one second, a pendulum one-quarter as long will vibrate in one-half of a second, and one four times as long will vibrate in two seconds; (3) that when the length of the pendulum is constant, the time of a vibration varies inversely as the square root of the force of gravity; and (4) that when the time of vibration of two pendulums at different points on the surface of the earth is equal, their lengths vary directly as the force of gravity. See Pendulum.

"Perpetual motion" is a continuous or incessant motion supposed to be attainable by a mechanical device with inherent motive energy and, therefore, which when once set in motion is capable of continuing that motion indefinitely or perpetually. Such a device or machine, if practicable, might be termed a "perpetual movement."

The various forms of mechanical movement embodying the principles of one or more of the mechanical powers already described are so innumerable that a detailed description of them is impracticable within the scope of this article; but they are classified as follows into several important groups according to the general purposes for which they are used.

Transmission of power appliances, consisting of ropes, belts and various forms of gears, pulleys, etc.

"Measurement of power appliances and devices," used for determining velocities, pressures, weights, number and quantities, such as brakes, counters, dynamometers, gauges, indicators, meters, planimeters, testing machines and weighing machines.
Steam power appliances, comprising boilers, locomotives, locomotive engines, oscillating engines, rotary engines, steam-engines, steam turbines, valves and valve-gears, parallel motion gears, governors and other engine devices.

Steam appliances, such as injectors, steam pumps, condensers, separators, traps and valves.

Motive power machines, such as gas-engines, internal-combustion engines, heat-engines, solar engines, etc.

Hydraulic power appliances and devices, consisting of various forms of waterwheels, water-motors, turbines, pumps, syphons, water-lifts, ejectors, hydraulic or water rams, meters, indicators, pressure regulators, valves, pipe joints, filters, hydraulic presses and hydraulic metal-working machinery such as riveters, rail-benders and punches.

Air power appliances, devices and apparatus consisting of air compressors, air pumps, air water-lifts, barometers, bellows, blowers, blow-pipes and compressed-air tools such as pneumatic drills, hammers, riveters and shearing machines. Also, gauges, ventilators and musical instruments.

Electrical power and construction appliances such as generators, motors, wiring devices, controlling and measuring devices, lighting arrangements, electric furnaces, heaters, fans, searchlights and drilling machines.

Navigation appliances used for operating steampships, sailing vessels and yachts, such as sails, rope knots, block and tackle, paddle wheels, screw propellers, steering gear, anchors, windlasses, capstans, cranes, etc.

Road appliances, used in the construction of roads, highways and railroads, such as scrapers, rollers, excavators, vehicles, automobiles, bicycles, motor adjuncts, wheels, road gates, lamps, etc.

Gearing, consisting of rack and pinion devices, spiral, elliptical and worm gears, differential and stop-motion gears, and epicycical and planetary trains.

Motion and controlling devices, consisting of ratchets and pawls,cams and volute cams, cranks and variable cranks, intermittent and stop motions, wipers, shafts, couplings and gyroscopes.

Horological apparatus and devices, mainly used for measuring time, such as spring and pendulum clocks, watch and chronometer movements, electric clocks and sundials.

Mining machinery and appliances, such as quarrying and cutting machines, borers, drills, valves, blowers, ventilators, safety lamps, hoisting drums, conveyors, crushers, pulverizers, hydraulic nozzles, presses, air-blast and magnetic separators, steam shovels, dredges, haulage appliances, furnaces and automatic dumps.

Mill and factory appliances, such as hangers, shaft bearings, ball bearings, steps, couplings, universal and flexible couplings, speed gears, shop tools, screw threads, hoists, stamp-mills, saws, punches, shears, bending machines, grinding machine, cotton presses, looms, knitting machines, etc.

Engineering construction appliances such as mixing machines, testing machines, stump and pile pulling machines, blocks and tackle, hoisting machines, tackles hooks, pile drivers, automatic dumps and dumping cars, stone grips, derricks, conveyors, timber splicers, metal welding devices, tools, wood-preserving apparatus, cable carriers, dams and embankment escalators and moving platforms, "Ferris" wheels, high structures and buildings, roof and bridge trusses, trestles and bridges.

Agricultural machines and implements, such as plows, tethering hooks, wash boilers, washing machines, mowers, grain harvesters, threshing machines, cream separators, refrigerating machinery, cold storage houses, refuse crematories, silos, kilns, ovens and furnaces.

Draughting devices, such as dividers, dotting pens, parallel rules, curve delineators, trammels, ellipsographs, pantographs, etc.

Tools, hand and machine, such as saws, chisels, mallets, planes, borers, etc.

Perpetual motion devices, consisting of various forms of hydraulic, hydrostatic and magneto-electric apparatus.

Bibliography:—For descriptions of a great variety of special movements, appliances and
MECHANICAL SIZING—MECHANICAL TERMS

devices, consult the works on the subject by Hiscox, Rheile, Ruleau and Spon, also the special articles on the various forms of appliances enumerated under the general classes stated in this article.

CHARLES H. COCHRANE,
Author of 'Wonders of Modern Mechanism.'

MECHANICAL SIZING. Classification of Dry Granular Material.—The mechanical classification of dry granular material is the result of the action of several natural laws operating in conjunction with a mechanical device so arranged as to permit the balancing of the action of one law with another. The combined motion places the relative action of the dry granular material completely under control of the mechanical device. The first active law in mechanical sizing is termed the laws of selectiveness. When mixed particles of various sizes of granular material are under agitation upon a level plane, the finer particles sink to the bottom and engage the surface while the coarser particles rise without regard to the specific gravity of such particles. The second active law is called the law of displacement or the displacement of the centres of gravity of particles upon an inclined plane. The relative difference in the tendency of coarse and fine material of granular shape to move down an inclined plane is due to the difference in the displacement of their centres of gravity upon the same angle of plane. The third active law is the law of friction of mass or the coefficient of friction.

Close observation of the action of these laws as well as the influence of other forces led to the design of a "mechanical sizer" simply arranged to best meet the requirements of these laws. In order to assist the law of selective action on an inclined plane, a series of several hundred tapered riffles or grooves are placed on the inclined surface of what is termed the deck of the device. This permits the "fines" to sink to the bottom of these grooves and force the larger particles over the top of the riffle, in accordance with the action of the law of displacement of centres of gravity. This is accomplished by the feeding of dry material to the inclined deck while the same is being agitated forward and backward by a specially designed head motion, which pushes the deck forward at one speed and causes it to return at a higher speed. This sets up what is termed a progressive action of material on the deck or causes the granular particles to travel in a forward direction, under the government, however, of the law of selective action and the law of displacement aided by the law of friction of mass. Under operation, the device is fed with dry ore, sand, grain or the like, the feed engaging a feed board where a preliminary rough separation is accomplished by a modified application of tapered riffles. The feed then engages the table deck at the head of its proper zone and here, because of the length and the great number of riffles, almost any number of carefully sized products may be taken off by placing receptacles at the bottom and far edges of the deck, from which falls, when in action, a constant sheet of granular material graded carefully from coarse particles to fine dust.

Mechanical sizing is applicable to every form of dry granular material such as crushed ore, salt, coal, sand, emery, cereals, unbroken or crushed, or, in fact, there is no field in dry sizing now filled by metallic screen devices that cannot be filled by a mechanical sizer and often with greater economy and efficiency. This is proved by the fact that metallic screens blind and lose their efficiency while the mechanical device cannot dog or blind and automatically cleans itself. Specific gravity has practically no effect upon mechanical sizing for the reason that granular particles of the same contour and volume, when placed upon an inclined plane, have the same displacement of their centres of gravity with the result that a particle of lead and a particle of sawdust of the same size and shape will discharge from the table at the same point, although the specific gravity of the one is many times that of the other.

MECHANICAL TERMS. Words, compound words and short phrases, having definite meanings other than those of ordinary usage and serving the purpose of tools and other mechanical appliances; to the construction and operation of machines, and to the methods employed and the manipulations required in the working and manufacture of the various kinds of materials used and the articles employed for engineering, structural and other industrial purposes.

A great many of these terms have been in use from the very beginning of the present period of industrial and manufacturing development, and are satisfactorily employed at the present time according to their original significance; but the creative mechanical effort of the last 40 years has either developed or produced so great a variety of mechanical devices and machines that the mechanical terminology as heretofore employed to indicate a much greater number of terms, which are more or less familiar to every one excepting those by whom they are habitually used in the execution of the particular line of work to which they are applicable.

Furthermore, the specializing methods of modern manufacturing systems, involving the restricted use of special terms, has not only tended to develop a class of one-sided workmen who are unquestionably skilful in their special lines of work and deplorably poor if not absolutely deficient in all other lines; but, the use of such methods has tended to decrease the ever-widening gulf which separates any one class of workmen from the rest, by eliminating the necessity of a mutual knowledge of the special terms used in allied processes, by the special classes of workmen employed therein.

At the present time the number of mechanical terms amounts to several thousands. Eliminating those of a more or less fanciful character, and also those employed in individual shops, the terms having definite meanings capable of universal or wide application probably exceed 12,000 in number, the great majority of which are employed in the metal manufacturing and metal working industries.

A superficial examination of this terminology conveys the impression that a definite classification of the various terms would be either impossible or quite difficult, but a closer inspection shows that they may be conveniently divided into several general classes.
making end-connections between the coils of an armature winding divided into segments. It is also applied to designate the frequency of a tone vibration produced electrically. As a musical term it refers to a succession of tone vibrations.

The character of a technical term or the class of work to which it belongs is usually very clearly indicated by the textual matter on any particular subject, but in the case of mechanical and electrical terms when the connection is not obvious, the special character of a term may be ascertained only by the nature of the power generated, controlled or applied.

For further information see articles under the titles AERONAUTICAL NOMENCLATURE; BOILER SHOP TERMS; FOUNDRY AND FORGE SHOP TERMS; ENGINEERING TERMS; ELECTRICAL TERMS; LOCOMOTIVE, PRINCIPAL PARTS OF; TOOLS; VALVE AND VALVE TERMS, and WORKSHOP TERMS, in this Encyclopaedia.

MECHANICS (physik, a machine), or DYNAMICS, the science that treats of forces (δύναμις, force), and of the motions produced by them. The notion of a force, as evinced to the senses as a push or pull, is common to all, but the notion of force as that which produces or destroys motion, which is the proper definition of force, is modern, and is to be ascribed to Newton, the chief founder of the science. It is a familiar fact that two opposite pushes or pulls may neutralize each other's effects, and thus fail to produce motion; we then speak of them as forces in equilibrium. The portion of Mechanics that treats of forces in equilibrium is denoted by the term Statics (στάσις, stand), contrasted with which we have the subject of Kinetics (κίνησις, to set moving), which deals with the effects of forces in acting to produce motion in bodies. Since we use the term motion only in matter, the laws of motion involve the essential properties of matter, so that Dynamics is a branch of Physics — indeed, its most fundamental branch, for, until recently, it was the effort of physicists to reduce all explanations of physical phenomena to descriptions of matter in motion.* Nowadays the tendency of interpreting mechanics in electromagnetic terms is making itself felt. As in geometry, instead of dealing with actual substance, we make abstraction and conceive of points, lines and surfaces apart from the substance in which they lie, so we may make abstraction and consider the motion of points, lines or geometrical configurations, quite apart from any matter or physical properties. This geometry of moving configurations or geometry of space and time is generally distinguished by the name of Kinematics (κινηματική, motion), and is included under treatments of Dynamics only for convenience, as it is impossible to make dynamical investigations except in kinematical terms.

The ancients knew but little of Mechanics, and what they did know belonged exclusively to Statics. Archimedes was familiar with the principles of the lever and of the pulley. Leonardo da Vinci generalized the principle of the lever, and Stevinus (1548-1620) extended to the principle of the inclined plane and of the composition of forces. Varignon clearly enunciated the principle of moments, and also of the

* Timaeus catarsa natura phainomena ex principiis mecha-
nicis sodem argumentabas genus daritur hicici. Newton
'Preface to Principia.'
composition of forces. Galileo, in the course of his investigations on the inclined plane, came to a recognition of a particular case of the Principle of Virtual Work, which was made general by Daniel Bernoulli. These are the chief names in the development of Statics. The beginnings of Kinematics were made by Galileo, who determined the laws of falling bodies, and introduced the fundamental idea of acceleration. Huygens, in his "Horologium Oscillatorium," published in 1673, examined in detail the laws of the pendulum, introduced the ideas of moment of inertia, of the centre of oscillation and of kinetic energy. Most important of all was the work of Newton, who in his "Principia Philosophiae Naturalis" (1687), not only universalized the idea of force, and introduced the notion of mass, but laid down the exact definitions and principles from which it has never been necessary to depart. Since the work of Newton the chief names have been d'Alembert, Lagrange and Hamilton, who have given us methods of great generality and convenience, but without changing in any essential the principles laid down by Newton.

1. Statics.—Although the principles of Statics may be geometrically deduced from those of Kinetics by assuming all velocities to be zero, it is simpler to follow the historical method and treat statics first, since we may dispense with the idea of time, and thus with the preliminary study of Kinematics. We begin by assuming the identical nature of all forces. For instance, the effect of any force may be neutralized by a pull on a string fastened to the point at which the force is applied. The tension on a string is produced by equal and opposite pulls on its two ends, and it may be cut anywhere, if at the cut end is applied a force equal to the one previously applied to the end. Such a force may be produced by the weight of any body hanging from the end of the string. But as a weight always acts vertically downward, while forces may act in any direction, we may suppose the string carried over a smooth pulley with horizontal axis, whose effect is assumed to be merely to change the direction of the string without changing its tension. Thus any force in any direction may be equilibrated by the tension of a string produced by a certain weight. Two forces are equal when they are equilibrated by the same weight. Two weights found to be equal (by equilibration), when hung from the same string, produce double the tension produced by one, and thus forces may be measured in terms of a single weight. A force having magnitude and direction may be geometrically represented by a line parallel to it, and of a length proportional to its magnitude. To this line an arrow-head may be attached to indicate the sense of the direction of the force. We may now enunciate the principle, capable of experimental verification, that when two forces, represented by \( AB, AC \), Fig. 1, are applied at the same material point \( A \), they may be replaced by a single force whose direction and magnitude are represented by the diagonal \( AD \) of the parallelogram formed on the sides \( AB, AC \). (The direction of the arrows must be observed.) This is the principle of the Parallelogram of Forces. Obviously it may be replaced by the equivalent statement that if we form a triangle by placing at the extremity \( B \) of one of the lines representing the forces the initial point of the line representing the other force, \( BD \), and complete the triangle, the line drawn from the initial point of the first to the terminal point of the second line will represent the resultant of the two forces, that being the term applied to the single force which replaces their effect. The original forces \( AB, AC \), are said to be the components of \( AD \). From the properties of the parallelogram, \( AB \sin (BAD) = AC \sin (CAD) \), so that the magnitudes of the components are inversely proportional to the sines of the angles they make with the resultant. Obviously the two forces may be equilibrated by a force equal but opposite to the resultant, so that if we draw \( AE \) equal and opposite to \( AD \) (Fig. 2) the three forces \( AB, AC, AE \) will be in equilibrium. As the angles \( BAD \) and \( BAE \) are supplementary, their sines are equal, similarly \( DAC \) and \( CAE \); consequently we have \( \frac{AB}{\sin (BAE)} = \frac{AC}{\sin (CAE)} \) and in turn considering each of the three forces as equilibrating the other two we get the theorem that the magnitudes of three forces in equilibrium are proportional to the sines of the angles lying opposite them respectively. This may be experimentally verified as in Fig. 3, where weights \( P, Q \) are hung from strings passing over pulleys, and united at \( O \) to a string carrying a weight \( R \). If a parallelogram be drawn on lengths proportional to \( P, Q \), its diagonal will be vertical, and proportional to the weight \( R \). A convenient form of the experiment is one in which the three strings are horizontal, and \( O \) is the centre of a horizontal circular table, on whose rim the three pulleys may be placed, their relative positions being read off on a graduation of the edge of the table.
MECHANICS

Obviously, by a reversal of the previous process, a given force may be resolved into components in any two given directions, as only one parallelogram can be drawn on a given diagonal, whose sides have given directions. If these directions are at right angles to each other, as in Fig. 4, OP is the component of OF in the direction OA and OQ the component in the direction perpendicular thereto. The length OP is called the projection of OF in the direction OA, and we have \( OP = OF \cos (POF) \). Having found the resultant of two forces applied at a common point, we may compound this resultant with another force, and so on, the simplest rule of procedure being by an extension of the triangle method above, that is, apply the initial point of each line representing a force to the terminal point of the preceding line; then the line drawn from the first initial point to the last terminal point will represent the resultant. The slightest consideration will show that the resultant is independent of the order in which the forces are compounded. This construction is known as the polygon of forces (Fig. 5). It is obviously not restricted to forces lying in the same plane.

In order to deal analytically with the composition of forces, it is convenient to assume three rectangular axes of co-ordinates, \( OX, OY, OZ \) (Fig. 6), and to resolve every force into three components along each. Thus \( OF \) may be resolved into the mutually perpendicular components \( OY \) and \( OP \), and \( OP \) may be resolved into \( OX \) and \( OZ \). Calling the resultant \( F \), the components respectively \( X, Y, Z \), we have

\[
\begin{align*}
X &= F \cos (Fx), \\
Y &= F \cos (Fy), \\
Z &= F \cos (Fz); \\
X^2 + Y^2 + Z^2 &= F^2 \cos^2 (Fx) + \cos^2 (Fy) + \cos^2 (Fz) = F^2,
\end{align*}
\]

since the sum of the squares of the direction cosines of any line is identically equal to unity. Since the projection in any direction of any broken line is the same as that of a straight line with the same end, it is evident that the projection of any resultant is the same as the algebraic sum of the projections of all its components. Thus the analytical expression of the principle of the parallelogram or polygon of forces is, if \( F \) is the resultant, \( X, Y, Z \) its components along the axes,

\[
\begin{align*}
X &= X_1 + X_2 + \ldots X_n = \sum X_i, \\
Y &= Y_1 + Y_2 + \ldots Y_n = \sum Y_i, \\
Z &= Z_1 + Z_2 + \ldots Z_n = \sum Z_i.
\end{align*}
\]

Any geometrical or physical quantity which possesses direction as well as magnitude, and is compounded according to the parallelogram law, and to which the whole of the above exposition applies, is called a vector, and the preceding process is called the composition of vectors.

2. A body so small that we may neglect the differences of position of its different points is called a material particle. The only principle necessary for the treatment of forces acting on such a particle is that for equilibrium the resultant of all the forces applied to it must vanish. The particle may be free or it may be subject to certain geometrical constraints, for instance, it may be obliged to move on a certain surface. Then there will be certain forces acting between the particle and the bodies causing the constraint, these forces being known as reactions due to the constraint. A surface is said to be smooth if the reaction between it and a particle at rest is normal to the surface. Thus let \( F \), Fig. 7, represent a force applied to a particle of weight \( W \), resting on an inclined plane making an angle \( \alpha \) with the horizontal. Let \( F \) be parallel to the inclined plane. Then the three forces, \( W, F, \) and \( R \), the reaction, normal to the plane, are in equilibrium. Writing these proportional to the opposite angles, as above, we obtain

\[
\frac{F}{\sin \alpha} = \frac{R}{\cos \alpha} = \frac{W}{1},
\]

which determine \( F \) and \( R \) in terms of \( W \). The same equations are obtained by resolving in the direction of the tangent and of the normal to the plane. The equation \( F = W \sin \alpha \) shows that the force required to sustain a particle on a smooth plane is to the weight of the particle in the same ratio as the height of the plane to its length, as was shown by Stevinus and Galileo.
In the problem just treated, it is evident that the resultant of the applied forces \( W \) and \( F \) is opposite to \( R \), that is, is normal to the plane. Similarly, for equilibrium on any smooth surface, it is necessary that the resultant of all the applied forces shall be normal to the surface, for if it had any component parallel to the tangent plane this component would move the particle along the surface. Since the particle is constrained to move on a surface, there will be a relation between \( x, y, z \), the co-ordinates of the particles, \( \phi (x, y, z) = 0 \), which is the equation of the surface; and since the direction cosines of the normal \( n \) are given by the equations

\[
\cos(mx) \cos(ny) \cos(nz) = \frac{\partial \phi}{\partial x} \frac{\partial \phi}{\partial y} \frac{\partial \phi}{\partial z},
\]

if \( X, Y, Z \) are the components of the resultant of the applied forces, we have as the condition for equilibrium

\[
\cos \left( \frac{FX}{F} \right) = \cos \left( \frac{NX}{n} \right), \text{ etc.,}
\]

or

\[
\frac{X}{\partial x} = \frac{Y}{\partial y} = \frac{Z}{\partial z}.
\]

(5)

If the surface is not smooth, the reaction between the particle and the surface is not normal, but there is a tangential component which is called friction. The force of friction is peculiar in that it cannot produce but only hinder motion, and in having its direction determined as opposite to the direction in which the other forces tend to make the particle move. The law usually assumed governing friction is that when motion is just about to take place the friction, or tangential component of the reaction, is proportional to the normal component, the factor of proportionality being a constant for two given substances, such as those composing the particle and plane, as above. Suppose that in the problem of the inclined plane the force \( F \) is the force of friction. Then we have \( F = \mu R \), where \( \mu \) is a constant for the given particle and plane called the coefficient of friction. Equations (4) then give

\[
F = R \tan \alpha = \mu R, \quad \mu = \tan \alpha,
\]

when the particle is just about to slide down. If the plane is any steeper than the value of \( \alpha \) thus given, equilibrium is not possible. This angle is called the angle of friction.

3. Let us now consider a rigid body, that is, one composed of a continuous distribution of matter having the property that the distance between any two of its points is invariable, no matter to what forces it is subjected. It is evident that if equal and opposite forces, \( P \) and \( Q \), Fig. 8, be applied to such a body at two points \( A \) and \( B \) such that the line \( AB \) has the direction of the forces, no motion will be produced, for reasons of symmetry with respect to \( AB \). Equilibrium is also independent of the position of \( B \) on the line \( AB \).

Consequently the force \( Q \) might be applied at \( A \), where it might be compounded with \( P \), giving a vanishing resultant. The principle that any force applied to a rigid body may be considered as applied at any other point in its line of direction is known as that of the transmissibility of force. As an application, if the lines of direction of three forces, \( P, Q, R \) (Fig. 9), intersect in a common point \( O \), they may be transferred to that point, and if they satisfy the conditions for the equilibrium of forces applied to a material particle, they will produce equilibrium of the rigid body.

Suppose we have two parallel forces \( P \) and \( Q \) applied at any points \( A, B \), of a rigid body, (Fig. 10). If we apply at \( A \) and \( B \) any two equal and opposite forces \( AR, BS \), in the direction of \( AB \), equilibrium will not be affected. Compound these respectively with \( AP, BO \) and transfer the resultants \( AC, BD \) to the intersection of their lines of direction \( E \) and there resolve them into components in the original directions. From the equality of the parallelograms \( EKFH \) and \( APKR \), \( ELGJ \) and \( BQDS \), the components \( EJ \) and \( EH \) are equal and opposite, so that there remain only the components \( EK \) and \( EL \), in the same direction, equal to the given forces \( AP, BO \), respectively. Thus the resultant of two parallel forces in the same direction applied to a rigid body is a force in the same direction equal to their sum. Obviously it may be considered as applied at any point \( O \) in the line \( KE \). Suppose \( O \) to lie on \( AB \). By similar triangles \( AF = OE \), \( BO = QE \), and by division, since \( AR = AO \), \( BS = BO \),

\[
AR = BS, \quad AP = BO.
\]

Thus the distance of the intersection of the line of direction of the re-
resultant with $AB$ from $A$ and $B$ is inversely proportional to the forces applied at those points. This is the principle of the lever, as known to Archimedes.

If the forces $P$ and $Q$ are the weights $w_1$, $w_2$ of two particles, placed at $AB$, the point $O$ is called the centre of gravity of the two particles. It is also called the weighted mean point of points $AB$ with the weights $w_1$, $w_2$. If we project the joints $A$, $B$, $O$ upon the coordinate axes, the projections of $AO$, $BO$, are in the same ratios as the lengths themselves; consequently if their co-ordinates are respectively $x_1$, $y_1$, $z_1$, $x_2$, $y_2$, $z_2$, $x$, $y$, $z$,

$$
\frac{x-x_1}{x_2-x_1} = \frac{y-y_1}{y_2-y_1} = \frac{z-z_1}{z_2-z_1} = \frac{m_1}{m_2},
$$

or

$$
\frac{x}{m_1} = \frac{x_1}{m_1} + \frac{x_2}{m_2}, \quad \frac{y}{m_1} = \frac{y_1}{m_1} + \frac{y_2}{m_2}, \quad \frac{z}{m_1} = \frac{z_1}{m_1} + \frac{z_2}{m_2}.
$$

By a generalization, we obtain for the centre of gravity of any number of points, or the resultant of any number of parallel forces,

$$
\frac{x}{m} = \frac{\sum x_i}{\sum m_i}, \quad \frac{y}{m} = \frac{\sum y_i}{\sum m_i}, \quad \frac{z}{m} = \frac{\sum z_i}{\sum m_i}.
$$

If the two forces $AP$, $BQ$, are in opposite directions, instead of Fig. 10 we have the construction of Fig. 11, and the resultant is evidently equal to the difference of the two components, while the point $O$ lies outside the segment $AB$. We may say that in general the resultant is equal to the algebraic sum of the components. In Fig. 11, if $AP$ and $BQ$ are made more nearly equal, the point $O$ recedes to a greater distance, and in the case of equality, when we have $AC$ parallel to $BD$, $O$ must be infinitely distant. The same result is given by the forimula (6), putting $m_1 + m_2 = 0$. In other words, two equal, parallel and oppositely directed forces applied to a rigid body cannot be replaced by a single resultant. Such a pair of forces is called a couple. The perpendicular distance between the two lines of direction of the members of the couple is called its arm. The product of the magnitude of either force by the arm of the couple is called the moment of the couple. The plane of the couple is the plane containing both forces. We have shown that a couple cannot be equilibrated by an single force, but it may be by another couple. This couple may be chosen in an infinite variety of ways. It may easily be shown by drawing the members of the second couple as about to be prescribed, and compounding the forces two and two, by the rules already given, that the equilibrating couple may be equilibrated by any of the following, and that the given couple may accordingly be replaced by: 1° An equal and parallel couple in any plane parallel to its own; 2° An equal couple in its plane turned about its point of symmetry; 3° A couple in the same place having different arm and forces but the same moment. Thus all that characterizes a couple is the magnitude of its moment and the direction of the normal to the plane of the couple. The couple then behaves like a directed quantity, and may be symbolized by a line in the direction of the normal to its plane, whose length gives the magnitude of the moment. That couples are also compounded by the vector law is easily seen, for consider for forces of the two couples to be applied at two points $AB$ in the line of intersection of their two planes. This can be done by bringing the couples to have the same arm. Let $P_1$, $P_2$ (Fig. 12) be the members of one couple, $Q_1$, $Q_2$ those of the other. Compound $P_1Q_1$ by the parallelogram law to $R_1, P_2Q_2$ to $R_2$. These being equal, parallel and oppositely directed, form a couple which, having the same arm as the original couples, has its moment proportional to $R$, that is, found by the parallelogram construction. If lines are laid off perpendicular to the three planes of $AB$ and $P$, $Q$, $R$, respectively, and proportional to the three moments, they will also follow the parallelogram law. Thus a couple may be represented by a vector perpendicular to its plane. This vector we shall speak of as the couple, and shall disregard the resolution into two separate forces.

Let us now consider the effect of any number of forces applied at various points of a rigid body. At any point $O$ (Fig. 13) apply two equal and opposite forces $P^\prime$' and $P^\prime\prime$ and parallel to a force $P$ applied at $A$. We thus have the force $P^\prime$ equal to $P$ applied at $O$ instead of at $A$, together with the couple $PP^\prime\prime$. Similarly all the forces applied at other points may be considered applied at $O$, by introducing in each case a couple. All the forces at $O$ may be compounded into a single resultant, and all the couples into a single couple. Thus the resultant of any number of forces applied to a rigid body is a single force together with a single couple. Evidently the resultant force does not depend upon the position of the
MECHANICS

point O, while the resultant couple does. In order to have equilibrium, both the resultant force and the resultant couple must vanish.

In order to express these conditions analytically, we must find an expression for the moment of a vector about a given point, that is, the product of the magnitude of the vector by the length of the perpendicular dropped upon it from the given point. This moment is thus numerically equal to the area of the parallelogram formed with the given point as one corner and the given vector as one side. As plane areas may be projected on other planes by multiplying by the cosine of the dihedral angle between them, which is equal to the angle between their normals, it is evident that the area of the parallelogram, and hence the moment, may be represented by a vector perpendicular to its plane, as already shown for the moment of a couple. Thus it is only necessary to find expressions for the three projections of a moment. Let the vector $F$ (Fig. 13).

of all the parts of the ladder is a single force $W$ applied at the centre of gravity $G$. Besides this we have to consider the normal reactions $R$ and $S$. Resolving vertically we find for equilibrium $W - R = 0$. Resolving horizontally there must be a force to balance $S$. Let this be $P$, applied at the lower end of the ladder. Then $P - S = 0$. This does not determine the value of $P$ or $S$, but we may do this by taking moments about any point in the plane of the figure. If we choose the lower end of the ladder, $P$ and $R$ will have zero moment, and if $l$ is the length of the ladder, $a$ the inclination,

$Sl \sin a = (Wl \cos a)/2 = 0$, $S = \frac{1}{2}W \cot a$.

If the floor is rough, and $P$ the friction, $P = \mu R = \mu W = S = \frac{1}{2}W \cot a$, $\mu = \cot a$, and if $a$ is less than the angle determined by this equation, the ladder will slip down.

4. All the principles of statics are comprised in the Principle of Virtual Work. The conception of work is equally important with that of force. Work is done when the point of application of a force moves, the amount of work being defined as the product of the magnitudes of the force and the distance moved by the cosine of the angle included by them. If $F$ denote the force, $D$ the displacement, the work is $FD \cos (FD)$. This geometric or scalar product of two vectors (not a vector, since it is not associated with direction, but merely with a number, or scalar) defined as the product of either by the projection on it of the other, is of much importance in our whole subject. The cosine of the angle between two directions is given by the symmetric function of their direction cosines

$cos (FD) = \cos (Fx) \cos (Dx) + \cos (Fy) \cos (Dy) + \cos (Fx) \cos (Dx)$.

Now if the projections on the axes of co-ordinates of the two vectors are

$F_x = F \cos (Fx)$, $F_y = F \cos (Fy)$,

$D_x = D \cos (Dx)$, $D_y = D \cos (Dy)$,

$D_z = D \cos (Dz)$,

we have

$FD \cos (FD) = F_x D_x + F_y D_y + F_z D_z$.

as the analytic expression for the scalar product. If one of the vectors is taken as of unit length,
the expression (11) gives us the value of the projection $F_s$ of any vector $F$ on any direction $s$.

$$F_s = F \cos(F_s) = F_z \cos(zx) + F_y \cos(sy) + F_x \cos(ss).$$

It is easily proved that the work of the resultant of two forces in a displacement is the sum of the works of the components.

In the case of an infinitely small displacement $dx, dy, dz$, the work is

$$dW = F_x dx + F_y dy + F_z dz,$$

and if the point is moved along a curve the whole work is

$$W = \int (F_x dx + F_y dy + F_z dz),$$

where $x, y, z, F_x, F_y, F_z$ are supposed given in terms of some parameter, so that the integration along the curve can be performed.

If some of the points of a system are not free, but constrained, a virtual displacement is one that is consistent with the constraints. Virtual work is work done in a virtual displacement. The principle of virtual work states that in a system of forces in equilibrium the work done in an infinitesimal arbitrary virtual displacement vanishes. Let us apply this principle to a number of simple cases. First, two equal weights $P$ hanging from a string over a fixed pulley are in equilibrium. If the system is displaced one weight falls as much as the other rises. For the one that falls the displacement is in the direction of the force, and the work is positive and equal to $PD$. For the one that rises the displacement is opposite to the direction of the force, and the work is negative and equal to $-PD$. The sum of these two quantities thus vanishes.

In the case of a weight hanging from a movable pulley (Fig. 16), if the string on the left is pulled up a distance $D$, the force $T_s$ does the positive work $T_D$; but from the geometry of the case the weight $P$ rises a distance of $D/2$ and the weight $W$ accordingly does the negative work $-PD/2$. The whole work is zero, if $T=F/2$. But this is the condition of equilibrium as found by resolution, since the tensions $T_s$ and $T_r$ are equal and we must have $T_r = T_s = P/2$. Consider a lever (Fig. 17) carrying the weights $P, Q$ at distances $h_1, h_2$ from the fulcrum. Then for equilibrium the principle of moments gives $Pl_1 = Ql_2$. But if the lever be turned through an infinitesimal angle $\alpha$, the end $A$ moves a distance downward $Dx = l_1 \alpha$, and the weight does the positive work $Pl_1 \alpha$, while the end $B$ rises a distance $Dy = l_2 \alpha$, and $Q$ does the negative work $-Ql_2 \alpha$. The whole work is zero if $Pl_1 = Ql_2$, which is the condition for equilibrium. In the case of the inclined plane (Fig. 7), if the particle is displaced a small distance $d$ up the plane, the force $F$ does the work $Fd$. The weight $W$ does the negative work $-Wd \sin \alpha$, since its direction makes an obtuse angle with the displacement. The reaction does no work, since it is perpendicular to the displacement. The whole work is therefore zero if $F=W \sin \alpha$. But this is the condition of equilibrium. The principle of virtual work is particularly convenient, since it enables us to leave the reactions out of account, since they do no work when the displacements are virtual. As a further example let us consider the equilibrium of a particle whose co-ordinates are $x, y, z$ on a surface $\phi(x, y, z) = 0$ under the action of forces whose resultant is $X, Y, Z$, omitting the reaction. Since the displacement is virtual, we must have $\phi = 0$ during the displacement, so that

$$d\phi = \frac{\partial \phi}{\partial x} dx + \frac{\partial \phi}{\partial y} dy + \frac{\partial \phi}{\partial z} dz = 0.$$

The principle of virtual work says that for equilibrium

$$X dx + Y dy + Z dz = 0$$

for any virtual displacement, that is, one in which $dx, dy, dz$ are not independent, but satisfy (15). Multiplying (15) by an undetermined factor $\lambda$ and adding to (16), we have

$$X + \lambda \frac{\partial \phi}{\partial x} dx + \left(Y + \lambda \frac{\partial \phi}{\partial y}\right) dy + \left(Z + \lambda \frac{\partial \phi}{\partial z}\right) dz = 0.$$

Both conditions are satisfied if we determine $\lambda$ so that

$$X + \lambda \frac{\partial \phi}{\partial x} = Y + \lambda \frac{\partial \phi}{\partial y} = Z + \lambda \frac{\partial \phi}{\partial z} = 0,$$

or eliminating $\lambda$.

$$\frac{X}{\partial x} = \frac{Y}{\partial y} = \frac{Z}{\partial z}.$$

But this is the condition (5) that the resultant is normal to the surface, and in fact only in this way can there be equilibrium, according to the definition of a smooth surface.

For a rigid body, a possible displacement is one in which all the points receive equal and parallel displacements, so that $dx, dy, dz$ are the same for all. We then have

$$\Sigma(X dx + Y dy + Z dz) = dx \Sigma X + dy \Sigma Y + dz \Sigma Z = 0.$$
MECHANICS

If this is to be true for arbitrary values of \( dx, dy, dz \) we must have

\[ \Sigma X = \Sigma Y = \Sigma Z = 0, \]

which are three of the conditions for equilibrium already found. A second possible displacement of a rigid body is one in which it is turned through an angle \( d\theta \) about the Z-axis.

Let us introduce polar co-ordinates, so that

\[ x = r \cos \theta, \quad y = r \sin \theta. \]

Then in the rotation, \( r \) being constant,

\[ dx = -r \sin \theta \cdot d\theta = -y \, dy, \quad dy = r \cos \theta \cdot d\theta = x \, dx, \]

\[ dz = d\theta. \]

Consequently the virtual work is

\[ 2 \left( X dx + Y dy + Z dz \right) = 0, \]

If this is to vanish whatever \( d\theta \) we must have

\[ 2 \left( x \, Y - y \, X \right) = 0. \]

But this is one of the conditions for equilibrium (9), already found, and the two others are similarly found by rotating about the other axes.

Suppose now that we have any number of points \( x_1, y_1, z_1, \ldots, x_n, y_n, z_n \), acted on by any forces, \( X_1, Y_1, Z_1, \ldots, X_n, Y_n, Z_n \), and subject to any number of constraints,

\[ \dot{\phi}(x_1, y_1, z_1, \ldots, x_n, y_n, z_n) = 0, \]

\[ \dot{\psi}(x_1, y_1, z_1, \ldots, x_n, y_n, z_n) = 0. \]

Then the equation of virtual work,

\[ \sum_{r=1}^{\infty} (X \, dx_r + Y \, dy_r + Z \, dz_r) = 0, \]

must hold for any changes of the co-ordinates which satisfy the conditions,

\[ \dot{d}\phi = \sum_{r=1}^{\infty} \left( \frac{\partial \phi}{\partial x_r} \, dx_r + \frac{\partial \phi}{\partial y_r} \, dy_r + \frac{\partial \phi}{\partial z_r} \, dz_r \right) = 0. \]

Multiplying these equations in turn by multipliers \( \lambda_1, \ldots, \lambda_k \), and adding to (25),

\[ \sum_{r=1}^{\infty} \left( \left( X_r + \sum_{s=1}^{k} \lambda_s \frac{\partial \phi_s}{\partial x_r} \right) \, dx_r + \left( Y_r + \sum_{s=1}^{k} \lambda_s \frac{\partial \phi_s}{\partial y_r} \right) \, dy_r + \left( Z_r + \sum_{s=1}^{k} \lambda_s \frac{\partial \phi_s}{\partial z_r} \right) \, dz_r \right) = 0, \]

which is satisfied for all virtual values of \( dx_1, \ldots, dx_n \), if we take

\[ X_r + \sum_{s=1}^{k} \lambda_s \frac{\partial \phi_s}{\partial x_r} = 0, \]

\[ Y_r + \sum_{s=1}^{k} \lambda_s \frac{\partial \phi_s}{\partial y_r} = 0, \quad r = 1, 2, \ldots, n. \]

\[ Z_r + \sum_{s=1}^{k} \lambda_s \frac{\partial \phi_s}{\partial z_r} = 0. \]

From these equations, eliminating the \( k \) multipliers \( \lambda_1, \ldots, \lambda_k \), we have \( 3n - k \) equations of equilibrium.

5. KINEMATICS.—Let us now consider questions of motion. The velocity of a point is defined as the limit of the space \( ds \) described by it to the time of description \( dt \), when both decrease indefinitely.

\[ v = \lim_{dt \to 0} \frac{ds}{dt}. \]

Since displacements are compounded as vectors, the resultant of a displacement \( AB \) (Fig. 1), and another \( BD \) being \( AD \), if the two displacements take place in the same time, the velocities are also proportional to the three lines, so that velocities are vectors, compounded by the parallelogram. Accordingly a velocity may be represented by its components along the co-ordinates axes. Its direction being that of the tangent to the path, its direction cosines are those of the tangent,

\[ \frac{dx}{ds}, \frac{dy}{ds}, \frac{dz}{ds}. \]

Consequently, its components are

\[ v_x = \frac{dx}{dt}, \quad v_y = \frac{dy}{dt}, \quad v_z = \frac{dz}{dt}. \]

Also,

\[ v^2 = v_x^2 + v_y^2 + v_z^2 = \left( \frac{dx}{dt} \right)^2 + \left( \frac{dy}{dt} \right)^2 + \left( \frac{dz}{dt} \right)^2. \]

Similarly, the projection of a velocity in any direction is the velocity of the projection of the point on a line having that direction.

If a point moves in a plane it may be convenient to introduce polar co-ordinates \( r, \theta \).

\[ \text{Fig. 19.} \]

If the point moves from \( A \) to \( B \) (Fig. 19), a distance \( ds \) in the time \( dt \), dropping a perpendicular \( AC \) upon the radius \( OB \), the displace-
ment may be resolved into $AC$ and $CD$, equal to $r \phi$ and $dr$ respectively, and accordingly the velocity may be resolved into the components in those directions.

\[ \omega = \lim_{dt \to 0} \frac{r \, d\phi}{dt}; \quad r = \lim_{dt \to 0} \frac{dr}{dt}; \]

Also,

\[ \phi = \lim_{dt \to 0} \frac{r \, d\phi}{dt} = \left( \frac{d\phi}{dt} \right); \quad \phi = \lim_{dt \to 0} \frac{dr}{dt} = \left( \frac{dr}{dt} \right), \]

as may also be seen from the expression for the arc in polar co-ordinates. The components $r \phi$ and $\phi r$ are called the radial and tangential components of the velocity respectively, while $d\phi$ is called the angular velocity of the radius.

The area of the triangle $OAB$ being \( \frac{1}{2} \rho r^2 \), the radius vector sweeps over area at the rate

\[ \frac{dS}{dt} = \rho \frac{dr}{dt}, \]

but since the area is also equal to one-half the product of $AB$ by the perpendicular on it from $O$, then we find this rate of area description to be equal to one-half the moment of the velocity about $O$. Using the formula (8) for moment of a vector we have

\[ \frac{dS}{dt} = \rho \frac{dr}{dt} = \left( \frac{d\phi}{dt} \right)^2 + \left( \frac{dr}{dt} \right)^2, \]

which may be easily verified by passing directly from rectangular to polar co-ordinates.

6. If the velocity of a point varies we define the acceleration as the limit of the increment of velocity to the time in which it takes place. We may consider the numerical change

\[ \lim_{dt \to 0} \frac{dv}{dt} = \frac{dv}{dr} \frac{dr}{dt} = \frac{dv}{dr}, \]

or the vector change. If $AB$ (Fig. 20) denote the velocity at a time $t$, $AC$ the velocity at

\[ \frac{ds}{dt} = a = \text{const.} \]

Integrating we obtain

\[ \frac{ds}{dt} = at + b, \]

where $b$ is a constant representing the velocity when $t = 0$. Integrating again,

\[ s = \frac{1}{2} at^2 + bt, \]

where $s$ denotes the space described since $t = 0$. Thus if the particle start from rest ($b = 0$), it describes spaces proportional to the squares of the times of description. It was found by Galileo that bodies fall toward the earth according to such a law, and that in a given locality the value of the acceleration is the same for all bodies. The value of this acceleration of gravity is generally denoted by $g$. Comparing the velocity attained by a body
falling from rest with the height, we obtain, by (43) and (44),
\[(45) \quad v = gt, \quad h = \frac{1}{2}gt^2, \quad v^2 = 2gh.\]

Conversely, if a body be thrown upwards with a velocity \(v\), it will reach the height \(h\).

If we consider the motion of a body under gravity, but possessing a horizontal velocity as well as a vertical component, since there is no horizontal acceleration the horizontal velocity \(v_0\) is constant. Calling the vertical distance fallen \(z\), the horizontal distance traversed \(x\), we have
\[z = \frac{1}{2}gt^2, \quad x = v_0t,\]
and eliminating \(t\) we have the equation of the path, \(z = \frac{1}{2}gt^2\), representing a parabola with the axis vertical. The velocity at any point and its inclination to the horizontal are found from
\[v_x = \sqrt{v^2 - v_0^2}, \quad v_y = vt, \quad \tan \alpha = v_y/v_x.\]

If, on the other hand, the particle be projected upward with velocity \(v\) at an angle \(\alpha\) with the horizontal, it will describe the same parabola, rising to the vertex in the time \(t\) and falling on the symmetrical half. This problem was also solved by Galileo.

Consider a particle revolving with constant velocity \(v\) in a circular path of radius \(r\). Then since \(z = vt\), by (39) we find that the tangential component of the acceleration vanishes. The normal component is given by (41) as \(v^2/r\). Thus the acceleration is constant in amount and always directed toward the center. It is to be observed that although the numerical velocity is constant, the vector velocity is constantly changing its direction, hence the acceleration is not zero, but is perpendicular to the velocity. If we resolve the uniform circular

and always in the direction \(PO\), its component along \(OX\) varies as \(\cos \phi\), that is, as the distance \(OQ\). In other words, a point describing a simple harmonic motion has an acceleration proportional to its displacement from the center of symmetry, and directed toward it. We may also consider harmonic motion analytically. If the acceleration is proportional to the displacement but opposite in direction, we shall have
\[(46) \quad \frac{dv}{dt} = -\omega^2 v,\]
where \(\omega\) is a constant. The integral of this differential equation is
\[(47) \quad v = A \cos \omega t + B \sin \omega t = a \cos(\omega t - \phi),\]
where \(A\) and \(B\) are arbitrary constants and \(A = a \cos \alpha, B = a \sin \alpha\). The constant \(a\) is called the amplitude, while the angle \(\alpha\), called the phase, depends simply upon the instant adopted from which to count the time. By taking for \(\alpha\) the values 0° or 90° we obtain either a cos \(\omega t\) or sin \(\omega t\).

If we compound two simple harmonic motions in lines at right angles to each other, if the amplitudes and periods are the same and the phases differ by a right angle, the previous construction shows that we obtain uniform circular motion. If the amplitudes and phases do not have this relation, we have
\[(48) \quad x = a \sin (\omega t - \phi),\]
\[y = b \sin (\omega t - \Phi),\]
Solving for \(\sin \omega t\) and \(\cos \omega t\)
\[(49) \quad \sin \omega t = \frac{x}{a} = \frac{a}{b} \sin \beta \quad \text{and} \quad \cos \omega t = \frac{y}{b} = \frac{b}{a} \cos \beta;\]
Squaring and adding we eliminate \(t\) and obtain the equation of the path,
\[(50) \quad \frac{x^2}{a^2} + \frac{y^2}{b^2} - 2 \frac{x}{a} \frac{y}{b} \cos \beta = \sin^2 (\alpha - \beta),\]
which represents an ellipse. The motion is called elliptic harmonic motion. The ellipse is evidently inscribed in a rectangle of sides \(2a, 2b\) (Fig. 22), and according to the values of \(\alpha - \beta\) may have any shape, reducing to a straight line when \(\alpha - \beta\) is zero or 180°. If the two harmonic vibrations are not of the same period, the resulting path belongs to a system of curves associated with the name of Lissajous. They may be easily constructed point by point, but the elimination of \(t\) will be possible only if the periods have a common measure.

Suppose a particle subject to the constant acceleration of gravity to be constrained to
move in a vertical circle of radius \( l \) (Fig. 23). The component of the acceleration \( g \) in the direction of the tangent is \(-g \sin \theta\), while the distance moved from the bottom of the circle

![Diagram of vertical circle](image)

is \( l \). We thus have the differential equation

\[
\frac{d\theta}{dt} = \frac{\sqrt{\theta}}{l} g \sin \theta.
\]

The solution of this equation requires elliptic functions, but if \( \theta \) is small enough we may neglect the difference between the angle \( \theta \) and its sine, so that the equation of motion is

\[
\frac{d\theta}{dt} = -\frac{\sqrt{\theta}}{l} g \theta,
\]

which is the same as the equation (46) of harmonic motion with \( \omega^2 = g/l \). Accordingly the small vibrations of a pendulum are harmonic, of the period \( T = 2\pi \sqrt{\frac{l}{g}} \), which is independent of the amplitude of oscillation. The fact of this isochronism of the pendulum, or independence of the period of the amplitude, was discovered by Galileo, while the laws of uniform circular and of harmonic motion, and of the pendulum, were found by Huygens.

The latter also used the formula \( g = \frac{4\pi^2}{T^2} \) to determine the value of \( g \).

Let us now examine the consequences of the celebrated laws discovered by Kepler as governing the motion of the planets about the sun. The first law states that the areas swept over by the radius vector from the sun to a planet in equal times are equal. Calling the area \( S \),

\[
\frac{dS}{dt} = \text{const.}
\]

But differentiating the value of \( dS/dt \) given in (34), we find

\[
2 \frac{dS}{dt} = \frac{dy}{dt} - \frac{dx}{dt} = x\frac{dy}{dt} - y\frac{dx}{dt} = \text{const.}
\]

But this is the moment of the acceleration with respect to the origin, and if it vanishes, the acceleration must be directed toward the origin. The kinematical interpretation of the first law is then that the planets are accelerated toward the sun. The second law states that the planets describe ellipses about the sun as a focus. The equation of a conic section referred to its focus is

\[
r = \frac{p}{1 + e \cos \phi},
\]

where \( a \) is the major axis, \( e \) the eccentricity. Now to resolve the acceleration along the radius vector, we multiply its components \( a_x \), \( a_y \), respectively, by the direction cosines of the radius vector, which are \( \cos \phi, \sin \phi \). Differentiating the equations for change of co-ordinates \( x = r \cos \phi, y = r \sin \phi \), twice, we have

\[
a_x = \frac{dx}{dr} \frac{dr}{dt} - r \sin \phi \frac{d^2 \phi}{dt^2},
\]

\[
a_y = \frac{dy}{dr} \frac{dr}{dt} + r \cos \phi \frac{d^2 \phi}{dt^2}.
\]

from which

\[
a_r = a_x \cos \phi + a_y \sin \phi = \frac{dr}{dt} \frac{d^2 \phi}{dt^2}
\]

Now by Kepler’s first law,

\[
\frac{ds}{dt} = \frac{dr}{dt} \frac{d\phi}{dt} = \text{const.} = h, \quad \frac{d\phi}{dt} = \frac{h}{r^2}.
\]

Changing the variable from \( t \) to \( \phi \),

\[
\frac{dr}{d\phi} = \frac{h}{r^2} \frac{d\phi}{dt} \frac{d\phi}{dt} = \frac{h}{r^2} \frac{d\phi}{dt} \frac{d\phi}{dt} = \frac{h}{r^2} \frac{d\phi}{dt}.
\]

Differentiating by \( t \),

\[
\frac{dr}{dt} = \frac{h}{r^2} \frac{d\phi}{dt} \frac{d\phi}{dt} = \frac{h}{r^2} \frac{d\phi}{dt} \frac{d\phi}{dt} = \frac{h}{r^2} \frac{d\phi}{dt}.
\]

From the equation of the path we obtain

\[
\frac{d\phi}{dt} = \frac{1}{r} + \frac{1}{r} \cos \phi.
\]

Thus the fact that the path is a conic section shows that the acceleration is inversely as the square of the distance from the focus. The negative sign shows that it is toward the sun.

The third law states that for different planets the squares of the times of description of the orbits are proportional to the cubes of the major axes. Since \( 2dS/dt = h \), if \( T \) is the time of a complete period \( hT \) is twice the area of the orbit.

\[
hT = 2\pi a = 2\pi a^2 \sqrt{1 - e^2},
\]

where \( a \) is the major axis, \( e \) the eccentricity.

Now since \( a^2/T^2 \) is the same for all the planets, we see that the factor of \( 1/r^2 \) in the acceleration is the same for all the planets. These kinematical interpretations of Kepler’s laws in terms of acceleration were given by Newton.

6. KINETICS—The whole of our experience of dynamical phenomena was summed up by Newton in his Axioms or Laws of Motion, which are as follows:

I. Every body persists in its state of rest or of uniform motion in a straight line, except in so far as it is compelled by impressed forces to change that state.

II. The property of persistence thus defined is called inertia. The law of inertia was recognized in a less definite way by Galileo, but Newton makes of it a criterion for the existence of force, and in fact implies that if a body is moving in any other way than uniformly in a
straight line, that is, without acceleration, it is acted on by a force. The second law gives a positive definition of force.

11. Change of motion is proportional to the moving force applied and takes place in the direction of the straight line in which the force acts.

In the explanation of this law, and in a corollary appended, Newton makes clear that it is intended to include the independent effect of two simultaneous forces, and their composition by the parallelogram.

In his introductory definitions, Newton states what he means by quantity of motion, to which force is proportional, namely, the product of velocity by mass, or what is now called momentum, but the motion of mass is best introduced by the third law, which is perhaps the most important, as well as original, of the three.

111. To every action there is always an equal and contrary reaction; or, the mutual actions of any two bodies are always equal and oppositely directed.

If the force were measured by the acceleration alone, the accelerations of the two interacting bodies would be equal and opposite; that is not the case, but they are found to be proportional, with a factor of proportionality which is found to be always the same for two given bodies, no matter how they act on each other. For example, let them be connected by a string, and act on each other through its tension, or by an elastic cord whose length may vary. If for symmetry we write a factor for each acceleration,

\[ (56) \quad m_1 \frac{dx_1}{dt} = -m_2 \frac{dx_2}{dt}, \quad m_1 \frac{dy_1}{dt} = -m_2 \frac{dy_2}{dt}, \]

the factors \( m_1, m_2 \) are called the masses of the bodies, and their ratio is determined by the ratio of the accelerations. Thus we may compare the mass of any body with that of a given body taken as a unit. The usual unit of mass is the pound or the gram.

By the introduction of the conception of mass and of momentum we pass from kinematics to kinetics, or dynamics proper. As long as we were concerned with one body at a time, like Galileo and Huygens, the notion of acceleration was sufficient, but when we deal with a number of bodies with mutual actions, the notion of force is necessary. The terms on either side of equations (56) represent the forces, and the equations express the third law. The second law may now be stated by saying that force is the rate of change of momentum. The forces generally are known in terms of the positions of the bodies, and perhaps of their velocities, and when given by their components \( X, Y, Z \) as functions of these quantities, the equations

\[ (57) \quad m\frac{dx}{dt} = X, \quad m\frac{dy}{dt} = Y, \quad m\frac{dz}{dt} = Z \]

are called the differential equations of motion.

Our kinematical examples of the previous section may now be dynamically interpreted. The fact that bodies fall with a common acceleration \( g \) shows that the forces with which they are moved toward the earth, or their weights, \( W = mg \), are proportional to their masses. The unit of force, namely, that force which produces in a pound an acceleration corresponding to an increase of velocity of one foot per second in each second, has received the name of poundal. The weight of each pound is accordingly \( g \) poundals. The unit generally used by scientists is the force which produces in a gram the acceleration corresponding to an increase of velocity of one centimeter per second in each second. This force is called a dyne, and the weight of a gram is \( g \) dynes. These units are called absolute units, as they do not depend on accidental circumstances of time or place, but are referred to three fundamental units, of time, length and mass, the latter two of which are preserved in concrete standards, the former is preserved in the rotation of the earth. The more familiar gravitational unit, which we have used in the section on statics, and which is the weight of the pound or gram, is not absolute, since \( g \) varies at different parts of the earth, according to the formula

\[ (58) \quad g = 980.62 - 2.6 \cos 2\theta - 0.00003h, \]

where \( \lambda \) is the latitude, \( h \) the height above sea-level, and the units are the centimeter and the second. The weight of a body is accordingly variable, but its mass is invariable. For \( \lambda = 45^\circ \), at sea-level we have

\[ \text{Weight of pound} = 32.17 \text{ poundals,} \]

\[ \text{Weight of gram} = 980.62 \text{ dynes.} \]

The popular usage of the term pound or gram to denote both a mass and a force is unfortunate, and should be avoided.

The fact that the weights of bodies are proportional to their masses was carefully tested by Newton by constructing pendulums of different materials, and finding that the acceleration, as determined by the time of oscillation, was independent of the substance.

The fact that a body moving uniformly in a circle has a centripetal acceleration \( c^2/r \) shows that it is acted on by a force toward the centre (centripetal force) equal to \( mr^2/r \). If the body, for instance, be moving in a horizontal orbit on a whirling machine, and be held in place by a string, this string may be passed over a pulley and support a weight, so that we may thus make a comparison between the absolute dynamical measure of force and the gravitational one previously used. By repeating the experiment with another revolving mass, we may compare the masses of two bodies, by the process of comparing both with the same weight. This illustrates the dynamical comparison of masses. The usual statical method of comparison by a balance is actually a comparison of weights, and gives a correct comparison of masses because the value of \( g \) is the same at each pole. If we used a balancebeam so long that \( g \) differed sensibly at its two ends, equality of weights would not mean equality of masses.

Another simple illustration of the dynamical method of comparison of masses is furnished by Atwood's machine, by which the laws of falling bodies may be studied. Two masses \( m_1, m_2 \), Fig. 24, are hung by strings passing over a frictionless pulley. Since the distance moved up by one mass is equal to that moved down by the other, the velocities and accelerations of the two are equal and opposite.
mass is acted upon by two forces, the tension of the string upwards and its own weight downwards. The tension is the same for both. Consequently we have for the acceleration $a$,
\[ m_0a = T - m_0g, \]
\[ m_0a = -m_0 = T - m_0g, \]
from which we obtain
\[ a = \frac{m_0 - m_0}{m_0 + m_0} g. \]

that is, the acceleration is to that of a body falling freely as the difference to the sum of the masses. Thus by observing the acceleration the masses may be compared. In the usual use of Atwood's machine that difference of masses is produced by an extra weight, which is taken off at a certain height by a fixed ring, after which the two remaining equal masses travel with uniform velocity, and by the velocity generated the acceleration is determined.

The properties of harmonic motion show that a body acted upon by a force proportional to its displacement from a fixed point will execute a harmonic vibration. When a point has a position of equilibrium and is displaced therefrom, forces will in general be brought into play tending to restore it to its position, and these forces will depend upon the displacement. If the displacement be small enough, the forces will be approximately proportional to the displacement, hence the frequency of harmonic vibrations in nature.- The vibration of the pendulum of a tuning-fork are examples.

From the generalization that all the planets are accelerated toward the sun with an acceleration $a = c/r^2$, where $c$ is constant for all, Newton, putting the force equal to $cm/r^2$, and seeing that the masses of the two interacting bodies, the sun and planet, must enter symmetrically, was led to assume $F = \gamma Mm/r^2$, and from the law of reaction this would also be the force urging the sun toward the earth. Thus he was led to the generalization of universal gravitation, namely, the statement that every mass in the universe attracts every other with a force proportional to the product of both their masses, and inversely to the square of the distance apart. (The number $\gamma$ is the same for all, depending only on the units used).

Newton tested this by comparing the acceleration of the moon due to the earth's attraction with the acceleration of a body at the earth's surface. Supposing the moon's orbit to be circular, of radius $r$ and period $T$, its acceleration will be $\omega = 4\pi^2 r/T^2$. If the acceleration varies inversely as the square of the distance, at the surface of the earth, it will be
\[ a = \frac{m_0}{R^2} \frac{4\pi^2 r}{R^2 T^2}, \]
where $R$ is the earth's radius.

Now we have
\[ T = 27d43 m = 39,343 m, 2\pi R = 4 \times 10^7 \text{ meters}, \]
\[ r = 60R, \]
from which
\[ a = \frac{2\pi \cdot 60 \cdot 4 \times 10^7 \text{ meters}}{(39,343 \text{ m})^2 \cdot (36 \text{ sec})^2} \]
\[ = 9.74 \text{ meters per sec}^2 = 974 \text{ cm per sec}^2. \]

This agrees well with the value of $g$ from terrestrial observations, while more exact calculations give a still better agreement.

The value of the Newtonian constant, $\gamma$, or the 'number of dynes of attraction' of two masses each of one gram, one centimeter apart, is $\gamma = 6.6576.10^{-10}$.

A highly important contribution was made by d'Alembert, who made it possible to reduce every problem of dynamics to one of statics. If a system of particles be not free, they cannot move under the influence of given applied forces as they would if not constrained, but the reactions will cause them to move otherwise, as in the case of the masses in Atwood's machine. For another instance, consider two bullets fastened together by a string and thrown at random into the air. If free each would describe plane curves, namely, vertical parabolas. Under the influence of the tensions of the string which causes the constraint, they describe looped or tortuous paths. If we knew the actual paths and motions, we could find forces which would produce the same motions if the particles were free. These d'Alembert calls the effective forces and they are given by
\[ X' = m_{1} \frac{dx}{dt}, Y' = m_{2} \frac{dy}{dt}, Z' = m_{3} \frac{dz}{dt}. \]

D'Alembert's principle states that the actual applied forces, together with the reversed effective sources, would form a system in equilibrium. If we express the equilibrium by means of the equation of virtual work, (25), we obtain
\[ \sum \left\{ (X_r - X_r') \delta x_r + (Y_r - Y_r') \delta y_r \right\} \]
\[ + (Z_r - Z_r') \delta z_r = 0 \]

or
\[ \sum \left\{ \left( \frac{m_{1} dx_{r}}{dt} - X_r \right) \delta x_r + \left( \frac{m_{2} dy_{r}}{dt} - Y_r \right) \delta y_r \right\} \]
\[ + \left( \frac{m_{3} dz_{r}}{dt} - Z_r \right) \delta z_r = 0. \]

This equation, given by Lagrange, was made by him the basis of all dynamics. Since the reactions would of themselves form a system of forces in equilibrium, they may be left out of the equation (58) of d'Alembert's Principle.

From the equation, (58) we can deduce all the principles of dynamics. Suppose every particle is free, then all the virtual displacements, $\delta x_r, \delta y_r, \delta z_r$, are independent, and in
order that the equation may hold for arbitrary
displacements, we must have

$$m_r \frac{dx_r}{dt} = X_r, \quad m_r \frac{dy_r}{dt} = Y_r, \quad m_r \frac{dz_r}{dt} = Z_r,$$

for every $r$. But these are Newton’s equations of
motion.

If the particles be free or form a rigid sys-
tem, a virtual displacement will be given when $dx_r, dy_r, dz_r$ have the same values for all the
particles. We may then remove these factors from
the summation.

$$\delta \xi = \left( \sum r m_r \frac{dx_r}{dt} - \sum_r X_r \right) \delta t + \delta \eta \left( \sum r m_r \frac{dy_r}{dt} - \sum_r Y_r \right) \delta t + \delta \zeta \left( \sum r m_r \frac{dz_r}{dt} - \sum_r Z_r \right) = 0,$$

and if $\delta \xi, \delta \eta, \delta \zeta$ are arbitrary, this requires

$$\sum r m_r \frac{dx_r}{dt} = \sum_r X_r, \quad \sum_r m_r \frac{dy_r}{dt} = \sum_r Y_r, \quad \sum_r m_r \frac{dz_r}{dt} = \sum_r Z_r.$$

Now we have

$$\sum r m_r \frac{dx_r}{dt} \delta t = \frac{dx_r}{dt} \delta t \sum r m_r = \left( \sum r m_r \frac{dx_r}{dt} \right) \delta t,$$

$$\sum r m_r \frac{dy_r}{dt} \delta t = \frac{dy_r}{dt} \delta t \sum r m_r = \left( \sum r m_r \frac{dy_r}{dt} \right) \delta t,$$

$$\sum r m_r \frac{dz_r}{dt} \delta t = \frac{dz_r}{dt} \delta t \sum r m_r = \left( \sum r m_r \frac{dz_r}{dt} \right) \delta t,$$

where $x, y, z$ are the co-ordinates of the centre of
mass, which obviously coincides with what
in the treatment of statics has been called the
centre of gravity. We thus find that the cen-
tre of mass of a free system, or of a rigid
body, moves as if all the forces of the system
were applied at that point and all the mass
were concentrated there. In particular if the
system is exposed to no external forces, but
only to its mutual actions, since these are
equal and opposite in pairs, they destroy each
other. Consequently the centre of mass of
such a system moves uniformly in a straight
line. This applies to the solar system.

Under the same conditions, a rotation
about an axis is a virtual displacement. Putting as
in (22) $dx_r = -y \delta \theta, dy_r = x \delta \theta, dz_r = 0$, and dividing out $\delta \theta$ we have

$$\sum r m_r \left( \frac{dy_r}{dt} \delta t = \frac{dx_r}{dt} \right) \delta t = \sum_r (x_r Y_r - y_r X_r).$$

The quantity on the right is the $s$-component
of the resultant moment of all the impressed
forces, as in (9), (23), which will be denoted
by the components $L, \beta, N$.

The quantity on the left may be written

$$\frac{d}{dt} \sum r m_r \left( \frac{dy_r}{dt} - \frac{dx_r}{dt} \right).$$

The quantity whose derivative appears,

$$H_s = \sum r \left( \sum m_r \frac{dy_r}{dt} - \sum m_r \frac{dx_r}{dt} \right)$$

is evidently the $s$-component of the resultant
moment of momentum of all of the particles of
which the system is composed. We thus have
the principle that if we construct a vector $H$
having the components $H_s, H_y, H_z$, where

$$H_s = \sum r \left( \sum m_r \omega_r \times v_r \right),$$

$$H_y = \sum r \left( \sum m_r \omega_r \times a_r \right),$$

$$H_z = \sum r \left( \sum m_r \omega_r \times \gamma m_r v_r \right),$$
in virtue of the equations

$$\frac{dH_s}{dt} = L, \quad \frac{dH_y}{dt} = M, \quad \frac{dH_z}{dt} = N,$$

the velocity of the extremity of the vector $H$
representing the moment of momentum of the
system, is equal and parallel to the resultant
moment of the impressed forces about the same
point. This principle, with that of equations
(61), suffices for the treatment of the motion of
a rigid body. By putting all velocities equal
to zero we obtain the conditions of equilibrium
as in (9).

If in equation (58) we put for $dx_r, dy_r, dz_r$, the
distance actually traversed by the various
points in the actual motion in the interval $dt$, we
obtain

$$\frac{dx_r}{dt} \delta t, \quad \frac{dy_r}{dt} \delta t, \quad \frac{dz_r}{dt} \delta t,$$

and we may write the sum of terms containing
the accelerations as an exact derivative,

$$\frac{d}{dt} \left[ \sum r m_r \left( \frac{dx_r}{dt} \delta t + \frac{dy_r}{dt} \delta t + \frac{dz_r}{dt} \delta t \right) \right] = \frac{d}{dt} \left[ \frac{1}{2} \sum r m_r \left( \frac{dy_r}{dt} \frac{dx_r}{dt} + \frac{dx_r}{dt} \frac{dy_r}{dt} + \frac{dz_r}{dt} \frac{dz_r}{dt} \right) \right].$$

The quantity $T$ whose derivative appears,
which is one-half the sum of the products of
the mass of each particle by the square of its
velocity, is the very important quantity called
the kinetic energy. Integrating equation (66)
between the limits $t_0$ and $t_1$

$$T_1 - T_0 = \int_{t_0}^{t_1} \left( X_r \frac{dx_r}{dt} + Y_r \frac{dy_r}{dt} + Z_r \frac{dz_r}{dt} \right),$$

where $T_0$ and $T_1$ denote the values of $T$
at the respective instants $t_0$ and $t_1$.

The integral on the right is the work (14)
done by all the applied forces during the motion.
We thus obtain the principle that the increase
of kinetic energy of a system is equal to the
work done by the forces. Suppose now that
the system be taken from one given configura-
tion, where all the co-ordinates have given
values, to a second, where they have other
given values, the particles describing given
paths, and they then be taken from the same
initial configuration to the same terminal one
but by other paths. Two cases are to be con-
sidered. Either the work done by the forces
depends upon the paths, or it is independent
of the paths, depending only on the terminal
configurations. If the integral

$$\int_{t_0}^{t_1} (X_r \frac{dx_r}{dt} + Y_r \frac{dy_r}{dt} + Z_r \frac{dz_r}{dt})$$
does not depend upon the path, it can be shown...
that every component of every force is the partial derivative of a single function $-\mathbf{W}$ of all the co-ordinates, by the corresponding co-ordinates.

\begin{align*}
X_t &= -\frac{\partial W}{\partial x_t}, \\
Y_r &= -\frac{\partial W}{\partial y_r}, \\
Z_r &= -\frac{\partial W}{\partial z_r},
\end{align*}

We then have

\[ \sum \int_0^{t_0} (X_t dx_t + Y_r dy_r + Z_r dz_r) = W_t - W_0, \]

and the equation (67) becomes

\[ T_t - T_0 = W_t - W_0, \]

or

\[ T_t + W_t = T_0 + W_0. \]

The sum of the two functions $T + W$ is then constant during the motion. As $T$ is called the kinetic, $W$ is called the potential energy of the system. Such systems are called conservative systems, and the above principle is called the principle of the Conservation of Energy. The motion of energy is of the greatest importance in dynamics. The principle was first used by Huygens and was generally stated by John and Daniel Bernoulli.

As an example of a conservative force we may take gravity. For a single particle we have $W = mgz$ (z being measured upward), so that the equation of energy is

\[ \frac{1}{2}mv^2 + mgz = \text{const} = \frac{1}{2}mv^2 + mgz_0, \]

\[ v^2 - z^2 = 2g(z_0 - z) = 2gh. \]

Accordingly the velocity attained by a falling particle does not depend on the form of the path, but only on the height fallen. This was known to Galileo, for bodies falling along the inclined plane or the arc of a circle. All forces acting according to the Newtonian law are also conservative.

We have now stated in summary fashion the principal theorems of Mechanics. The scope of this article does not permit us to enter into the details of the various methods which arise for treating the more complicated problems, say of the motion of a rigid body. By means of the equations (65), however, we may form an idea of some of the properties of such motions. We have seen that the centre of mass moves as if the whole body were concentrated and all the forces applied there. To find the motion of rotation we have to investigate the moment of momentum of a rigid body. If the body rotate about an axis with angular velocity $d\theta$, we obtain the velocity of a point at a distance $r$ from the axis by differentiating the equations $x = r \cos \theta, y = r \sin \theta, z = z$, yielding:

\[ v_x = -r \sin \theta \frac{d\theta}{dt}, \quad v_y = r \cos \theta \frac{d\theta}{dt}, \quad v_z = \frac{d\theta}{dt}, \]

and the moment of momentum is

\[ H_\theta = \sum m_r (x_r v_r - y_r v_z) = \frac{d\theta}{dt} \sum m_r (x_r \cos \theta + y_r \sin \theta). \]

The quantity $K = \sum m_r (x_r^2 + y_r^2) = \sum mr \overline{r}^2$ is called the moment of inertia of the body with respect to the axis. Suppose the axis is horizontal, and the body influenced only by gravity. The resultant of the weights of all the particles of the body is a force $W = Mg$ applied at the centre of mass, which is, say, at a distance $h$ from the axis, the plane through it and the axis making an angle $\theta$ with the vertical.

Then the moment of all these forces about the axis is $N = Mgh \sin \theta$, and we have the equation of motion

\[ \frac{dH_\theta}{dt} = -K \frac{d\theta}{dt} = -Mgh \sin \theta. \]

This is the same as that of a simple pendulum of length $l = K/Mh$, which is called the length of the equivalent simple pendulum. A point at a distance $l$ from the axis and in line with it and the centre of mass is called the centre of oscillation. This problem of the so-called compound pendulum was solved by Huygens, who also showed that if the body be suspended from a parallel axis through the centre of oscillation the period would be the same.

If a rigid body move in any manner with one point fixed, it may be shown that its motion at any instant may be described as a rotation with a certain angular velocity about a certain axis. All the particles of the body are then moving in various directions tangent to circles with planes parallel to each other, but owing to lack of symmetry the direction of the resultant moment of momentum has no simple relation to the direction of the axis.

As the motion goes on the direction of the axis changes in the body, and so does the direction of the moment of momentum. Thus the phenomenon is a complicated one, and can be dealt with only by lengthy analysis. If, however, the axis of rotation is an axis of symmetry, as in the case of the axis of a symmetrical top, Fig. 25, it is evident that the particles may be grouped in symmetrical pairs, $m_t, m_n$, Fig. 26, so that the moments of momentum $H_t, H_n$ about the fixed point $O$ will be symmetrical with respect to the axis, and the resultant moment will be in the direction of the axis.

If then we apply to the axis a force $F$ (Fig. 25),

it will have a moment $M$ (Fig. 27), perpendicular to the plane of $F$ and the fixed point, and according to equations (65) this will be the direction in which the vector $H$ will move toward $H'$. The end of the axis will, therefore, move at right angles to the direction in which it is pulled. This is the basis of the explanation of the curious phenomena of all tops and gyroscopes. In the ordinary top, the weight
MECHANICS OF DEVELOPMENT — MECHANICS' INSTITUTES

acting downwards at the centre of mass produces a horizontal moment; the point of the
top accordingly begins to move horizontally,
cause of a movement of precession. When the
precession begins, the rotation is no longer
about the axis of symmetry, and the vector \( H \)
no longer coincides with the geometrical axis
of the top, but the end of the vector \( H \) always
travels in a horizontal plane, and the axis of the
top moves about it in a motion of so-called
rotation. The rotary motions of the planets
are explained in a similar manner. It has re-
cently been demonstrated by Einstein that the
classical, Newtonian mechanics presented here
is only a first approximation to the facts.
The discrepancies between the Newtonian and the
Einsteinian mechanics are due to the fact that
time and space, as ordinarily conceived, are
not independent dimensions of being. See
RELATIVITY, PRINCIPLE OF.

ARTHUR GORDON WEBSTER,
Professor of Physics, Clark University.

MECHANICS OF DEVELOPMENT OR EVOLUTION.
A term applied by Ger-
man embryologists and biologists to the changes
coincident with the reproduction, fertilization and
later growth of organisms. In the organic
world, living bodies are constantly undergoing
changes of state, these changes being most con-
spicuous during the period of embryonic de-
velopment. The changes in the conditions of
life together with heredity and selection have
caued the evolution of the world of plants
and animals. These changes have been com-
plex, and yet in every way have been made
with exactness, order and regularity, and the
larger knowledge of development mechanics has
in a great measure been due to the researches
of Pander, Lortz, Born, Wilson, Loew, Ryder,
Wyman, Driesch and others. Probably the
most noteworthy treatises, though of op-
posing schools, are those of Von Wilhelm
Roux, 'Programm und Forschungsmethoden
der Entwickelungsmechanik der Organismen'
(Leipzig 1897) and of Dr. Oscar Hertwig, 'Zeit-
und Streit-
fragen der Biologie: Mechanik und Biologie'
(Jena 1897). Nature does for man in the
organic what he has to effect in the inorganic
world, and it is only necessary that he observe
these changes to be able to state a series of re-
lations of antecedent and consequent. See
LIFE; GROWTH; KINETOGNOSIS.

MECHANICS' INSTITUTES. The es-
establishment of mechanics' institutes marks the
struggle of the artisan to provide for his own
education. Denied a technical education, un-
able to take advantage of college and univer-
sity education because of financial and economic
stress, the artisan nevertheless demands for
himself such educational opportunities as he can
use during his free hours. His needs are pec-
cular. His range of interests is prescribed by
his trade or vocation, his time is limited, his
preparation is likewise limited and variable.
His demands cannot be satisfied, therefore, by
conventional methods and equipments. A
special organization must be set up. Mechanics' 
institutes are a distinctive product of England,
other country having developed an equal
number of such organizations. Nor are such
institutions characteristic of any other national
educational scheme. The reason for this is the
conservatism of English universities' opposition
to educational institutions generally. The artisans
was not provided with a systematic training
beyond the fundamentals of his trade as given
by a more or less definite apprentice system.
Industrial education and manual training were
not made a part of public education until late
in the 19th century. Hence the necessity for
the artisan to devise a scheme for educational
extension into his adult years, an education
that would meet his specific needs. Birming-
ham and Glasgow were the leaders in de-
veloping educational opportunities for me-
chanics. In Birmingham Sunday lectures in
mechanics and in the physical sciences were
given as early as 1789. An *Artisan Library
was maintained. Glasgow organized its Me-
chanics' Institute in 1823. This is probably the
first use of the term. The London Mechanics
Institution was founded in the same year and
was under the leadership of Dr. Birkbeck, who
had been instrumental in the maintenance of
the work in Birmingham. Liverpool followed
with its Mechanics' and Apprentices' Library
in 1825. Other cities followed and in 1839 a Met-
ropolitan Association of Mechanics' Institu-
tions were formed; in 1848 a similar associa-
tion known as the Yorkshire Institution was formed with 86 institutions as members.

The range of work became wider as the
movement grew. The Manchester Mechanics' 
Institute announced its purpose to be 'to enable
artisans of whatever trade become ac-
quainted with such branches of science and art
as are of practical application in their trade.'
The subjects offered either by lecture or class
instruction were as follows: natural philoso-
phy, science, natural history, literature, writ-
ing, grammar, composition, algebra, geometry,
drawing, music, French, German, Latin. This
is indicative of the scope of the work at-
tempted.

The aim of the mechanics' institutes was to
bring education within reach of the middle and
lower classes in England. The fact that it was an effort to give as much of the
traditional content of education as these classes
could assimilate. It was education given to
mechanics, but much of it was not about me-
chanics nor yet about industry or closely re-
lated matters. Herein lies the explanation for the decline of the movement. The institutes failed because the people and the artisans lacked the necessary educational background. But out of and on these foundations have grown the highly efficient technical schools which are in successful operation to-day.

Mechanic's institutes were also established in the United States, notably in Boston, Philadelphia, New York and Rochester, N. Y. A few are still in successful operation. It is notable that they are taking an important part in the development of vocational and industrial education in the United States. With free public schools, especially free State colleges and State universities, giving extensive courses in the mechanic arts and in the sciences, there is less demand for these private institutions with their special appeal to the mechanics' interests. Their function has been that of the pioneer. They have blazed the way for engineering and technical schools and are now doing the same for vocational and trade schools. See Education, Industrial; Education, Vocational; Apprenticeship; Cooper Union; Vocational Education.

A. R. BRUBACHER,
President, State College for Teachers, Albany, N. Y.

MECHANICS' LIENS, in statute law, a lien or claim upon real estate to secure payment for work or labor performed on, or materials furnished for, buildings or other improvements thereon; which labor or material has been furnished at the request or with the consent, express or implied, of the owner of such real estate or other property. In early English law lands were charged with liens by express agreement of the owner and were generally covered by mortgages. Courts of equity also recognized mortgage agreements. By statute other liens were created, including judgment liens and liens for taxes and assessments. In the United States the increasing number of independent contractors who constructed buildings on contract, and of dealers in building material, resulted in the enactment of numerous measures. Such laws have also been enacted in Canada, but not in Great Britain. The statutes hold that the value of real estate is increased by the addition of improvements and that the property should accordingly be held subject to such claims. Mechanics' liens are valid prior liens over all other claims, such as mortgages, judgments or taxes, and the term covers all claims for labor, whether skilled or unskilled, and for all building materials furnished. But liens are held against the property and not personally against the owner. The lien only attaches to the very property upon which the work was done, and has no effect on other pieces of real estate of the owner. In most States the law provides that the work to which the owner is entitled under a contract must be entirely performed before the contractor can file a lien, but where owners' payments are made in installments, some codes permit the filing of a lien when the owner defaults in the payment of an installment. Liens usually take precedence according to the time of their filing in the county clerk's office. In some States subcontractors, who have not had direct dealings with the owner, may nevertheless file liens against the property for the work performed by them.

The statutes of mechanics' liens vary in the different States in the manner of details, time of filing, method of procedure, etc., and State statutes should be consulted. See Lien; Mortgages.

MECHANICSBURG, mé-kän'iks-bèrg, Pa., borough, in Cumberland County, on the Cumberland Valley Railroad, eight miles west by south of Harrisburg. It was settled in 1806 and in 1828 was incorporated as a borough. It is situated in a rich agricultural region where chief manufactures are drop forgings for automobiles and carriage hardware, spokes, wheels and wheel materials. The borough is a distributing centre for the surrounding region and a shipping point for a large quantity of agricultural products. Irving College for Young Women is located here. Pop. 4,469.

MECHANICSVILLE, Battle of (also called battle of Beaver Dam Creek). After the battle of Oak Grove (q.v.), 25 June 1862, the Army of the Potomac was thrown upon the defensive by the sudden appearance of Stonewall Jackson on its right. As the Chickahominy McClellan had but one corps in position, that of Fitz-John Porter, temporarily strengthened by McCall's division of Pennsylvania reserves. McCall held the extreme right of the line at Mechanicville and Beaver Dam Creek, with three brigades and five batteries of 26 guns. His main position was along the east bank of the creek, a tributary of the Chickahominy, and was very strong, his left resting on the Chickahominy, his right and advance extending to a body of woods near and overlooking Mechanicville, held by a regiment and a battery. Rifle-pits had been constructed for the infantry, epaulements had been thrown up to cover the guns and a strong picket-line was in front from Mechanicville Bridge to Meadow Bridge along the Chickahominy. A. P. Hill's Confederate division and Cobb's Legion were in plain view from the left, intrenched on the opposite side of the Chickahominy. About noon of the 26th Hill's men were seen in motion. At 12.30 the Union pickets at Meadow Bridge were driven in, and McCall formed line; Reynolds' brigade on the right, covering the crossing of the road from Mechanicville to Bethesda Church; Seymour on the left, covering at Ellerson's Mill the crossing of the road from Mechanicville to Gaines Mill; and Meade's brigade, with two batteries, in reserve. A. P. Hill had 14,000 men in his division, which he had concentrated near Meadow Bridge, under orders from General Lee to co-operate with Jackson, who was marching from Ashland to turn McClellan's right. Hill sent Branch's brigade and a battery to cross the Chickahominy seven miles above Meadow Bridge and communicate with Jackson's advance, and when Jackson had crossed the Virginia Central Railroad, Branch was to cross the Chickahominy, push down the river and uncover Meadow Bridge, which Hill was to cross at once and then sweep down to Mechanicville, uncovering in turn the Mechanicville Bridge, which Longstreet's and D. H. Hill's divisions were to cross, when all were to push down the bank of the Chickahominy and cut off McClellan's communications with his base at White House on the Pamunkey, and thus force him to abandon his operations against Richmond and
MECHANICVILLE—MECHANISM

retreat down the Peninsula. Jackson was behind his appointed time, and it was 10 o'clock before Branch opened communication with him. In the few important and decisive hours that went by after this nothing was heard from Branch or Jackson, and at 3 P.M. put his five brigades and six batteries in motion. Field's brigade seized Meadow Bridge and crossed, closely followed by the brigades of J. R. Anderson and Archer. The brigades of Gregg and Pender then crossed and marched across the country to support the right of the attacking column. Field's advance was met by a severe artillery fire; but, forming line, with Pegram's battery in the centre, it forced the Union advance of a regiment and battery from Mechanicville back to the main line beyond Beaver Dam Creek. It had not been General Lee's intention to attack McCall in position, but to have Jackson turn it. Jackson was not up in time; McClellan would doubtless penetrate his design and make a counter-attack against Richmond; time was everything; the day was declining, and Lee ordered A. P. Hill to attack. The brigades of Field, Archer and Anderson were ordered to advance on the Mechanicsville road against Reynolds. They were met by a withering fire of artillery and musketry and were bloodily repulsed, though one of Anderson's regiments on the left succeeded in making a temporary lodgment beyond the creek. Parts of Porter's corps now came up and strengthened Reynolds' right. Following the repulse on the left, Pender's brigade and Ripley's of D. H. Hill's division made a most determined attack upon Seymour at Ellerson's Mill, but a mile across swampy ground and other obstacles were in their way, and Seymour's direct and Reynolds' flank fire checked and then repulsed them with great loss. The attack was renewed, and a still more bloody repulse was the result, some of the regiments losing all their field officers and half their men. It was now sunset, and no further effort was made to assault the position, but the firing was kept up until 9 P.M. On the next morning McCall was ordered to fall back to Gaines' Mill (q.v.). The Union loss was 49 killed, 207 wounded and 105 missing. The Confederate loss, killed and wounded, was over 1,500; Longstreet says between 3,000 and 4,000 killed, wounded and missing, which is probably excessive. Longstreet further says: 'Next to Malvern Hill, the [Confederate] sacrifice at Beaver Dam was unequalled in demoralization during the entire summer.'

E. A. CARMAN.

MECHANICVILLE, me-kən'iks-vil, N. Y., village, in Saratoga County, on the Hudson River and the Champlain Canal, and on the Delaware and Hudson and Boston and Maine railroads, about 20 miles north of Albany. The village is extensive and has diversified manufactures transmitted from Mechanicville to manufacturing establishments in Schenectady. Some of the manufacturing establishments of Mechanicville are knitting mills, collar and shirt factories, mattress factories, iron bed works, sash and blind factories, paper and pulp mills and machine shops. It contains a fine city hall, a large school building and several churches. The village owns and operates the waterworks. The commission form of government is in operation. Pop. 6,634.

MECHANISM, or the MECHANICAL THEORY, in its most general significance, means the relation of a limited number of invariable substances to each other in such a way that they vary in their relations according to invariable laws. More specifically it means the explanation of phenomena by the universal laws of matter in motion. It is closely connected with the attempt to resolve bodies into their simplest elements and to explain their qualities as due to uniform laws of connection and interaction among these elements. The mechanical theory has usually been held in connection with some form of atomism. Since the aim of this kind of explanation is to reduce qualitative determinations to quantities and many of the mechanical relations of elements, these elements have usually been conceived to possess only such qualities as were necessary to explain the empirical qualities, the ideal being to find a single homogeneous element possessing only these characteristics essential to corporeity. The term mechanical is also used in a looser sense, though still within the limits of the general definition given above, to describe any explanation which regards all the qualities of a body as due to the mere summation of the qualities of its parts; e.g., a mechanical theory of society.

Mechanism as a Theory of the World.—As a philosophical theory, mechanism is the attempt to regard the entire universe as a closed system of causes and effects in which every change is ultimately reducible to a change of motion. In this sense, therefore, it is practically synonymous with materialism (q.v.).

Mechanism as a Method of Explanation.—After the Middle Ages the development of the new science, at the hands of Copernicus, Kepler, and Galileo (q.v.), and many of their contemporaries, depended very largely on the application to nature of the method of mechanical explanation. Francis Bacon (1561-1626) (q.v.), by his opposition to the use of teleology in scientific explanation, did much to bring about the acceptance of mechanism, and it was firmly established as the true scientific method of dealing with nature by Descartes (1596-1650) (q.v.), who, though not an atomist, still denied to matter all but quantitative characteristics and defined the method of science as strictly mechanical. Even the physical phenomena of living bodies (everything in the world, in fact, except the res cogitans in man) he regarded as capable of a purely mechanical explanation. From this time on mechanism became the recognized method of science, and consequently it soon became an urgent philosophical problem to discover a satisfactory way of reconciling the mechanical conception of nature with a teleological and idealistic conception of the universe. Thus Leibniz (1646-1716) (q.v.), while admitting the necessity of reducing all natural phenomena to motion, held that ultimate reality consists of an infinity of centres of force (monads), which he conceives as in some sense analogous to minds. Accord-
ingly, metaphysical explanation must be in terms of teleology, though mechanism is the sole valid explanation of the phenomenal manifestation of reality in nature. A similar conception, having its historical origin in Leibniz, was held in the 19th century by Lotze (1817-81) (q.v.), who proclaims the burden of his philosophy to be "to show how absolutely universal is the range of mechanism, and at the same time how completely subordinate the significance of the function which it has to fulfill in the structure of the world" ("Microcosm," Introductions). Kant also regards the mechanical categories as the sole valid means of scientific explanation. The causal category is, for him, rigorously constitutive of our experience and hence is determinant of our conception of all objects in the world of experience; teleology, on the other hand, though a necessary means of regulating our investigations of organized matter, remains a merely subjective principle which can give no insight into the origin of any being. When we deal with the teleological thought by use as regards their possibility, according to the principle of mechanism, we may treat them as if they were teleologically ordered; but "nothing is gained for the theory of nature or the mechanical explanation of its phenomena by means of its effective causes, by considering them as connected according to the relation of purposes." The phenomena of the moral life, according to Kant, lie outside the realm of scientific experience and hence are not subject to mechanical explanation. Since Kant's time, many thinkers, perhaps the majority, have followed him in regarding mechanism as the ultimate principle of explanation for science; thus Helmholtz, F. A. Lange, Dubois-Reymond, Clausius, Thomson, Maxwell, etc. Wundt attempts to find for it a logical justification as the only theory which can afford an adequate conception of natural causality. On the other hand, more recent writers, especially among physicists, have taken the opposite view. According to them, the pre-eminence of mechanical explanation is merely a dogma based on its successful use in science. E. Mach, Stalio, Helm and H. Cornelius take this position. These thinkers maintain that the purpose of scientific explanation is to condense into a single compact statement (e.g., a mathematical formula) a large mass of empirical data. A scientific law is merely a short-hand statement of the facts, and its value is purely economic. So long as the mechanical theory affords useful analogues for the formulation of other phenomena, it is a valid scientific method. Whenever this ceases to be the case, mechanism must be superseded by a more economical theory. Kant's conception of mechanism as a mode of dealing with experience has been developed by contemporary English idealism. The general problem of all rational knowledge is conceived to be the construction and maintenance of a coherent and systematic experience. In all thought, therefore, there is implied a totality which manifests itself in different categories of thought and in varying degrees of perfection. "Matter and motion are the abstractions in which the sensuous world is reduced to homogeneity in order to be susceptible of quantitative treatment, and in this treatment they are able to a large extent to represent genuine and actual relations of that world" (Bosanquet, "Logic," Vol. I, p. 200). Mechanical explanation, therefore, is one form in which the unity of thought may be manifested; it is "that form of identity and difference in which an identity is regarded as the sum of the difference in which it is presented" (ib., p. 201). Its value for knowledge is therefore said to be instrumental or methodological, because it is a method which thought uses in its effort to construct a rational experience. It is a true truth just in proportion to the degree of rational unity which it achieves in experience as a whole.

In psychology the term mechanism is sometimes used to describe a theory which seeks to explain mental phenomena as due to the combination or interaction of simply psychic elements. This usage is an analogy with the atomic theory of matter. The classical example is Herbart (q.v.), who gave the term currency. According to his theory every representation has a constant quality and a variable force. These forces stand in relations of greater or lesser opposition and the whole state of consciousness is conceived as a resultant of all the forces involved in it. Consult Th. Ribot's "German Psychology of Teachers" (Eng. trans. by J. M. Baldwin, pp. 24 ff.). For mechanism in biology see MECHANISM AND VITALISM.

GEORGE H. SARINE,
Leland Stanford University.

MECHANISM AND VITALISM. The Neuvian mechanics has long constituted an ideal for all the natural sciences. It is the result of the elegance of its form and the clearness of its definitions. There has consequently been a tendency to reduce biology as well as chemistry, astronomy, optics, etc., to a mechanical basis and to explain all biological phenomena in terms of motions of particles. This tendency is known as mechanism, and those who follow it are called mechanists. Now, a living organism, even from the purely mechanical side, is of the greatest complexity and intricacy of structure. Practically all organic tissues are colloidal in nature, and the physics and chemistry of even a simple colloid are as yet very imperfectly understood. Furthermore, the most minute observable portion of living tissue is far from being a simple colloid, but is distinct and highly complicated structure. As a consequence, all mechanical explanations of living processes are bound to be of an extremely sketchy nature. Now, the actions of animals and plants are subject to fairly simple descriptions in terms derived from our own consciousness. When a spider catches a fly, we seem to read that fact intelligible to ourselves by saying that it wants to eat the fly. As a consequence, our biology as it exists is permeated through and through by anthropomorphic con-
cepts, such as purpose, desire, sensation, etc. While the mechanists claim that, as far as a scientist is concerned, all the facts ordinarily described through the mediation of these concepts are susceptible to a correlation in a fashion which, though purely mechanical, is too complicated for our own human faculties to grasp, the case is otherwise with the so-called vitalists, who deny this possibility. The vitalists may either discover a peculiar purposive, anthropomorphic force active in biological matters alone, as does Driesch, or they may, like Bergson, regard the purposive account of the world as everywhere prior to the mechanical account. They draw their arguments from certain processes which, like the regeneration of lost parts, or the adaptation of the individual to the environment by mutation, appear peculiarly fitted for purposes of explanations involving some prevision of the future. These processes they regard as not merely non-mechanical, but counter to the current of mechanism, involving either indeterminism, or determination through factors which have no mechanical correlates. The paucity of the fruits of purely mechanical research in biology is obvious; on the other hand, the methods of the vitalist are generally so crude and his definitions so vague that there is no great body of biological knowledge which has been gained from the vitalistic standpoint. The terminology of vitalism abounds in such expressions as \textit{élan vital}, or \textit{entelechy}, which are only defined \textit{per ignotum}. In short, whether a complete mechanization of biology be possible or not, biological investigation has been fertile precisely in so far as it has subjected itself to the norms, if not to the concepts, of physical science. It would consequently seem that mechanism is methodologically correct, even if it be metaphysically wrong. See also \textbf{Materialism}; \textbf{Mechanism}.

\textbf{Norbert Wiener}.

\textbf{MECHANISMS, Mental}, are modes of thought obtaining both in the unconscious and in conscious mental activity, the most important of which are identification, compensation, projection, introjection and rationalization. In the earliest infancy the individual gradually makes a distinction between self and external reality, tending to regard as \textit{himself} those parts of his experience which give him pleasure and as \textit{external} those parts which give him pain. He thus very early unconsciously identifies himself with certain portions of his environment. This unconscious habit of thought continues throughout life. All persons constantly identify themselves with persons and things surrounding them or which come within their mental purview. This has the very important result of making them regard those external persons or things as having an influence over themselves and their acts and their emotions. Thus a man who defended the actions of a celebrated physician who was condemned and executed for murdering his wife was giving, in his defense, an illustration of identification of himself with the murderer, as was shown later to some extent by his confession that he had lived subject to evil influences which he was unable to escape and which he was unable to escape and which he sympathized with the criminal who had succeeded in getting rid of his partner in that way. Two varieties of identification are distinguished, namely, the subjective form or introjection, and the objective or projection. In introjection the subject accepts an idea which really has an external origin, and identifies it with some portion of his own mind, as for instance when one reads a description of some disease and infers that one has that disease in oneself. This is a characteristic of impressionable and hypersensitive natures who feel an excessive sympathy for other people. It leads to various forms of introversion in which the individual tends more and more to live a life within himself and to become more and more unable to achieve objective success in the world. Projection, on the other hand, is that objective form of identification which takes an idea which has had actually an internal origin and believes that it has an external origin. Examples of this mechanism in its pathological aspects are found in the mental malady known as paranoia (q.v.), in which the suspicions of the individual, having a purely subjective origin, are projected upon the external social environment. The paranoid believes that he is a great man, taking his belief from some idea which occurs to him as a compensation [see below] for an unconscious feeling of\textit{ inferiority}, and he views external reality more and more as conspiring against him to prevent the realization of his wishes for superiority. It is true that all individuals give evidence in thought and act of both introjection and projection, but it is only when these mechanisms are unduly developed that the discrepancy between the unconscious wish and the actuality become such as to render the individual obnoxious. All normal adults identify themselves with parts of their environment to some extent, as with their possessions and with the members of their family and of their social milieu, but such identification is productive of good both in action and in thought. It should not, however, be allowed to go too far, and a rigorous critique should be exercised by comparison with real things in order to prevent excess.

\textbf{Compensation} is that mechanism of the unconscious which secures an activity sometimes quite the opposite from that found to be the goal of the unconscious wish. For example when a person shows an extraordinary interest in antivisivism or the prevention of cruelty to children or to animals, it is frequently discovered upon analysis that this form of activity is a compensation for an unconscious sadism or desire to inflict cruelty. Lynchings, which ostensibly aims at the punishment of an offender, is in reality mediated through an unconscious desire to inflict cruelty or to see it inflicted. Much of the action of extravagant chivalry is also an illustration of an unconscious desire to indulge in acts of cruelty. This is an apparent contradiction, but numerous analyses have shown the truth of this statement. The fact that a conscious and an unconscious unconscious wish are satisfied both at the same time makes the compensation all the more ambiguous. That is, the individual consciously believes that he is satisfying only the wish to \textit{right} a wrong, not being conscious of the fact
that in taking especial pleasure in righting a wrong, he is unconsciously satisfying a wish to occupy his mind with the wrong itself. It is not known to the militant suffragette that her conscious desire to arrogate to herself the privileges of men is a compensation for an unconscious desire to be dominated by a man. Compulsion is a physiological mechanism too, by virtue of which the function of one organ, say the kidneys, is taken over at times by that of another, for instance the skin, in excreting certain waste products. An aim is sought by nature and failing in attaining this aim through one avenue, she tries another. Similarly in the mental processes, the psyche is aiming constantly at the satisfaction of desire, and if it fails to get it consciously, it will get it unconsciously by compensation, that is, the desire of which the individual is not aware, though it may be fundamental in his psyche, will nevertheless gain its satisfaction in some substitutive form, through something which symbolizes in conscious life the object of the unconscious craving. A very infantile partial trend (q.v.), namely, the child's desire to be looked at, is gratified by the actor in a domestic performance where he may be utterly unconscious of the fact that his primary desire is to exhibit his body but unconscious only of the fact that he wishes to represent a character for the edification of the public.

Rationalization is the constant tendency on the part of all people to give an ex post facto reason for their thoughts or acts. This is why "a man convinced against his will is of the same opinion still." The term rationalization was introduced into analytic psychology by Dr. Ernest Jones. If a person is hypnotized and during the hypnotic sleep is told by the hypnotizer to do something when he wakes up, such for instance as putting a chair on a table, he will do so, and when it is asked to give a reason for this act, he will fabricate a wrong one, because he does not know the right cause. The cause of his act was the hypnotic suggestion, and is perfectly well known to the hypnotizer. But to the hypnotized subject the cause is unknown as it is contained in his unconscious, and, having been given to him in his unconscious state, it does not emerge into consciousness. This is paralleled by almost every instance in which a reason is given for doing anything. The entire cause in the case of some persons is, as with the hypnotized person, in the unconscious, while with the majority of people a large proportion of the causes of all their actions is in their unconscious and is unknown to them. The reasons which people then give for their actions are termed rationalizations and the tendency of all persons to feel that they have to give reasons when they are asked for them is what is meant by rationalization. See also Symbolism and consult Fink, H. W., 'Morbid Fears and Compulsions' (1918) and Jones, Ernest, 'Papers on Psychoanalysis' (2d ed., 1918).

Smith Ely Jelliffe, M.D.

MECHANOTHERAPY, the healing of disease by mechanical means, which includes all systems of physical therapeutics, such as massage, baths, electricity, vibration. It is really nothing more than forms of exercise adapted to the special needs of the patient. See Massage and consult Graistrom, 'Mechano-Therapy' (2d ed., Philadelphia 1904).

MECHIANISTS, měk'ē-ī-tā'ri-ists, a sect of Armenian Christians acknowledging the authority of the Pope, but retaining their own ritual. The name originated from Mechitar Da Petro (1676–1749), who in 1701 founded a religious society at Constantinople for disseminating a knowledge of Armenian literature. They soon removed to the Morea, whence in 1713 they went to Venice, and later to the island of San Lazzaro. There are branches of the sect in Vienna and elsewhere. At Venice its printing presses have turned out the best works in Armenian literature, and the Bibliotheca Armeniana of Tiberias has a large circulation. Consult Boré, 'Le couvent de Saint Lazare à Venise, etc.' (Paris 1837); Scherer, 'Die Mechitaristen in Wien' (5th ed., Vienna 1892); and 'La vie du serviteur de Dieu, Mechitar' (Venice 1901).

MECHLIN, měk'lin (Dutch, měk'lin), or MALINES, mä-lin, Belgium, a city on the Dyle, 14 miles southeast of Antwerp. The ancient walls and moat have been replaced by a wide boulevard and canal, the streets are wide and regular and it has fine squares and public buildings. It is the see of the Roman Catholic archbishop and has numerous churches. The present primate is the illustrious Cardinal Mercier (q.v.). Saint Rombold's Cathedral, a vast building covering nearly two acres, was built in 1437–52; the clock-tower, however, 324 feet high, remains unfinished; the cathedral contains Van Dyck's 'Crucifixion.' The churches of Saint John and Our Lady contain works by Rubens; the town hall dates from the 15th century; the Cloth Hall, now used as a guardhouse, from 1340, while almost adjoining it is the modern archiepiscopal palace, the Beguinage and the Salm Inn (1534). The manufacture of pillow lace and of cloth, so famous in the 15th, 16th and 17th centuries, has been largely transferred to Brussels; the chief industries now are carpentry, caps and woolens, candles, starch, tobacco, cabinet-making, brewing, horticulture and agriculture; extensive railway works have been established here. In 1914 the city was occupied by the Germans, who were later driven out by the garrison troops of Antwerp. The Germans retook the city after a violent bombardment, during which most of the city was laid in ruins. Pop. 59,000.

MECKLENBURG, měk'lin-boorg, Germany, a territory on the Baltic Sea, a former Saxon province, now divided into the grand-duchies of MECKLENBURG-SCHWERIN and MECKLENBURG-STRELITZ.

(1) Mecklenburg-Schwerin, bounded on the north by the Baltic Sea, elsewhere chiefly by Prussia and Mecklenburg-Strelitz, has an area of 5,135 square miles. The capital is Schwerin. Mecklenburg-Schwerin is watered by several rivers, most important of which are the Elbe and its tributaries, the New Elbe and the Sude, on the southern border, the Warnow, the Recknitz and the Stepenitz, which flow toward the Baltic. There are many lakes and ponds, the largest of which are the Müritz (14 miles), the Schweriner See (23 square miles), the Köliner and the Plauer See. The country is generally flat, though here and there intersected by low ranges of hills, and its surface is extensively covered with wood. Near the sea
are large tracts of sand and morass. The climate, though raw, is mild and healthful; the average temperature throughout the year is 46° and the precipitation is 21 inches.

The principal industries are agriculture, dairying and stock-raising. About 50 per cent of the population are tillers of the soil. The landholders are hereditary tenants of the peasant class, title being vested in the upper classes, as the emperor, the aristocracy, clergy, etc. The chief crops are rye, oats, barley, cotton, peas, beans, beets, turnips and potatoes, and tobacco is cultivated to some extent. The principal manufacturing industries are foundries, machine shops, brick yards, tanneries, paper mills, sugar refineries, breweries, distilleries, tobacco factories, etc. There is considerable commerce through Warnemünde (Rostock) and Wismar. The railway mileage is 1,694 miles. The predominating form of religion is the Lutheran. Besides the university at Rostock there are several gymnasia and numerous parochial and other schools. The two Mecklenburg duchies have a common assembly or Landesunion, consisting of the representatives of the landed aristocracy or Ritterschaft and the burgomasters of 49 towns; the tenement-holders of the royal domains have no representation. The assembly meets once a year, alternately at Malchin and Sternberg. The executive authority in Mecklenburg-Schwerin is vested in a cabinet of four ministers; there are also a permanent committee consisting of nine members at Rostock, who represent the two estates when the assembly is not in session, and department and convocation diets, which may be assembled upon special occasions and for special purposes. Mecklenburg-Schwerin has two votes in the federal council and six representatives in the Riksdag, the only elective offices. Each duchy has a separate system of lower courts but they have a Supreme Court at Rostock in common. There is no general financial budget for Mecklenburg-Schwerin; there are three entirely distinct systems of finance. The budget of the first system is called the administration of the sovereign; the second, the states administration and the third the ordinary budget of the common administration. In 1913 the public debt amounted to $2,717,005. Technical education is well advanced and higher education is provided for by the University of Rostock. Pop. 639,958.

(2) Mecklenburg-Strelitz, divided by Mecklenburg-Schwerin into two large districts, the circle or lordship of Stargard, and the principality of Ratzburg, both on the east, and on the west in several smaller districts, existing in separate patches, has an area of 4,131 square miles. Pop. 106,347, capital Neustrelitz. The country is flat and similar in physical characteristics to Schwerin. Strelitz has one joint representative chamber with Schwerin, but Ratzburg is not included in these estates and is governed directly by the grand duke. The grand duke gave Ratzburg a representative constitution 1869. Mecklenburg-Strelitz has one vote in the federal council of the empire and one representative in the diet. Consult Raabe, W., 'Mecklenburgische Vaterlandskunde' (3 vols., Wismar 1896).

MECKLENBURG (mék'lên-bér'g) DECLARATION, in American history, a series of rebellious resolutions adopted 20 May 1775, at Charlotte, Mecklenburg County, N. C., by a convention held at midnight and representing each militia company in the county. The resolutions declared that the people of Mecklenburg County were free and independent of the British Crown, and not only was the general tenor that of the Declaration of Independence, but many phrases in the resolutions are word for word as they appear in that document. The minutes of the midnight meeting are said to have been destroyed by fire in 1800. Whether the Declaration of Independence followed the words of the Mecklenburg Declaration, or whether the latter, having probably been replaced from memory, was tinted with the former, is a disputed question. In 1831, the day of 20 May was made a legal holiday in North Carolina. Consult Cooke, 'Revolutionary History of North Carolina' (1853); Draper, 'The Mecklenburg Declaration' (1874); Graham, G. W., 'The Mecklenburg Declaration of Independence, May 20 1775,' and 'Lives of its Signers' (New York 1905); Hoyt, W. M., 'The Mecklenburg Declaration of Independence' (1907); Moore, J. H., 'Defense of the Mecklenburg Declaration of Independence' (Raleigh 1908).

MECONIC ACID, an organic acid occurring in opium and having the formula C₄H₄O₆(OH)(COOH). In preparing it, the opium is exhausted with water at 100° F., the infusion is neutralized with calcium carbonate and evaporated to a syrup, and calcium meconate is precipitated by adding a concentrate of calcium chloride. Two crystallizations from hot dilute hydrochloric acid follow, and the free acid is then deposited in the form of small scales, containing three molecules of water. Upon heating to 212° F. the hydrated crystals lose their water, and become white. Meconic acid is readily soluble in alcohol, but only slightly so in ether and in cold water. It has a sour taste and a pronounced acid reaction, and its solutions are red by ferric chloride. FeCl₃. It forms numerous salts ("meconates"), as well as various organic derivatives; but none of these is of importance in the arts.

MEDAL, a piece of metal in the form of a coin, stamped with a figure or device to preserve the portrait of some eminent person, or the memory of some illustrious action or event, and not to be circulated as money. Medals belong to two periods, ancient and modern, separated by a wide interval. Early Greek and Roman medals were struck for prizes in athletic games, or in commemoration of great events. The Roman series of medals or medallions is very extensive in gold, silver and brass or copper. The gold medals begin with Constantine and continue to the fall of the empire; the silver begin under Gallienus and continue as long; the copper from Augustus to Alexander Severus.

In more modern times the art of medal-making has been brought to great perfection, and most of the principal nations have adopted the plan of preserving their history by these durable monuments. The French series is deserving of special mention as the most perfect and complete in the world. It commences under Louis XI and continues to the present date, illustrat
Medal of Honor—Medallion

581

ing every important event in the history of France. The English series commences under Henry VIII, but as works of art the medals have not high rank. The British battle medals, however, form an admirable series. The Italian and German medals of modern date are very fine. The medieval are interesting and bold in design, but rude in execution. The papal series, commencing with Paul II, are worthy of attention.

One of the earliest American medals is that presented to Gen. John Armstrong for his successful attack in 1756 on the Indians at Kittanning. Most of those struck during the Revolution were made in France. The next American medal of which there appears to be any record is that which was presented to General Gates after the surrender of Burgoyne, 17 Oct. 1777. On 23 March 1776, when news of the British evacuation of Boston reached Congress, that body resolved that its thanks be presented to the Commander-in-Chief, and that a gold medal be struck in commemoration of the event. This medal was nearly two and three-quarters inches in diameter. On one side was a profile head of Washington, with the legend in Latin: "The American Congress to George Washington, the Commander-in-Chief of its armies, the asserter of freedom." On the reverse the device showed troops advancing toward a town, others marching toward the water, ships in view. General Washington in front, mounted, with his staff, whose attention he is directing to the embarking enemy. The legend is: "The enemy for the first time put to flight." Then, too, at the time of his death, among minor honors paid to the great general's memory, was the publishing of a silver commemorative medal.

There is the record of one medal only granted by Congress in commemoration of any naval victory during the War of the Revolution, and that was a gold one presented to Paul Jones for his defeat of the British frigate Serapis when commanding the Bonhomme Richard, 23 Sept. 1779. Other gold medals were those presented to Commodore Perry and Lieutenant Jesse D. Elliott for the part which they took in the battle of Lake Erie, 8 Oct. 1812; to Captain Lawrence, who, in command of the Hornet, 24 Feb. 1813, captured the British brig Peacock; to Captain Warrington of the Peacock — then under the Stars and Stripes — for the capture of the Ebertin, 20 April 1814; to Capt. Thomas Macdonough, who commanded the American squadron in Plattsburg Bay, August 1814; to Captain Decatur, who, in command of the United States, captured the British frigate Macedonian, 25 Oct. 1812; and to Captain Jones and Captain Blakely, who, when commanding the Wasp — the one, 12 Oct. 1812, and the other 28 June 1814 — captured respectively the Frolic and the Reindeer from the British navy.

The giving of medals went out of fashion after the second war with Great Britain, and but little was done by the government during the War of the Rebellion. Maj. Robert Anderson received two medals for his gallant defense of Fort Sumter, but one was presented by the city of New York, the other by the Chamber of Commerce of the same city. After the successful operations by Grant in East Tennessee and at Chattanooga, Congress voted him thanks and a gold medal with suitable emblems, devices and inscriptions. It is worthy of re-

mark that no less than 189 medals were struck in honor of Abraham Lincoln, and later medals have been issued in memory of Garfield and McKinley, and in honor of Sampson, Schley, Dewey and others in the Spanish-American War. (See also Coinage; Numismatics; Token Money.) Consult Hawkins, "Medallic Illustration of the History of Coinage in Ireland" (London 1885); Loubat, J. F., "Medallie History of the United States" (New York 1878); Leduc, "Histoire des décorations en France" (Le Mans 1890); Hill, G. F., "Portrait Medals of Italian Artists of the Renaissance" (New York 1912).

Medal of Honor, United States Military, an honor bestowed upon army and navy officers and men for specific services; regarded as a higher token of the war hero than the Victoria Cross of England, the medal of the Legion of Honor of France, or the Iron Cross of Germany. It is given not for the sheer performance of duty, no matter how hazardous that duty may be, but for some voluntary act of valor, beyond the bounds of mere obedience to orders. Out of the millions of men who have battled for the United States in the different wars this country has had, the total number of those history shows, performed their duty. Of these, however, have been about 2,000 men who have done more, who have braved dangers when they were not expected to brave them, overcome difficulties that were regarded by the rest as insurmountable, and faced death when it seemed it meant the sacrifice of their own lives. Many are the ways these medals have been won. By the Act of 12 July 1862 the United States government authorized the striking of 2,000 medals to be given to non-commissioned officers and privates for gallantry in action and soldierlike qualities. On 3 March 1863 the sum of $20,000 was appropriated for making the medals, and officers were made eligible to receive them. Medals were also authorized by Congress in recognition of acts of bravery performed (during the war with Spain in 1898) in the naval battles of Manila and Santiago, the Manila medals bearing the portrait of Admiral Dewey, and the Santiago medals a portrait of Rear-Admiral Sampson. These medals consist of a five-pointed star within a circle of stars, suspended by a trophy of two crossed cannons surmounted by an eagle, united by a ribbon of 13 stripes of red, white and blue. Consult Rodenbough, "Uncle Sam's Medal of Honor" (New York 1886), and 'United States Army Regulations' (latest issue).

Medal of Honor Legion, an association of officers and enlisted men of the United States army, who were awarded medals of honor for special acts of bravery and devotion. At first limited to participants in the Civil War, it was subsequently extended to all medal holders. The association has altogether about 400 members among the army veterans and among naval veterans. The meetings are held annually.

Medallion, mē-dāl'yon. (1) The term medallion in numismatics is applied to those productions of the mint of ancient Rome, or struck in the provinces under the empire, which, if gold, exceed the aureus in size; if silver, the denarius; and if copper, the first or large brass. Medallions are not numerous. Those struck in
the Greek provinces are more common than the Roman, but of inferior workmanship. A beautiful and famous gold medallion exists of Augustus, and one of Domitian, but few, in any metal, are known. Perhaps the largest are those of Hadrian and Antoninus; those in brass are the largest, many of them being several inches in diameter, and for the most part of admirable workmanship. (See Medal.)

(2) In architecture, an oval panel carved in high relief, usually carrying a head or figure. The same term is used for a color design.

MEDANO, mä-da'nō, the Spanish name for peculiar moving sand-hills in Peru. They are seen on the plain of Islay near Arequipa, and are crescent-shaped bodies of white sand, which move across the desert in the direction of the winds which blow from sunrise to sunset. The sand composing the medano seems different from the desert sands over which the moving mass is blown or carried.

MEDARY, Samuel, American editor and politician: b. Montgomery Square, Montgomery County, Pa., 25 Feb., 1801; d. Columbus, Ohio, 7 Dec., 1863. He settled at Beresford, Clermont County, Ohio, and in 1828 established the Ohio Sun in support of Jackson's candidacy for the presidency. He sat for Clermont County in the State house of representatives in 1834–35 and was a member of the State senate in 1835–37. In 1837 he purchased at Columbus the Western Hemisphere, later the Ohio Stateman, which he edited until 1857. In 1857–58 he was governor of Minnesota Territory and in 1859–60 of Kansas Territory. He was named Minister to Chile in 1853 but declined. He established the Crisis at Columbus in 1860, and was its editor until his death. He gave active aid to Morse in the promotion of the electric telegraph, was a firm supporter of the Jay and Douglas; it is said to have originated the battle-cry "Fifty-four forty, or fight!" in connection with the Oregon boundary dispute, and was often called the "old wheel-horse of Democracy." There is a monument to his memory at Columbus, Ohio.

MEDEA, me'dē-ä, a powerful sorceress of the Greek hero age, daughter of Aeetes, king of Colchis. By some her mother is said to have been Idia, daughter of Oceanus; by others Hecate or Neera. By her profound knowledge of the magical virtues of plants she practised witchcraft. She became the wife of Jason (q.v.), the leader of the Argonauts. For 10 years she lived with him after having supported him in every danger, till the charms of Glauc, or Creusa, the daughter of King Creon,kindled a new passion in him, and he deserted Medea, who brooded on revenge. With this purpose she sent the bride, as a wedding gift, a poisoned garment, also a poisoned crown of gold, which Glauc put on and died in agony. The sorceress reduced Creon’s palace to ashes by her magic arts, murdered her two children by Jason and then mounted her dragon chariot and escaped. Some say that she went to Hercules, others to Athens, to King Aegeus, by whom she had Medus. From Athens also she was banished as a sorceress. She finally turned to her mother, where her son Medus reinstated her father, who had been dethroned by her brother Perses, after which she died. The story of Medea has often been a subject of tragic poetry ancient and modern. The tragedy of this name, by Eschylus and Ennius, have perished, as well as the Colchides of Sophocles. The Medes of Euripides and Seneca are the only parts of the story which have been dramatized by Corneille and Grillparzer. Cherus- bini made this myth the subject of an opera Consult Lübker, F., ‘Reallexikon des pallaschischen Altertums’ (8th ed., Leipzig 1914), and Mailinger, Léon, ‘Méde étude sur la littérature classique’ (Paris 1898).

MEDEA, The, a play of jealousy and revenge, in which the interest is something from the beginning to the very end, and is artistically almost without a flaw, was brought out by Euripides in 431 B.C. Few tragedies of ancient or modern times are more dramatic. None exhibits the working of a fiercer and more intense passion. With the Hippolytus it forms the double summit of the poet’s works, and probably no Greek tragedy has been more famous in the modern world. The great enchantress, who fell in love with Jason when he came to Colchis in quest of the Golden Fleece, escapes with Jocasta and her son Deiphobus and lives with him for many years. Later Jason and his barbarian princess are obliged to flee to Corinth. In this city the scene of our play is laid. The old nurse speaks the prologue: Jason has deserted his wife for the daughter of Creon, king of Corinth. Dishonored, forsaken, the hapless woman sits brooding. The pedagogus enters and reports a conversation he has just overheard: Creon proposes to banish Medea. Medea is heard bemoaning her fate: oh, that she had never listened to the smoothing words of the deceitful Greek. Embittered, she imprecates curses on Jason and her children and prays that the whole house may be blasted to naught. Then she comes out and explains her position to the Corinthian women, who form the chorus. Creon enters and orders Medea to get her gone. She dissembles: the king is mistaken in believing that she is dangerous — she is simply hot with hate against Jason. Let me remain. I shall yield to the stronger hand and hold my peace. The chorus relents and consents for her to remain one day. A great change comes over the woman scorned after Creon’s departure: I would not have groveled so before him except to get revenge. I shall bide my time, find first a safe refuge, then compass their destruction in secrecy by craft. Till then, my soul, sit still. By the Queen of Night that habits my heart’s dark shrine, no one shall ever vex my soul with impunity.

The chorus sing: the old order is upturned; piety and fear, religion, justice, truth, loyalty all decline to their contraries, and naught but confusion lives. Jason appears and upholds his wife for her froward spirit; she may rail at him, but not against the king. He had tried to appease the incensed ruler, but she persisted in her folly. But he will not desert her even in this dire extremity. O most pernicious and pernicious man! You front me, you, the most hateful, insolent wretch on earth? But I am glad you came, for I shall tell you what you are, that you may know the effect of my realizing a wine. I saved you, slaying the dragon and delivering you from death. I abandoned my home and followed you. Yet now you forsake me, the mother of your children. A loyal
spouse I have in you! I, a poor lorn woman, with her two babes, a fine reproof for our newly wedded prince! Jason feels that he must come to a place where he was uncertain of her words; but he declares that she received more than she gave, for she lives in a good Greek land, where law and justice reign — she is no longer an obscure barbarian. He had her welfare at heart when he contracted the marriage. Women are as unknown to that they know not where their fortunes lie. Jason withdraws and the chorus sing a song on the power of love. King Aëgeus of Athens enters. He promises to protect Medea, if she comes to his city seeking refuge. Then she sends for Jason and asks his forgiveness for the rash words spoken in angry mood: "Ho, children, come forth and welcome your father with me." But the thought of impending death, when she beholds her babes, is too much even for Medea's iron courage; they fasten themselves to her pitying eyes. In explanation of her weakness she tells Jason that she is a woman, naturally born to tears, prone to weep, subject to fears: her heart melted at the thought of death and war, but praise for her altered mood; may his children grow to manhood triumphant — 'er his foes. Medea weeps. Jason asks her why she turns her face away and hears not with joy his ben- sons. "Tis nothing — I bare them, bred them, loved them, and when you prayed that they might live, I wondered whether this would come to pass." She begs Jason to intercede for her children and allow them to remain in Corinth — she will send his bride royal gifts. The children carry the presents in a casket to the palace. The chorus sing an ode and the pedagogus enters to inform Medea that the children may remain. "Be of good comfort, thy children will yet bring thee back home." "Nay, I shall first send others home. Alas! O children, you have a home, but I go to another land, just when I begin to feel that I am blest in you. Out upon my daring! 'Twas all for naught I toiled for you, my children. Ah, the fond hopes that your dear hands would minister to me! The tears of pity from the throne around me. Oh, why do you look at me thus? My heart is unequal to the task. My babes' bright morning faces unnerv my arm. I cannot do it. I will take my children with me. Why, to wring their father's heart, give my own a double pain? But am I to be mocked? Shall I let my foes go unpunished? I must do it. Out upon my cowardice! Go in, children. Nay, my heart, let them live; spare the tender babes, my unblown flowers, my life, my joy. For Medea's iron courage, I laugh at the gods, I, will not give up my children to my foes. But I must see them before I go. O my darlings! O sweet mouth and form and face, sweet kiss, sweet embrace! O balmy breath and tender touch of your delicate cheeks! Go in, go in. I can look no longer, I faint." The chorus sing an ode on the comparative benefits of having children and having no children. A messenger enters: "when your children entered the palace we were all glad! The rumor spread that you were returning." One kissed the hands of the children, the other their flaxen hair. The princess sat with fond look on Jason; but when she espied the pair, she pulled down her veil and turned away in scorn. Jason entreated her to allay her wrath: "Accept these gifts and ask your father to remit the doom of exile, for my sake." And when she saw the wish of her lord's desire. Then she took up the robe — after they had gone — and tried it on. The golden crown she placed upon her head and arranged her hair before a mirror. Then she rose and walked about the room, stepping lightly with delicate foot and gliding oft toward the lowest folds around her ankle. Suddenly a ghastly spectacle presented itself. A pallor spread 'o'er her face. Back she tottered all a-tremble, and barely reached her couch before she fell, frothing foam around her lips, her eyeballs rolling wildly. One servant darted to her father's chamber, another flew to call the bridegroom. The hapless girl lay full a minute speechless. Then she roused and gave forth a scream, for a double agony had charged upon her. From the inclusive verge of golden metal around her brow a marvelous stream of fire shot forth, while the robes began to eat her delicate flesh. Up she started and sped across the room, a pillar of fire, shaking hair and head in vain at naught. But firm it held. Whene'er she shook her locks the flames started up twice as high and fierce. O'erwhelmed she sank upon the floor, past recognition save to a parent's eye: the clear calm look was gone, the comely features marred, drops of intermingling fire and blood dripped from her head, while gobbets and flakes of flesh dropped from her bones, like tears of resin from the pine, as those unseen jaws of the poisonous drug fed on her form. All feared to touch the corpse. Suddenly her father entered. He knelt and clasped her in his arms: "Oh, my poor child, what god brought thee to this cruel death?" At last he stayed his tears and tried to raise his old bent form, but the robes did cling to him as the ivy to the laurel. He writhed upon his knees and tried to wrench himself away, but only pulled the flesh from off his bones. At last the ill-starred sire gave up the ghost. Now their corpses lie side by side, a spectacle to draw tears of pity from the hearts of the royalty. Medea informs the chorus that she must say her children and hasten away: "Now, my heart, put on thy armor for the deed. Shrink not. Think not on the happy days agone. For this one brief day forget thy children — even if thou dost slay them, they are most dear, and I the most unhappy woman in the world." Medea enters the house and soon the screams of the children are heard within. Jason enters and asks for Medea; he feels anxious for his children; the king's relatives may do them hurt. "Wretched man, your children are dead, slain by their mother's hand." Jason is overwhelmed. He orders the gates to be unbarred. Medea appears aloft in a chariot. Jason asks for the bodies; but she refuses to give them up: she will take them herself, that her foes may not desolate the grave. She intends to go to the land of Erechtheus to live with Aëgeus. She prophesies that Jason will die most miserably, struck on the head by a piece of fallen timber from the Argo. She scorns away, and Jason calls upon Zeus to witness the treatment he has received at the hands of the tigers. Thus the play, in which we see the perfection of Euripides' art,
ends. The fury of her vengeance is as the love of Phaedra in the 'Hippolytus'; but instead of overwhelming her soul, it excites to action, arms it against the deepest instincts of mother-love and makes it triumph over everything in a kind of grandiose and savage egoism. The more impetuous the fury, the more pathetic the struggle of feminine instincts. In no other play is there anything more characteristically Euripidean than Medea's celebrated monologue. Next to the human passions it is the natural and articulate love and tendermess of parents for their children, the love of brothers and sisters, of husband and wife, that Euripides portrays best.

JOSEPH E. HARRIS,
Author of 'The Greek Tragic Poets,' etc.

MEDELLIN, më-del′-yên′, Colombia, a city, the capital of the department of Antioquia, and an episcopal see, picturesquely situated in a mountain valley 4,850 feet above sea-level on the Porce, an affluent of the Cauca, 150 miles northwest of Bogotá. It was founded in 1674 and has a cathedral, college, seminary, technical school, mint, hospital and other public buildings. The development of the gold and silver mines in the region has contributed largely to its modern progress. It has manufactures of pottery, porcelain ware, cloth, candles, cigarettes, clocks, shoes, paper and jewelry and has a considerable trade, exporting gold, silver, coffee and hides. Pop. 70,547. Consult 'Censo general de la republica de Colombia' (Bogotá 1912).

MEDFORD, Mass., town, in Norfolk County, 20 miles south of Boston; on the New York, New Haven and Hartford Railroad. The town is the seat of Medford State Hospital. Bricks and straw hats are manufactured. Hannah Adams, the historian, was born in Medfield. Pop. 3,466.

MEDFORD, méd′fôrd, Mass., city, in Middlesex County; on the Mystic River and on the Boston and Maine Railroad, five miles north-west of Boston. The area is about 10 square miles. It was founded in 1630 by people from Salem who called the place Medford. In 1892 it was chartered as a city, having within its limits the villages of South Medford, West Medford, Heßlade, Glenwood and Wellington. It is a residential suburb of Boston, but it has some important industrial interests, chief of which are the manufacturing of machinery, cotton goods, dyes, chemicals, carriages, brick and novelties. It is the seat of Tufts College (q.v.), and has the city and the college libraries. The Craddock House, built in 1634, is one of the oldest, if not the oldest building in the United States which retains its original form. The city has four large public parks, many miles of boulevard (Metropolitan Parkways) and includes many acres of State reservation (called Middlesex Fells) where game is protected and public is allowed to enjoy the natural beauties of the country. The Royal Horticultural Society is located in the city. A historic (Colonial) interest is preserved by the Royal House Association, it is of the finest type of Colonial design. Oak Grove, the largest of its three cemeteries, has an area of 34 acres. The charter granted in 1892 is still in force and provides for the administration of the municipality by a mayor, who holds of-
MEDIATION

In the ancient world, the concept of mediation was used to resolve conflicts. For example, the Assyrian king Sargon I conquered Media in 715 B.C., and Media became a part of the Assyrian Empire. However, Media, being a mountainous region, was difficult to conquer and it resisted Assyrian rule. When the Assyrians finally managed to conquer Media, it was at the cost of a great deal of bloodshed and resources.

Similarly, in the modern world, mediation is used to resolve conflicts. In 1899 and 1907, the Hague Peace Conferences adopted the following rules which were embodied in a convention which was ratified by practically all the powers of the world.

1. In case of serious disagreement or dispute, before an appeal to arms, the Contracting Powers agree to have recourse, as far as circumstances allow, to the good offices or mediation of one or more friendly Powers (Art. 2).

2. Independently of this recourse, the Contracting Powers deem it expedient and desirable (the italicized words were added in 1907) that one or more Powers, strangers to the dispute, should, on their own initiative and as far as circumstances may allow, offer their good offices or mediation to the States at variance.

3. Powers, strangers to the dispute, have the right to offer good offices or mediation, even during the course of hostilities.

The exercise of this right can never be regarded by either of the parties at variance as an unfriendly act (Art. 3).

MEDITATION, in international law, is the friendly intercession of a third power or powers with a view to bringing about the settlement of a controversy between two or more states, to avert threatened hostilities between them or to bring to a close a war in which they are engaged. Most writers on international law make a distinction between 'good offices' and 'mediation.' The employment of good offices by a third power consists in the giving of friendly advice or the offering of suggestions to the disputing parties with a view to bringing about a settlement of a dispute or the conclusion of a treaty of peace, if they are engaged in war. A government which renders its good offices is understood to be willing to suggest a compromise as a common basis of agreement between the contending parties, to arrange preliminaries for the negotiation of a treaty of peace and to do anything else that may serve the parties in settling their controversy or in ending their hostilities.

Mediation, on the other hand, has more of the character of friendly intervention. A mediator assumes the rôle not merely of adviser or conciliator but takes the part of a middleman,—usually the leading part,—in the conduct of the negotiations between the disputants. If a mediator is a friendly power, for mediation is not arbitration, nor is he an advocate for either side but, to use the language of Sir James Mackintosh, he is a 'common friend, who counsels both parties with a weight proportioned to their belief in his integrity and their respect for his power.' With a view to giving more frequent recourse to mediation as a means of settling international controversies and in order to define the rôle of the mediator, the Hague Peace Conferences of 1899 and 1907 adopted the following rules which were embodied in a convention which was ratified by practically all the powers of the world.
The part of the mediator consists in reconciling the opposing claims and appeasing the feelings of resentment which may have arisen between the States at variance (Art. 4).

The duty of the mediator is at an end when once it is declared, either by one of the contending parties, or by the mediator himself, that the means of reconciliation proposed by him are not accepted (Art. 5).

Good offices and mediation, undertaken at the request of the contending parties or on the initiative of Powers strangers to the dispute, have exclusively the character of advice, and never have binding force (Art. 6).

The acceptance of mediation cannot, in default of agreement to the contrary, have the effect of interrupting, delaying or hindering mobilization or other measures of preparation for war.

If mediation takes place after the commencement of hostilities, the military operations in progress are not interrupted, in default of agreement to the contrary (Art. 7).

It will be seen that the tender of good offices or mediation by third powers prior to or during hostilities is declared to be a legal right, though not an obligation. The Convention, however, imposes on the disputants an obligation to have recourse to this mode of settling their controversies so far as circumstances allow. Each disputant is therefore the judge as to whether the circumstances in a particular case create an obligation to accept the offer tendered. At the outbreak of the European War the President of the United States made known his willingness to serve as a mediator whenever he should receive assurances that an offer would be acceptable by the warring powers. Again in 1910, when war between the United States and Mexico seemed imminent, the governments of several of the Latin American republics made known their willingness to offer their good offices in bringing about a settlement of the dispute but the American government declared that the circumstances were not such as to make recourse to this form of sentiment expedient. The same express declaration of The Hague Convention that the exercise of the right of mediation by third powers shall never be regarded by either of the disputing parties as an unfriendly act was designed to remove all possibility that an offer of mediation might be construed as an act of gratuitous interference rather than the act of a disinterested friend of both parties. The rôle of the mediator is defined in article 4 as that of reconciliation and article 5 lays down the circumstances when his mission is terminated. Article 6 which declares that mediation has no binding effect on the parties but is entirely advisory in character removes the possibility of further misunderstanding concerning its purpose and effect.

The historical instances of recourse to good offices and mediation are numerous. A few of these may be mentioned as illustrations. During the war of 1812 between Great Britain and the United States, the Tsar of Russia offered to act as a mediator with a view to bringing about a termination of hostilities. The offer was accepted by the United States and to avoid delays plenipotentiaries were at once appointed by the President to conclude a treaty of peace but the offer was refused by the British government and nothing further came of the Russian proposal.

Early in 1861 several Latin American republics tendered their good offices to avert the civil war which threatened to spread the hostilities the British and French governments through their ministers at Washington expressed a willingness "to undertake the kindly duty of mediation" if the President should desire it. President Lincoln expressed appreciation for "all the generosities of the generous and peace-loving people of France" but stated that "we cannot solicit or accept mediation from any, even the most friendly quarter." On various occasions during wars in South and Central America the President of the United States tendered his good offices to bring about the adjustment of difficulties or to terminate hostilities already existing. One of the most remarkable of such examples of mediation on the part of the United States was that which was begun in 1865 and concluded in 1872 for the purpose of terminating the war between Spain on the one hand, and the allied republics of Peru, Chili, Bolivia and Ecuador on the other. During the Franco-German War of 1870-71 France requested the United States to join other powers in an effort to bring about a just peace. President Grant replied that he anxiously desired to see the war ended and peace restored and that he would be glad to use his efforts in bringing about peace if Germany also desired the employment of his good offices. At the same time the French government was informed that it was a part of the Monroe policy of the United States not to act jointly with European powers in interference in European questions. During the Chino-Japanese War of 1894 the government of the United States made known to both belligerents its willingness "to contribute in such a manner toward the restoration of peace" but when an inquiry was made asking whether the United States would be willing to join England, Germany, France and Russia in an intervention between China and Japan the President repiled that the United States could not in the present condition of the government be entitled to join such an intervention. During the Boer War of 1899-1902 the government of the United States alone of all the governments approached by the South African republics tendered its good offices but the offer was not acceptable to the government of Great Britain.

A remarkable recent example of the employment of good offices by the President of the United States to bring about the termination of war was that of President Roosevelt in 1905 which resulted in the conclusion of the Convention of peace between Japan and Russia. On 8 June 1905 the President caused identical notes to be sent to the governments of both belligerents expressing his wish that "the terrible and lamentable conflict now being waged" might be brought to an end and urging them "not only for their own sakes but in the interest of the whole civilized world to open direct negotiations with one another." He also expressed his entire willingness to do what he properly could if the two powers felt that his services would be of any aid in arranging the preliminaries as to the time and place of the meeting of the plenipotentiaries which they might appoint. The suggestion of the President was promptly acted upon and plenipotentiaries were appointed to negotiate...
MEDICAGO — MEDICAL CORPS

a treaty of peace. They met at Portsmouth, New Hampshire, and a treaty of peace was signed on 23 Sept. 1905.

An example of successful mediation was that of 1914, which resulted in the temporary termination of an existing conflict between the United States and Mexico. On 25 April, the diplomatic representatives of Brazil, Argentina and Chile addressed a communication to the Secretary of State tendering the good offices of their governments for "the peaceful and friendly settlement" of the controversy. The offer was promptly accepted both by the President of the United States and General Huerta, President of Mexico, and both parties agreed to a mutual suspension of hostilities at the request of the mediators.

At the suggestion of the mediators commissioners representing both parties were appointed and they met at Niagara Falls, Ontario, in May 1914. The mediating planners, however, turned over to the committees and presented over the conferences. On 24 June a protocol embodying the terms of agreement was signed and it was duly ratified by both governments. See also ARBITRATION, INTERNATIONAL.

James W. Garner, Professor of Political Science, University of Illinois.

MEDICAGO, genus of leguminous plants common throughout the greater part of the globe and including such forage plants as alfalfa, medic and burr and mail coves. Some species are annual, others perennial. In all there are about 50 species, of which about six are native to the United States. These include Medicago lupulina, M. dentata, M. Arabica. In general the perennial species have violet flowers, the annuals small bright yellow flowers. The pods are single-seeded, curved and spineless in some, while in others it is spirally twisted, has spines on the edges and contains several seeds. Medicago sativa is the most important species, since it includes the valuable alfalfa and lucerne.

MEDICAL ASSOCIATION, American. See AMERICAN MEDICAL ASSOCIATION.

MEDICAL CODE, a set of regulations adopted by a medical association outlining the conduct of members of the profession. The various codes prohibit advertising in public prints, as well as the endorsement of proprietary or secret remedies. The ethics of both regular and homeopathic schools define the relations of patient and physician and of attending and consulting physician, and provide that a physician shall attend the immediate family of a brother physician without charge, except when unusual labor, expense or exposure is involved. The medical code in this country was founded on the English code of medical ethics prepared by Thomas Percival in 1803. In 1847 the American Medical Association adopted a general code which superseded codes existing in individual states, which was unopposed till 1882. In the latter year a majority of the members of the New York County Medical Society voted to disobey the provision of the code which forbade them to consult with any but "regular" physicians, claiming the right to consult with any physicians that the legislature of each state decided to be legally qualified. Similar action was taken by a majority of the members of the New York Academy of Medicine. This antagonism affected the whole profession in this country, and the immediate result was the formation of New York County and State associations, whose delegates were received by the American Medical Association to the exclusion of those from the old societies. In 1893 steps were taken to heal the divided and unite the rivals into one body, with the code so modified in effect as to allow individual liberty in the matter of consultation. Consult Flint, 'Medical Ethics and Etiquette' (New York 1883) and 'Principles of Medical Ethics' (Chicago 1912), the official work of the American Medical Association.

MEDICAL COLLEGES FOR WOMEN. See EDUCATION, PROFESSIONAL; MEDICAL EDUCATION IN THE UNITED STATES.

MEDICAL CORPS. The Medical Department includes the Medical Corps, Dental Corps, Medical Reserve Corps, Hospital Corps and Nurse Corps. The Medical Corps consists of one surgeon-general, with rank of brigadier-general, who is chief of the medical department, 14 colonels, 24 lieutenant-colonels, 105 majors and 300 captains or first lieutenants, who have rank, pay and allowances of officers of corresponding grades in the cavalry and of the service. An applicant for appointment in the medical corps of the army must be between 22 and 30 years of age, at the time of taking the preliminary examination, must be a citizen of the United States, must have a satisfactory general education, must be a graduate of a reputable medical school legally authorized to confer the degree of doctor of medicine, and must have had at least one year's hospital training, including practical experience in the practice of medicine, surgery and obstetrics. The appointments are made by the President, upon the recommendation of the surgeon-general, after the applicants have passed the prescribed examination, consisting of two parts — a preliminary examination, and a final or qualifying examination, with a course of instruction at the Army Medical School intervening. Qualified applicants are appointed to the medical reserve corps with the rank of first lieutenant, and upon pledging themselves to accept a commission in the medical corps, if found qualified in the final examination, and to serve at least five years thereunder, unless sooner discharged, are ordered to the Army Medical School, Washington, D. C., for instruction as candidates for admission to the medical corps of the army; if, however, a greater number of applicants qualify than can be accommodated at the School, the requisite number are selected according to their relative standing as marked by the Army Medical Board. Graduate candi-
dates who are found physically qualified and who obtain a general average of 80 per cent in their preliminary professional examination, in their course at the Army Medical School, in their clinical examination and in their general aptitude, are eligible for appointment in the medical corps. Eligible candidates may, if they so desire, take a special examination in ancient or modern languages, higher mathematics, or scientific branches other than medical. Proficiency therein is rated along with proficiency attainable by instructions from the surgeon-general. The relative standing for appointment of eligible candidates is determined by the total number of points obtained in the preliminary professional examination, in the School, in the clinical examination, in general aptitude, and in the special examination, if one is taken. See ARMY MEDICAL SCHOOL; HOSPITAL CORPS; MEDICAL ORGANIZATION IN THE ARMY.

MEDICAL EDUCATION, Colleges and Schools, Legal Supervision, etc. Before the establishment of medical schools in this country medical students either went abroad to study or served an apprenticeship with some practising physician. The latter custom was common in view of the expense incident to work abroad, and continued till very recently. As a rule the apprentice had little opportunity for study, but was forced to depend on what he could absorb by contact with his preceptor. The physicians of the 17th and 18th centuries who had studied abroad were usually classical students and in their preliminary training set an example that it would have been wise to follow. The first public lectures on anatomy before a class of students in this country are said to have been delivered by Dr. William Hunter of Newport, R.I., in 1752. It seems, however, that Dr. Giles Firmin as early as 1647 delivered readings on human osteology in New England; that Dr. Thomas Cadwallader of Philadelphia gave instruction to students in anatomy between 1745 and 1751; and that Drs. John Barnard and Peter Mitchell dissected the human body in New York City in 1750 for purposes of medical instruction. 1762 Dr. William Shippen of Philadelphia gave a course of lectures on anatomy, illustrated by actual dissections. These lectures were continued till the organization of the Medical College of Philadelphia (now the medical department of the University of Pennsylvania) in 1765. Dissections were rarely performed prior to 1760 and even autopsies were seldom permitted. At the time of the American Revolution, with a population of 3,000,000, there were probably about 3,500 physicians in the colonies, of whom it is estimated that not more than 400 had received medical degrees. In New England the clergyman was often the only available physician. Two medical schools were organized in the colonies, the Medical College of Philadelphia (now a department of the University of Pennsylvania) in 1765, and the medical department of King's (now Columbia) College, in 1768. The first medical degree conferred in the country, that of bachelor of medicine, was granted to 10 men by the Medical College of Philadelphia in 1768. The degree of doctor of medicine was first conferred in 1770 by the medical school of King's College on two students who had taken the bachelor's degree in 1769. Fifty-one medical degrees had been conferred by these institutions before 1776, when operations were suspended by the war. In the colonial period two medical societies (the State Medical Society of New Jersey, in 1766, and the Delaware State Medical Society, in 1771) were organized. Harvard University Medical School was organized in 1782, Dartmouth Medical College in 1797, the School of Medicine of the University of Maryland and the College of Physicians and Surgeons of New York in 1807. In 1813 the medical department of Columbia College was finally discontinued, the College of Physicians and Surgeons took its place in 1800. Of the 148 medical schools now existing in the United States and registered by the University of the State of New York three were established between 1765 and 1800, 12 between 1801 and 1825, 19 between 1826 and 1850, 29 between 1851 and 1875, 80 between 1876 and 1900, 5 between 1901 and 1904. At the time of the organization of the early medical schools the practical side and not the theoretical was relegated as a rule to ignorant midwives; physiology, histology, organic chemistry, pathology, and surgery, as now recognized, were hardly known. The schools at first conferred the degree of bachelor of medicine for students who had studied two years with a preceptor and attended one course of lectures, the degree of doctor of medicine after three years of study and two courses of lectures. The bachelor's degree was abandoned in 1813. At first the Medical College of Philadelphia required for admission some knowledge of Greek and Latin, physics, natural history and botany, but the requirement was abandoned about the time of the reorganization of the University of Pennsylvania in 1792. For a century there were as a rule practically no requirements in preliminary general education for admission to medical schools, and even to-day this is their greatest defect.

In 1839 the New York State Medical Society resolved that teaching and licensing ought to be separated as far as possible. Further discussion of this question led to a convention of delegates from all medical schools and societies in the United States, held in New York in 1846, from it sprang the American Medical Association. This national body, thoroughly representative in character, gave a new impetus to medical societies. The following societies have exercised an important influence in promoting higher standards: Association of American Medical Colleges (1841); American Institute of Homeopathy (1844); National Confederation of Eclectic Medical Colleges (1871); Southern Medical College Association (1892). These prescribe for admission to medical schools a preliminary general education equivalent to that of one year in a high school. All prescribe courses of lectures in different years as a condition for an M.D. degree, though they give an allowance of one year to graduates of reputable literary colleges and of other professional schools. All tend to improve facilities for teaching, dissection, and checking of schools registered by these societies are 72, 19, 7 and 13 respectively.

In 1859 the Chicago Medical College, now the medical department of Northwestern University, was established to test the practicability of a four-year period of training. Students were divided into three classes, and each class was examined at the close of the
Medical Education

While the actual number of physicians graduated is half that of 1904, the number per thousand of population is still twice as great as it is in Europe. The number of medical students was not affected by the European War nor was the actual number of medical students and teachers affected by the selective draft, for the Medical Officers' Reserve Corps and the Enlisted Medical Reserve Corps provided against this.

Class A colleges require a four-year high school course and two years of work in a college of arts and sciences approved by the council on education of the American Medical Association. The council also specifies what is required in the studies both in high school and college, and also what is to be expected of the medical schools themselves, both in supervision, equipment, teachers, clinical facilities [including, for instance, daily dispensary cases, at least six maternity cases for each senior student and 30 necropsies for each senior class of 100 students or less], medical library, museum, dissect material, etc. In 1918 there were 69 medical colleges of Class A in the United States and two in Canada.

Medical schools of Class B are those which have met the standards of Class A but have not yet been made acceptable by general improvements. Of these there are 14 in the United States and six in Canada. Class C contains those which require complete reorganization, do not keep satisfactory records, or enforce entrance requirements or give a major portion of their instruction after 4 p.m., or are privately owned and conducted for profit. Of these there are 12 in the United States.

The comparative value of the work done now and 14 years ago is realized when it is known that in 1904 only 2.5 per cent of medical schools required college work as an entrance requirement, while in 1918 92.2 per cent did, and that in 1904 only 6.2 per cent of the medical students of the country were in the high grade medical schools, while in 1918 there were 95.3 per cent in the high grade schools, and that in 1904 but 6.4 per cent of the graduates in medicine came from the high grade colleges, while in 1918 the latter graduated 90.3 per cent.

In 1915 a national board of medical examiners was inaugurated with funds from the Carnegie Foundation. The board consists of six representatives from the government [two from the army, two from the navy and two from the public health service], three members of State licensing boards and seven other physicians appointed at large.

Of the 82 medical colleges in the United States in 1914-15 the most highly endowed had an income of $411,570, and the lowest $6,080.

About 1903 a rapid improvement in medical education began in the United States, resulting in a very great decrease in the number of medical colleges and it was thought that a dearth of physicians would follow. Fears were also expressed that the medical education, the cost of which was thus greatly increased, would be the privilege of the rich, and that it would undemocratically exclude the poor boy, a fear which has not hitherto been realized. Subscriptions were also felt that the raising of the standard of medical education would have the effect of decreasing the supply of physicians for
rural communities. This, however, has been obviated by the improvement of facilities in communication—automobiles, better roads, etc.

Out of 90 medical schools, 60 are now coeducational, although 16 out of the medical colleges admitting women have no women students. Out of 590 medical schools for negroes, in 1910 only two were efficient.

More attention should be paid in the United States to instruction in hygiene and state medicine. In Great Britain no one can be appointed a medical officer unless he has been trained in public health. In this country little opportunity is afforded for general or special sanitary work on broad lines. This subject is now under discussion and doubtless progressive States will soon provide places where medical officers of health or other persons engaged in sanitary work can obtain practical and scientific training. The scientific investigations which would be made in the laboratories of such schools would be of great value to the public.

In 1736 a law providing exclusively for physicians was passed by Virginia in 1639, but like the later act of 1736 it was designed mainly to regulate their fees. The act of 1736 made concessions to physicians who held university degrees. In order to get the 13 colonies were well-considered laws enacted to define the qualifications of physicians. The general assembly of New York in 1760 decreed that no person should practise as physician or surgeon in the city of New York till examined in physic and surgery and admitted by one of his majesty's council, the judges of the supreme court, the king's attorney-general and the mayor of the city of New York. Such candidates as were approved received certificates conferring the right to practise throughout the whole province, and a penalty of $5 was prescribed for all violations of this law. A similar act was passed by the general assembly of New Jersey in 1772. In 1840 laws had been enacted by the legislatures of nearly all the States to protect citizens from the impositions of quacks. Between 1840 and 1850, however, most of these laws were either repealed or not enforced as a result of the cry that restrictions against unlicensed practitioners were designed only to create a monopoly.

State Supervision.—Careful attention needs to be given to the difference between a license and a degree, the one carrying with it the right to assume a title which is evidence of scholastic ability, the other the right to enter on the practice of a profession or a pursuit, both emanating from the same authority, the State, either directly or through intervening mediums. As foreigners are often puzzled to account for the diversity in our legislation, the fact is again emphasized that all matters of internal police control are left exclusively to the several States, and that national laws regulating professional practice cannot be enacted. Hence the laws of the United States will be silent concerning licenses and degrees except in so far as they may emanate from the District of Columbia and certain recent federal dependencies.

Licensing.—The requirements for admission to practise a profession in the 54 political divisions of the United States vary as greatly in the various professions as the political divisions differ in area, extent, population and importance. However, two general items appear in full or in part in the various statutory requirements for licensing; namely, (1) the general preliminary education requirements; (2) the professional preparation. The general preliminary are given uniformly under the synonym of requirements.

Supercilious In medicine all political divisions except Alaska now have examining and licensing boards. In some States the stringent laws against non-medical practitioners are enforced; in others quackery receives such legal protection that no person may treat "the sick or suffering by mental or spiritual means without the use of any drug or material remedy." This is due largely to the fact that so many statutes lack specific definitions as to what constitutes the practice of medicine, and without these definitions the conviction of such practitioners cannot be secured through the courts. There is much misunderstanding in this country regarding the duty of the State in relation to the health of the people. It does not consist in licensing exclusively to physicians. Numerous arts besides that of medicine and surgery exist that are within the province of the State. It is not the function of the State to control practice, but rather to prevent harm or injury to the public. There is a great need of uniformity in medical laws.

Medical Sects.—As commonly understood regular physicians have no distinctive theory or practice; homeopathists treat diseases with drugs that excite in healthy persons symptoms similar to the morbid condition treated; eclectics make use of what they regard as specific remedies, chiefly botanic; physiomediastists use only botanical remedies, discarding those which are poisonous. In practice these distinctions are not always observed. The following political divisions specify homeopathists, eclectics or osteopaths as constituting part of their examining boards or have other than regulars on them. Arizona, Arkansas, California, Colorado, Georgia, Hawaii, Idaho, Illinois, Indiana, Iowa, Kansas, Kentucky, Michigan, Minnesota, Missouri, Nebraska, Nevada, New Jersey, North Dakota, Ohio, Oklahoma, Oregon, Pennsylvania, Rhode Island, South Dakota, Tennessee, Texas, Utah, Vermont, Virginia, Washington, Wisconsin, Wyoming.

In the Philippines and Porto Rico the examining boards, the former of three appointed by the director of health for the Philippines, the latter of five appointed by the governor.

The following have separate examining boards for each recognized school of medicine: Arkansas, Connecticut, Delaware, District of Columbia, Florida, Louisiana, Maryland.

Midwifery.—Special fees for certificates of registration as midwives are required in California, Illinois, Iowa and Texas. In the following political divisions the provisions of the medical practice acts do not apply to women engaged in the practice of midwifery: Arkansas, Colorado, Florida, Georgia, Idaho, Kentucky, Louisiana, Maryland, Mississippi, Montana, New Mexico, North Carolina, South Carolina, Tef Columbia, Washington. In the District of Columbia and divisions, though there are some special provisions for certain localities, the general acts regulating the practice of medicine make no reference whatever to the practice of midwifery by women. It would seem, therefore, that these laws restrict the practice of midwifery to licensed physicians. Practically the conditions
in political divisions where the laws seem to restrict the practice of midwifery to licensed physicians are little better than in political divisions where women without a license is authorized by statute. There will probably be little change for the better till the midwife receives legal recognition, and the practice of midwifery is regulated by definite statutory provisions.

The following States have reciprocity clauses in the law, but they are operative in few cases only, namely: Alabama, Arizona, Arkansas, California, Delaware, District of Columbia, Georgia, Idaho, Illinois, Indiana, Iowa, Kansas, Kentucky, Louisiana, Maine, Maryland, Michigan, Minnesota, Mississippi, Missouri, Nebraska, Nevada, New Hampshire, New Jersey, New Mexico, New York, North Carolina, North Dakota, Ohio, Oklahoma, Pennsylvania, South Carolina, South Dakota, Tennessee, Texas, Utah, Vermont, Virginia, West Virginia, Wisconsin, Wyoming.

The law provides for a preliminary education in all political divisions except the Canal Zone, the District of Columbia, Hawaii, Massachusetts, Porto Rico and Wyoming. The law provides for four years of high school in all political divisions except the Canal Zone, the District of Columbia, Idaho, Illinois, Massachusetts, Nebraska, Philippine Islands, Porto Rico, South Carolina and Wyoming, and for an academic college course in the following States, the number of years of such course required being given in parentheses after each: Alabama (2), Alaska (2), Arizona (2), Arkansas (2), California (1), Colorado (1), Connecticut (1), Florida (1), Illinois (1), Indiana (2), Iowa (2), Kansas (2), Kentucky (1), Louisiana (2), Maryland (2), Michigan (2), Minnesota (2), Mississippi (2), Montana (2), New Hampshire (2), New Jersey (2), New Mexico (2), New York (2), North Carolina (1), North Dakota (2), Oklahoma (2), Pennsylvania (1), Rhode Island (2), South Carolina (2), South Dakota (2), Tennessee (1), Texas (1), Utah (1), Vermont (2), Virginia (2), Washington (2), West Virginia (1), Wisconsin (2). A four years medical course is required in all the political divisions except the Canal Zone, the District of Columbia, Idaho, Massachusetts, the Philippines, Porto Rico, West Virginia and Wyoming. The number of hours of the medical course is specified as 3,000 in Colorado, and in Indiana and New Mexico, 3,200 in Illinois, 3,600 in Michigan, North Dakota, Texas and Vermont, 3,744 in Connecticut, 4,000 in California and 5,120 in Georgia.

Registration of Nurses.—See Nurse, Trained.

Dentistry.—See Dentistry.

Revised by Smith Ely Jelliffe, M.D.

MEDICAL EDUCATION IN THE UNITED STATES. In the colonies until about 1725 there was no formal medical teaching. The apprenticeship system prevailed and young men took service with a physician and after some years went into practice for themselves. Usually this was not far from their preceptors and they had to recur to them for consultation. Sons of the better-to-do colonists desirous of studying medicine crossed to Europe and received the advantage of medical training in Edinburgh, London, Paris or the Netherlands. Considering the long, difficult, dangerous voyage, the surprise is how many young men founded a European medical education. Manifestly medicine was taken very seriously. The preliminary education was excellent and the medical training thorough. Dr. Morton ('History of Pennsylvania Hospital') does not hesitate to say: 'We find that the professional men of the seventeenth and eighteenth centuries were generally much better educated than most of their successors of the present time. Almost without exception they were classical scholars, their graduating theses must be written in Latin.'

The ideals in medical education were high. Dr. Thomas Bond's essay on 'The Utility of Clinical Lectures' (Philadelphia 1765) insists that the student must join Examples with Study before he can be sufficiently qualified to prescribe for the sick, for Language and Books alone can never give him Adequate Ideas of Diseases, and the best methods of Treating them. Bond argued that clinical teaching was absolutely necessary and he suggested that the teaching should be by what we call the ward class method with questions to bring out the knowledge of the disease and parts affected. He even recognized and proclaimed that the only policy that would lead to real advance in medicine was to follow up clinical observation in fatal cases by a post mortem and acknowledge mistakes in the hope to be able to avoid them in other cases. His words deserve to be publicly posted in every hospital and medical school of the country. 'If the Disease battles the power of Art and the Patient falls a Sacrifice to it, he then brings his Knowledge to the Test, and fixes Honour or discredit on his Reputation by exposing all the Morbid parts to View, and Demonstrates by what means it produced Death, and if perchance he finds something unexpected, which Betrays an Error in Judgment, he like a great and good man immediately acknowledges the mistake, and, for the benefit of survivors, points out other methods by which it might have been more happily treated.'

About 1750 there are indications of waking up to the need of formal medical teaching. William Hunter, a relative of John Hunter of London in Rhode Island, Cadwalader in Philadelphia, and John Bard and Peter Middleton in New York did some anatomical teaching with dissections in this decade. In 1762 Dr. William Shippen, Jr., recently returned from London and Edinburgh, commenced a course of anatomical lectures with dissections at his father's residence in Philadelphia and this was attended by 12 students. This led to the organization of our first medical school as the Medical Department of the Philadelphia College in 1765. Shippen's principal auxiliary was Dr. John Morgan, who had been with him in London and Edinburgh, where they agreed to found a medical school in America. The secretary of the medical society secured the Medical Department of King's College, New York, established in 1768. New York anticipated Philadelphia in the giving of the degree of Doctor in Medicine, the first being conferred June 26, 1770, on Robert Tucker in 1770. Benjamin Franklin secured the first Bachelor in Medicine in 1768, but did not confer its first degree of Doctor in Medicine until June 1771. Though medical teaching had not been organized physicians abounded. It was
calculated just before the Revolution that there were some 3,500 physicians practising in the Colonies, of whom less than 400 had degrees. New York City, containing about 10,000 inhabitants, "could boast of more than forty gentlemen of the faculty, the greatest part of whom were mere pretenders to a profession of which they were entirely ignorant." (Independent Reflexion, New York, 1753).

Medical education received an almost complete setback everywhere throughout the Colonies by the Revolution, though in New York the practice of the surgeons who accompanied the British army proved instructive for the physicians who remained in the city, and courses in anatomy and some other medical subjects were given. Immediately after the Revolution steps were taken to restore the medical schools. Philadelphia indeed granting degrees at a commencement held June 1780, but personal and professional jealousy held them back. The charter of the college of Philadelphia and it was not until this was reorganized that the medical schools settled to work. Over 100 medical students were in attendance there in 1790. Medical teaching in New York suffered from a similar friction of personalities, but it lasted much longer. The Medical Department of King's College, changed after the Revolution to Columbia, was reorganized, but there was a hitch with the educational authorities of the State. An independent medical school was organized mainly through the influence of Dr. Nicholas Romayne and when this was refused recognition by the Regents he appealed to Queen's College (now Rutgers), at New Brunswick, N. J., for authority to confer degrees. This appeal to outside institutions came to be a favorite device of medical faculties throughout the country who had severed their connection with regularly incorporated medical institutions. No less than three times in the first half century Rutgers was thus appealed to, again in 1811 and 1826, and then a Geneva Medical Faculty was organized in New York City, until the practice was declared illegal.

After the Revolution other medical schools soon began to make their appearance. H. 1818 Dartmouth established a medical department in 1797. The medical department of the University of Maryland in Baltimore was founded in 1807 and continued under that name though there was no university, and that of Yale University in 1810. Unfortunately anatomical teaching was very much hampered by popular prejudice. There was no legislation permitting the use of or providing bodies for dissection purposes. The bodies of those killed in duels were by law devoted to anatomical purposes, but resurrectionism had to supply the rest. As a result of popular suspicions there were attacks on dissecting rooms in many places. New York had its Doctors' Riot in 1789, Philadelphia, Baltimore, New Haven and Saint Louis had theirs much more serious in the 1820's, the last actually as late as 1844. This was not a medical or legal reversion as it is often called, for dissection had been very freely permitted in many places, in the Middle Ages, but a modern intolerance not only in that which had been done, but the legal reversion in this country.

The early medical schools in this country, as pointed out by Dr. Nathan S. Davis, although originating in different States wholly independent of each other and in direct rivalry for patronage, were remarkably similar in their organization. In the 18th century the number of professors in each school was small and the college term eight or nine months. The bachelor's degree in medicine was conferred after three years of study with a preceptor followed by one college term, and the doctor's degree after one or two additional years of practice and a second course of college attendance. The degree of Bachelor of Medicine was abandoned by the College of Philadelphia in 1789, by the University of Pennsylvania in 1791 and by all the medical colleges in this country in 1813.

Medical schools soon began to multiply. In 1810 there were the six schools already mentioned. In the 30 years down to 1840, 26 medical colleges were added. They were in the border of their foundation. The College of Physicians and Surgeons of the Western District of the State of New York at Fairfield, Herkimer County, founded in 1812. Though in rural surroundings this did excellent work, had some medical teaching in 1797. ROCKY CREEK 1840 about 3,000 students on its rolls. In 1817 Transylvania University, Lexington, Ky., finally succeeded in organizing a medical department. There had been chairs of medicine before. Samuel Brown, M.D., was appointed in 1795 to the professorship of anatomy, surgery and chemistry. In 1801 Frederick Ridgley, M.D., was elected professor of medicine. In 1805 James Fishback, M.D., was appointed to the chair of theory and practice. Twenty students attended the first full course of medical lectures in 1817-18. One of them received the degree of M.D., the first degree conferred west of the mountains. In 1818 the Castleton Medical School, afterward named the Vermont Academy of Medicine, was founded, the degree of Doctor of Medicine being conferred under the authority of Middlebury College until 1827, after which it was conferred directly by the medical faculty under its amended charter.

Dr. Daniel Drake resigned from Transylvania University, Athens, Ohio, in 1797 established a medical school in Cincinnati which held its first course of lectures in 1820. Altogether he held 11 chairs at six different medical schools at various times. The Medical School of Maine was organized in 1820 also as a department of Bowdoin College at Brunswick with Dr. Nathan Smith as the faculty. In 1821 a medical school developed at Brown University, Providence, but did not continue long. The Medical School of the University of Vermont was organized at Burlington in 1822. In 1823 The Berkshire Medical Institution was organized at Pittsfield, Mass., under the charter of Williams College. In 1824 the Medical College of South Carolina was organized at Charleston. In 1825 the medical department of Columbian College, District of Columbia, was organized. This school sustained 1824-35 but resumed in the latter year under the name of the National Medical College, now as the medical department of Columbian University. In 1825 Jefferson Medical College, Philadelphia was chartered to Dr. Barton in 1819 after an unsuccessful attempt in 1816. Jefferson owes its name to its connection with Jefferson College, Cannon-
burg, Pa., through which its degrees were granted. In 1825 the medical department of the University of Virginia, charter 1819, was organized. In 1826 the Medical School of the Valley of Virginia, familiarly called The Winchester Medical College, was organized at Winchester, Va. Both of these Virginia colleges prosposed to have terms of nine months instead of the shorter terms in vogue and the method of teaching was by recitations and demonstrations as in other schools of the day; no scientific literary study and not merely by lectures. About the middle of the 19th century the University of Virginia was graduating men after two courses of four and a half months each given in the same calendar year, but its examination standards were high and its graduates were taking the best places in the army and navy service. In 1827 the Washington Medical College, so-called because its degrees for the first six years were conferred by Washington College, Pennsylvania, was organized in Baltimore. Afterward a charter was granted by Maryland. In 1831 the Medical College of Georgia was chartered and the first course of instruction given in the following year. An Academy of Medicine, similar in purpose, was organized in 1827 at Augusta by Dr. Milton M. Anthony, the founder of the Southern Medical and Surgical Journal, the first medical periodical published in the South. It was from him that came the suggestion of a convention of the faculties of the medical colleges of the United States for the regulation of medical education and the improvement of the professional status of physicians. The movement thus initiated ripened into the organization of the American Medical Association. After this the medical schools multiplied rapidly. In 1834 the Medical School of Willoughby University, Willoughby, Lake County, Ohio, was chartered and its first course of instruction commenced in 1835. In 1835 the medical institute at Geneva College at Geneva, N. Y., the medical department of Cincinnati College at Cincinnati, Ohio; the Vermont Medical School at Woodstock, Vt., and the medical department of the University of Louisville at New Orleans were chartered by the respective states as separate medical departments of the University of Louisville, Ky., and of the University of the City of New York were organized, and in 1838 the medical department of Hampden Sydney College at Richmond and in 1839 the Albany Medical College at Albany, N. Y., and the medical department of the Pennsylvania College at Philadelphia. Philadelphia continued to be for long as it had been from the beginning of the nation's history the principal centre for medical education. It was our largest city in the early days and New York's development was hampered by professional bickerings. In the 35 years following down to the completion of the first hundred years of our history in 1876, 47 new medical schools were created, not including five or six abortive attempts so transient as to leave a record difficult to trace. This made 80 altogether established during the first 100 years, 16 of which had been discontinued, leaving 64 medical colleges in the United States. Of these Maine had two; New Hampshire one; Vermont three; Massachusetts one; Connecticut one; New York nine; Pennsylvania four; Maryland three; Virginia two; South Carolina one; Georgia three; Alabama one; Louisiana two; Texas one; Tennessee one; Kentucky three; Missouri three; California two; Oregon one; Iowa two; Illinois three; Indiana three; Ohio seven; Michigan two; and the District of Columbia three; leaving 13 States without any medical college. Of these, four, two in New York City, one in Philadelphia and one in Chicago, were devoted to the education of women in medicine. The whole number of students attending the five medical colleges in 1810, for Yale though chartered was not yet receiving students, was about 650, of whom about 100 were graduated that year. The population of the United States was about 7,250,000. In 1840, with the population two and a half times as numerous the medical students numbered 2,500, nearly four times as many, and about 800 graduated that year, eight times as many. In 1873-76 the population of the United States was over 40,000,000. It had multiplied once more two and a half times, but the medical students now numbered 6,650, having again increased faster than the population, and that year 2,200 were graduated. With this great increase of medical organizations the medical needs of the population, the inevitable struggle for existence led to the lowering of standards. The temptation to concentrate the teaching into a brief a space as possible, partly because of competition for students but mainly to secure more profit for and less call upon the time of professors who were engaged in active practice, gradually compressed the time required for study. At the same time preliminary requirements lessened and anyone who could write his name, and he did not have to write it very plainly, could take the study of medicine. The preceptor was practically superseded and the college terms shortened to four months each with the lectures not graded, the students listening to the same course two years in succession. The degeneration of the medical education was brought about by the failure of the schools to set aside medical education for money-making purposes, neglecting scientific development. Even when the medical schools bore the names of well-known universities, and the medical departments of the University of Columbia, the university administration had practically nothing to do with the medical school curriculum or management and the fees were divided among the historic seaport of professors who became firmly entrenched everywhere and refused to permit of reforms until their hands were actually forced by certain reforming elements, mainly younger members of the medical profession. There were vigorous protests against this unfortunate degradation of medical education which all could not but acknowledge and the American Medical Association was organized on the initiative of the New York State Medical Society with one of its main purposes the reform of medical education. An attempt was made to sidetrack the organizing convention by the delegates from the faculty of the Medical Department of New York University in whose halls the preliminary meeting was held. This failed and the national organization became a fact, but was able to make a thorough reform of medical education for a generation. Numerous discussions were of no avail. All were ready to admit that medical students should
have better preliminary education and that the
lecture courses should be graded and that there
should be a systematic division of the branches
taught into groups appropriate for each year of
study, and that there should be at least three
terms of six or better still eight or nine months,
each year. The faculty of each school frankly
acknowledged the defects of the system in
vogue, but "each waited for the other to move
first lest by placing higher requirements mean
the time and resources of the student it should
cause its own halls to be deserted for those of
its less exacting neighbor" (Davis). Some
very praiseworthy attempts were made, how-
ever, to get away from the current unfortunate
state of affairs. The New York Medical Col-
lege was established in 1850 with a three-year
graded course and the beginnings of clinical in-
struction. Unfortunately the Civil War proved
fatal to it, but not before it had demonstrated
the possibility of raising standards in medical
education. In 1859 the Chicago Medical Col-
lege was organized for the express purpose of
testing the practicability of establishing a school
with a thoroughly graded and consecutive sys-
tem of instruction. In the face of these difficul-
ties the influence of President Eliot adopted a fully
graded system of instruction, dividing her
classes and extending the courses throughout
the collegiate year. The new medical school of
Syracuse University adopted the same
policy about the same time.
In the 35 years after 1876 the number
of medical schools doubled. The great majority
of the new schools were of the same low stand-
ards as so many of their predecessors and
indeed were founded with the idea not of foster-
ing medicine but of producing revenue for the
professors directly or indirectly. In the mean-
time in 1878 Dr. Francis Delafield established
the first laboratory in this country in connection
with the College of Physicians and Surgeons
in New York. Later that same year Dr. Will-
iam H. Welch opened the pathological labora-
tory of Bellevue. By degrees the better schools
followed these examples and many other schools
found themselves compelled to take up this de-
velopment of medical education or lose in
attendance. It was not until 1893 that a definite
advance in medical education was made by the
foundation of Johns Hopkins Medical School,
Baltimore. This required a bachelor's degree
from every student and required four years
medical study. The better known schools were
now stimulated to follow the example of Hop-
kins. Above all the special feature of clinical
instruction worked out there gradually spread
to the great benefit of medical education.

At the beginning of the 20th century the
Council on Education of the American Medi-
cal Association began its work of registering
medical schools after examination according to
the grades which they deserved. In order to
secure a class A rating the medical school had
to have six full time professors, at least $100,-
000 investment, be provided with laboratories
properly equipped, require four years of med-
ical study and at least one year of preliminary
college work. The class B schools were de-
prived of the privilege of the course in
medicine and a number of medical colleges began to drop off.
At the end of the first decade of the century
the investigation of medical education in the
United States by the Carnegie Foundation for
the Advancement of Teaching revealed the de-
fects in many existing schools and called at-
tention to what should be the absolute require-
ments for medical teaching in our day.
An increasing interest in medical education has
brought about the enactment of a legal regula-
tion in many States requiring a fifth year of
preparation for the practice of medicine which
is to be passed in a hospital. The entrance re-
quirements are constantly growing higher and
now two years of college work are required as
a preliminary to medical study in most places
and a number of schools have adopted or are
about to adopt the bachelor's degree as a pre-
requisite. Curiously enough this modern stand-
ard is nearly a replica of the old medizeval re-
quirement that there should be three years of
preliminary study at the university before tak-
ing up medicine, four years at medicine and
then a year of practice with a physician before
the medical degree could be awarded. Fortunately our scientific developments in med-
ic education were completed just in time to
enable us to be independent of foreign medical
teaching during the war and the magnificient de-
velopment of American surgery put us in a
position to offer excellent opportunities for the
higher study of medical and surgical problems
from a thorough scientific standpoint to
students from Europe who after the war will
find it easier to obtain them with university
studies under favorable circumstances over
there because of the destruction wrought by
the war and the sad gaps in teaching staffs
due to war losses involving so many of the
progressive younger men.

Medical Education of Women.—The de-
development of medical education for women in
America gave back to the world the opportunity
for feminine medical study which had been
freely granted in the Middle Ages and then
without so many other privileges was denied in
the modern times. The first woman student of
medicine was Dr. Elizabeth Blackwell who after
being refused permission to study at most of the
medical colleges in the country finally
secured the privilege at Geneva, N. Y., when the
faculty feeling sure that her application could
be rejected put it before the students and they
voted unanimously to allow it. She was gradu-
ated in 1849. Her sister Emily was refused
two years later at Geneva and Rush Medical
College, Chicago, was censured by the State
Medical Society for receiving her for a term.
She was graduated at Western Reserve, Cleve-
land. The women resolved to found medical
colleges of their own. The first of these the
Women's Medical College of Pennsylvania was
founded in 1850. It had a quasi predecessor in
the Gregory School of Medicine established to
train women as midwives, founded in Boston in
1848 and lasting until 1874. The Woman's
College of the New York Infirmary was opened
in 1865 and closed in 1874. Hence for itself it
opened its medical course to women students. The
Women's Medical College of Baltimore was
founded in 1862, that of Cincinnati in 1886 and
that of Kansas City in 1895. The University of California was a pioneer
in opening its courses to women in 1869 and was followed in this policy by all the universities of Western States. This development also included medicine so that the special need of medical colleges for women ceased in the West. When Johns Hopkins, Baltimore, opened its medical school in 1893 women were accorded the same privileges as men. Gradually prejudices disappeared and other medical schools opened their doors to women, but it was not until the great outbreak of smallpox in 1870 began for the physicians during and after the war that Harvard and Columbia removed the restrictions against women in their medical schools. No barriers to the medical education of women in the United States either in undergraduate or post-graduate work will remain after the war.

JAMES J. WALSH, M.D.

MEDICAL ELECTRICITY. See ELECTROTHERAPEUTICS.

MEDICAL JOURNALISM. One of the earliest newspapers on record, the Gazette de France, was issued by a physician, Renaudot (Paris 1631). He had been appointed Commissioner-General of the Poor of France when poverty was rife, just after the religious wars, and created a Bureau of Addresses where those out of work might learn of chances for employment. He established the Gazette to give publicity to his scheme for bringing employers and employees together. The Gazette was a quarto sheet, printed in four columns on one side. Medical matters were not treated directly in the Gazette, but its purpose was the prevention of disease and suffering by lessening poverty. With the origin of scientific societies in Italy at the time of the Renaissance, these published many articles of medical interest. The first journal paying considerable attention to medicine was Le Journal des Scavans. This was published every Monday for three months at Paris, at the beginning of 1665, the next year it continued longer, and then every two weeks rather regularly. It lasted some 10 years, and altogether some 700 pages were printed. Early issues contained reviews of Willis' 'Cerebri Anatomia,' and Steno's 'De Musculis et Glandulis,' and other medical reviews of current interest. The German Society of Naturalist Physicians (Gesellschaft der Naturforschender Aerzte), founded in 1652, began for the first time in 1670, with a coming under Imperial protection, its Transactions monthly under the name Ephemerid. A more purely medical periodical was the Acta Medica Hafensia, edited by Thomas Bartholin at Copenhagen in 1671. The Royal Society chartered by Charles II began to publish its well-known philosophical Transactions in 1665. Included among its publications were the works of Malpighi and Leeuwenhoek in the 17th century and those of Galvani in the 18th. All these were in Latin. The first medical periodical in the vernacular was the Nouvelles Découvertes sur toutes les Parties de la Médecine, issued monthly (Paris 1679-81). It was published by Nicholas de Bligny, a somewhat irregular medical practitioner of the time who realized the value of print. He decided opposition from the medical profession, who deprecated not only his methods but above all the publication of medical matters in the language of the people. He waked the French medical profession, however, to the value of a medical publication and not long after, a Journal de Médecine was published by the Abbé de la Roque and continued by Claude Brunet, who established a monthly, Progrès de la Médecine (1695-1709). French medical journalism then went to sleep, to use the expressive phrase of Südhoff, for some 50 years. Formal German medical journalism began with the Acta Medorum Berolinensium, founded in 1717. This appeared twice a year at first, and then annually until 1720. In 1717, there began at Leiden a quarterly publication called the Collection of Natural History and Medical Information. This continued for many years. The second half of the 18th century saw a thorough waking up to the advantage of medical journalism. At Hamburg in 1759 the weekly, Der Arzt, began, in various German cities, a series of medical Bibliotheks, that is, regularly issued reviews of medical books, made their appearance. In 1767, the German medical journal, Neue Arzneien (New Remedies) was founded. Most of these journals lasted only a few years until their founder became occupied with other things or his enthusiasm evaporated.

Eighteenth century medical journalism or its equivalent, at the time common, had a great extent of the transactions of various medical societies. A number of very important contributions to medicine were published originally in these and they have a distinct bibliographic value. Südhoff suggests that the material for the cultural history of medicine in this century lies buried in the files of its forgotten medical periodicals. These were very numerous and Garrison has given a check list in chronological order of some hundred of them.

Toward the end of the 19th century, the special journals of the scientific departments of medicine began to make their appearance. Probably the most important of these was
Reil's Archiv für die Physiologie (1795), which was the incentive for the foundation of Johannes Müller's Archiv für Anatomie, Physiologie und wissenschaftliche medicin (Berlin and Danzig, 1817), continued by Reichert of Du Bois Reymond and still published at the present time. Siebold's Lucina (Leipzig 1802-11), Langenbeek's Bibliothek für die Chirurgie (Göttingen 1805-13), Grafe's and Walther's Journal der Chirurgie und Anatom.-Heilkunde (Berlin 1820-50), Magendie's Journal de physiologie experientielle (Paris 1821-31), Malgaigne's Journal de Chirurgie (Paris 1843-46), Bulletin de la Société anatomique de Paris (founded in 1826 and still current), and the Mémoires and Bulletin de l'Académie de médecine are typical examples.

About the middle of the 19th century, yearbooks began to be regularly published. About the same time Virchow's Archiv für Pathologie, Anatomie und das Comptes rendus of the Société de Biologie of Paris began publication. There are now literally hundreds of such journals published in the various countries and languages. The tendency to extreme specialization in medical journalism became marked in the second quarter of the century when special journals for narrow interests were published. Mind (1876), Brain (1879), and La Cellule (1884), are typical examples. Garrison notes that the contribution of the 20th century to medical journalism is the large number of recent periodicals devoted to the psychological and sociological aspects of the sexual instinct.

In Italy medical journalism developed rather slowly, Italian professors being inclined rather to write books than the shorter articles. Certain special subjects like electrotherapeutics, because of Galvani's and Volta's discoveries, were covered early. Il Galvani, with the subtitle Giornale di Elettro-Idro-ed Aero-Terapia, was published at Milan at the beginning of the 19th century. All medical therapeutics was reduced to electrical terms by it. Since then the Italians have the habit of calling their medical journals after their great physicians, and have had journals named for Cesalpino, Malpighi, Spallanzani and a number of other distinguished physicians.

An early attempt at the publication of a medical journal in America was made through a translation of the French Journal of the Military Hospitals, under the title of A Journal of the Practice of Medicine, Surgery and Pharmacy in the Military Hospitals of France (Vol. I, No. 1, New York 1790). This contained some 120 pages but is the only number that has come down to us.

The first medical journal published in America was the Medical Repository, a quarterly, under the editorship of Samuel L. Mitchell, Edward Miller and Elihu Smith. It was founded in 1797, and the interest which it aroused can be best appreciated from the fact that of volumes I and II, a second edition was printed in 1800 and exhausted, and a third edition issued in 1804. This is the only time in the history of American medical journalism that this has happened. The Medical Repository continued publication until 1824. Its success led after a few decades to the almost simultaneous foundation at Philadelphia of two medical journals, The Medical and Physical Journal (1804-09). Though neither of these lasted long, the establishment of other medical journals went on apace. In Boston, the Medical and Agricultural Register was published for two years (1806-08). The American Medical and Physical Recorder for a similar period (1808-09). An effort was made to attract additional readers in these journals by including subjects of cognate interest. This was also the case with regard to the American Medical and Philosophical Register (New York), which lasted, however, only some five years (1810-14). The New England Journal of Medicine and Surgery had a happier fate, enduring some 15 years (Boston 1812-28). Philadelphia had by this time, owing to professional jealousies and politics and the mismanagement of medical schools in New York, come to be the centre of medical education in the United States and the medical journalism of the country focused there. The American Medical Recorder (1813) lasted more than 10 years and was followed by the Philadelphia Journal of the Medical and Physical Sciences, founded in 1820 by Nathaniel Chapman. In 1825, the title of this journal became the American Journal of the Medical Sciences, and in 1829, the journal was named after Dr. Isaac Hays and his son, this became the representative American medical journal long known as Hays' Journal. The oldest American medical weekly in existence is the Boston Medical and Surgical Journal, founded in 1828, whose editors have been some of the most distinguished physicians of Boston. The Medical News, founded in Philadelphia by the younger Dr. Hays in 1843, was transferred to New York (1896) and combined with the New York Medical Journal (1905). This latter was founded in 1865, followed almost immediately by the Medical Record (1866), both still in existence.

The first medical journal issued west of the Alleghenies was the quarterly Reporter of Medicine, Surgery and Natural Sciences, issued at Cincinnati, 1822. The first Canadian medical periodical was the Journal de Médecine au Quebec, issued in 1826.

The founder of medical journalism in its modern sense, as not only a carrier of news and information for physicians but also a force for the uplift of the profession, the regulation of the practice of medicine, the direction of medical legislation, and the exposure of abuses, was Thomas Wakley, an Englishman who in 1823 founded The Lancet in London. When this appeared there were a great many abuses, especially in hospital practice and medical education needing correction. Hospital posts and even sometimes medical professorships had become family matters, subjects of inheritance. Hospital instruction was so given that it reached but a very limited number. Wakley began by publishing the hospital lectures of professors for the benefit of the profession. When Abernethy, the distinguished London surgeon of the time, applied for an injunction against the publication of his lectures without his permission, Lord Eldon decided that lectures delivered in hospitals were public property. The trial proved a good advertisement for Wakley and he became the most important factor in England for the correction of social abuses by legislation. The
Lancet has always continued the work of its founder in this regard, and has been noted for its crusades against food and drug adulterations, its campaigns for the correction of medical abuses, and its leadership of the medical profession of England generally for the amelioration of medical social conditions. The work of The Lancet was not only supplemented but extended in England, when the British Medical Journal, representing the British Medical Association, was founded in 1857. The association, organized in 1832, published yearly "Transactions" until 1853, and then the Association Medical Journal, which was succeeded by the British Medical Journal after some five years. The British Medical Journal has come to be a most powerful factor for the correction of medical abuses and the exposition of impositions of various kinds upon the profession as well as the public. The American Medical Association, founded in 1847, did not establish its journal until 1858. This was scarcely to be expected in a weekly "Transactions" until under the management of Dr. George Simler, the American Medical Journal, at the beginning of the present century, it began to be thoroughly representative of the best interests of the medical profession in America and of the genuine medical interests of the public, taking its place hopefully beside the British Medical Journal. The Journal A. M. A. initiated the reform of medical education by securing four-year courses and full-time professorships in the medical schools, and this has secured a noteworthy reduction in the number of schools of medicine in the country, decidedly to the advantage of medical teaching generally. It was enabled to do this through its reorganization of the American Medical Association which strengthened State and county medical organizations and brought a reform of their medical journals. The advertising abuses of medical journals were emphatically pointed out and an initiation of reform secured. The Journal A. M. A. has done extremely valuable work for the medical profession, and is in the lead with one of the best of the medical journals.

MEDICAL JURISPRUDENCE, the science of applying medical knowledge to the purposes of legal investigation; the application of the principles and practice of various branches of medicine in judicial proceedings requiring the explanation of doubtful questions, such as those relating to conception and birth, time and cause of death, physical and mental diseases, etc. Medical jurisprudence is often spoken of as forensic medicine, that is, the medicine of the forum. It embraces subjects both purely medical and purely legal, and covers a very wide range. These questions have usually been considered under five divisions: (1) such as arise out of the relation of sex, including impotency, pregnancy, legitimacy, particularly by the poor, were shown to contain either such harmful materials as alcohol or cocaine as their chief ingredient, or else to be made up of absolutely inert materials like salt or sugar and water, slightly colored. The success of the London Lancet led to the foundation of the Lancet Française in 1828, which followed the plan of reporting hospital lectures and afterward became the Gazette des Hôpitaux, which still continues. The Gazette Médicale de Paris was founded in 1830. Other French journals in large numbers were founded in the second half of the 19th century and the weekly newspapers were supplemented by the Progrès Médicale, paying attention particularly to current medical items, Paris, 1873. In London the first of a series of such weekly journals meant to carry medical news and represent the medical profession as well as organize the correction of abuses, were founded in various parts of the world. The Buche Medicinale in St. Petersburg in 1875, Vrach in Saint Petersburg in 1880, and Geneva, Munich, Prague, Rome, Vienna and many other cities came to be represented in this way.

At the beginning of the European War, there were some 1,700 medical journals published in the various languages. Their distribution was as follows: the United States had 630; Germany, that is, the Germany-speaking countries, 451; the French, 268; the British, 152; the Italian, 75; the Spanish, 29. This was entirely too many for the maintenance of such proper standards as would make them seriously valuable and prevent abuses. Many of them were published almost entirely as a means of propagating information for business purposes with regard to various drugs and preparations, the journals being established for this purpose, or the proprietors allowing their columns to be used for such exploitation because of the money paid for advertising. The more medical journals the lower the standards. The war, with its scarcity of paper, has brought an end to a great many of the proprietary medical journals and undoubtedly will in its course do much to purify the field of medical journalism.

Bibliography.—Chereau, "Journalisme Medicale Francais" (L'Union Medicale, 1867); Garrison, "Medical Journalism" (article in "Reference Handbook of the Medical Sciences," New York 1918), and "History of Medical Journalism" (New York 1918, 2d ed.); Sondhoff, "Das Mediz. Zeitricht-Wesen im Deutschland" (Münich Med. Wochenschrift, 1903).

JAMES J. WALSH, M.D.
MEDICAL ORGANIZATION IN THE UNITED STATES ARMY

MEDICAL ORGANIZATION IN THE UNITED STATES ARMY

The Medical Department of the Army, of which the surgeon general is chief, aims: 1. To conserve the strength of men and officers—(a) Through prompt attention to disease and disabilities revealed by physical examination; (b) through supervision of sanitary conditions.

2. To move non-effective to the rear without using effective fighting men for such service and without in any way obstructing military operations.

3. To provide medical and surgical care for the sick and wounded (including control and management of military hospitals), restoring the disabled to active military service or to useful and remunerative places in civil life.

The service of the medical man is constant. Every recruit must be examined before entering the army must be without weaklings and without disease. Health must be maintained. Prophylactic measures must be instituted and insisted upon and remedial measures applied both for illnesses in camp and as a result of battle casualties. It is the doctor's job to make and keep the soldier fit to fight. His work is to a tremendous degree effective in preserving the morale of the army. It is the task of the medical department to succor the wounded so swiftly that their comrades may know that, should their turn come, they will be cared for as expeditiously and efficiently as is possible. Thus the medical man directly heighten the morale of troops.

The army doctor used to be one who could do a little of everything in an emergency—he was pretty much in the same class with the country doctor of 30 years ago. Major-General Gorgas once said: "I do not think we have a more useful man in the army than the medical man who can pull a tooth, bind a finger, or take charge of the casualties that occur in a moving command, and do all these things equally well."

The medical department consists of the medical corps, medical reserve corps, contract surgeons, dental corps, dental reserve corps, veterinary corps, veterinary reserve corps, nurse corps, sanitary corps, ambulance corps and enlisted (formerly hospital corps) men.

The insignia of the medical department is a cadiac of bronze metal one inch high; the letters D., S. A. and C.S. in gilt metal superimposed, designating, respectively, Dental, Sanitary and Ambulance Corps and Contract Surgeons. Also, all persons belonging to the sanitary service, and chaplains, wear on the left arm a brassard bearing a red cross on white ground—the emblem of the sanitary service.
of armies—and all sanitary formations display the Red Cross flag with the National flag. All sanitary service material is marked with the Red Cross emblem. Green lanterns distinguish sanitary units at night.

Expansion of the Medical Organization during the Great War.—In the Army Appropriation Bill of 29 June 1918 (H. R. 12281), provision for an increase in the number of officers in the higher commissioned grades of the medical department was made as follows:

*Increase in medical department.—That the medical department of the regular army be, and is hereby, increased by one assistant surgeon-general, for service abroad during the present emergency as now provided by law for the Medical Corps of the regular army: Provided, That nothing in this act shall be held or construed so as to discharge any officer of the regular army or deprive him of a commission which he now holds therein.*

The proportion of commissioned medical officers in the regular army is not to exceed seven for every thousand of the total enlisted strength of the regular army. They must be citizens of the United States. The relative rank percentages of the commissioned officers below brigadier-general is as follows: colonel, 3.16; lieutenant-colonel, 5.42; major, 23.70; captain and lieutenant, 67.72.

---

**At the entrance of the United States into the World War (April 1917) the Medical Corps comprised 452 officers, and there were 2,600 members of the Medical Reserve Corps enrolled but inactive. Officers commissioned in the medical department for the week ended 4 Oct. 1918 totaled 35,374, the distribution being as shown in table on following page.**

An applicant for appointment in the Medical Reserve Corps was required to be between 22 and 55 years of age, and to be qualified to practise medicine in the State or Territory in which he resided. In general, the personnel of the Medical Reserve Corps were successful physicians and surgeons in private practice. To join, one had to apply to the adjutant-general of the army for examination; then followed successively, preliminary examination, physical and mental. After qualifying as to physical stamina, clinical skill and aptitude for the mili-
surgical service, the applicant was recommended for a commission by the surgeon-general, and appointment by the President followed.

The provision that a major might not be appointed after 45 was changed when the need for medical officers for the Great War became acute.

Of the 10 per cent sanitary personnel, 4 per cent or 5 per cent were allotted to the Zone of the Advance and the balance to the Line of Communication or to home territory, or wherever sick or wounded sent to the rear were to be cared for. War experience had shown the necessity in the sanitary service of one individual for every man sick or wounded, because more than one-half of the personnel was held ready to render first aid and transport the disabled to the rear, and consequently not available for their care thereafter.

For an army of 2,000,000 the National army organization provided for 20,000 medical officers and 200,000 enlisted men of the medical personnel—one officer and 10 enlisted men for every 100 enlisted men of the combatant forces. Thirty per cent of the entire authorized strength of the medical department was made up as follows: Master hospital sergeants, ½ per cent; hospital sergeants, ½ per cent; sergeants first-class, 7 per cent; sergeants, 11 per cent; corporals and privates, 6 per cent. Each authorized horse-drawn ambulance company, or similar organization, had a horseshoer, saddler, farrier and mechanic. Privates first-class were eligible for ratings for additional monthly pay as follows: As dispensary assistant, $2; as nurse, $3; as surgical assistant, $5.

Dental Corps.—The Dental Corps comprised commissioned officers of the same grades and proportionately distributed among such grades as were provided for the Medical Corps. There was one dental officer for every thousand of the total strength of the army. The dentists of the country were particularly alert during the war with Germany, and the profession was mobilized to such a degree that there were sufficient dentists available for an army of 5,000,000 men. In the examination of recruits dental defects were remedied by the gratuitous performance of hundreds of thousands of operations. The Dental Corps division of the surgeon-general’s staff enrolled dental officers recommended them for assignment and promotion, appointed examining and review boards and developed plans for service in the United States and abroad. The examining and review boards consisted of an officer from the Medical Corps and two officers from the Dental Corps. Mobile operating dental units in the shape of motors equipped as dental offices on wheels were in use at camps in the United States and with the army in France. Dental officers were assigned to base and general hospitals, and the dental surgeons showed special skill in dealing with new problems.

Veterinary Corps.—The Veterinary Corps of the regular army consisted of 62 commissioned officers at the outbreak of the World War and was expanded to 2,100 officers and over 20,000 enlisted men. Veterinarians from civil life were commissioned in the grade of second lieutenant and by promotion might reach any grade to include that of colonel. Candidates were required to be graduates of recognized veterinary schools, between the ages of 22 and 55, and to pass a satisfactory mental and physical examination. The enlisted men assisted the veterinary officers and were not required to be veterinary graduates. They were enlisted in the grade of private and might be promoted to privates first class, farriers, horseshoers, wagoneers, cooks, corporals, sergeants and sergeants first class, for aptitude in the duties required in these various grades. The Veterinary Corps organized and operated mobile veterinary laboratories for examining and treating animals possessing public animals. Each regiment of cavalry, field artillery and engineers had two veterinary officers and six enlisted men attached to it for the care of sick and the preservation of the health of domestic animals. Each division had a division veterinarian who supervised the veterinary service of the division. All animals purchased by the government had first to be passed on, as to soundness by an army veterinarian. Shipments of animals by rail and all boats for transporting them overseas were accompanied by veterinary officers and enlisted men. Veterinary laboratories were maintained to aid in the detection and elimination of communicable animal diseases. The Veterinary Corps was also responsible for recommendations pertaining to veterinary sanitation wherever there were public animals. The meat inspection service of the Veterinary Corps covered the inspection of all meats and meat food products used by the entire army at the time of purchase and when issued to troops. All meats bought for shipment overseas were inspected by veterinary officers to make sure they were fit for human consumption and that they complied with govern
MEDICAL ORGANIZATION IN THE UNITED STATES ARMY

ment specifications. Animals slaughtered in the field for food purposes were also subject to inspection as were dairies and milk herds supplying milk to the army.

Veterinary hospitals and units were organized and operated by the Veterinary Corps for use in the theatre of operations. Some of these were established as hospitals on the line of communication and at the base, and others operated from the front to collect sick and injured animals and evacuate them to hospitals in the rear. Animals able to walk were led to the point where they could be loaded into railroad cars, while the more seriously injured ones were conveyed in motor ambulances. The hospitals were equipped with operating tables and complete outfits of instruments so that any necessary surgical measurement might be carried out. Special hospitals for communicable diseases were also established where infected animals were isolated for the protection of others. By these means it was possible to restore to usefulness many thousands of animals which would otherwise have been lost.

Army Nurse Corps.—The Army Nurse Corps recruits nurses for the service, enrolls them and controls their movements. There is one superintendent appointed by the Secretary of War, and chief nurses and reserve nurses are appointed and removed by the surgeon-general with the approval of the Secretary of War. The Army Nurse Corps consists of trained nurses. The Red Cross as the reserve of the Army and Navy Nurse Corps has supplied many nurses for the Army Nurse Corps. When once assigned to the Army Nurse Corps the nurse is subject to the rules of the army as administered by the surgeon-general’s office.

At the entrance of the United States into the war with Germany there were about 400 nurses and 7,000 enlisted men in the medical department. Less than a year later there were 7,000 nurses, and in September 1918 there were more than 6,000 nurses, making the Army Nurse Corps, of which number (from April 1917 to 1 Aug. 1918) the Red Cross had placed 13,111 nurses, the rate of assignment of nurses to the military authorities by the Red Cross having been 35 per day from the beginning of the war. The assignment of graduate nurses eligible for the Army Nurse Corps (as of 2 July 1918) was 22,736, including those serving in the Army Nurse Corps. It was estimated that 50,000 nurses would be required for an army of 2,500,000 (one nurse for 10 beds if 25 per cent were hospitalized, the maximum provided for, based on British experience, or with a minimum hospitalization of 17 per cent, 51,000 nurses for an army of 5,000,000). Emphasizing the need for nurses, the acting surgeon-general of the army stated on 17 Sept. 1918 that not only must 25,000 nurses be obtained before 1 Jan. 1919 (9,000 in addition to the 16,000 then in service), but (if the war continued) that by 1 July 1919, 50,000 would be required—thus indicating that in less than a year, 34,000 would have to come forward to meet the need. To increase the number of nurses there was established on 25 May 1918, under the surgeon-general, an Army School of Nursing, which gave immediate opportunity for enrollment providing an adequate course of training for young women between the ages of 21 and 35, who had a high school education or its equivalent; it at the same time made possible the release of a large number of graduate nurses eligible for service in the Army Nurse Corps. Under date of 13 Sept. 1918, the surgeon-general announced that the 50 American hospitals which organized base hospital units for service in France had been notified that they might invite a limited number of their student nurses to go to France, where they would have the privilege of rendering service and, at the same time, complete their training under representatives of their own schools in base hospitals abroad. These were mostly seniors, and those who went across included the young women who were first to be enrolled in the Army School of Nursing. Each unit of 25 was in charge of a graduate nurse. Student nurses not so far advanced were placed in base hospitals in the United States. Women called “hospital assistants”—a position created by the surgeon-general for women offering to nurse wounded soldiers—were enrolled through the Red Cross and assigned to convalescent hospitals in the United States, where training units were not established. These hospital assistants were married women between 21 and 40, whose husbands were overseas, and single women between the ages of 35 and 45. They were high school graduates or had present educational equivalents.

At the request of the surgeon-general certain well-known medical colleges allied with hospitals gave special three months’ courses for nurses’ aids. These young women were to serve as anesthetists, laboratory assistants, nurses’ helpers and, in emergency, ward nurses. There were, on 1 July 1918, 45,000 in training schools for nurses, and a campaign to recruit 25,000 student nurses was launched (July 1918), conducted under the auspices of the committee on nursing and women’s committee of the Council of National Defense, with the cooperation of the surgeon-general’s office and the American Red Cross.

Ambulance Corps.—The Ambulance Corps, which had in August 1918, 9,000 or 10,000 men with 80 sections serving behind the French, English and Belgian lines and 30 sections behind the Italian trenches, was temporarily distributed, on 23 Aug. 1917, in training at Allentown, Pa., was started at Allentown in May 1917, to meet the emergency needs of the French in response to an appeal by Marshal Joffre. One hundred sections were trained in driving ambulances, carrying the wounded in and in first-aid treatment. Forty colleges sent men, and there were soon 4,500 on hand. The service abroad absorbed the privately raised and financed automobile ambulance units manned by American volunteers. An ambulance section consisted of a captain or lieutenant commanding and 45 enlisted men. An officer of the Motor Transport Corps checked up on operation and maintenance. Hospital units of various kinds came to Allentown for training prior to departure abroad. The camp became strictly medical, with men in training not for all branches in this service, the men for the laboratory units, field hospital units and organization to conduct base hospitals being obtained principally from the medical training camps at Fort Oglethorpe and Fort Riley.

Hospital Corps.—The men of the Hospital Corps available for service with line
organizations and with the sanitary train are designated in time of peace, and at the time of mobilization for war they are ready to join their respective commands. Each has the proper personal equipment and has been instructed as to first-aid treatment. Field equipment is maintained at designated stations ready for use.

Sanitary Officers.—Medical officers in command of sanitary units attached to units of the line smaller than a division (the sanitary units being temporarily separated from direct headquarters control) report these units to the senior line officer in command.

The department surgeon is chiefly an advisory officer, but in matters relating to activities of the sanitary service within his department he acts in an administrative capacity, supervising the work of the department and examining and passing on reports. His watchfulness over sanitary conditions is constant and he immediately reports orally to the commanding officer as to remediable defects, with recommendations. In mobilization camps physical examinations are made and recorded by the department surgeon and sanitary inspector and their assistants, who also vaccinate against smallpox and typhoid fever, and report the sick list to the company commander, making appropriate records. Each mobilization camp for State National Guard troops was in charge of an officer of the regular army. He had on his staff a camp surgeon, usually a medical officer of the regular army. Surgeons at ports of embarkation and at rest stations were the sanitary advisers of the commanding line officers in all matters pertaining to the Medical Department. The Medical Department sees to it that all individuals and organizations in the army are furnished such equipment as pertains to the Medical Department, and such training in sanitary matters is given to both line troops and sanitary troops as is possible and as is appropriate to each.

The regulations defining duties of medical officers contain the following: *While officers acting as technical advisers of their commanders are responsible for pointing out sanitary conditions and making proper recommendations for their correction, the direct responsibility rests with the commander. If, however, the commander authorizes the medical adviser to give orders in his name for the correction of defects, then the duties and responsibilities of the latter are correspondingly increased.*

Contract Surgeons.—Contract surgeons are not given commissions, but they wear the uniform when on active duty. They are expected to give their entire time to the public service. Such medical officers are engaged by the Medical Department, and are medical officers in charge of large medical centers, hospitals, or other large medical institutions. They are, in effect, medical directors of large medical institutions.

Civilian Personnel.—In administrative offices, supply depots and hospitals, there are civilian employees, including clerks, watchmen, contract nurses, cooks, packers and laborers, those other than unskilled laborers being subject to civil service rules. Service volunteered in emergency by individual civilian physicians, nurses, litter bearers, cooks, et al., is often accepted by the surgeon of any organization operating independently, or by the commanding officer of a general hospital, with the consent of his commanding officer and under the authority of the surgeon-general.

The personnel of the Medical Department, and all other persons assigned to duty with it, are subject to a general order of the Surgeon-General.

Co-operating Agencies.—Other auxiliary and co-operative aids of the Medical Department, with which the office of the surgeon-general is in communication but does not control, include the War Department and Navy Department Commissions on Training Camp Activities (having supervision of regulations dealing with the suppression of the sale of alcoholic liquors within the five-mile zone around camps and cantonments and of prostitution within 10 miles), United States Public Health Service of the Treasury Department (which has recently taken over the work for civilian co-operation in combating venereal diseases), the Chemical Warfare Service of the War Department (which now has charge of gas defense activities), and the General Medical Board of the Council of National Defense.

General Medical Board.—The last-named body worked in close co-operation, and aided in the expansion of the nation's medical program during the war through co-operative interaction with federal resources with those of the government. It stimulated enrollment of physicians in the Medical Reserve Corps, and organized the Volunteer Medical Service Corps, aimed to enlist the services of all physicians, both men and women, during the emergency, who were not already in the government service. In November 1917 the provost marshal-general requested the Council of National Defense to nominate a man in each State as medical aide to advise the governor as to medical questions which would arise in connection with the operation of the Selective Service Law. The chairman of the General Medical Board appointed a committee on medical advisory boards, which met and selected a representative from each State. These were called to Washington and received their instructions. The committee on medical advisory boards formulated a plan, outlining the duties of these aides, in the selection of the personnel of medical advisory boards and organizing of medical activities under the Selective Service Act. Rules of procedure were prepared and approved by the provost
marshal-general. It was announced, 28 Sept.
1918, that medical aides in the States had a
position in the army of more than 500,000
personnel, and in other States with the grade of
captain.

The General Medical Board has committees
on child welfare, civilian co-operation for com-
bating venereal diseases, dentistry, editorial,
hospitals, hygiene and sanitation, industrial
medicine and surgery, legislation, medical ad-
visory boards, medical schools, nursing, pub-
licity, research, States' activities, surgery, volun-
teer medical service corps and women physi-
cians.

Surgeon-General's Office.—The office of
surgeon-general, as the heart of the Medical
Department of the army, during the war had a
great administrative group, with the immediate
office management in charge of chief clerk and
civilian employees, the several divisions being in
charge of army officers of special experience
and qualifications.

The enormous expansion in the work of the
surgeon-general's office is indicated by a few
continuing the work during the war and in
the United States (6 April 1917) that a state
of war existed between the United States and
Germany, the surgeon-general’s office staff
comprised six officers, including Surgeon-Gen-
eral Gorgas, and 20 clerks, and occupied three
rooms in the State, War and Navy Building.
By 1 Dec. 1917, 165 officers were detailed here,
there were 535 clerks, 300 office rooms were
required, five whole buildings and parts of 20
others were being occupied, and more space
was needed. By 1 Aug. 1918 officers in 13
special sections comprising 27 units of activity.
Within a year after the war began the whole
administrative force comprised 359 officers and
1,008 clerical employees, including enlisted men,
and 150,000 mail items and 9,500 telegrams were
being handled monthly. These figures do not
include the gas defense service, which later be-
came the Chemical Warfare Service of the War
Department, and attached to which there were
2,364 commissioned officers and 20,544 enlisted
men. On the evening of 31 March 1918, the
department personnel increased from 8,000 to
106,000; 900 officers to 18,000; 375 nurses to
7,000, and an ambulance service of 6,000 men
was entirely created. The seven hospitals in the
United States were increased to 63, with more
to come; their bed capacity of 5,000 was
increased to 58,400, and provision of bed ca-
pacity in France was made for 20 to 25 per
cent of the strength of the American Expedi-
tionary Forces. Whereas the appropriation for
the Medical Department in peace times was
about $1,000,000 a year, appropriations for the
fiscal year ended 30 June 1918, totaled $130,-
000,000, of which there had been expended up
to 1 April 1918, $95,000,000, and the current
annual outlay was at the rate of $160,000,000.

The Finance and Supply Division, in charge of
medical supply and disbursing officers, pur-
chases, stores and transports all supplies and
material for the Medical Department and dis-
burses and accounts for its moneys. Medical
supplies are issued in definite units and
amounts, the supplies to the various units of the
medical service and the sizes of original
packages being fixed by definite supply tables.

In addition to vehicular units for the trans-
portation of supplies, other units of transport-
tation in the Medical Department during the
war included mobile hospitals, wards and oper-
ating rooms, motor units in commission to
offices on wheels, x-ray motor outfits—the
modern substitute for the probing methods of
old-time military surgery—lorries bearing
steam delousing apparatus or disinfectors and
laundry trucks. Pack mules carry fixed quantities of
supplies. An officer of the newly-created Motor
Transport Corps was stationed with each com-
mand to check up on operation and mainte-
nance.

As the functions of the department were
and are preventive and curative, the Division of
Field Sanitation was of great importance, for
it recommended sites for camps, looked
after mosquito prevention, drainage, water sup-
ply, ventilation, the disposal of waste and the
elimination of flies. Spots near camps where
mosquitoes and flies breed were cleaned up.
Each camp had a division or camp surgeon,
and, as assistant, a sanitary inspector who had
the assistance of a sanitary engineer and
from 100 to 200 enlisted men, all trained and
designed to protect the health of soldiers. The
sanitary engineering section of the surgeon-
general’s office and sanitary engineers of the
construction division of the army co-operated
in inspections as to the need of increased sanita-
tory facilities and sewage disposal plants.
Ditching and oiling still bodies of water and
daily spraying with oil of breeding spots were
among the duties performed. Much of this
work was done in co-operation with the United
States Public Health Service and in a radius of
a mile outside the camps. Buildings where
food was prepared or stored were screened, and
a report in the late summer of 1918 stated that
22,700,000 square feet of screen had been placed
in all the camps and 6,000 fly-traps placed in
each camp. This work was largely responsible
for the prevention and control of epidemic
diseases.

Hygienic standards, collective and individ-
ual, of troops in camp and in transport on land
and sea, were being constantly improved.
Hygiene is taught West Point cadets and all
commissioned officers, so that they were en-
abled to teach the enlisted men; moreover,
the latter were given instruction by their
company officers in first-aid hospital train-
ing and field hospital work; this instruc-
tion being supplemented by drills of sanitary
units in the presence of the enlisted men.

Mamphlets and moving pictures were further
used in instructing in hygiene, and in the pre-
duction of venereal diseases. In addition to thour-
ough physical examination, all officers and en-
listed men of the army under 45 years of age
were required to be immunized against typhoid
fever. All recruits and all the personnel of a
military command were vaccinated against
smallpox when the surgeon responsible deemed
it necessary. Special units were provided for
men with remediable physical defects, special-
ists aiding the surgeons in charge. Tests also
were made to detect syphilis.

The precautions and supervision in the
camps for the young men taken from civil life
into the army resulted in the showing for the
week ended 9 March 1918 of an annual death
rate from disease of 6.6 per 1,000, a figure be-
low that of men in civil life ranging from 20
to 39 years of age, the census bureau giving the rate for this class as 6.7. Steady reduction of the disease continued in the succeeding months and for the week ended 26 July it was reported that the annual death rate from disease, based on combined reports of the American Expeditionary Forces and of troops stationed in the United States, was 1.9 per 1,000 less than two men per 1,000 per year. The average annual death rate from disease during the two months ending 26 July was 2.8 per 1,000. For the sake of comparison, in the Crimean War the English and French lost 350 of every 1,000 men through disease; in the Mexican War in the 40's the annual death rate from disease of United States troops was 100 per 1,000; in the Civil War, 40 per 1,000 in 1862 and 60 per 1,000 in 1863; in the Spanish War, 25 per 1,000; and in the Russo-Japanese War, 20 per 1,000, this being the lowest previous annual death rate from disease. From statistics of the executive division of the general staff of the army, it appears that, in the Mexican War, seven men died from disease to one killed in battle; in the Civil War the disease mortality, though greatly reduced, was still nearly double the battle mortality; and in the Spanish War there were more than five deaths from disease to one in battle; and in the first 10 months of American participation in the World War the records of the American Expeditionary Forces show an exact parity between battle mortality and disease mortality, but this is little more than half of the battle mortality and less than a third the disease mortality of the Civil War.

Particular attention was paid to empyema and to pneumonia epidemics. A special commission of physicians and pathologists studied the problem, aided by special teams of physicians and pathologists in each camp. The division of surgery perfected arrangements, in accordance with the system recommended by the commission, for quarantine and isolation and prophylaxis. The methods employed were necessary on account of the gatherings of large bodies of recruits. If, despite precautions, empyema did result, the surgeons adopted the policy of treating by operation for drainage of the chest.

The division of food and nutrition placed number of officers in every camp, and where at least 10,000 were in training, in the United States and abroad. Nutritional surveys were conducted for the purpose of investigating food in storage, in transit and in preparation; cooking and wastage were studied in all the camps, methods improved, economies instituted, and dietetics taught. Studies as to the exact amount of food consumed and percentage of waste in more than 100 messes in 40 camps were made and instructions given to mess officers. The bill of fare was carefully balanced for wheat, starch, fat, protein, minerals and vitamin, and for sugar. The soldiers under General Pershing received 3,500 to 4,200 calories of heat units daily as compared with the 2,500 calories deemed sufficient for the ordinary citizen. All nutrition officers were food specialists, mainly men and women who had been connected with colleges and public bodies as physiologists, chemists and food inspectors. As a concrete result of a two-day survey of seven companies (1,135 men), the average edible waste was found to be 1.12 pounds per man per day. Appropriate instructions as to food and menus were given to mess sergeants and cooks, and a few of the same companies showed waste of .43 pounds per man per day—a saving of .69 pounds, which was equal to $61.75 per day for the seven messes, $225.54 per year. If this rate prevailed throughout the camps of 15,000 men, the total saving would be about $300,000 per year.

A statistical bureau attended to the collection and co-ordination of memoranda and records of sick and wounded, from the time of injury until discharge from the hospital. These records were kept in the most approved way in the surgeon-general's office with the aid of punching, tabulating and sorting machines.

Deaths of officers and men of the military personnel were immediately reported in writing to the commanding officer. Deaths of medical officers were reported by the attending surgeon or the nearest medical officer to the department surgeon, duplicate being sent to the surgeon-general.

Medical and dental students in civilian life, whose age placed them within the jurisdiction of the selective service law, were permitted to enlist in the Enlisted Reserve Corps and placed on inactive duty so that they might continue their college courses while subject to call to active service. The Army Medical School in Washington gave instruction to junior medical officers who had passed their examinations for entrance into the regular army. The faculty, comprising commandant, professor and assistant professors, were detailed by the War Department from among the officers of the Medical Corps. Special professors were nominated by the faculty with the approval of the surgeon-general from among distinguished members of the Medical Reserve Corps. As instructors there were officers of other branches of the army detailed by the War Department to give special courses. Officers of the Medical Reserve Corps who were candidates for appointment in the Medical Corps attended as students; also such officers of the army and organized militia as might have been ordered or authorized to attend; also enlisted men of the Hospital Corps. The equipment included library, laboratory, and all the other usual appointments of a medical college. Important in the system of training was the training school at Camp Greenleaf, Fort Oglethorpe, Georgia, where 2,500 physicians from civilian life entering the Medical Reserve Corps as officers and enlisted men of the medical department (Hospital Corpsmen) were constantly undergoing an intensive three months' course in training for all phases and branches of military medicine and sanitation, including physical instruction and administrative duties. The physicians could here study branches for which they might never have opportunity in their civilian practice. Special opportunity for instruction in surgery was afforded by three schools in New York City, and one each in Philadelphia, Rochester, N.Y., New Orleans, Chicago, Saint Louis and Cleveland. A medical and surgical school in Paris for surgeons of the American Expeditionary Forces afforded an intensive course of one month in administration, surgery and sanitation.
with lectures by experienced surgeons; and young American surgeons had an opportunity of observing methods at French and British casualty clearing stations before being placed in base hospitals for their initial war work. The next step of the young surgeon was as head of an operating surgical "team" manning an evacuation hospital.

The Division of Internal Medicine, Tuberculosis and Cardio-Vascular Diseases selected expert examiners to eliminate the physically unfit and to guide defective men to treatments calculated to restore them to future efficiency in military and civil life. Hundreds of thousands of examinations for tuberculosis and diseases of the heart were made. This division provided hospitals for incipient cases of tuberculosis as well as for advanced cases. It also provided for examinations of gastro-intestinal diseases.

The Division of Infectious Diseases cooperated with the Division of Sanitation by selecting bacteriologists, pathologists and other laboratory men, establishing pharmacies, laboratories for army posts and mobile units for general, special and research work, a laboratory being attached to every army post, mobilized division and army corps. Tests of blood specimens and analyses of stomach contents and water from laboratories were made in the division. The medical officer is held responsible for the application of approved methods for preventing the spread of infectious diseases, the three infections most dangerous to armies being venereal, the pneumonias and cerebrospinal meningitis. Typhoid and paratyphoid are controlled at the start by vaccines, the efficacy of which was first developed by Sir Almroth Wright. Quarantine guards against measles, diphtheria and influenza; diarrhoea and dysentery are kept to the minimum by pure water, pure food and reduction of the fly nuisance. Modern medical science keeps away the old plagues of army camps—cholera by isolation, disinfection and vaccine; and spotted typhus by delousing and by heating shelters.

In the early stages of the World War, tetanus was common in the European armies, but the Americans were in the lucky position of having relatively few cases. Research into causes of trench fever and tests in which the famous 66 volunteers from among the American soldiers played an important part, have led to the discovery that its transmission was due to the bites of body lice. An appropriation of $100,000 and co-operation and research with French and British surgeons are to be credited for this achievement. Trench fever had been incapacitating 8 to 10 per cent of our personnel during 1916-17 for periods of from two to three months. The importance of eliminating body-lice or "cooties" led to provision for delousing apparatus, with twin disinfecting chambers mounted on a five-ton lorry so that operation could be carried on near the trenches. Steam at five pounds pressure was passed through the air-tight chamber containing clothing to be treated, killing all living matter. Eggs remaining in seams after the disinfecting operation were removed by stiff wire brushes.

The Division of Urology (genito-urinary diseases) looked after the prevention of venereal diseases by employing prophylactic, sociological and educational measures—through the enforcement of public health and vice laws, recreation for the soldier, educational measures such as lectures, moving pictures, exhibits and literature, and also through thorough prophylactic treatment and segregation. It published a manual on venereal disease, in co-operation with the Council of National Defense Committee for Civilian Co-operation in Combating Venereal Diseases, and with the War Department and Navy Department in Coordinating Training Camp Activities. There was strict enforcement of the provisions against alcohol in the five-mile zones surrounding camps and cantonments and against prostitution within ten-mile zones. This work in the civilian territory adjacent to the camps and cantonments was placed under the United States Public Health Service of the Treasury Department in the summer of 1918.

The Division of Psychology sought to eliminate the mentally unfit and to facilitate the placing of men according to ability. All company officers and enlisted men were examined and the mentally superior encouraged by assignment to duties for which they were evidently fitted. Of the 130,000 examined by this division, more than 1 per cent were rejected as mentally unfit for military service. The Division of Neurology and Psychiatry was organized because it was the experience in the Allied armies that a large number of neurotic, mental and other defectives were found, who soon became useless for field service. While physically sound, they were incapable of becoming soldiers because of insanity, mental defect, epilepsy, drug habit or other nervous disorders. This division took special charge of victims of the varieties of "shell shock," who are cared for in a base hospital specially set aside for such cases, and it also had charge of aimless for insane and of the men in the nervous and mental wards in the military hospitals.

The Division of Surgery classified the surgeons in the Medical Reserve Corps—continuing the code card system begun by the General Medical Board of the Council of National Defense—trained them in special schools, assigned them to posts and provided for an adequate and time for hospital supplies at such posts. Military surgery was largely revolutionized during the war. Wounds were thoroughly operated upon as soon as possible after a man was hit, all lacerations and surrounding flesh being cut away and the danger of infection by tetanus or gas gangrene bacilli reduced to a minimum. Owing to modern methods of sterilizing infected wounds, of the wounded who survived six hours, 90 per cent recovered; of those who reached field hospitals 95 per cent recovered; and of those who arrived at base hospitals 98 per cent recovered. Paraffin compounds found favor with many surgeons as dressings for burns and scalds. The subdivision of military orthopedic surgery dealt with the correction of deformities resulting from wounds and injuries, and supplied standardized splints, artificial limbs and similar appliances. This section paid particular attention to soldiers' feet and the shoes they wore and took measures to prevent and cure trench feet, insisting upon properly drained trenches and prescribing loose, comfortable foot
and leg wear and nightly washing and greasing the feet (clean socks in abundance). Under its supervision were orthopedic work-shops for making plaster casts, artificial limbs, splints and other supplies incident to the correction of deformities.

The Division of Special Hospitals and Physical Reconstruction became of greater and greater importance as the war progressed. In addition to the separate hospitals for the relief of cataracts and special provision was made for groups of medical and surgical injuries, the blind and the deaf.

The Division of Surgery of the Head included four sections: ophthalmology, otolaryngology, plastic and oral surgery, and brain surgery. This division supervised the selection, classification and intensive training of medical reserve officers in brain surgery, specialized surgery of the mouth and jaw, and eye and throat. It also equipped the Ophthalmology and Material hospital and selected optical equipment for use at the front. Those in charge of this division were instrumental in perfecting methods for making artificial eyes to take the place of those previously made by women and were also responsible for devising excellent types of goggles for aviators. This division published a monthly magazine, Survey of Head Surgery, containing articles and abstracts of articles calculated to be of value and interest to military surgeons. Through close teamwork of the oral surgeon, dental surgeon and dentist comprising each unit at the front, many unusual operations were performed during the war, in the repair of portions of the face and jaw and of men injured in battle, new features and jaws being supplied by the experts in plastic and dental surgery.

In general, the purpose of reconstruction was to return the injured man to complete or partial military duty or to his former occupation in civilian life, or to train him anew in a curative workshop. This work of reconstruction in the American army was on a comprehensive scale. Individual study of each injured soldier was made and his repair attempted according to best surgical and physical principles. No man was discharged from the army until every possibility had been exhausted to put him back in the best physical condition. Massage and various electrical appliances and mechanical devices were used in convalescence, to restore muscular movement in limbs and extremities, and artificial limbs were employed enabling the mutilated man to use all manner of tools and implements and to perform the daily functions of civilized life. The Division of Physical Reconstruction edited and the American Red Cross published a monthly magazine, Carry On, relating to phases of this important work.

The Division of Hospitals planned and organized all army hospitals, convalescent camps, depots and hospital trains, supplying all their personnel including specialists in surgery, medicine, bacteriology, epidemics, heart, head, nerves, feet and the more prevalent and dangerous diseases. Up to the entrance of the United States into the war, there were only seven army hospitals in the United States, seven having a bed capacity of 3,843. Including the army post hospitals, the bed capacity was about 5,000. A survey of prospective needs led to requests for 80,472 beds and of these there were ready in March 1918, 48,632, and hospitals with capacity of 29,140 were under construction. Hospital requirements in the United States when the war began were estimated at 200,000 beds by then Brig Gen. Robert E. Noble of the surgeon-general's staff in late September.

The hospitals in the United States were of three types: (a) receiving hospitals at ports of departure; (b) base hospitals, of which there were 44, including 32 at National Army and National Guard camps; and (c) general hospitals. Of the total of 79 hospitals established, 29 were equipped to care for more than 1,000 patients each, and 17 to accommodate 2,000 each.

The sending of large forces to France necessitated the establishment of a great medical and hospital organization under the medical officer on the staff of the general commanding the American Expeditionary Forces. With headquarters in Hoboken, N. J., had jurisdiction over operations on the Atlantic coast from Canada to Florida and had on July 1918, 33 medical department organizations. In addition to the officers, the 15,000 doctors and nurses, 2,649 enlisted men and 65 civilians. The divisions included those on personnel, correspondence, dental service, history and statistics, sanitary inspection, property, finance, transport supply, transport, transportation (with seven hospital trains and 23 ambulances), transatlantic transport service, medical detachment, overseas casualty camp, sick and wounded, medical supply depots, nurses' mobilizing stations, attending surgeons, laboratory (for pathological, bacteriological, chemical and microscopic examinations and analyses), hospital building and domiciliary hospital (in charge of convalescent hospitals in private homes, with capacity of from two to 50 patients each and a total of 1,200 patients) in addition to the hospitals. The 13 hospitals had 12,500 beds, of which 11,000 were ready for occupancy on Oct. 1918. A man found sick in a unit about to go across was quickly sent to an embarkation hospital; when he recovered, he was reappointed to his own unit or transferred to a unit other than that to which he originally belonged. Embarkation Hospital No. 1, at Hoboken, had 763 bed capacity; No. 2 for scarlet fever, mumps and measles, was at Secaucus, N. J.; and No. 3, for communicable diseases, off Hoffman's Island, had 694 beds. On the Columbia University oval, Williamsbridge, New York City, was General Hospital No. 1, with 1,100 bed capacity; United States Auxiliary Hospital No. 1 (Rockefeller Demonstration Hospital for demonstrations and training on scientific investigations), was at 66th street and Avenue A, New York City, and it had 150 beds; Port Newark Terminal, N. J., had a post hospital with 30 beds; the base hospital at Camp Merritt, Tenafly, N. J., had 1,866 beds; the base hospital at Camp Mills, Long Island, had 1,506 beds, and the hospital at Schuette Park, N. J., was planned for 400. At the deharkation hospitals the patients were sorted and sent to various special hospitals at sanitarium post hospitals, state and private homes, throughout the United States. The deharkation hospitals were: No. 1, Ellis Island, 1,075 beds; No. 2, Fox Hills, Staten Island, 1,762 beds; No. 3 (Greenhut Department Store)
Sixth avenue and 18th street, New York City, 2,514 beds; No. 4, Long Beach, L. I., 1,800 beds, and No. 5, the Grand Central Palace, Lexington ave. and 46th street, New York City, rented for $385,000 yearly, with 3,300 beds.

The general hospitals, of which there were 27, were the only ones for troops returning from Europe. Twenty-two were in September 19, completed, or nearly so. The total bed capacity in these general hospitals was about 20,000. It was planned to have one general hospital for each of the 16 draft districts of the country, distributed so that sick and wounded soldiers could recover near home. Orthopedic hospitals were established at Washington, D. C., Baltimore, Md., and Colonia, N. J. There were neuropathic hospitals at Fort Porter, N. Y., and New York City.

The surgeon-general designated the following 15 general military hospitals for the work of physical reconstruction: Walter Reed General Hospital, Washington, D. C.; General Hospital No. 2, Fort Henry, Md.; General Hospital No. 3, Colonia, N. J.; General Hospital No. 6, Fort Monroe, Va.; General Hospital No. 8, Roland Park, Baltimore (for the blind); General Hospital No. 8, Otsisville, N. Y.; General Hospital No. 4, Fort Porter, N. Y.; General Hospital No. 9, Lakewood, N. J.; General Hospital No. 11, Cape May, N. J.; General Hospital No. 15, New Haven, Conn.; General Hospital No. 17, Markleton, Pa.; Letterman General Hospital, San Francisco, Cal.; United States Army Hospital, Fort Des Moines, Iowa; Plattsburg Barracks Hospital, Plattsburg Bar- racks, N. Y.; General Hospital, Fort Bayard, N. M.

No man was brought to this side as long as there was a reasonable chance of his being able to return to the firing line. Eighty-five per cent of all wounded were returned to the firing line in a comparatively short time. Fifteen per cent of the total sick and wounded were not able to return to the firing line within six months and they were classified and tagged in France according to wounds, sickness and disease, all located on arrival on this side and sent by train to the various general hospitals. Of the 15 per cent brought to the United States, one-third were later capable of some kind of military service. Of these, some were sent back to the firing line of trained for limited military service.

Those disabled to the extent that they were unfit for further military service, if it was deemed desirable, were fitted again for their former employment; or, if their injury precluded or circumstances indicated that change of occupation would be to their advantage, they were encouraged to take advantage after discharge of the benefits afforded for vocational training by the Federal Board for Vocational Education, which had charge of the rehabilitation, generally, of this class of ex-soldiers and sailors. It was recognized that a small group was and will be unfit for any work.

It was estimated that about 1 per cent of the soldiers would require substitute for vocational training; as the United States army has about 4,000,000 men, there are 40,000 to retrain. A half of the men susceptible of recuperation need medical rather than surgical care. Of the 20,000 surgical cases, about 2,000 are dismemberment cases, where there has been actual loss of arm, leg, hand or foot. Of the 2,000, about 250 have lost legs, and about 175 an arm or arms.

There were seven hospital trains in the United States. Each train was in charge of a transportation officer. In each train there was a convalescent capacity for 250 patients, and a bed patient capacity of 30. The trains were provided with every convenience and there were several types of coaches, kitchen cars, dining cars and unit car for the staff. On occasion, special coaches were provided for disabled returning soldiers to be attached to passenger trains. There were six hospital boats, ready with picked crews and nurses.

Staffs of hospitals were administrative and professional. The commanding officer in charge of a general hospital was a colonel or lieutenant-colonel of the Medical Corps. He had, as adjuvant, a major of the Medical Corps whose staff of 17 includes surgeons, privates and civilian employees. The registrar was a major or captain of the Medical Corps; he had a staff of nine sergeants and privates. The quartermaster was a major or captain of the Medical Corps; his staff of 61 included a captain or lieutenant of the Medical Corps (who was in charge of the hospital mess) and 60 sergeants, corporals and privates, and civilian employees. Officer of the day, officer of the guard and chaplain completed the administrative staff. Professional division—the chief of the medical service was a major and serving under him were two sergeants and two privates.

The surgical service consisted of one major, one captain or lieutenant, one sergeant, two privates and five army nurses. In the wards there were 12 captains or lieutenants of the Medical Corps, 6 sergeants of the Hospital Corps, 70 privates, Hospital Corps, and 52 nurses of the Army Nurse Corps. In the laboratory there was a captain or lieutenant of the Medical Corps, a sergeant first-class, two sergeants and four privates, all of the Hospital Corps. The dental service was in charge of one lieutenant of the Dental Corps, who had one private of the Hospital Corps as assistant. The nursing service comprised one chief nurse, nine assistants and 53 nurses. One head nurse in each ward served eight hours daily and was on night duty one month in three. In each convalescent camp there was a captain or lieutenant of the Medical Corps and one sergeant first-class, one sergeant and six privates, all of the Hospital Corps.

The grade classification of the personnel of a general hospital was as follows: Twenty medical officers (1 colonel commanding, 1 major, operating surgeon; 18 captains and lieutenants, including quartermaster, pathologist, eye, ear, nose and throat specialist, 2 assistant operating surgeons, 12 ward surgeons, dental surgeon); 8 sergeants first-class (1 general supervisor, 1 each in charge of office, quartermaster supplies and records, kitchen mess, detachment and detachment accounts, patients' clothing and effects, medical property and records dispensary); 16 sergeants (1 in dispensary, 3 in storerooms, 1 in mess and kitchen, 4 in office, 2 in charge of police, 6 in charge of wards); 14 acting cooks; 115 privates first-class and privates (68 ward attendants, 3 in dispensary, 5 in operating-room, 1 in laboratory, 14 in kitchen and mess, 6 in storerooms, 4 or-
they might in no wise hamper the movements of the combatants. They were constructed or adapted specially and solely with the view to aiding the wounded, sick and shipwrecked. Each was painted white with a broad horizontal band of green.

The personnel of a hospital ship having 200 bed capacity consisted of 5 medical officers (1 lieutenant-colonel or major, 4 captains and lieutenants), 1 sergeant first-class, 4 seamen, 5 acting cooks, 30 privates first-class, of whom 29 were nurses and 1 an orderly.

The Division of Roentgenology provided X-ray apparatus and trained specialists to cooperate with surgical units. The importance of the X-ray as the modern substitute for the probe was recognized and X-ray laboratories were established in hospitals in the United States and France. Mobile X-ray units also came into use. Each vehicle was a standard army ambulance with a few modifications, having complete X-ray equipment including a dark-room in which plates and films could be developed. It had its own power-plant distinct from the propelling engine of the vehicle. An X-ray ambulance of Surgeons and ten on call service. The main headquarters of the mobile hospital branch was in charge of a colonel and 5 chiefs of the surgical staff for 5 sections.

Hospital trains specially fitted and arranged for the comfort of the wounded were in use in the theatre of operations to convey the wounded from the evacuation hospitals to the base hospitals. One of the American hospital trains in operation in France was 190 feet long and consisted of 16 coaches. There was a fracture ward and an infectious disease ward, and the train accommodated 560 patients in cots, or 480 sitting down and at the same time 120 in cots, making 600. Each ward had 36 cots hung in tiers of three. The equipment was as complete as that of any hospital in the United States. The staff of the train included 3 medical officers, a manager, 2 lieutenants, a surgeon first-class, 2 surgeons, 2 cooks and 8 enlisted men. Operating-room, kitchen, pharmacy, stores and staff carriages were also provided.

Hospitals for prisoners of war were located adjacent to prison camps and stockades. The three hospital ships, the Solace, Mercy and Comfort, placed in commission, were originally 10,000-ton merchant ships. The Mercy, a typical hospital ship, carried 321 bunks for the sick, and it was possible to use space for 100 to 200 more by use of cots and Gosso beds. Every department found in a well-equipped hospital was provided and there were surgical, medical, gyno-urinary, eye, ear, nose and throat, contagious and convalescent wards. Each department was presided over by a specialist with an assistant, regular or reserve force officers of the navy. There also were roentgenologists, laboratory men, dentists, pharmacists, 8 pharmacists’ mates and 3 trained male nurses. There was a library, and as recreation for convalescents, music was provided by a band and victorias, and there were facilities for moving pictures. The ship was provided with 100 ambulances and motor boats, each accommodating about 16 stretchers.

Regulations provided that military hospital ships might not be captured while hostilities lasted, their names having been communicated to the belligerent powers before their use, but

In the Air-Service Division, flight surgeons and physical directors were appointed, the corps being large enough to equip each training field and camp for fliers in the United States and in France, with a proper organization. The medical branch of the air service selected the fliers and looked after their care and condition, as so to reduce to the minimum accidents due to physical unfitness. The flight surgeon at a camp prescribed rest, recreation or temporary relief from duty, as the case required. He made sick calls on aviators, visited cases in hospitals and consulted attending physicians regarding these cases. Tests were conducted to determine effects of rarefied air upon aviators. The flight surgeon and the physical director, who is his assistant, lived in close touch with the fliers. The physical director supervised the recreational and physical training. For use in emergency at flying fields or airfields there were ambulance air planes or flying ambulances — standard training planes with the rear cockpit cleared and enlarged sufficiently to permit of a combination stretcher seat to enable the injured man to be propped up and rest easily. These air ambulances were of value because of their speed, ability to reach places not readily accessible by automobile ambulance, and because they assured a gentle and comfortable journey. The flight surgeon and a skilled pilot went in the flying ambulance when emergency arose, the surgeon taking necessary for first-aid and minor operations. Flight surgeons qualified as pilots whenever possible.

Army medical men used the results of chemistry, medicine and mobilization attention to combat and overcome poison “mustard” gas and the various other scientific diabolical methods of warfare in which Germany set the pace. The Division on Gas Mask Defense (later placed under the Chemical Warfare Service,
the United States Army

a separate branch of the War Department) established schools in each camp, in which every officer and man was instructed in gas defense. A gas mask giving far greater protection than the German mask and at least equal to that used by any other army was devised and supplied to both the men and horses in the American forces. Special sections provided the masks, insuring their use in daily drills and attended to repairs overseas. Soldiers were required to adjust masks in six seconds.

The Army Medical Museum and Library of the surgeon-general's office are important aids in the work of the Medical Department and instruction in military medical matters. The Museum, of which Col. William O. Owen was for many years the officer in charge, is operated for medical and scientific research and is a central clearing-house for pathological specimens. It contains the most remarkable collection of gunshot fractures in existence (from the Civil War), also laboratory workshops, art department, complete motion picture department. Pathological specimens from the front were assembled, catalogued and co-ordinated with the corresponding clinical histories for investigation purposes. The library, which is really the National Medical Library, is a source of medical information to the Medical Corps and to the medical public in general. It is second only to that of the Paris Medical Faculty in number of volumes and is the most useful and valuable of all medical libraries in that it has the finest collection of medical periodicals in the world.

Here the Surgeon-General, a statutory organ of the Medical Corps and of the Association of Military Surgeons, is edited and published. The surgeon-general passes on medical articles for publication by medical officers through the board of publications. Much valuable material bearing upon the Great War has already been issued with his sanction.

Records of health conditions, reports and statements of sick and wounded, and all manner of other data will be here available for the 'Medical and Surgical History of the War,' which is being compiled, to be published within five years after peace is declared. Medical and surgical material of value bearing on epidemics, group diseases or unusual surgical cases, were sent to a new divisional hospital; after September, 1917, made tabular statements concerning the movement of preventable diseases, based upon periodic telegraphic reports made to the Division of Sanitation from the 31 separate cantonments. This compilation will be made a first installment of the history of the mobilization of the United States army.

The senior medical officer on the staff of the commander of a field army is a chief surgeon; the senior medical officer of the line of communication is a surgeon, base group; the surgeon in charge of the zone of the advance is a division surgeon, with the grade of colonel; of a brigade operating independently, brigade surgeon, of a detachment (regiment or small command); the medical guards from the line are detailed to sanitary formations and the commander of the guard is a commissioned officer, he confers with the medical commander as to the character of guard duty desired, but exercises no control over the sanitary formation. Guards may use their arms in self-defense or in defense of the sick and wounded. Field hospitals when not parked with divisional trains are ordinarily guarded by ambulance companies. All sanitary troops and camps are surrounded by sentinels detailed to guard sanitary formations, falling into the hands of the enemy do not become prisoners of war, but are disposed of under Article 12 of the Geneva Convention, 1906.

The mobility of an army is essential; therefore the Sanitary Service must operate efficiently, in such a manner as not to obstruct military operations, and with a minimum amount of transportation and personnel. In the Zone of the Advance the medical administration provides only emergency treatment and prompt transportation of the wounded to the rear, always with such disposition that men fit for duty are retained at the front and the fighting force relieved of the impediment incident to the presence of men incapacitated for duty. When battle imponds, the resources of the Sanitary Service behind the Zone of the Advance are placed in readiness to meet the demands for the care and transportation of the wounded, which may reasonably be expected, and personnel and supplies are advanced as near the seat of operations as practicable, reaching forward into the Zone of the Advance if conditions warrant it. The Sanitary Service of the Line of Communication (1) provides such facilities that the wounded may return to the front without delay; (2) furnishes prompt evacuation service so that the fighting forces will be promptly relieved of wounded and the Sanitary Service of the Zone of the Advance can keep in touch with their combatant organizations; (3) furnishes a system of supply to enable the sanitary troops in the Theatre of Operations to replenish equipment and supplies by direct method and without delay; and (4) maintains satisfactory sanitary conditions among the troops on the Line of Communication and, if necessary, takes charge of sanitation among the inhabitants of occupied territory.

The Ambulance Service supervises transportation of wounded from the first-aid stations to the base hospitals. On the march not in the immediate presence of the enemy an entire ambulance company may be placed with the advance guard. Ambulances of one or more companies may be distributed through the entire body, an ambulance following each regiment or independent battalion; later, these join their companies. An ambulance company operates in two parts, with personnel at war strength as follows: (a) With the dressing station, including the litter bearers, with equipment on mules; four officers, one sergeant first-class, six sergeants, one acting cook, 40 privates first-class and privates—all of the Medical Department—and (b) with the wheeled transportation; one officer, one sergeant first-class, one sergeant, one acting cook, 28 privates first-class and privates (one as farrier, one as saddler, 20 musicians, 12 as ambulance drivers and 12 as ambulance orderlies)—all of the Medical Department; also, one sergeant (blacksmith) and three privates (drivers) of the Quartermaster Corps. Regulations provide that all ambulances, wagons, animals, hospital trains, ships and boats, with their personnel assigned to the Medical Department, shall not be diverted from the medical service. Supplies for the sick
and wounded are transported so far as possible by the medical superintendents of the Transport Service. For evacuation of the wounded to the rear, all transport available is pressed into service, including combat wagons, field train wagons, automobiles and other civilian transportation of all kinds.

While the organization of the Medical Department may logically be treated first with a general consideration of the various branches of the service and divisions of the surgeons' general's office, and with the successive steps taken in building the service from the interior to the battlefield, in considering the Theatre of Operations one must visualize the entire cone above the base, through the Line of Communication and Zone of the Advance to the very forefront of battle. And as casualties regularly pursue a course backward from the active front, consideration of medical activities in the Theatre of Operations will well be in this order.

The wounded man applies a dressing from his own first-aid or converts his belt or shoe lace into a tourniquet if able—or a comrade does it for him if he is incapacitated.—when medical aid by a regimental medical orderly is not available. As the engagement develops, an Aid Station is established for each regiment as the number of wounded brought in by the field ambulance bearers warrant. (In many cases bandmen are assigned to duty as stretcher bearers for first aid.) The time and place for opening an aid station are determined by the organization commander, unless he has authorized the surgeon to use his discretion in the matter. In this case, the surgeon of each regiment, with the necessary equipment carried on a pack mule, establishes the station. The Aid Station is always in immediate touch with the combatant unit. The requirement that the sanitary personnel with combatant organizations keep in touch with those organizations may make it necessary for them to leave the wounded where they fall, pausing only to administer such aid as may be absolutely essential. In the case of mounted troops, the sanitary detachment accompanies troops during the whole course of the operations. As quickly as possible, enough time to render first aid and to collect the wounded at a place where they can be turned over to an inhabitant to be cared for. Cases left behind will be collected and cared for by the dressing station party as it advances. In some cases dressing station and aid station are located together. Treatment at the Aid Station at which the wounded are originally assembled by the Sanitary Service is usually limited to first-aid and to readjustment of dressings, with sometimes an emergency operation. During and after an engagement diagnosis tags are attached to all wounded (and also the dead) as soon as practicable; they are made out in duplicate. At these stations the Sanitary Service with the troops connects with the service of the sanitary train. Men with trivial wounds are sent back to their commands when the wounds are dressed. Those slightly wounded but able to walk are directed to the station for slightly wounded, several miles in the rear, so that dressing stations and field hospitals have not to be congested unnecessarily. If time has permitted the installation of a more elaborate system, the wounded may be taken by trolley from the trench first-aid station through a communicating trench to the Advance Dressing Station; otherwise they are taken on hand stretcher or perambulator.

Each ambulance company establishes a dressing station (including field ambulance) in a definite location, usually some distance in the rear of the aid station (in trench warfare about 400 yards from the front trench) and an advanced surgical post adjacent, where urgent operations under bomb-proof are performed. The number and location of dressing stations are determined by the division surgeon, acting under instructions of the division commander, and the director of ambulance companies supervises their opening. At these dressing stations light nourishment is provided, dressings are examined and adjusted, splints applied, antitetanus serum injected, morphia tablet given if the man is suffering acutely, and an iodine cross mark on the forehead to show that this attention has been he in this order.

As soon as a dressing station is opened, bearers proceed under the direction of a medical officer to the front as far as the enemy fire permits. Ordinarily they will be divided into as many sections as there are aid stations, and each section under a noncommissioned officer will proceed toward an aid station. These men direct wounded able to walk to the station, for slightly wounded, and they transport other wounded from the aid station to the dressing station. As soon as the line of evacuation of the wounded is determined, ambulances are brought to the dressing station; they must arrive as early as possible, even at the risk of losses. Quick action is necessary to provide shelter, nourishment and emergency treatment.

The system of evacuation of the wounded may be carried on by narrow-gauge railroad from the advanced surgical post to the field hospital, man-power push-carts being used.

If the wounded man arrives at the field hospital in good condition, he is not unloaded but is sent on to the evacuation hospital. The field hospitals generally have only a limited equipment, no beds or cots, but straw over which blankets are spread. During and after an engagement diagnosis tags are attached to all wounded (and also the dead) as soon as practicable; they are made out in duplicate. At these stations the Sanitary Service connects with the service of the sanitary train. Men with trivial wounds are sent back to their commands when the wounds are dressed. Those slightly wounded but able to walk are directed to the station for slightly wounded, several miles in the rear, so that dressing stations and field hospitals have not to be congested unnecessarily. If time has permitted the installation of a more elaborate system, the wounded may be taken by trolley from the trench first-aid station through a communicating
of whom is an adjutant and quartermaster and four are ward surgeons); three sergeants first-class (one acting first sergeant in general supervision of the hospital and in charge of medical property and records; one in charge of transportation and quartermaster property and records; one in charge of mess supplies and cooking in hospital proper; one in charge of dispensary, one in charge of operating equipment, one in charge of patients' clothing and effects, three in charge of wards); three acting cooks; 55 privates first-class and privates (45 attendants, 9 orderlies, 10 hospital police, one medical orderly, four orderlies, three supernumeraries), and of the Quartermaster Corps, one sergeant (waggon-master) and seven privates (drivers).

The regimental camp infirmaries and the four ambulance companies are all in charge of one major, designated as director of ambulance companies. He makes frequent inspections, supervises the removal of wounded and directs the opening of dressing stations and advanced surgical posts. He is assisted by a sergeant and a corporal in each company, one in each of the ambulance companies, and in each of the ambulance units, both mounted.

The evacuation hospital (casualty clearing station) has been styled the keystone of the military hospital system. It is the first sanitary unit in which provision is made to retain patients for any length of time, and it is in the evacuation hospital that the great mass of rapid war surgery is done. Evacuation hospitals are often located in pairs and occasionally with special hospitals for shock and head cases in connection. They are from 5 to 10 miles from the front, but as near up as possible and on good roads, often on railroads. But all their equipment is light and mobile, so that it can be quickly removed if the exigencies of the conflict require. They have facilities for X-raying, the location of the foreign body being indicated by an indelible cross on the patient's skin. Teams of expert young surgeons perform the operations in these units, and these surgeons get 90 per cent primary healings in war surgery. It is a rule that no war wounded that is to pass out of the control of the operating surgeon before it is healed is to be closed primarily. If operation is deferred, wounds are thoroughly cleansed and packed with gauze solution, the entire area is wrapped in compresses, solidly bandaged, strapped or splinted, and the patient is ready to be shipped 100 miles. In some cases an evacuation hospital is pushed forward and takes charge of the patients in the vicinity of the field hospital. In other cases vehicles from the advance section of the line of communication are sent forward to the field hospital to receive the patients, and in many cases the trucks going 90 per cent primary will transport the patients back to the refilling point, where they will be turned over to the vehicles sent forward from the advance section. The evacuation hospital is equipped with cots, blankets and comforts, but ordinarily it will be cleared of patients as early as practical in order that it may be ready to receive others from the front.

Between the evacuation hospitals and the base group there are rest stations and Red Cross hospitals. One of the officers of the group, the medical officer in charge being known as surgeon, intermediate group.

Patients usually are brought back by trains or boats to the base hospitals, where all possible comfort and facilities for their care are provided. The sick and wounded who will be able to return soon for duty will be retained in these hospitals rather than turned over to the service of the interior. These base hospitals are operated with methodical régime and have all facilities for substantial surgical work and to expedite convalescence. By far the greater proportion of the operations here are "civil surgery" as distinguished from "war surgery." The bed capacity in the rear of the zone of the advance is aimed at being adequate to care for 10 per cent of the total forces when troops take the field, with facilities for rapid expansion. One base or general hospital is established for each 500 beds to be provided. The base hospitals are centres of great medical activity. Often there are contagious disease hospitals in connection. Here are located medical supply depots, materials being accumulated here and sent forward as required. Here also are field laboratories and casual camps for sanitary troops. There are also Red Cross units, sanitary inspectors having the rank of lieutenant-colonel, and who are assistants to the division surgeon, supervise the medical operations, with the surgeon, base group, in immediate charge.

FRANKLIN MARTIN, M.D.,
Chairman Committee on Medicine and Sanitation, Advisory Commission, Council of National Defense.

MEDICAL PEDAGOGY. The theory of education in its application to medicine still is mostly traditional, like many of the subjects it includes, for the pedagogy of the great number of medical schools has no steady, carefully arranged and planned-for, taught-for, curriculum based on personal and educational psychology and knowledge of the modes in which a young (or old) person learns. Both the method and the curriculum at present are largely traditional, like much of medicine in general.

The origin of this method has a certain amount of historic interest. As every one knows, a century ago and less the becoming "doctor" received all that he knew of medicine before approaching his vicarious vocation with the same care and intimate attention on one or more, usually one, more or less successful practitioners. It was the same condition as obtained and is still in use in the study of the law, only here the young man was more dependent on his "preceptor" than in the case of the "reader" and the old judge in his law office. The remnants of this old preceptor-system, as late as the year 1900, say, were to be seen in the medical schools even in New York City.

Some of the more ambitious and some also of the more lazy students joined a tutoring or "quiz class in each of the important subjects of the curriculum; they were vigorously quizzed once or twice per week and enthusiastically "rammed" before the carefully-calculated examinations. Some students took in small classes, as many as six or eight of these private courses, and the cost of each ranged from $5 to $25 for a year's quizzing. The "preceptor," usually a college-bred, successful, wide-awake practitioner, was often a young man who was called a "quiz-master," and, much admired by his students (to whom often he gave much personal and social care and help), he was at
least tolerated by the colleges, already aware that their course was in a sad lack of recita-
tional reviews. Not infrequently the instructors have resorted to quizzes.

When systematic laboratory work developed, largely in the richer medical schools, and reci-
tations began to be systematically held, this preceptor-system—employing a practitioner to be guide, philosopher and friend, as well as tutor—gradually disappeared, except as still maintained in or about all institutions of learning in some form or other. In this pedagogic respect, then, the medical school tends continually to imitate more and more successfully the didactic methods of the university, which, of course, are ancient.

The requirements for admission to and graduation from colleges holding membership in the Association of American Medical Colleges are 14 units of high school work and two years (60 semester hours) of college work.

THE HIGH SCHOOL REQUIREMENT.

(A) Required, 7 units.

Colleges may reduce the number of hours in any subject not more than 20 per cent, provided that the total number of hours in a division is not reduced. Where the teaching conditions in a college are best subserved, the subject may be, for teaching purposes, transferred from one division to another. When didactic and laboratory hours are specified in any subject, laboratory hours may be substituted for didactic hours.

Note.—At the 1916 meeting the Committee on Education and Pedagogy was instructed to revise this curriculum to meet the present requirements.
MEDICAL PEDAGOGY

Women in Medicine.—During the past year there were 581 women studying medicine, or 29 less than last year, but 15 more than in 1916. The percentage of women to all medical students is 4.3, a percentage approximating those of previous years. This is true also in regard to women graduates. There were 106 women graduates this year, 47 less than last year and 28 less than in 1916. Of all the women matriculants, a smaller percentage were in attendance at the two medical colleges for women, while 511 (87.9 per cent) were matriculated in the sixty coeducational colleges. From the two women's colleges there were 12 graduates while 94 secured their degrees from coeducational colleges. This increase of women students in coeducational colleges is not surprising, since in recent years some of the largest and oldest medical schools, as Columbia, Tulane, the University of Pennsylvania and Harvard (and McGill University in Canada), have thrown open their doors to women. (Journal American Medical Association, Vol. 7, No. 7, 17 Aug. 1918).

It is distinctly claimed that in the following remarks there is any intention of finding "fault" with the present and better methods of medical education. This mode of discussion is the most convenient one. It is all, for pointing out the present pedagogic status of "studing to be a doctor." It would be invidious to find fault with such a system without offering something to replace it; ideally to destroy without immediately afterward restructuring the plan in a better form; and it may frankly be said that no such reconstruction is contemplated in this little article, or even hinted at.

Many medical schools need, and as much as anything else at all, except it be finances, an adequate survey by some wise and practical professional educator who would point out, for example, some of the inconsistencies and the lack of co-ordination between the different courses. "Visiting" committees frequently try to demonstrate to chance readers of their reports their own personal importance, but they seldom have any knowledge worth while concerning educational theory. An assistant or teaching fellow in almost any university department of education would be of more use in a really conscientious medical school than the wealthiest and most dignified of these committees.

The principles of pedagogic fatigue, of overwork, and of under-recreation are ignored in most medical schools, with a consequent great waste of mental energy. As has already been hinted, the medical student needs normal recreation as much as any other student, if not more. A course in the economics of learning should be given in the first semester of every medical freshman year.

This suggests medical psychology in general. The everyday psychology of the emotions, for example, especially in relation to the functions of the body and its growth, should be studied and even understood by every medical man while yet a student. The present writer happens to be one of the early ones to say this, namely in Science in July 1901. Medical psy-
herent materialism of the medical schools has begun to soften, without a doubt, and to-day some at least of the medical colleges realize practically that education, any kind of education, that has ignored the study of mind and motive and behavior is incomplete and false in quite the most fundamental kind of way. This common lack of adequate psychology, however, seems still to be the chief pedagogical defect of medical education—man is both mind and body.

Whatever just criticism may be made of American medical education, it still remains the best in the world, its monetary wealth having put it practically ahead even of the famous old schools of England.

GEORGE VANNESS DEARBORN, M.D.,
Medical Corps, United States Army.

MEDICAL SCIENCE AND THE WORLD WAR. Army medical departments everywhere had, before the war, prepared for the treatment of surgically clean wounds made by modern fire-arms in distance engagements. The field first-aid kit, with its sterile dressings sealed from contamination, was expected to maintain this freedom of wounds from infection almost without exception. Aseptic wounds assure prompt and uncomplicated recovery. Serious injuries of important organs would still often be fatal, but all others, as a rule, would be followed by convalescence without delay or complication. These anticipations were sadly disappointed by the immediate recourse to trench warfare as almost the sole mode of conflict. In the trenches recently dug in fields which had been under cultivation for hundreds of years, bacteria abounded and infections inevitably occurred. Two extremely fatal forms of infection, tetanus and gas gangrene, raged among the troops. Both of these were often fatal and the gas bacillus caused long illness and often extensive mutilation, even when recovery took place. Tetanus, after the early sad experience, was prevented by injections of anti-tetanus serum as soon as the wounded came under observation, the injections being repeated at regular intervals if convalescence from the wound was prolonged, for it was found that delayed infections occurred. The gas bacillus proved a much more difficult problem because of its utter unfamiliarity with it at first. It was unknown in Great Britain before the war, was not seen during our Civil War, and is very rare in civil life. Some 70 per cent of the wounds received in the trenches during the first year of the war were infected by it. It was never noted in wounds of the face or neck where the blood supply is abundant and the tissues well oxygenated, for the bacillus of it, discovered by Welch at Johns Hopkins, like the tetanus bacillus, is anaerobic, that is, grows best out of the presence of the air. The successful methods of treatment included thorough opening up of wounds, the use of hydrogen peroxide, so as to provide additional oxygen for the tissues, and after careful investigation, the use of sera for curative and prophylactic purposes, elaborated by various agencies.

The large number of badly infected wounds to come under treatment proved very discouraging to the surgeons at first and iodine was found so valuable that it was used in large quantities until it was suggested that this would be known in medical history as "the iodine war." The student would naturally ask what the difference was between the healing of the wounds of soldiers and sailors led to an important development in the treatment of large shell wounds and penetrating wounds of various kinds in which foreign particles were carried deeply into the tissues. Soldiers thus wounded in the trenches suffered almost invariably from septic developments, often fatal and always with a protracted convalescence. Months after a bad shell wound, a soldier, if he recovered, would only be past the border line of danger, while sailors with similar wounds would usually be entirely well at the end of a month. The sailors had often been subjected to exposure to cold sea water, sometimes for an hour or more after the reception of their wounds. The influence of salt water as an application to the surfaces of large wounds was studied and it was found that when of about the specific gravity of sea water, it caused a pouring out of serum and a consequent cleansing of the wound by the discharges. Besides, the outward current set up carried off septic materials which would have been serious if allowed to remain. Mainly through the observations of Sir Almroth Wright, salt water was used extensively as a dressing for wounds, with some excellent results, and this principle is evidently to be of service after the war.

The important development in the treatment of wounds came when Dr. Alexis Carrel of the Rockefeller institute, in charge of a French hospital in Compiegne during the second year of the war, set about the practical application of Lister's principles. Ordinary surgical antisepsics were too poisonous to be used for the flushing out of large wounds. A solution of hypochlorites proved to be bactericidal, yet non-toxic and non-corrosive to tissues. After experiment, Dakin's fluid, so called from the inventor of it who had been the director of the Herter Chemical Institute, New York, was found the most efficient solution of the hypochlorites. The important part of this treatment was the bacteriological control. After removal of all foreign particles and all injured tissues, wounds were thoroughly flushed with Dakin's fluid maintained by careful microscopic examination that the secretions contained very few bacteria and none to be feared. The wound was then closed up and permitted to heal without further interference. The results were excellent. Healing took place rapidly as a rule, convalescence was brief and absorption of septic material so as to produce constitutional disturbance rare and without danger. The after result was better than that produced by any other method and the hospitals where it was employed took on a new aspect from that which had been seen in the war hospitals before.

The most important development of the surgical treatment of war wounds has been what is called by the French debridement, that is, the thorough excision of all injured portions of tissue. The extent to which this clearing out of the wound was carried in war practice would have seemed utterly unjustified in civil surgery before the war. Where a penetrating bullet wound shows signs of infection, a cylindrical
portion of the tissue around it is removed. In larger shell wounds, a layer of injured tissue is, as far as possible, removed, from every portion of the wound so as to present perfectly fresh vital surfaces for healing purposes. Large amounts of tissue are thus often removed, for experience has shown that it is in the end ever so much better for the patient. Any injured cells spark with retained fluid, exudation, and sepsis, have a tendency to die and then break down into material which forms an excellent culture medium for microbes. Where drainage is instituted, most of this will come away, but that is a much slower process and much more exacting than that of the patient, and the healthy cells are handicapped by the presence of infected cells in their struggle against bacteria.

The war's experience with head injuries has developed a mode of treatment quite different from that common use before. The surprise for military surgeons has been the wonderful tolerance of the brain to injuries. It was not an unusual thing to have wounded soldiers come into dressing stations as 'walking cases,' who were suffering from fracture of the skull, even complicated by other injuries. The best surgery for these cases has proved the greatest possible limitation of intervention. Depressed bone fractures must, of course, be lifted, but missiles should not be searched for. There is least danger to the patient when the missile is left in situ, unless symptoms directly traceable to its presence develop. As a rule, antiseptic rather than aseptic precautions are most valuable in saving lives in these cases. The experience of four years seems to indicate that the after effects of the retention of foreign bodies within the skull does not justify manipulations in reaching them.

The use of poison gas has given rise to the most unsatisfactory medical feature of the war. In spite of the German signature to The Hague Convention article condemning the use of gas, the Germans proceeded to employ this mode of attack and found the Allies and the medical departments unprepared for it. At first heavy gases containing mainly bromine were used, favoring winds carrying them. Later gas hand grenades were employed. These had an intensely irritant effect and produced suffocation or were followed by severe pulmonary bronchitis. Pulmonary edema often proved fatal. Gas masks overcame this mode of attack. Then long range gas shells were employed, sometimes with delayed action, so as to lull against precautions. At times, shells containing 'sneezing' or 'vomiting' gases were used for the displacement of masks. In the last phase of the war, "mustard gas," said to be chemically dichlorehyilsulphide, was employed. It was persistent and would hang about for hours and even days, perilously burned the skin, and clothes moistened with it produced escharotic effects. Many of the most important German advances were made by means of these gases as a preliminary. The Allies learned to neutralize and reply effectively to all of them.

When the gas was not concentrated enough to produce suffocation or set up fatal pulmonary edema, the men usually recovered, though many of them went through a period of awful discomfort which was, of course, the reason why the use of gas was forbidden at The Hague. Comparatively few of those who survived presented serious lung lesions, though they had to be treated by the open air method, as for tuberculosis, as much as possible. We have learned from tuberculosis how tolerant the lungs are of even severe pathological conditions and how readily, after a time, compensation is secured. The question whether gasing predisposes to tuberculosis has been settled in the negative, though undoubtedly in certain cases latent foci of tuberculosis were made active by the process.

Comparative mortalities from wounds and disease in modern war show what a great gain was made by surgery and sanitary science in the war. In the Russian campaign against Turkey in 1828, some 80,000 died of disease, about 20,000 of wounds. In General Scott's campaign in Mexico the deaths from disease were 33 per cent of the effective strength. In the Crimean War, out of a total force of 300,000, the French lost by disease 75,000 and by wounds 20,000. In the Prussian war against Austria, of but seven week's duration, the losses by disease were 6,427 and by wounds 4,450 in an army of 437,000. In the Spanish-American War 2,565 deaths were from disease and 345 deaths from wounds, in an army of 157,717. In the South African War the deaths from disease were 69 per thousand strength; from wounds, 42 per thousand. In the Russo-Japanese War the deaths from disease were 41.8 per thousand strength and from wounds 72.9 per thousand strength, the ratio for the first time reversed. Out of 300,000 dead in the Civil War, in the armies of the North over 200,000 were from disease. In the Confederate armies, of 200,000 deaths, three-fourths were estimated as due to disease and one-fourth to the casualties. (Figures furnished by the United States Surgeon-General's Office).

According to 'Medical and Surgical History of the Rebellion' (Medical volume, part I, pages xxv and xxvi) and "The War in the Northern armies altogether 235,583 gunshot wounds with a resulting mortality of 33,653 or 14.2 per cent. These figures represent the total returns from about nine-tenths of the mean strength of the Union army and exclusive of the injuries of those killed in action. In the late war, so far as the figures are available from the beginning, the deaths from wounds, that is of all those who came to the surgeons alive, no matter how badly wounded, have been calculated to be less than 5 per cent. This is, of course, merely an approximation but made on reasonable grounds. Exact figures will not be available probably for some time. The serious infections with tetanus and the gas bacillus at the beginning of the war make the available statistics much worse than would otherwise be the case. With the control of these the mortality among the wounded in the closing phase of the war was probably below 3 per cent.

The health of army camps at the beginning of the war was most satisfactory. As Doc-
trench fever, its etiology and its successful treatment as well as prevention, has been one of the triumphs of the war.

The second phase of the war was the development of a large number of cases of a very severe form of functional nervous disease. Men lost control of themselves completely, very often had disturbances of the special senses,—deafness was rather common, blindness not so frequent,—and sensory disturbances of other kinds, with mutism and tremor or paralyses of various kinds, were noted. At first a great many of the cases were set down as forms of insanity and the patients were sent to insane asylums, but after careful study the purely neurotic character of the affection was determined. The cases were called "shell shock" and unfortunately, early in the war the war was grouped under this term, besides the neurotic cases, a number of latent injuries to the brain were passed over, as from actual wounds by minute particles of shells at high velocity, severe concussions and the like. It was thought for a time that the intense compression of the air with immediate release near an exploding shell or piece of shrapnel might be given off from the blood, leading to rupture of capillary arteries of the central system or other definite physical lesions resembling those of caisson disease. The prompt and complete recovery of many serious cases under proper treatment contradicted this theory and made it clear that there must be no organic basis. The term shell shock was suggestive of something much more than a psycho-neurosis, which the affection really was, and the term nervoussness, the word sick or wounded in parenthesis being added to the diagnosis according to the external conditions to which the man was exposed at the time of breakdown, was suggested for it. This would have been a much better term but the original name maintained itself, as so often happens. The condition was entirely due to an emotional storm with loss of control over nerves, and nothing else. Its importance will be readily appreciated from the fact that during the first half of the war, one-seventh of all the discharged from the American army, or one-tenth of the discharged, if those from wounds were not included, were for shell shock. It was four times as prevalent among officers as among men. Cowardice was excluded as the basis and there was no malingerer, except in cases readily recognizable. The study of the affection has thrown great light on the psycho-neuroses of civil life and above all has been valuable in the matter of treatment.

These patients need special treatment in special hospitals. In ordinary military hospitals, surrounded by sufferers from actual physical conditions, they are the subject of unfavorable suggestion and little incentive to get well. They must not be kept under circumstances, either at home or in hospital, where much sympathy is afforded them and their stories must not be listened to sympathetically, for they have the tendency of all neurotics to assimilate as their own, experiences gleaned from various sources. The first requisite of successful treatment is a careful examination that determines absolutely that no organic morbid condition is present. Then the patient must be given the feeling that his case is of no special signif-
cance, but, on the contrary, is well understood and above all, has nothing exceptional in it. He must be made to understand that just as soon as the attending physician has the time to give to him, he will be able to remove his symptoms without delay. Three principles are insisted on in the treatment of hysterical patients. (1) suggestion, (2) re-education, (3) discipline. The aim of suggestion is to make the patient believe firmly that he will be cured and then after treatment that he is cured to stay so. Re-education overcomes the bad habit of lack of control which breaks down the psychic-resistance of the patient to the idea of recovery. For such symptoms as mutism or deafness, the patient is told that electricity will cure him and that as soon as he feels the current when the electrode is applied, his power of speech or hearing will be restored pari passu, with sensation. The same method is used for blindness and other sensory symptoms. Paralyses are favorably affected the same way, though tremors are harder to deal with and a single current is the best method, for the patient readily relaxes unless he has been made to feel that he has recovered his powers completely and that it would be his own fault to permit his symptoms to recur. The cases of hysteria, though typical hysterical symptoms, crying, the making of curious noises, hysterical convulsions, are rarely seen at the front. The experience has made it clear that rest is nearly always an abuse in the treatment of such cases and invites the symptoms. The physical condition must be improved but the state of mind must be changed completely at once, if cure is to be effected.

A very interesting development of the treatment of these affections among the French, who had large experience, requiring over 20,000 places in their hospitals for the cases, was with regard to the value of severe discipline. In refractory cases, patients were put in solitary confinement without reading or writing materials or tobacco. This changed the mental attitude and helped to make counter-suggestion effective. In certain cases, strong Faradic currents were used which caused severe pain, so that patients who were mute had to scream out and those who could not use muscles were compelled to use them. Once it became known that treatment of this kind was being used, symptoms were much less persistent. The reason why the neuroses in officers were more difficult of treatment was that these measures were seldom employed on them. It became clear that the infliction of pain on a neurological patient up to the point where he yields up his pathological suggestion is effective therapeutics. Some older severe methods of dealing with these cases which were condemned in our milder day are now justified by war discipline.

The surgical feature for which this war will be noted is the definite reconstruction work for the wounded which has been organized for the first time in history. Not only have artificial limbs and helpful apparatus of various kinds been provided, but how best to do the work they are particularly suited for in their maimed condition. It has been found that some 85 per cent of those who lose an arm or hand can go back to their old occupations, while a very large proportion of those who have lost a leg can be trained to bench trades or given clerical or similar occupations which will make them thoroughly independent of assistance. Even with the loss of both legs, a man can be self-supporting. Indeed, the care exercised in training the crippled has resulted in a great many cases of them having a better occupation in life than they had before. The temper of this aid has been such as to give men a hearty spirit of courage in facing life, so that they do not feel their handicap as an incubus, but on the contrary, are ready to do their bit in civil life as well as they did in war. The idea that they are crippled is not allowed to overcome them and the old custom of having begging cripples after the war is not to be allowed. Even the blind and the deaf are made self-supporting and at the same time given such occupation of mind as keeps them from being depressed. The effect of example on the part of some of the more courageous has proved a wonderful stimulus, so that though the war is to leave many maimed men, it is a spirit of creating many helpful and the spirit of helpfulness does not provide useless sympathy and paralyzing charity, but just such encouragement as enables the men to help themselves.

Chronic affections of various kinds which have developed as a consequence of the war are being treated by the same far-seeing after-treatment that is given to the maimed. In a word, the soldier taken in health is either dismissed, after thorough examination, in as good health as before,—or usually much better,—or else he is given the advantage of scientific thoughtfulness and pre-vision in regard to his case, so as to restore him just as far as possible to his former usefulness as a member of the community.

JAMES J. WALSH, M.D.,
Author of 'The Thirteenth Greatest of Centuries'.

MEDICI, mëd'e-chë or mà'dë-chë, a Florentine family who rose to wealth through commerce, became prominent in the affairs of the state, gained supeml power and were in general known as patrons of literature and art. GIOVANNI (1360-1429) rendered important service to Florence and became gonfalonier in 1421. His son, Cosmo, also became an artist and called "Pater Patriae," gained vast wealth, was a munificent patron of art and letters and combined statecraft with commercial enterprise. He was for 34 years the sole arbitrator of the republic and the adviser of the sovereign houses
of Italy. His grandson, Lorenzo the Magnificent (1449–92) governed the state in conjunction with his brother Giuliano (1453–78) till the latter was assassinated by the Pazzi, a rival Florentine family. Later, he conducted a war with Ferdinand of Naples, with whom he signed a decisive peace in 1480. The rest of Lorenzo's reign was passed in peace and in those acts of profuse liberality and magnificent patronage of arts and sciences, in which he followed his illustrious grandfather. He left three sons—Pietro (1471–1503), Giovanni (afterward Pope Leo X), and Giuliano, Duke of Nemours. Pietro succeeded his father, but was deprived of his estates when the French invaded Italy in 1494. He finished his career in the service of France. His eldest son Lorenzo came to power by the abdication of his uncle Giuliano, who became Duke of Urbino. He died in 1519, leaving a daughter, the famous Catharine de' Medici (q.v.), queen of France. After several reverses in the family, Alessandro, a legitimate son of the last-named Lorenzo, was restored to Florence by the troops of Charles V, and by an imperial decree was declared head of the republic, and afterward Duke of Florence. The next name of importance in the family is that of Cosimo the Elder (1519–74), who in 1537 claimed Duke of Florence and afterward Grand Duke of Tuscany. A learned man himself, he was a great patron of learning and art, a collector of paintings and antiquities. Francisco Maria I, his son, obtained from the Emperor Maximilian II, whose daughter Joanna he had married, the confirmation of his title of grand duke in 1575, which continued in his family until it became extinct in 1737 on the death of Giovanni Gasto, who was succeeded by Francis, Duke of Lorraine.

MEDICINE, American Academy of. See American Academy of Medicine.

MEDICINE, Eclectic. Eclecticism is the practice and principle of the only established American school of medicine. Eclecticism was not the most fortunate, for at no time has it adequately defined the school's position. When chosen, the term was very popular and was borne by several education systems and books, and was moreover well known to the laity. The name American School of Medicine, as proposed by Dr. A. H. Baldridge, one of its pioneers, would have been more expressive, would have avoided misunderstandings and would have saved the school much criticism regarding its position among the existing systems of medicine. Eclecticism is the direct successor of the American Reformed System of Medicine originated by Dr. Wooster Beach of New York City in 1825. It should not be confused with Thomsonism (Thomsonianism), or the doctrines of the eclectic school and herbalists promulgated and practised in the early part of the 19th century by Samuel Thomson of New Hampshire, the peculiar theories of which the Eclectic school never adopted; the majority of the followers of Thomson being among their most bitter antagonists. In later years, however, many of the Thomsons joined the Eclectic school and creditably assisted in up-
building it. The most successful organizer of the Eclectic school was Dr. Thomas Vaughan Morrow of Kentucky. The investigations in medical botany and materia medica by Schoepf, Benjamin Smith Barton, W. C. P. Barton, Constantine Rafnesque, William Tully and others gave an impetus to the movement which resulted in the establishment of the new school. The Reformed School of Medicine, by which name what was later denominated Eclecticism was first known, was organized in opposition to the drastic practice of the dominant school of medicine,—bleeding, blistering, and abuse of the salts of mercury and antimony,—against which Eclectics, as well as the followers of Thomson and Hahnemann, protested. Instead of these barbarous remedies the reformer sought to substitute milder measures and to employ vegetable medicines whenever possible. Yet, in the light of the present the substituted practice of the early reformers would be regarded as but little less barbaric than that which they sought to supplant. The basis of Eclectic philosophy, however, with its inherent forces, the avoidance of depleting remedies, and the selection, as with the ancient Eclectics, of the best of remedies and means from all sources, even despising not the primitive medicines of the untutored American Indians. They did not rest contented, however, with merely selecting the best; they endeavored to improve on such selections. To the reformer the practice of the dominant school was cruel and inhuman, the remedies barbaric. Out of the common stock of remedies he chose those best suited to his purpose in what he believed to be a more humane practice. He looked forward to certain ideals and objects not in accord with the views and practice of the dominant school. For his presumption in thus opposing the authorities in medicine and by inaugurating unwelcome innovations he was branded an irregular; was ostracised by the self-styled regular physicians. An outcast, he was thus forced to organize a school in accord with his theories and practice.

There are three epochs in the history of Eclectic medicine,—the period of reformed medicine, from 1825 to 1845; the formative period, from 1845 to 1869, which was largely concerned in organizing and establishing schools of plant remedies; and the period of specific medication, from 1869 to the present, in which the best work of the school has been accomplished, and during which the theory of specific medication was promulgated and has been most largely practised.

The educational history of Eclecticism dates from 1825, when Dr. Beach privately instructed students at his clinic in New York, where, in 1827, he established an Infirmary, which in 1829 he expanded into the Reformed Medical Academy. In 1830 it assumed the more dignified title of the Reformed Medical College of the City of New York. It was well equipped and continued in operation until about 1838. Textbooks of a high order were prepared by Dr. Beach and by other medical men from this body an expansion movement was begun by the selection, in 1830, of Dr. John J. Steele as an agent to proceed westward and explore the towns on the Ohio River with a view to selecting an eligible site for a branch of the New York College. A circular of the society having reached Worthington, Ohio, Col. James Kilbourne, president of Worthington College, invited the promoters to establish their school in that town. Dr. Steele accepted and Drs. Thomas Vaughn Morrow and Ichabod Gibson Jones were sent to perfect the organization. The Reformed Medical Department of Worthington College, as this school was called, entered upon a successful career in 1830, with Dr. Morrow as the leading spirit, but lack of proper facilities, the machinations of enemies, internal dissensions, and the financial crisis of 1837 caused it to be abandoned. Morrow next removed to Cincinnati, Ohio, and assisted by Drs. Lorenzo Elbridge Jones and Alexander Holmes Baldridge, at once organized the Reformed Medical School of Cincinnati. In 1845 this college was chartered by the State of Ohio as the Eclectic Medical Institute. From this time the term Eclectic has been employed to designate the system and its physicians.

The formative period of Eclecticism began with the chartering of the Eclectic Medical Institute in 1845 and establishment of the institution of specific medication in 1869. During this period large classes attended the Institute. The Western Medical Reformer, begun in Worthington in 1836 and suspended in 1838, was revived and published as the Eclectic Medical Journal. Barring a brief half year suspension this periodical has continued to be published to the present time. In this period, Dr. John King, justly styled the father of modern materia medica, began the publication of his numerous textbooks, among which the 'American Dispensatory' gave the school an enduring and monumental work on materia medica. The pharmacy of the school advanced from crude drugs in powder, infusion and decoction past the resinoid and alkaloid distraction to improved galenicals. In this connection be it recorded that Professor King discovered and introduced the resins of podophyllum and macrotyl, which together with the alkaloids of hydastis and sanguinaria, were afterward prepared by Dr. William Stanley. These valuable agents, together with the oleoresins of iris and capiscum attracted the attention of pharmacists. A host of indefinite compounds were added by others and the market was flooded with what purported to be Eclectic resinoids or concentrations. This heterogeneous class of pharmaca was denounced by Professor King and others who had sought to introduce only elegant and definite compounds. This much abused class of resinoids served, however, a temporarily useful purpose in the evolution of a more perfect materia medica.

The educational history of Eclecticism dates from 1825, when Dr. Beach privately instructed students at his clinic in New York, where, in 1827, he established an Infirmary, which in 1829 he expanded into the Reformed Medical Academy. In 1830 it assumed the more dignified title of the Reformed Medical College of the City of New York. It was well equipped and continued in operation until about 1838. Textbooks of a high order were prepared by Dr. Beach and by other medical men from this body an expansion movement was begun by the selection, in 1830, of Dr. John J. Steele as an agent to proceed westward and explore the towns on the Ohio River with a view to selecting an eligible site for a branch of the New York College. A circular of the
cinnati which had a large following. This school was absorbed by the Institute in 1859. The Civil War seriously threatened the educational progress of the cause and the withdrawal of a large quota of Southern students caused a marked shrinkage in the attendance at the Northern schools. Times were hard and the outlook gloomy. Dr. John Milton Scudder, a graduate of the Medical Institute in 1856, now became the head of that institution. By strict business management he inaugurated a period of renaissance and Eclecticism soon became a recognized force in medicine in America. Specific medication, introduced by Dr. John M. Scudder in 1849, though at first vigorously opposed, is at present the basis of practice of fully three-fourths of the Eclectic physicians and is the leading therapeutic doctrine taught in all the Eclectic colleges. In fact, modern Eclecticism is the practice of specific medication. Its theory is as follows: Disease is a wrong or impairment of life. It is manifested clinically by certain well-defined symptoms. The totality of symptoms express a condition, to which, in the usual nosological classification, a special name is given. This disease name is of value only in the study of the natural history of diseases, for statistical data, for the purpose of recognizing contagious and infectious diseases, and for establishing a prognosis, certain necessarily fatal diseases allowing only of palliative treatment. The specific medecinist, like practitioners of other schools, pursues such a method of nosological diagnosis for the purposes named, but not as a guide to treatment, in which to him it is of little or no value. For therapeutic purposes he reverses this process and studies his case by analysis, not by synthesis, to discover, if possible, the varying conditions which make up the disease, as evidenced by specific and well-defined symptoms revealing disease expressions. Remedies have a certain force, and are definite in action. Like effects follow like causes. Hence, having found, by repeated experimentation, the opposing action of a drug in a certain condition of disease, as expressed by certain specific symptoms, objective or subjective, the same remedy will always relieve or cure like abnormal conditions. The believer in specific medication holds that there is a fixed relationship between drug force and disease expression.

The Eclectic has no specifics for diseases but specific remedies for specific conditions of such diseases. Specific diagnosis implies diagnosis to discover the condition curable by a certain remedy, as established by previous experimentation, and specific medication means the application of the known remedy for the pathological condition so found. Specific diagnosis is therapeutic, not nosological diagnosis. In practice the specific medicatist is guided in the selection of his remedy by "specific indications," as illustrated by the few following examples: The strong, excited, bounding pulse indicates veratrum viride; sharp, cutting or lancinating pain in serous tissues. Bryonia; the full, oppressed pulse with a sensation of praeordial fulness and dyspnea, lobelia; marked periodicity, with moist tongue, open pulse and freedom from nervous excitement, quinine; rapid, heat, fetor of the secretions, potassium chloride, etc.

The modern Eclectic recognizes no law of cure, and does not accept a remedy as a specific until the extended successful employment of it in some particular condition has given it the right to be so called. Empiricism and experimentation are the foundations of knowledge concerning each remedy denominated a specific medicine. The havoc wrought Eclectic pharmacy at the close of the formative period had now to be remedied. The school had been nearly shipwrecked on the shoals of selfishness, as seen in the instance of the resins. Calamities often bring about future good, so in this instance the commercial mistakes of a few gave a renewed impetus to better the conditions of Eclectic pharmacy. Uncertain preparations were supplanted by definite medicines. As a result the school has now a materia medica and system of therapeutics much sought by the descendants of those who endeavored to block the efforts of the pioneer Eclectic, in his zealous devotion for pure and representative medicines. Dr. Scudder, supported by Dr. King and others, advocated office pharmacy as a step toward a better knowledge of drugs and to secure definite remedies. Special attention was given green and freshly dried products. The formulae name is given. This of specific medicines. Finally in order to secure the integrity of these medicines and protect them from conscienceless manufacturers. Dr. Scudder copyrighted the labels. These bore the title "Specific Medicines" and gave the specific indications for their use. The manufacture of medicines bearing these labels was entrusted to competent pharmacists and from that time the school has been free from objectionable pharmacy. Dr. Scudder advocated the use of specific medicines in the study of the relationship of medicine to disease expressions. The Eclectic of the formative period selected from other schools, but endeavored to improve. He substituted milder for harsher methods; he opposed the use of the lancet and blister, and the abuse of mercury and antimony salts. The modern American Eclectic advocates the use of kindly curative remedies, and the avoidance of depressing or depleting medication. He has been the pioneer in the study of the indigenous materia medica, with special reference to specific indications of the medicines employed. He contends for the best possible pharmacy so that the minimum amount of medicine may accomplish maximum results. Harmful medication as exemplified in excessive drugging he has consistently opposed, hence over-drugging having been one of the most potent causes leading to the necessity for the establishment of an Eclectic school. He advocates liberality of thought, the highest medical education, the cultivation of professional dignity, and the ethics that govern gentlemen.

The position of the Eclectic school of medicine is now well established, and the attitude of malice and persecution formerly shown it by rival schools is fast becoming a memory. The school numbers upwards of 8,000 Eclectic physicians. For a period of about 10 years this numerical relation has remained nearly stationary, but because of better facilities for teaching, enlarged literature, and harmony in the ranks of the school it has never occupied so favorable a position nor had a better outlook for the future than it has to-day. Never before in its history has it been so free from internecine bickerings, attacks by rival schools, and unpleasant entangle.
ments and alliances. It challenges all ages in the wealth and completeness of its materia medica. Recognizing the merit of the work accomplished the regular profession in many localities now invites Eclectics to join its associations providing they drop their distinctive title. This the Eclectic is unwilling to do, believing that the school has acquired the right to be regarded and recognized as a distinct sect in medicine. Its work in the special fields of materia medica and specific diagnosis and specific medication entitle it to this right. The Eclectic school has a "good foothold" in the medical profession. The chief generality of the State and local societies. A national reform association was founded in 1829, and a second at Worthington, Ohio, in 1836. In 1848 the first National Eclectic Medical Association was organized in Cincinnati, Ohio, with Dr. T. V. Morrow as president, and it held annual sessions until 1858. The present National Eclectic Medical Association was organized at Chicago, Ill., in 1870, with Dr. John W. Johnson, of Connecticut, as president. It holds annual sessions and paper meetings. Cincinnati has been a center in the United States. Eclectic practitioners now hold positions as examiners in the more important life insurance companies, and are not now debarred from the army and navy medical service as in the earlier days of medical ostracism. No discrimination is now made against them as surgeons for the great railway systems. These recognitions have been earned in the face of vigorous medical opposition, by the consistent and honorable course pursued by the Eclectic school as a whole. The Eclectic Medical College of Cincinnati, Ohio, the parent school of medical Eclecticism, chartered in 1845 as the Eclectic Medical Institute, is the leading college of this American system of medicine.

HARVEY WICKES FELTER, M.D.,
Prof. of Materia Medica and Therapeutics, and Medical History, Eclectic Medical College, Cincinnati, Ohio.

MEDICINE, History of. Within the past three centuries the average working life of English-speaking men has doubled, and some strong or favored ones had efficient working powers as long; but the common life was worn out in what is now middle age. In Shakespeare's time the 50's were very rare. Old John of Gaunt, time-honored Lancaster, was 58 when supposably so addressed; and Admiral Coligny, murdered at 53, is described by his contemporary biographer as a very old man. Now, when we hear of a death in the 60's we instinctively feel it an untimely cutting off in what should be still fresh and vigorous age, and even at 80 it seems but just fair ripeness for the sicle. The three factors which have wrought this change are advanced physical comfort, medicine and its handmaid hygiene, and surgery. And in the mitigation of the frightful and mortal nature of physical torment which has racked every age down to the present, and which has scarcely been alleviated till the past century, medicine stands incomparably first.

If foundations had been laid, it is true, in the century previous, and men were at work in the true scientific spirit. Great masters had stimulated their successors to study in the essential preliminary subjects, the constitution and functions of the body. The mighty Boerhaave of Holland (1668-1735) had revolutionized clinical observation; Morgagni of Italy (1682-1771) had "introduced anatomical thinking into medicine" (Virchow), and had done something the same service for pathology which Haller of Germany (1708-77) did a generation later for physiology; while John Hunter (1728-93) had not only introduced capital improvements into operative surgery, but had set the pace in research into anatomical and physiological problems. But the influence of old theories, founded on guesses and imperfectly interpreted observation, still lay heavy on the body of practitioners. The chief generality of the 18th century were those of William Cullen (1710-90) and his pupil and assistant, John Brown (1736-88), of the University of Edinburgh; the former—a great advance on the older theory of "humors," and on the right track—made the nervous system the seat of diseases; the latter divided all diseases into two classes,—the atheric, resulting from over-excitation and treated by depletion, and the asthenic, resulting from under-excitation and treated by stimulation. On the Continent, at Hamelburg, in the reign of its "homoeopathy,"—a very different thing from what later passed under the name, though the latter retraced the way. Besides his "law of similars," which Hippocrates had formulated before him, he rejected theory utterly, declaring that it was impossible to know anything about pathological changes out of sight; that we can only know symptoms, and if those are removed it indicates of necessity that the disease which produced them must be gone also. He also alleged that the fact of a given dose causing certain symptoms in a healthy person was obvious proof that it must be too large for a sick one; further, that to possess healing power the dose must be too small for recognition by the senses or chemical analysis; and that trituration, or dilution and shaking, of minute doses caused molecular changes which infinitely increased their power—"dynamization," he termed it. The exaggeration of symptomatics and empirics was a reaction against the current reliance on unbiased theories; the paradox of infinitesimal doses, against the monstrous beluses and draughts with which patients were often treated. There was usefulness in both reactions, but he went so far as to declare that a child could be cured while asleep by holding the pellets near it.

But the reign both of guesswork theorizing and of groping empirics, as exclusive methods, was coming to an end, and the first great blow was delivered in the first year of the century. France now came to the front where other countries had thronged. Bichat, a genius who wore himself out at 31, as did Clifford at 34, published the year before his death (1801) a work on general anatomy which broke the barrier to the entire science by showing that the different organs have membranes and tissues in common, and therefore that the seat of disease was in the constituent tissues and not in the organs as such. This not only simplified anatomy and physiology in much the same way that the alphabet simplified hieroglyphics, but threw the investigation of pathological changes into an entirely new channel. Parallel with this work, the followers in the footsteps of Morgagni were carrying on his work in studying morbid anat-
OMY, THE APPEARANCES OF DISEASED ORGANS; THIS, TOO, WAS REMODELED ON BICHAT'S DISCOVERIES. IN 1808 AND 1816 BROUSSAIS OF PARIS (1772-1838) PUBLISHED A TREATISE WHOSE THEORY IS MERELY THE STHENIC AND ASTHENIC IDEA OF BROWN, BUT WHICH LED TO NEW RESEARCH IN PATHOLOGICAL ANATOMY AND LOCAL AILMENTS. PERCUSSION HAD BEEN DEVISED BY AUNENBRUGGER OF VIENNA (1772-1800) IN 1761, AND CORVISART OF PARIS (1755-1821) REVISED IT; BUT ANOTHER IMPROVEMENT WAS EFFECTED BY THE INTRODUCTION OF AUSCULTATION 1816-19 BY THE BRETON LAENNEC (1781-1826) AT PARIS, WHERE HE WAS CORVISART'S PUPIL. HE INVENTED THE STETHOSCOPE TO DIAGNOSE DISEASES OF THE LUNGS, HEART AND ABDOMINAL ORGANS, BY MEANS OF ALTERATION IN THE NORMAL SOUNDS OF THEIR ACTION; AND HIS OWN USE OF IT, AND OBSERVATIONS ON THE DISEASES OF THESE ORGANS, WERE THE GREATEST ADVANCE MADE IN CLINICS SINCE BOERHAAVE, AND MAY BE SAID TO HAVE FOUNDED MODERN CLINICAL SCIENCE. IN 1827, RICHARD BRIGHT AT LONDON (1789-1858) FIRST PUBLISHED HIS RECOGNITION OF THE TRUE NATURE OF THE KIDNEY DISEASE CALLED BY HIS NAME, AND OF THE GENERAL CHARACTERISTICS OF RENAL COMPLAINTS, THE FOUNDATION OF WHICH IS THE TARGET OF THEIR DIAGNOSIS.

A SPECIAL BRANCH OF INVESTIGATION AND ANALYSIS IN THE FIRST HALF OF THE CENTURY WAS IN DISCRIMINATING THE CONTINUED FEVERS; ONE OF THE MOST ACTIVE AND ANXIOUS BATTLE-GROUNDS FOR PRACTITIONERS AND THEORISTS SINCE MODERN MEDICINE TOOK ITS RISE; THOUGH ERUPTIVE AND MALARIAL FEVERS WERE WELL DIFFERENTIATED. THE FIRST TO BE DISCRIMINATED WAS TYPHOID, BY LOUIS OF PARIS (1789-1872). HIS AMERICAN PUPILS, W. W. GERHARD (1809-72) AND ALFRED STITLÉ (1803), WITH C. W. PONNECK (1799-1867), ALL OF PHILADELPHIA, AND GEORGE B. SHATTUCK OF BOSTON, PROVED THAT TYPHOID AND TYPHUS, THEREFORE LOOSELY CLASSED TOGETHER, WERE INDEPENDENT DISEASES, THOUGH GENERATED BY SIMILAR CAUSES. THIS WAS CONFIRMED BY THE WORK OF A. P. STEWART AT GLASGOW AND SIR WILLIAM JEMER AT LONDON. DENGUE OR BREAK-BONE FEVER, YELLOW AND RELAPSING FEVERS, AND THEIR KIND, WERE CAREFULLY STUDIED. AMONG THE OTHER NAMES ASSOCIATED WITH THIS LABOR ARE R. J. GRAVES (1797-1853) AND WILLIAM STOKE (1804-78) OF DUBLIN, GEORGE BUDD (1808-82) OF LONDON, AND DANIEL DRAKE (1785-1852), S. H. DICKSON (1798-1872) AND AUSTIN FLINT (1812-86) IN AMERICA. THIS WORK WAS SOUNDLY BASED BY 1850 IN REGARD TO FEVER CLINICS.

the sway of any authority whatever; recognizing that even the seemingly soundest conclusions of the present are but working hypotheses, which may have to be abandoned at any time on fresh evidence,—the true scientific spirit. No part of life has been left as it was, the digestive and assimilative, circulatory, respiratory and excretory spheres and the nervous system itself have all been illuminated by a flood of light. Especially this has been wonderful in the study of the brain, whose functions not only are so intangible and elusive, but apparently so impossible of experimentation without destroying the subject of experiment. Not only have we penetrated deep into the secrets of the paths and operations of sensory and motor impulses, the localizations of functions and the mechanical implements of thought and memory, but we have been enabled to apply with great success a number of curative measures not before dreamed of, or even if so, not deemed possible of use.

A further marked feature of the age is the development of specialization, in which we have set off a lack of co-ordination and breadth of knowledge or judgment against an extension of knowledge not possible by any other method. Scientifically, no other means has been so potent in revealing the mysteries of the brain. The scientific fact, practically, no other has been so effective in developing curative processes. This specialization must not be confounded with that of the lung doctors and fever doctors of former days, mere quackery, empiricism of uneducated practitioners; it rests on a basis of competent general medical knowledge and thorough education in the specialty besides. The physicians who give their time and thought to one limited field—diseases of women, of children, of eyes and ears, of throat, of teeth, of the brain, or who, though less exclusively, choose diseases of the heart or the liver or other organs for their preferred field—have won for the profession some of its most signal triumphs. American physicans especially have stood at the very head of those who have perfected dentistry and ophthalmology, as well as gynaecology or diseases of women. In this branch the blessings they have conferred not only on the sick but on the diabetic and the blind, on both of them, their male relatives, and their children, by the saving of life and health, in the special crises of the sex, cannot be estimated.

One of the finest branches of this specializing is that of alienism: and the change in the mental attitude of the public toward it in consequence of that study has been most remarkable and gratifying. From a matter of derision, as it was largely in the Middle Ages, or ineffectual commiseration as an act of God, or mere terror and aversion, it has come to the sym pathetic study, often relieved, and always recognized as a mere functional disease. Starting from the labors of our own Rush, of the English Tuke, of the German Jacobi and Hasse, and the French Pinel and Esquirol, this reform has built up a body of physicians in every civilized country not only to study mental aberration scientifically, but to introduce humane and rational methods into its care and cure. America is not behind any other in the treatment of mental disease; particularly is this true of the far western States and Canada; good causes in America — politics — is a blight upon this science still in too many States.

Prophylactics.—"Prevention is better than cure" has reached its most brilliant exemplification in the 19th century. It is true that nations far back in antiquity have grasped some of the chief conditions under which diseases most prevail, and have even carried systems of public hygiene much farther than even yet we have been able to do. The laws of Moses furnish a remarkable example, in its insistence on cleanliness, isolation and diet; the Greeks systematized diet and exercise and general physical training thoroughly, their ideal being "the fair mind in the fair body" (and had discovered that professional athletes do not make good soldiers from lack of endurance); the Romans and Greeks made the bath almost a fetish, far beyond even the English, and the public benefactor of the day gave his city baths, not to libraries. But modern science goes much farther: it discerns the causes which create the disease itself, and removes or neutralizes them. In the 18th century some light had been thrown on this: Howard had seen that typhus was in direct ratio to the crowded conditions under which Captain Cook and Sir Gilbert Blaine had perceived and removed the conditions that generate scurvy. Jenner had gone still farther and anticipated the methods of modern preventive medicine by vaccinamoeimunization. But all these attempts could only be feeble and groping attempts until there was a scientific basis for them. This was furnished by bacteriology, and a few words upon that are needed to make later explanations intelligible.

The Bacteriological Basis of Preventive Medicine.—The ancients speculated with great eagerness and sometimes acuteness on the origin of life, and had guessed that disease and living germs were in some way related; and the relation of disease and putrefaction was not doubted. As soon as the first weak crude microscope was invented, it was used to investigate the organisms of decay. The Jesuit Kircher in 1671 examined the "minute worms" in putrid milk and olive oil; a Dutch merchant named Leeuwenhoek improved his lenses and studied the "animalcula" in rainwater, saliva, intestinal fluids and putrid substances; and the physicians of his day were quick to suspect and suggest that these organisms might be the cause of all disease. In 1762 the Viennese Pleinicz, who had studied fluids in all conditions, gave his firm adhesion to this belief. But this was not the whole; whence came these organisms — were they self-generated, or simply transmitted from other bodies and multiplied? Despite even the microscope, the theory of spontaneous generation maintained itself tenaciously far past the middle of the century. A distinguished chemist maintained it as the result of chemical action; some believed that germs were so generated, and even the proof that the organisms were forms already existent did not convince him or his followers. It was reserved for Pasteur in 1851, and finally (with Koch and Cohn) in 1876, to crush this theory forever. Following quickly on the first came the discovery of the anthrax germ by Pollender and Davaine in 1863; shortly afterward Lister's epoch-making researches into wound infection, making possible the triumphs of antisepsis that even yet are far from forgotten. The solution of the germs of relapsing fever, leprosy, and typhoid. But towering above all, from the
enormous difficulties overcome, were Robert Koch's isolations of the tuberculous germ in 1882, and of that of Asiatic cholera in 1884.

Thence on, a crowd of discoveries of the germs of certain diseases have left their mark; but few—unfortunately, some of the worst—unrevealed, diseases of animals and insects having been investigated as well as those of men.

Thus much for the history of discovery; but what are these germs? The popular mind is very apt to confound the subject. Bacteria are generally thought of as a sort of worm. In fact, they are not members of the animal but the vegetable kingdom; the smallest organisms known. They are protoplasm, a jelly-like substance, enclosed in a hard membrane exactly like wood fibre. They are classified by shape in three groups: cocci (spherical), bacilli (rod-like), and spirilla (corkscrew or undulatory shape). The cocci are found in pairs, fours, clusters, or chains; they include the smallest known organisms, some of them being as small as 1/150,000 of an inch in diameter. The bacilli are larger but vary much, from 1/25,000 to 1/4,000 of an inch in length, and 1/125,000 to 1/6,000 in diameter; some of them have organs of locomotion, called flagella. The spirilla, of all, sometimes 1/600 of an inch. They all increase either by fission into two, or by developing a spore or seed. Their rate of multiplication does not seem rapid, but that is because we forget our old arithmetical "catches." A bacterium dividing each hour, and each new bacteria dividing, would obviously have increased to 8,388,608 in 24 hours; and in three days to a number beyond all verbal expression, weighing nearly 7,500 tons. Of course this is a reductio ad absurdum, as the body they feed upon would be exhausted early in the series; but outside of starvation, nature has other ways of arresting their multiplication.

Before discussing this point, let us look at the nature of bacteria as a whole. It is a misapprehension to think of them simply as a principle of disease and death. They are a universal principle of life as well, and the few species which cause harm are lost in the myriads which do good. But for them, organic existence would perish; it has been suggested that the first organic things on earth were bacteria, organisms needing only nitrogen for support, and life means their multiplication. They abound in air and water, in the soil to nine feet deep or so, and in the outsides and insides of all organisms; but naturally their number varies with the conditions for sustaining existence, and there are none at extreme altitudes or in glacier ice, and few in the polar regions or the deep seas. Those conditions are (1) moisture, without which all die; (2) air, as to which there are three classes,—aerobes which must have it, anaerobes which must not have it, and facultative anaerobes which care nothing either way; (3) food, which must be living tissues for a few, may be dead ones for most, and can be mineral salts or atmospheric nitrogen for some; (4) temperature, which has for possibilities of their multiplication, though not of their life, extremes of 32 and 170° F.; for an average most favorable tract 60 to 104°; and for disease germs (as evolution would imply) 98°, or blood heat is most favorable; (5) light, of which direct sunlight is death to all, and common daylight, of no importance either way to most. Their enormous number gives them a power of accomplishment seemingly almost miraculous, and certain of the farm products and dairy products, of fattened stock or wool, of hides or horn, and many other familiar articles, is due to them; and they are the scavengers of our water supply from pollution, as well as some of them deriving power for harm from it. Still more to our surprise, peas and beans certainly, and all plants probably, gain their life from the soil through the medium of bacteria which live in their roots, decompose nitrogenous minerals and feed on atmospheric nitrogen also, turning both kinds over to the plant for its nourishment.

Hence the processes of health and disease alike are functions of bacteria. What medical science has specially to do is to trace the progress and manifestations of harmful bacteria commonly called "infection," and the methods by which the system's natural tendency to starve or poison them can be reinforced. Before entering upon the phases of prevention and cure, we must indicate briefly how they obtain entrance, the quality of their effects, and what is the reaction of the body thereupon.

The first is naturally limited in variety; they enter by being injected from the bites of animals or insects, from wounds or abrasions from inhaling infected air, from eating or drinking substances containing them. Specific cases will be considered later. The action of the microbes is by generating a set of poisons known as toxins, which produce either languor, loss of appetite and vague general discomfort, or more active pains, headaches, fever, inflammations of the tissues, perhaps entire stupor.

The action of the body is complex and difficult and not thoroughly worked out, but some things are known. The normal blood and tissues have a germicidal power, varying in different bodies even of full health, and varying still more as to specific germs, each body having its own set of germs to which it is congenial or maleficient. The struggle of the body against their multiplication, dependent on this unfavorableness of the soil for their propagation, is called "general resistance," and on its strength depends the immunity against ordinary disease; and the secret of inoculation is, that if the soil favorable to the propagation of a specific bacterium is wiped out, it is usually very slow in fresh growth. The disease microbe gains no lodgment because there is nothing to live on. But in addition to this passive resistance, an active one is carried on by the white blood cells or "phagocytes," the wandering cells, and those of the tissues chiefly invaded, as well as those of the spleen and lymphatic glands; these and others seem to work among the toxins and produce a change in their chemical constitution, at last elaborating counter-poison or antitoxins which neutralize the first, and enable the cells to carry on the war against the disease microbes till one or other is overcome; and as said, if there is recovery, a partial or complete immunity is afforded against further ravages of the same class of microbe.

But it is evident that if this process can be shortened and made more certain, so that the antitoxins can perform their work before the
disease microbes arrive at all, a great system of prophylactic or preventive medicine can be helpful. If desolated the world is a case of similar disease, they will strengthen the natural power of the body to develop them, and greatly aid it in throwing off the disease. This is the new system of serum-therapy, begun by Pasteur in 1877, and continued by a set of brilliant experimenters since. The infected blood is chosen as a medium for injection into the blood of the patient. Pasteur with fowl cholera, Raynaud with cowpox, Salmon and Smith in this country in 1886 with hog cholera, fully proved the possibility of the treatment, curing animals previously inoculated with the most virulent disease poisons, and rendering healthy animals immune; but these excited but languid interest till Behring's announcement in 1892 of a diphtheria antitoxin, with incontestable proof of its value. Oddly, not only laymen but physicians in many cases opposed it; partly from misunderstanding, partly from humanitarianism as involving experiments on animals. Most of its opponents have now been won over by the crushing weight of evidence, and the brilliant work of its supporters. Diphtheria alone has reduced its mortality one-half since the introduction of the serum treatment little more than a decade ago.

To illustrate the general methods of preparing all the serums for infectious diseases, that of diphtheria will serve as a model. The bacilli are cultivated for 8 or 10 days in alkaline beef broth, found to develop a peculiarly virulent poison under its work; then they are isolated and its strength precisely estimated, then set aside in sterilized vessels. A healthy horse, found by experiment the most suitable animal, has injected under the skin of its neck or forequarters 20 cubic centimeters of toxin and perhaps half that of antitoxin, three times five days apart; then it is given heavier and heavier doses of toxin alone, a week apart, till it can endure doses speedily fatal at the outset. After two months it is bled and its serum tested; if satisfactory, it is dosed as before for another month, when the maximum quality of serum is usually reached. The animal is then bled sufficiently, the blood being caught in a sterilized vessel and placed in a refrigerator. The coagulum, when finished, the serum is drawn off from the clot and its strength accurately determined in the laboratory, an antiseptic is added to keep it, and it is bottled for use. Antitoxins for tetanus and snake bite have been similarly prepared, and the present century will see probably every infectious disease and every venom with its bacterial antidote.

Specific Results of Preventive Treatment.

—An abstract of the work already done in preventive medicine can best be given by a note of the great maladies of men and animals more or less controlled by it, with their bacteria. But it must be noted that of the ones cited, the bacteria of smallpox and hydrophobia (though the former has been almost exterminated by vaccination) as well as whooping cough and measles, have not yet been isolated. The reason may be excessively small size, since that of cattle pleuro-pneumonia is barely visible under the microscope; or it may be that the organisms are not bacteria but unknown beings. The diseases may be classified variously, and some admit no special classification, but we will begin with the great scourges which have desolated the world in a case of desolation, owed their virulence and destructiveness, though not their direct origin, to filth and overcrowding and general unsanitary conditions.

(1) The Great Plague, or Bubonic Plague. The frightful devastations of this in the post need not be recited; it is only remembered that it was the "Black Death," which swept off from a third to a half the population of Europe in the latter part of the 13th century. Long thought almost extinct, it reappeared with fearful intensity at Hongkong in 1894, spread to India, and had several occasions of violent outbreak, raging in Turkey and on some parts of the Mediterranean coast, and in small volume has shown itself in Glasgow, South American ports, New York and San Francisco. But in western Europe and America it has been easily put down, and serum inoculation has been fairly successful in India. Its bacillus is known to enter the body by wounds of the skin, and very largely by bites of fleas from infected rats.

(2) Asiatic Cholera. This terrible plague even in the middle of the 19th century swept away thousands of lives in America; now it has been so thoroughly controlled that it is not feared even to the extent of disturbing commerce when it appears. It originated on the banks of the Ganges in India, where Koch found its spirillum and the means of its spread, almost entirely through drinking infected water, though very slightly by contact—so little that since 1873 the disease in Great Britain and the United States has never got farther than the port of entry. How thoroughly a city's immunity depends on its water supply is strikingly shown by the twin city on the Elbe in 1892; Hamburg, using the unfiltered river water, had about 18,000 cases and 8,000 deaths; Altona, with a filtration plant, had 516 cases, largely refugees from Hamburg.

(3) Typhus Fever. It is hard to believe that this was once so steady and frightful a curse in the West that one investigator says its history would be that of Europe. In all the large cities, in camps and ships, hospitals and jails, it was almost permanent and its rate of mortality appalling. It depended so entirely on filth and overcrowding and cessation of packing, sewers and a good water supply, have practically exterminated it except in a few slums. The rate has been reduced in England from 1,228 per 1,000,000 in 1838 (typhus and typhoid together, not then discriminated) to 137 typhoid and 3 typhus at the present time. In 1915 announcement was made that the bacterial origin of typhus fever had been established.

(4) Typhoid Fever. This disease, long identified with typhus, is now not only known to be separate, but dependent on somewhat different generating conditions. It depends not so much on dirt and crowding as on sewer gases and contaminated water and milk. Given pure water and perfect drains, a city practically has no typhoid,—except when its milk supply is drawn from infected sources, as often happens; while seaside resorts are notorious generators of the disease, from the sand-driven wells and the crowded privies draining into them. The germ was discovered by Eberth in 1880.
and called \textit{bacillus typhosus}. The continued prevalence of the disease in our cities is due partly to the great battles of hygiene which can exist in the body of a patient long after recovery and be a means of contamination. The outbreak in the Spanish-American War seemed due to over-crowding, but more likely to the contaminations caused by it, as in the seaside cases. In the country districts there is no mystery about it: often there is no rural sanitation and even the wells are grossly neglected, sometimes on a slope below a barn. In the typical example at Plymouth, Pa. (about 8,000 people), the evacuations of a typhoid patient were thrown out during the winter on the banks of a stream which fed the town reservoir; the spring thaw carried them into it and the town had a typhoid epidemic which struck down 1,200 people. The people precautions are the use of boiled water and of distilled-water ice, the thorough inspection of dairy surroundings and water sources and great care on the part of physicians and nurses to prevent discharges, are the true prophylactics.

(5) Diphtheria. This bacillus was discovered in 1883-84 by Klebs and Loeffler, and has been given their joint names; it enters either by inhalation or the stomach. The antitoxins thus made possible of preparation have reduced the mortality one-half; the hygienic precautions have greatly reduced the primary prevalence. The latter are isolation and disinfection, watchfulness during convalescence, careful examination of the least throat disorder and—since the mild and often unsuspected cases where the children go about and to school freely are the worst in spreading the disease, because not guarded against—regular inspection of school children's throats. Children's teeth and mouths should also be carefully attended to and the tonsils removed where tonsilitis is frequent.

(6) Yellow Fever. The germ of this has not yet been isolated. Its dependence on dirt, however, would seem almost as sure as typhus, thorough sanitation having practically eradicated it in its favorite tropic home, Havana, and in the Southern cities once ravaged by it. Jamaica has been almost freed from it in the same way. This once widespread and sometimes destructive scourge, almost dreaded for life than for death, has been so nearly eradicated by vaccination, and vaccination alone, that the persistence of a strong section of the community opposed to it is one of the strangest of phenomena. The evidence is overwhelming. Wherever smallpox breaks out, it is in an unvaccinated district, country or body of people, and the fatalities are almost all among the unvaccinated and never among the re-vaccinated; where two bodies of men lie side by side under the same conditions, as the French and German armies in 1871, the vaccinated body scarcely suffers, the unvaccinated one is decimated; and in Egypt, where the natives are compulsorily vaccinated and the foreigners escaped it, the fatalities among three natives, though the latter are far poorer, worse housed and fed and medically cared for, and would naturally be supposed the chief victims. If all the people of a country were vaccinated and re-vaccinated at fair intervals, the disease would absolutely disappear, as it has in the German army: it is the ones who escape vaccination that maintain its existence. The ravaging of India and of the French Canadians is a constant example of what it has been. For instance, on 1 April 1885 there was a smallpox death in the Montreal hospital the \textit{Hôtel Dieu}; the patients who had not had it were sent home; the disease spread like wildfire, and by the end of the year 3,164 persons died of it, the city's business for the winter was destroyed, and the loss was millions. It has been proved that not above one in 100 of the vaccinated takes the disease when exposed and almost none die; of the unvaccinated, fully 99 per cent take it and 25 to 30 die. It must be remembered, however, that there cannot be perfect security without frequent re-vaccination, as the power of the cowpox varies with different persons and is rarely permanent, sometimes not over a year or two. With animal lymph there is no danger of the introduction of other diseases, the fear of which is made an excuse for refusal.

(8) Tuberculosis (including "consumption of the lungs"). called by Holmes the "white plague"; the most destructive single agency of death, and responsible for 120,000 deaths a year in the United States, more than all other infectious diseases together, except pneumonia. Formerly believed hereditary (to a slight degree), it is now known to be the product of a bacillus, isolated by Koch in 1880-82, and the hereditary conditions are mainly environment, with some tendency to anaemia. The communication, though in a few cases by infected milk, in the overwhelming mass proceeds by inhalation of the particles of dried sputum from other consumptives' lungs, blown about in the dust of streets or houses, or even wards of hospitals. Naturally, the greatest mortality is in places where free circulation of air is not possible, as jails and "institutions." Nature seems to have provided for the largest possible distribution of them: one patient may in extremes be known to give off from two to four thousand millions of germs in 24 hours; they are shaken from handkerchiefs from the beard or mustache, from the furniture and other things handled by consumptives, beaten up from contaminated floors. So universally diffused are they that it seems probable there are few persons in a tuberculous lesion of some organ, for it is not confined to the lungs. The great weapon against it are, first, maintaining the standard of nutrition and cleanliness as high as possible; with careful protection of the chest; second, the education of the public in the dangers of the dried sputum; third, enforcement of notification and registration of cases; fourth, public sanatoriums for treatment of early cases; fifth, special hospitals for incurables. In very recent progress has already been made: the rate in Massachusetts, one of the chief seats of the disease, has fallen from 42 to under 21 per 1,000 since 1853; and in New York, Glasgow and other great cities the drop has been similar.

(9) "The foreigner..." is a germ, a coccus growing in pairs and chains and entering by inhalation; and with one-fifth of healthy persons, present in the saliva. This is almost the one disease which has not diminished under medical and hygienic science, and has apparently increased, ranking
next to consumption in deadliness. It is especially a disease of languid circulation, as in the aged (as a typical disease) and a child and the intemperate; but it lays low vast numbers of the strong as well. The treatment has been revolutionized from the bottom, but still from one-fifth to one-fourth of all attacks are fatal. Thus far the most valuable novelties have been measures to prevent its spread, especially with the bachelors who pretend to believe that their health needs the indulgence and will not marry, and to use every effort to prevent the disease being carried to others; the latter to let no scruples of delicacy or affected ignorance stand in the way of thorough public supervision. The operation to himself is natural: women feel it adding an unfair stigma to an already shameful load of injustice; decent people feel that legal recognition is legal palliation and defense, and there is the real danger shown by experience, that if it is once shielded by the law the weight of the police force will be thrown on the side of protecting instead of abating houses of ill fame, as with liquor saloons, but with far more disastrous results. But any risk is preferable to the present shocking conditions, which make city brothels a stream of contamination to what should be the purest of homes.

(12) Puerperal Fever. Remembering not merely the formerly fatal and the disease—terribly frequent in nursing mothers and in maternity institutions rising from 5 even to 10 per cent—but the double bereavement it usually involves, the almost entire extermination of this disease is one of the grandest triumphs of modern medicine. Its contagiousness had long been suspected, when Oliver Wendell Holmes in 1843 published a full and clear statement of the facts leading to the belief; but for many years the profession generally scorned it—a wit and poor—could be granted any authority in medical science. Others gradually took his view, but it was the Lister antiseptic treatment which enabled it to be fully tested. Now the mortality is but about one-third of one per cent.

(13) Hydrophobia. This disease, though widely distributed among animals, is not very common among human beings in America, but excites a widespread horror from the multitude of pets, any one of which may chance to be stricken and to communicate it. In Europe it is less rare. The germ has long been suspected, but Pasteur ascertained its calculable effects on the nervous system, and that certain inoculations could render healthy animals immune and neutralize a powerful dose of the virus. He founded an institution in Paris for its treatment, and the mortality among those bitten by certainly rabid animals was reduced to less than one-half of one per cent. In dogs, quarantine and muzzling are the only precautions needed.

(14) Leprosy. This is a disease by a bacillus which probably enters the body through abrasions of the skin, and probably only from contact with another person; even so, it is but slightly contagious, contrary to the popular notion. It was discovered by Hansen in 1879, and since then an active and very hopeful investigation into prophylactic conditions has been carried on. Known to be old and widespread in Asia, it is not generally known that it came into San Francisco with the Chinese, that the Norwegians by their misery and bought a foothold in the Northwest and that in Louisiana there is an endemic condition of it, and slightly in some other southern States. It exists in New Brunswick likewise. Still more important for the United States is its great

Vol. 18 — 37
abundance in Hawaii and the Philippines. It can be readily kept in check by segregation and inspection.

There are other bacilli may be mentioned, of which the discovery has not as yet been followed by large results in prevention. The deadliest known is that of lockjaw or tetanus, discovered by Nicolas in 1884; it enters by wounds, and in some tropic parts all lesions tend to develop tetanus as surely as other sections do gangrene. Influenza, or "the grip," has one of the smallest bacilli known; it is spread by dried nasal discharges and enter by the nasal tracts. Anthrax is a disease mainly of cattle and sheep. Its bacilli were the first micro-organisms of disease to be isolated and can enter either by inhalation, infected food or abrasions.

Changes in Therapeutic Method. — It is only restating the same fact to say that new practice has followed on new theory, in rather new scientific knowledge of the nature of diseases. The only object of acquiring the knowledge was to embody it in practice. With the discovery of the zymotic principle in disease, traced finally to bacterial action, there can be not the same doubt or plagiarism as when the body was supposed to be possessed by conflicting "humors"; or when a fever was supposed to be an abnormal increase of vital fluids needing to be drained off; or when diseases were supposed to have no relation to any function of the body except the organs furnishing the dominant symptoms; or when one school supposed them waves of some sort, to be overcome by more powerful waves of the same class, and another school refused to entertain any theoretical suppositions at all, but relied on the history of cases, printed or traditional or experimental. But it may be said that the greatest revolution in the century, or at any rate the last half of it, is in the position assigned to drugs. At the outset the old faith in blood-still held great sway: Boerhaave himself made almost the whole art of medicine consist in its proper application, and at the end of the 18th century Washington had been sacrificed to it. But by the middle of the century both the homoeopathic and the regular schools based their practice, and many still base it, on the study and administration of drugs. They differed in the size and strength of doses, from huge boluses or powders or draughts whose efficacy was supposed to be in proportion to their nauseousness, to small bland triturations or dilutions; but not in the assumption that in them lay the one efficient method of dealing with disease.

The advanced school of the present does not discard medicines; so far from it, it studies them with more care than ever, and values a few, well tried and certain of quality and action, as highly as ever. It knows the mass of current medicines to be inert or worse, uncertain of action and applied to human functions still more an uncertain action; but it seeks to study thoroughly and apply scientifically the few real medicines or healing agents which must be used — quinine and digitalis and opium, and mercury and iodide of potash — instead of a mass of varying materials. It is significant that some of the stand-bys are extremely old; iodine, as ashes of burnt sponge, was known in classic times, and ergot impressed its peculiar action on stockraisers' minds from very early ages; even Peruvian bark is nothing new. We have not as yet made as many additions of panaceas as we might. But chemistry has done vast services for us, and will probably do far more. Aside from the discovery of new substances like cocaine, it has given us the active principles, of calculable strength and purity, in place of crude drugs whose varied strength at best, and of varying purity age, and there is no reason why we may not have new specifics as sure (and for as important diseases) as quinine.

But the new school does not feel itself under obligation to give any medicines whatever, while a generation ago not only could physicians have held their practice unless they did, but few would have thought it safe or scientific. Of course there are still many cases where the patient or the patient's friends must be humored by administering medicine or alleged medicine where it is not really needed and indeed often where the buoyancy of mind which is the real curative agent can only be created by making him wait hopefully for the expected like treatment as when the physicians still cannot unload their old training. But the change is great. The modern treatment of disease relies very greatly on the old so-called "natural" methods, diet and exercise, bathing and massage; in other words, giving the natural forces the fullest scope by easy and thorough nutrition, increased flow of blood and removal of obstructions to the excretory systems or the circulation in the tissues. One notable example is typhoid fever. At the outset of the 19th century it was treated with "remedies" of the extreme violence — bleeding and blistering, vomiting and purging, and the administration of antimony and mercury and plenty of other heroic remedies. Now the patient is bathed and nursed and carefully tended, he rarely given medicine. That is just the result of the remarkable experiments of the Paris and Vienna schools into the action of drugs, which have shaken the stoutest faiths; and partly of the constant and reproachful object lesson of homœopathy. Both the regular physician would be forced to admit that the homœopathic medicine, the infinitesimals, could do any good as direct curative agents, and yet it was perfectly certain that homœopaths lost no more of their patients than others. There was but one conclusion to draw — that most drugs had no effect whatever on the diseases for which they were administered.

These "natural methods" have been indicated above, but some further analysis of the individual elements is worth while. It will be noted that this is not, as a hasty reader might assume, the discarding of all the results of civilization and a return to barbarism. That the natural methods are efficient is precisely because scientific knowledge and modern improvements in application, as well as the thousand civilized devices for comfort and cleanliness, unattainable even a generation ago, have raised them to the level of first-rate therapeutic agents.

Perhaps foremost in the rank is the trained nurse, a swarm of dubious and anxiety. In place of ignorant and stubborn
usually conceited and often superstitious women, who pride themselves on defying all the doctors. Their common observation is that women can be relied on to carry out all his injunctions, to watch carefully for indications of danger and to furnish notes enabling him to view the progress and hourly changes of a critical case.

The importance of diet in therapy, and indeed in the preservation of health before the system becomes a subject for the physician, has never been wholly lost sight of, but at no time has it been so thoroughly recognized, so firmly insisted on, raised to so high a place in therapeutic agencies. Too much food, improper or ill-prepared food, over-haste in eating, all have their part in the dyspepsia which is a byword among foreigners as the national malady, and through much lessened, is still most formidable. Over-eating, too, is largely responsible for the prevalent Bright's disease and degeneration of the arteries. Sweetmeats and the mixtures of the drug-stores, ice-cream soda and artificial flavors, are other potent causes; especially of girls in the early part of their life between meals. The business man's five-minute meal at the lunch counter saves his business time often to the permanent ruin of his health. The question of alcoholic drinks is usually left to the forum of morals or politics, but it has a serious bearing on health, though not nearly so much as one or two generations ago. The introduction of light beers has not only lessened drunkenness, but also drunkenness of the liver, stomach, heart and arteries.

Few influences on general health have been greater or more beneficial than the enormous multiplication of the means of cheap enjoyable outdoor exercise in America within the past generation. Owing to the climate it is much harder to keep up habits of steady exercise here than in Europe, and unless there can be sociality with it, most people will not put themselves under the stress. We have not been a people addicted to sport or play, and formerly there were not sufficient means provided for us. Now tennis and golf and the bicycle and their kind are improving the constitutions, especially the nervous condition, of vast numbers. Of course there must be judgment in these matters, and probably some elderly people injure themselves by indulging in severe athletic sport only fit for young people with sounder tissues.

Massage need only be mentioned; its aim is primarily to remove obstructions to circulation. The normal blood should be sufficient to establish normal bacterial and other conditions, and massage gives it the freest play. The essence of bathing, called when practised scientifically "hydrotherapy," is the same, save that its special function is to free the obstructed perspiratory system.

To these might be added a fourth, which in some sense is the most natural of all; for it has been practised in ages more remote by many thousands of years than the suspicion of either of the others, and by savages almost at the beginning of recorded history, and evoking no suggestion or hypnosis. The main difficulty of this sort of treatment is that so little has been done to make it utilizable in practice, or to provide any certain means of assuring a definite result. Another is, that as with all the forms of mental science, its vogue, its mystery, the impossibility of regulating its manifestations, surround it with so hopeless an atmosphere of fraud and of that open-mouthed credulity which irresistibly invites fraud. Yet after all, the psychical method has always played an important though largely unrecognized part in therapeutics. It is from faith, which buoyed up the spirits, set the body free and the nerves playing their parts without disturbance, that a large part of all cures arises. Despondency or lack of faith will often sink the stoutest constitution almost to death's door; faith will enable a bread pill or a spoonful of clear water to do almost in a moment of healing, when the best medicines have been given over in despair. The basis of the entire profession of medicine is faith in the doctor and his drugs and his methods. This is no new discovery: it was said by Galen that "he works the most cures in whom most have faith," and the doctor-chemist-charlatan Paracelsus, who died of taking a universal panacea too poisonous even for his confidence, told his patients to have full faith and a strong imagination and the world will see the effects.

The subject of hypnotism, originally called mesmerism from its 18th century describer and practiser, can only be touched upon. Different practitioners have had such varying results from its use as to suggest that here too the personal equation is very important. Braid of Manchester, England, who first made a scientific study and attempt at utilizing it, was not successful; while an English surgeon in India, Esdaile, was highly successful, performing 208 operations on patients with all the effect of anesthetics, not then introduced. Its possibilities have been greatly exaggerated, not so much by the claims of the persons using it (except impostors) as by the eager credulity of the public. It seems not so much to create a new condition of sensitiveness to suggestion as to increase what normally exists. In organic disease it is practically useless. Its great service has been found to be in various affections which may all be classed as of the nervous system: hysteria, spasmodic functional complaints, children's vicious habits, and the vicious habits and alcohol habits, occasionally in childbirth and surgery, but it is precarious and not free from serious dangers. It should no more be practised without witnesses present than dentists give nitrous oxide, and the law should restrict its practice to special licensees or physicians of a certain grade.

William Osler, M.D.,
Regius Professor of Medicine, Oxford University.

MEDICINE, Preventive. See Preventive Medicine.

MEDICINE, Recent Progress in. Of none of the departments of human knowledge can it be said that it is thoroughly and positively progressive more than of the science of medicine. The new birth of medicine may be said to be associated with the names of three men, Virchow, Pasteur and Lister (qqv.), all of them men of the 19th century. Virchow, while not the discoverer of the different cells of the body, determined that its tissues were entirely composed of cells of various kinds, and he particularly identified the different types of diseased structure of the
tissues by the form of cell which predominated in each of them. Pasteur opened to the vision of the world the vast field of the infinitely small, discovered and described many varieties of bacteria, separated them from one another, cultivated them on artificial media and demonstrated their enormous significance for good or evil. As the father of the science of bacteriology (q.v.) he was one of the greatest benefactors the world has ever had. Lister, who died in 1912, may justly be called the apostle of cleanliness. To him more than to anybody else is due the demonstration that cleanliness is really next to godliness. By avoiding dirt of all kinds, by the use of chemicals to destroy germ life and finally by the simple practice of absolute cleanliness in every department of surgery he revolutionized that art, and made possible, as matters of everyday occurrence and of comparative safety, procedures which before his time were considered extra hazardous and which in the great majority of cases resulted fatally.

The stimulus produced by investigation of Lister in the realm of antisepsis during the seventieth decade of the last century was quickly reflected in surgery. The chief points in Lister’s recommendations consisted in cleanliness of wounds and all their surroundings; cleanliness of the surgeon, especially of his hands and finger-nails; the use of carbolic acid, particularly in the form of spray in the operating room during an operation, to destroy the disease germs in the atmosphere, and the use of antiseptic dressings or coverings upon wounds.

The older surgeons smiled at all these details which seemed to them foolish and unnecessary. After 25 years practically all opposition had been overcome. The results compared with the results under the old system simply compelled the adoption of the new principles. But experience also showed that the use of powerful chemicals was unnecessary in the treatment of wounds, and that often it was really injurious. It was then determined that the sterilization of every thing which had any relation to a wound could be accomplished quite as effectually through heat and dressings as with chemicals and with a greater degree of comfort and safety. Consequently the instruments, the dressings and all the apparatus connected with an operation were subjected to a high temperature sufficiently long to destroy all germ life, and the surgeon himself and all his assistants put on freshly laundered white clothing, and washed and scrubbed their hands, face and arms with soap and water sufficiently long to ensure relatively complete cleanliness. Then rubber gloves were put on as an additional safeguard against the contamination of the wound which was about to be made.

This is practically the procedure which is now carried out in a surgical operation in every modern hospital throughout the world. Such precautions enable surgeons to penetrate any portion of the body with absolute fearlessness, and with the confidence that in the great majority of cases in which proper judgment has been shown in selecting the case, and proper skill and care applied, the patient will recover. It will not bring the dead to life, but it will often restore those whose lives hang by a mere thread. Thus surgeons are able to perform operations within the skull, within the cavity of the chest, within the cavity of the abdomen, and within the joints and upon the brain, the heart and lungs, the stomach, liver, spleen, intestines, pancreas, ovaries and uterus and the kidneys, ureters and bladder, which were impossible before the time of Lister, or if they were performed the patients almost invariably died.

One of the most recent developments in surgery consists in the transfer of blood from the arm of a healthy person directly into the circulation of one who is almost at death’s door either from loss of blood, from the shock of a surgical operation or from some other cause. An attachment is made between an artery in the arm of the healthy person and a vein in the arm of the sick person by means of a suitable tube which is carefully adjusted into openings made in the vessels above mentioned so that the two persons, the outward being so gauged that it will be known when the proper quantity has been withdrawn. The method has proved life-saving in a number of instances, but it is not without danger, for should a clot or clog form in the outflowing blood it might check the circulation in the receiving person or might quickly cause death by interference with the heart action.

Another important procedure which has been perfected during the past 25 years is what is known as the Cesarean section, which consists in removing a child from the womb of its mother through incisions in the abdominal wall and the womb. This is a very ancient operation and is attempted when it is believed that the child cannot be born by the ordinary channel. The result was formerly fatal in the great majority of cases to the mother if not to the child. Under the modern methods of surgical procedure it is now done with great frequency, sometimes even by doctors of inferior surgical skill and experience, and in most of the cases both the mother and the child recover.

Under the influence of the reforms instituted by Lister the practice of obstetrics is far safer, both for the mother and for the child than ever before. Before the advent of antisepsis the mother was little better than a graveyard. If a mother survived the immediate danger of parturition she was very likely to die from the blood-poisoning or sepsicaemia which followed. Now, thanks to the influence of Semmelweis, Holmes, Lister and those who have followed them, a maternity hospital is the safest place in the world for a woman to give birth to her child, not alone because the doctors in such hospitals have more skill and experience, but because they are clean themselves, and everything around them is clean.

In the treatment of disease great advances have been made. There are many more drugs upon the market than formerly and doctors seldom write out a surgical prescription nowadays. The medicine makers have forced their wares upon the profession, and for every disease it would seem as if there were a hundred remedies. Some of these remedies are valuable, but the greater number are valuable chiefly in the eyes of those who make a living at the expense of the patient who can induce the public to use them and have faith in them.

But there is one marvelous remedy which
has been brought forward within the past few years which is known as "Salvarsan," or popularly as "606" because its discoverer, Professor Ehrlich, made 605 chemical combinations before he hit upon this one. (This number has since been increased to 914, the new compound being called "Neo-salvarsan"). This substance is a compound of arsenic and is used in the treatment of syphilis, which is one of the most deadly diseases, in the wide extent of its ramifications, of all the diseases of which human beings are victims. A single injection of this substance into the tissues will sometimes cure a case of many years' duration. But it is not infallible, it sometimes is followed by bad results, it must sometimes be used during a considerable period of time and its best effects are sometimes obtained when it is combined with a suitable preparation of mercury, which heretofore has been the mainstay in the treatment of syphilis.

Investigations have been constantly proceeding to endeavor to find a cure for that greatest scourge of the human race — cancer. Many so-called remedies have been discovered and announced, only to be quickly abandoned. As cancer is known to be a local disease in its inception, it is often cured by the surgeon's knife when attacked sufficiently early and with sufficient thoroughness.

The recent studies of Wassermann and Ehrlich in the endeavor to find a substance, synthetically composed, which shall have a selective action for the cells of cancerous tissues and be inactive upon other tissues seems to have been successful in cancer in mice, which form one of the few species of animals, if not the only one, in which the disease may be transmitted from human beings. If the result should prove what is great reason to believe it will prove, it would be one of the greatest victories in all the annals of medicine.

Tuberculosis is yielding to the steady attack which is being made upon it in city and country. It has long been known that it was curable, all that it has needed has been a concerted attack upon it, and now by means of a few drugs, a proper diet, plenty of pure air and an out-of-door life, the conquest of this terrible disease is improving, and open air institutions of treatment, public and private, for men, women and children are being established in all suitable parts of the country, and the number who are being radically cured of the disease is increasing enormously every year. What is really better is the intelligent perception and comprehension of the disease which will prevent people from contracting it, and in course of time we may expect it will occur with comparative infrequency.

There is no disease into the study of which more enthusiasm has been thrown in recent years than that of tuberculosis and many sanatoria have been established in various parts of the country for the care of the tuberculous. One of the most important aspects in the treatment of this disease consists in the care of the children of tuberculous parents. It has led to the organization of open-air homes for their treatment. One of the most useful of this class of institutions is the Preventorium, as it is called, the buildings of which are located at Farmingdale, N. J., with suitable buildings and equipment. It takes selected children of tuberculous parents, debilitating and susceptible to disease, between the ages of 4 and 14, to a comfortable place where they will have plenty of wholesome food, 12 hours of rest in bed at night and an additional hour after the midday meal. It gives them two and a half hours of school instruction and requires a few trifling household duties. The remaining eight and a half hours are devoted to play in the woods and fields.

One of the great discoveries of the past 20 years was what is known as the X or Röntgen rays. Their power of making invisible things visible is well known and their application to the photography of the interior of the body has been of priceless value. They have also been used in the treatment of certain diseases, sometimes with alleged success, but often with positive harm. Their influence in producing severe burns, which it is almost impossible to cure, is well known. In not a few cases their use has led to the development of cancer in those who worked with them. Quite a number of physicians have lost their lives as the result of malignant disease produced by their influence.

The influence of serums, vaccines and cultures of bacteria and their products in the treatment of disease is absorbing a vast amount of attention both in the laboratory and in the treatment at the bedside. It would seem as if we were at the threshold of an entirely new order of things in this respect. Fever which has long been considered baneful is now regarded as frequently beneficial.

The bacteria which are constantly in the body are found to be harmful, or beneficial or indifferent according to the conditions of the body. Harmful bacteria when killed and injected into the body may sometimes cure diseases which at other times they would cause. The constituent elements of the blood are ingredients in a great reservoir, some good and some bad, and good or bad according to certain conditions.

The statements which have been made in the past few paragraphs will indicate the trend of thought at the present time, which is largely in the direction of preventive medicine (q.v.). Prevention is, of course, often better than cure. The great object now seems to be to find substances which will make one immune or proof against the attacks of various forms of disease. In pursuance of this doctrine inoculations with properly prepared germs or the products are now made for smallpox, diphtheria, typhoid-fever, lock-jaw, pneumonia and various other diseases. It is a field which is full of promise and of hope.

This article should not be concluded without a word in regard to the great triumphs which have been achieved by the development of sanitary measures. It is known that certain diseases are propagated by insects. Malaria is propagated by a particular species of mosquito and the same is true of yellow fever. It is known that the mosquito breeds in stagnant water. The elimination of these diseases from the places where they abound would seem therefore to be dependent upon the elimination of the mosquito. This has been tried on a grand scale in the building of the Panama Canal (q.v.) and in the cleaning up of the city of Havana. The drainage and sanitation of
the Canal Zone are the work of an army doctor, Colonel Gorgas. Without this work the canal could not have been built. By doing this work the Canal Zone has been transformed into an area of health resort.

The recent history of medicine has also been marked by the establishment of sanatoria for the treatment of particular forms of disease and of various institutions and laboratories for special investigation and research. Fifty years ago none of these were in existence. The plan of these institutions is to study exhaustively a single disease or group of diseases, experimenting patiently and continuously upon human beings and animals by means of chemical and biological procedures, by mechanical measures and by means of every other form of assistance which human ingenuity can devise.

This work is prosecuted unceasingly until the cause of the disease is ascertained, and when that point has been reached the study is continued for the removal of the cause or for its effective overcoming. In other words, a life and death struggle is going on between the forces of disease and the intelligence of man as it has never been seen before, and other strongholds of disease are being battered down. Not only in this country, but in all the countries of the civilized world has this spirit of inquiry into the cause and treatment of disease infected men, as with a consuming fire of the improved state of medical education which quickly senses the advantages of public health work. Efforts to improve the knowledge of physicians who have taken their degrees, but who are too much occupied with their work to be able to go to a distant medical school for post-graduate work, are now being made through a system of post-graduate work at home, a plan originating with the Medical Society of the State of Pennsylvania, in a series of clinics and discussions before county medical societies. This plan was also adopted in North Carolina. The Great War in Europe has brought out extraordinary resources in medicine with the result that while the conditions known to former warfare have been repeated on a scale of a magnitude, there have been new elements, such as the intensity of the explosions, causing "shell-shock," and the new features such as poisonous gas. Poison gas, "mustard gas" (dichlorelthyl-sulphid) was hurled in shells in liquid form and resulted in burns of various severity. When inhaled it caused inflammation of eyes, nose, throat and lungs. As its poisonous effects are produced only in moist conditions and as it has itself very little odor, the results are not manifest for some time. Distress in the stomach and vomiting ensue after several hours accompanied with acute conjunctivitis, running of the eyes and photophobia, or oversensitivity to light, frequently complicated with laryngitis and bronchitis. If the skin is touched by the liquid, burns result producing blistering and desquamation. In spite of the much more deadly methods used in modern destructive warfare, the deaths due to disease have been reduced from 97 per cent of all deaths in the Napoleonic War to 2.5 per cent in the Boer War, where the deaths from disease were 67 per cent to 4 per cent in the late war.

A tendency to develop research in medical
fields solely through laboratories in which the intimate structure of the body was studied and the influence of the chemical constituents of the body made it possible to study the pathogenic elements, both endogenous and exogenous, resulted in a high degree of specialization in which the general practitioner found himself at a loss to keep up with the advances in his field. He was therefore more and more in the habit of referring his patients to specialists who confined their researches to the physiology and pathology of a single organ, such as the eye, the ear, the stomach, the intestines, etc., and the interrelation of the exceedingly complicated details of the physiological process was almost impossible adequately to realize. The weakness of the laboratory and specialist method of treating disease was felt mainly because of the fact that only the advanced or at least well developed stages of the disease came to the laboratory. This procedure failed utterly to take into consideration the registration of the disease in its early stages, a physical condition which is of course actually present, though not visible, and is the veryStuff on what are known as "physical signs." These, which are but a limited portion of the true symptoms of disease, are among the last to appear as evidence of the presence of a diseased condition. It has therefore been realized that there are symptoms of great importance in certain conditions which may be but premonitory of a later organic disease, and that these symptoms are not physical signs but are mental. This enlarges the function of the general practitioner, whose knowledge of the lives of his patients and of their antecedents is much more valuable for the treatment than any amount of such knowledge collected by laboratory methods could be. It is also in line with a tendency which is most prominent today in practical medicine, namely that which has developed the subject of preventive medicine (q.v.) to its present proportions. This recognition of the mental registration of disease antecedent to its physical registration as a physical sign is important in the introduction into psychotherapy of psychoanalysis (q.v.), a procedure which originally included only the mental treatment of mental diseases. But it is now realized that many physical diseases as well as giving mental signs of their onset before the physical signs have a mental origin, are in other words psychogenic, a point of view which opens a new field not only to medicine but also to education. Indeed it is now seen that much of what was formerly attributed to purely physical causes must now be assigned to faulty or incomplete mental processes. Therefore the modern physician needs to know all he can possibly learn of human psychology and its advances into the knowledge both of conscious life and of the unconscious; and the old materialistic attitude of the physician who thought that the physical signs and the drugs or operation *indicated* constituted the whole of therapeutics, is giving way to that of the modern practitioner who finds that almost nothing is irrelevant to the total situation as presented to him, and that he cannot treat the body exclusively. If he thinks he is doing that, he is shutting his eyes to the very patent fact that by his authoritative position he is producing a mental effect upon the patient which in turn has a secondary physical effect which he cannot afford to ignore. In short it may be said that the field of medicine in recent years has widened enormously and has at the same time deepened, including as it does not merely the mental signs of approaching illness, as well as the formerly recognized physical signs of its later and well developed stages, but also the unconscious as well as the conscious element in the mental factor, a condition which has quadrupled the sphere of usefulness of the physician of to-day as compared with that of the specialist of yesterday.

**S. Smith Ely Jelliffe.**

**MEDICINE BOW MOUNTAINS,** a range of the Rocky Mountains on the west side of Laramie Basin in central Wyoming. Medicine Bow Peak, the highest summit, is 12,005 feet above sea level. Most of the area is a high plateau covered with pine forest and included in the Medicine Bow forest reservation.

**MEDICINE DANCE,** a common practice among the American Indians; dances being conducted by the medicine men of the tribe for various purposes, and in preparation for different events, like warfare, the hunt, etc. Both in the dance before a battle and in the conflict itself the medicine chief is the one man most worthy of consideration. If war takes place he courts the thick of the fight if for no other reason than to show his immunity from danger. The funeral dance of the Yaqii tribe is a representative example of the medicine dance; the chief medicine man arranging the ceremony, which ensures the safe passage of the dead to the spirit world. The dancers to the number of half a hundred appear in the centre of the assembled tribal gathering, naked except for a cloth about the loins. Their bodies are painted in imitation of skeletons. Over their heads they wear masks fringed with long horse-hair, dyed in many hues, eyelashes and eyebrows hang over the rudely designed faces and beards reach nearly to the waist. On their legs they fasten strings of rattles cut from rattlesnakes, and the sound of these is most gruesome to the spectators. Each dancer carries two knives, one in each hand, with which he gesticulates violently in imitation of the act of slaying imaginary enemies. Every man dances after his own ideas, each seeming to ouordo the other in the violence of the motions. Music for the dance is furnished by tom-toms. After the dance a great feast follows, continuing until midnight.

**MEDICINE HAT,** Canada, a city in the southeast corner of Alberta, 600 miles west of Winnipeg and 167 miles southeast of Calgary,
MEDICINE MAN — MEDICINE AND PSYCHIATRY

in lat. 50° 2' N., and long. 110° 40' W., and is 2,181 feet above sea-level. It is situated on the slope of the South Saskatchewan River while given it a drainage slope of much superior towns on the open prairie. The city took its rise in 1883 from the advent of the Canadian Pacific Railway. It is on the main line of the railway and is the terminus of the Crow's Nest Line. For many years it remained a centre for the ranching industry the surrounding country was excellently suited, the chinook winds which prevail in this part of the country enabling the horse and cattle to range in the open throughout the winter as during the summer. But the large ranches are rapidly disappearing as the land is being brought under cultivation by the homesteaders. In 1899 Medicine Hat was incorporated as a town and in 1907 as a city. As its earlier development was due to ranching and then farming its late development is due to the rise of manufactures. Like Lethbridge it is one of the four principal coal mining centres of the province but its most valuable resource is water. It lies in the centre of one of the largest fields of natural gas on the continent. The gas was first discovered about 1895 when the Canora to Medicine Hat on the Canadian Pacific Railway bored on the banks of the river to find coal deposits. The first gas well was drilled in 1890 by a company of local citizens. For many years the gas was gradually developed for domestic consumers but from 1907 it has been more extensively developed as a cheap and excellent fuel for manufacturing purposes. Both gas engines and steam boilers heated by gas are used. The analysis of the gas is as follows: methane 99.49 per cent; hydrogen 0.51 per cent; B.T.U. per cubic foot 1,100. The city has 17 gas wells with an average daily open flow of two million cubic feet and distributes this to domestic consumers at 15 cents and to manufacturers at 5 cents per 1,000 cubic feet. The city owns and operates its own utilities. The electric plant and the water plant are operated in conjunction, the same boilers providing the power for operating the pumps and the dynamo. The city water supply, taken from the Saskatchewan River, is passed through a sedimentation basin and filtered and is pumped to a reservoir on a hill overlooking the city from which it is carried by gravity pressure. There is also a sanitary sewage system, the sewage being deposited in the river some distance below the city. The streets are all 66 feet wide, are all macadamized and have been well planted with trees. The sidewalks are of cement. The manufacturing and business section is built of brick while the private residences are mostly of wood construction. There is a dry-farming demonstration farm, also a business college, a general hospital, a grain elevator, flour, linseed-oil, rolling and planing mills, brick works, a steel plant, lumber, glass works, foundries and machine shops. Pop. 9,272.

MEDICINE MAN, among the American Indians, South Sea Island tribes and other savages, a man supposed to possess mysterious healing powers. No other man among savages so much as the medicine man occupies much the same position as that held in civilized communities by two of the learned professions — medical and clerical. The medicine man is both priest and physician, and is at once the repository of all that a tribe knows, fears and believes. In very low stages of human development, however, he is at best only a maniac, dealing in terrors, possessed of occult powers, but laying claim to no special medical knowledge. Thus, among the aborigines of North Queensland, the tribal doctors do not attend on the sick — an invalid being cared for by wife or mother. They are not ostentatious, a fact which the belief that the surrounding country was excellently suited, the chinook winds which prevail in this part of the country enabling the horse and cattle to range in the open throughout the winter as during the summer. But the large ranches are rapidly disappearing as the land is being brought under cultivation by the homesteaders. In 1899 Medicine Hat was incorporated as a town and in 1907 as a city. No other man among savages so much as the medicine man occupies much the same position as that held in civilized communities by two of the learned professions — medical and clerical. The medicine man is both priest and physician, and is at once the repository of all that a tribe knows, fears and believes. In very low stages of human development, however, he is at best only a maniac, dealing in terrors, possessed of occult powers, but laying claim to no special medical knowledge. Thus, among the aborigines of North Queensland, the tribal doctors do not attend on the sick — an invalid being cared for by wife or mother. They are not ostentatious, a fact which the belief that the surrounding country was excellently suited, the chinook winds which prevail in this part of the country enabling the horse and cattle to range in the open throughout the winter as during the summer. But the large ranches are rapidly disappearing as the land is being brought under cultivation by the homesteaders. In 1899 Medicine Hat was incorporated as a town and in 1907 as a city. As its earlier development was due to ranching and then farming its late development is due to the rise of manufactures. Like Lethbridge it is one of the four principal coal mining centres of the province but its most valuable resource is water. It lies in the centre of one of the largest fields of natural gas on the continent. The gas was first discovered about 1895 when the Canora to Medicine Hat on the Canadian Pacific Railway bored on the banks of the river to find coal deposits. The first gas well was drilled in 1890 by a company of local citizens. For many years the gas was gradually developed for domestic consumers but from 1907 it has been more extensively developed as a cheap and excellent fuel for manufacturing purposes. Both gas engines and steam boilers heated by gas are used. The analysis of the gas is as follows: methane 99.49 per cent; hydrogen 0.51 per cent; B.T.U. per cubic foot 1,100. The city has 17 gas wells with an average daily open flow of two million cubic feet and distributes this to domestic consumers at 15 cents and to manufacturers at 5 cents per 1,000 cubic feet. The city owns and operates its own utilities. The electric plant and the water plant are operated in conjunction, the same boilers providing the power for operating the pumps and the dynamo. The city water supply, taken from the Saskatchewan River, is passed through a sedimentation basin and filtered and is pumped to a reservoir on a hill overlooking the city from which it is carried by gravity pressure. There is also a sanitary sewage system, the sewage being deposited in the river some distance below the city. The streets are all 66 feet wide, are all macadamized and have been well planted with trees. The sidewalks are of cement. The manufacturing and business section is built of brick while the private residences are mostly of wood construction. There is a dry-farming demonstration farm, also a business college, a general hospital, a grain elevator, flour, linseed-oil, rolling and planing mills, brick works, a steel plant, lumber, glass works, foundries and machine shops. Pop. 9,272.
tion—principles of the relation of body and mind; and above all be forced to realize, against the old traditional materialistic prejudice, that every patient is mind quite as importantly as body. Every reader knows this for himself.

Because, in part, of his varied education, the present writer was almost a pioneer in practical attempts to correct this particular narrowness of American medical education, although laboring meanwhile under quite characteristic difficulties, such as the tradition of a formal and lack of time and of funds. To repeat part of an article in Science, 18 years ago (26 July 1901):

The education given to the medical student seems in general too grossly materialistic, too somatic. He learns but one side of this twosided story; from the first year to the fourth, from the dissecting room to the gynecological or otorhinal clinic the routine student sees and hears of muscles and bones, and viscera, sense-organs, nerves; he learns by little and countably little, of that other aspect of men and women which to these very men and women is their life, while these other, these organs, are but needful instruments of that life's attainment. And their point of view, it need not be said, it also needs to shift it, and illogical confusion follows. The layman cares little or nothing for his stomach's condition so long as it gives him no pain and takes good care of what his will and his appetite lead him to supply to it. The woman in search of a happy family life thinks seldom of her reproductive mechanism so long as it gives her healthy children whom she can love. There is something beside cell-built tissue for the gynecologist in charge of an operative case to consider when of two women, alike in vigor, who undergo identical ovariotomies, for example, one goes in three weeks from the hospital a new woman, cheerful, capable and happy, while the other becomes an hysterical wreck never perhaps to equate her former self in happiness or in health. As every surgeon knows, such differences are met conjunctively and they puzzle him. Why is it that present medical education takes no account of the principle of this variant?

So far as the student is concerned, the course, four years or three years long, quite ignores in general the emotional and temperamental factors which in one way or another, directly or indirectly, less or more, enter into almost every chronic case and into many of the acute cases which the general practitioner is called upon to treat. Instead of striving to teach the student what conditions underlie mental habits and idiosyncrasies, medical instructors are now in the habit of practically ignoring them regardless of possible great benefits to come from their study as psychological data.

Too often is the medical man the most materialistic-minded member of a community, when his view should be much deeper, into the controlling forces of life. This is the natural outcome when in a long medical course no part of the individual is shown to the student except what he can feel with his hands or see through the microscope. Yet how commonplace is the preoccupation with the hallucination of a woman, not his or her body, but the will, affections, habits, character, of the individual, while (what is more immediate to our argument) these same aspects of consciousness are often the direct molders, or destroyers of disease and, as one side of an inseparable psychophysical organism, have more control or influence over the functions purely somatic than the average practitioner of medicine appreciates. Not mind controlling body nor body controlling mind, but both together always sensitive to the stimuli of a common environment, combined into the actual individual.

The whole trend of modern biologic science is toward the appreciation that neither factor of personality, body or mind, in justice to the medical student and through him to the public may be longer ignored. Agreeably to such convictions, the catalogue of the Tufts College Medical School of 1900-01 contained announcement of a course in "Normal Medical Psychology." This was continued for nine years, when by arrangement with Prof. Morton Prince, it was developed into a course termed "Psychology and Neurology," and Psychiatry. In 1912 (for lack of funds to pay the lecturers) the psychological work was abandoned. Such a record of pioneer development in medical curriculum is instructive in several respects to all of those who believe that a physician should realize that his patients have minds influential to a degree at present quite indefinable but more and more appreciated. So far as known, the Johns Hopkins medical department alone preceded in the practical and systematic realization of this basal fact.

The slowness with which adequate courses in normal medical psychology are made required parts of medical curricula, is another depressing sign of the essential narrowness of the average professional outlook into life and philosophy, just as it is another evidence that medicine is for some of its practitioners still largely a trade wherein no facts are either of interest or desirable, no breadth of view admissible, that has not a bank-note or its equivalent closely attached. Hasten the progressive day when without the broadening education of the college bachelor's course at least no man or woman shall be allowed for gain to take charge of the human personality of a fellow mortal if he knows on but the barest half of the being with whom he pretends thoroughly to understand.

The reasons in particular for this insistent need of psychology in medical education the writer already in part has summarized in an article in the New York Medical Record of 30 Jan., 1909.

The Physician's Need of Psychology.—The most obvious and immediate need for systematic medical psychology comes, of course, from psychiatry and neurology. The demand does not come even more insistently than it does from the teachers of these subjects, especially of the former, is one of the anomalies of the whole matter. When one does not expect a student to understand the deranged movements of the heart who has never seen a healthy heart or a representation of one, why should the multitude of third- and fourth-year men who know nothing of the processes of perception and imagination be expected to comprehend an hallucination? And those who have never been told of the mechanism of the emotion of fear to understand the depression and misery of melancholia? One asks too much in
expecting any man to really comprehend a case of paranoia who has no notion of the processes of ideation. And neurasthenia, the bread-and-butter malady to practitioners of nervous disease, does any suppose it is not so intertwined with mental relationships that to unravel it in full is to make use inevitably of no little various and intricate psychology? The modern variants of the "rest cure" require a knowledge of the motor relationships of the mind, and else this valuable system of retraining the mind back to health through controlled voluntary use of the muscles would lose much of its precision and basal usefulness.

In a less technical way, perhaps, but quite as importantly in the long run, the surgeon as a surgeon needs to be familiar with mental processes. It is especially important that he should realize the often surprising life-lengthening support and stimulation, technically called dynamogeny, that belongs to the joyful emotions. Scarlessly useful oftentimes, expli- cit or implicit, the vitalizing influence of determination, of vigorously expressed will to thrive and to live. Aristotle and John Hunter down to the latest of them all agree in admitting these facts, however the future science of man shall in time interpret and explain them. Does the sceptic (if such, perchance, persist into these "latter days") know of a single really great surgeon who does not inevitably inspire the almost perfect confidence of every patient under his care? Can the master-surgeon actually cut us up invariably so much better than his struggling neighbor in the next block uptown? Or is his far greater success due in part to his exaction of confidence in his knowledge of human nature as really it is—mind as well as body,—giving us confidence and so inspiring hope and all the guarding and reparative powers of pleasant and stimulating emotion? The physiology and psychology of this important influence we now fairly well understand.

In a still more general way, the successful practitioner in medical cases as distinct from surgical, consciously or otherwise, uses the principles of psychology in a very large proportion of his practice. One need not attempt the labeling this task of surgery, 73.5 per cent of our practitioners must nowadays realize to some extent the mental factors in every complex disease.

The Need of Psychological Instruction for Breadth.—In a department of the science of medicine there is always an urgent demand for a broader outlook than the average medical student can obtain without a preliminary college course. It is easy to underestimate the influence and the importance to humanity of the profession of medicine.

Medical philosophy reaches out into almost every aspect of human relationship, and thus it pervades, and in considerable part directs, every phase of modern human society. That it does not do so to even a greater extent than it is capable of doing is largely due to the fact that mental activity is not adequately studied in the medical school. Many phases of the individual are often exhaustively considered, but at present it is no one's business to combine these scattered parts into the whole of the life of the individual, or man or woman. And yet every patient is an individual, a personality, and has a heart

and kidneys and nervous system and all the rest only as parts ministering to this personality.

It is one of the important tasks of the medical psychologist to weave these scattered threads of organic knowledge into this actual personality. Then at last the average physician, perhaps in some measure at least, how to follow the sound advice of the numerous orators at commencement who advise the graduates "to treat not the disease but the individual suffering from the disease." The somatic aspects of the malady are adequately treated in many, perhaps, the most essential, but of the inner side of the "arc of personality" one hears but little as yet from the teaching faculties of medicine.

The tide, however, is coming in.

The psychology of sex is a phase of education for which there is continually a more obvious demand from a grossly wronged and degraded society, and consequently from educators.

The course in legal medicine in the medical schools demands for its greatest usefulness the basis of psychological knowledge which should precede it in the curriculum. Human misery and crime often depend on motives more psychological than physiologic.

Psychology in the Physician Personally.—Medical instruction in psychology undoubtedly would make the physician more sympathetic with his patients than he is now. With this added sympathy he would serve them better because more understandingly. He would tend to approach them as the ideal of the old-time family practitioner, "guide philosopher and friend." Knowledge of the processes and relations of mind would be the physician himself a source of great and unending satisfaction. Related to it is not only the knowledge of human nature, that never tiring source of interest and delight, but psychology leads outward in all directions into the true wisdom of divine philosophy.

In 1913 the American Psychological Association, by a committee, investigated the status of psychology in American medical schools. One of the questions asked the deans related to the advisability of special instruction in psychology. Of the 71 schools (only 71) answering this question, for every 20 affirmative, 12 per cent in the negative, while 15 per cent gave a qualified answer one way or the other. How slow is the recognition that emotions and ideas control the body!

Psychology in Relation to Psychiatry.—It is obvious that the medical care of insanity cases, if more than "asylum," is to be offered these "unhappy" souls, must depend as much on the physician's knowledge of psychology as on somatic medicine. At present it is in a widespread area of our country nothing less than a reproach to so few professional psychologists are trying to relieve and to cure the insane. In every case, from the irrational paranoiac to the terminal dement, much knowledge of the normal mind would seem to be a the nature of professionalism in an attending physician! As yet the percentage who have such knowledge is so small as to constitute a reproach to organized medical efficiency and nothing less than that. Even the superintendents of the institutions conducted for the cure or the care of diseased minds are seldom or never psychologists. And still many
of the hospitals have no such modern improvement about the place.

GEORGE VAN NESS DEARBORN,
Medical Corps, United States Army.

MEDICINES. See CHEMISTRY, PROGRESS OF.

MEDICK, a plant genus of the natural order Leguminosae, native of the temperate and warm belts of the Old World. The pods have spiral twists and the genus includes very many species, both annual and perennial, with trifoliate leaves, and containing the Globes. Some species have been introduced into the United States, of which lucerne and alfalfa are economically the most important. Several Russian species which require little moisture have recently been introduced in the arid and semiarid regions of the West and have been proved a success. See Medicago, and consult 'Bulletin 108' of the Texas Agricultural Experiment Station (1908) and 'Bulletin 165' of the Alabama Agricultural Experiment Station (1912).

MEDILL, mé-dill', Joseph, American journalist, b. New Baltimore, Canada, 6 April 1823; d. San Antonio, Tex., March 18, 1878. Having early removed to Massillon, Stark County, Ohio, he was admitted to the bar in 1846, practised at New Philadelphia, and in 1849—51 published at Coshocton the Republican, a Free-Soil paper. In 1852 he established at Leavenworth and in Foremost City, a Whig organ, which in 1853 was united with the Free Democrat and called the Leader. In 1855 he sold his interest in the Leader, removed to Chicago, with two partners purchased the Tribune, advocated radical anti-slavery measures and supported Lincoln in 1860. He was a member of the Illinois constitutional convention of 1870; United States civil service commissioner in 1871 and in that year was elected mayor of Chicago. In 1874 became editor-in-chief of the Chicago Tribune, in which relation he remained until his death. It was largely due to his individual efforts that the city of Chicago was selected for the World's Fair of 1893.

MEDINA, José Maria, hō-sā mà-ra'ē-sā mà-de'ā, Central American politician. b. Honduras, 1818; d. Santa Rosa, 8 Feb., 1878. He was president of Honduras in 1862—63 and was re-elected in 1864—66 and in 1870. The war with Salvador in 1871 disturbed his hitherto successful administration and at the next election he was defeated by the Liberal party who elected their candidate Arias. Defeated again by Leiva in 1874 Medina raised an unsuccessful revolt in 1875—76 and in 1877 a second revolt was punished with death by court-martial.

MEDINA, José Toribio, Chilean bibliographer; b. Santiago de Chile, 1852. He received his education at the National Institute and the University of Santiago, being graduated in law at the latter institution in 1873. At the age of 22 he was appointed secretary of legation at Lima. In that city he made investigations in the archives and in 1878 after his return to Chile he published a history of Chile. Already in 1874 he had published a metrical translation of Longfellow's 'Evangeline.' In the war with Peru, Medina served in the army and at the close of the war was made judge of first instance courts ceded by Peru. He was made secretary of legation at Madrid in 1884 and here also he delved into the Spanish archives dealing with the Spanish in America and especially the history of Chile. He returned to his native country after several years' residence in Europe. He went abroad again in 1902 and also visited the United States to make further historical studies. Medina's great work is the 'Biblioteca hispano-americana,' 1493—1810 (7 vols., 1898—1907), which contains notices of 10,000 works. Other bibliographical works are: 'Historia y bibliografia de la Imprenta en el antiguo virreinato del río de la Plata' (1892); 'La imprenta en Manila desde sus orígenes hasta 1810' (1896); 'Biblioteca hispano-americana septentrional' (1897); 'Biblioteca hispano-chilena, 1523—1812' (3 vols., 1897—99); 'La imprenta en Bogotá, 1779—1821' (1904); 'La imprenta en Guadalajara de México, 1793—1821' (1904); 'La imprenta en Guatemala, 1660—1821' (1910); 'La imprenta en la Habana, 1707—1810' (1904); 'La imprenta en Lima, 1584—1824' (4 vols., 1904—07); 'La imprenta en México' (1907—); 'La imprenta en pueblas de los Estados, 1640—1821' (1908); etc., etc. Medina's historical works are also important since they are based on manuscript sources. They include 'Historia de la Inquisición en Lima' (1887); 'El Tribunal de la Inquisición en la Inquisición en Chile' (2 vols., 1890); 'Juan Diaz de Solis' (2 vols., 1897); 'La Inquisición en las Islas Filipinas' (1899); 'La Inquisición en México' (1905); 'El Portugués Esteban Gomez' (1908); 'El veneciano SebastianCaboto' (2 vols., 1908); 'Medallas coloniales hispano-americanas' (1900); 'La instrucción pública en Chile' (2 vols., 1908); 'Diccionario biográfico colonial de Chile' (1906). He edited 30 volumes of 'Colección de documentos inéditos para la historia de Chile.' Consult Chiappa, V. M., 'Noticias acerca de la vida y obras de Don José Toribio Medina' (Santiago 1907).

MEDINA, or MEDINEH, mé-de'na, Arabia, the native Medina-al-Nabā'ī of the City of the Prophet (also Medina al-Rasul Allah, City of the Apostle of God), 500 miles southeast of Palestine, 250 miles north of Mecca, and about 10 miles east of Yembo on the Red Sea. It is reached from Damascus by an 820-mile railway journey. The city is celebrated for containing the tomb of Mohammed, whence it ranks second to Mecca as a pilgrimage resort of Islam. It is situated in the most fertile spot of all Hejaz, the streams of the vicinity tending to converge in this locality. An immense plain extends south from it; in every direction the view is bounded by hills and mountains. The town forms an oval, surrounded by a strong stone wall, 30 to 40 feet high, that dates from the 12th century, and is flanked with towers, while on a rock, at its northwest side, stands the castle. Of its four gates, the east Bab-el-Misr, or Egyptian gate, is remarkable for its beauty. Medina has no large buildings, but a few mosques, two smaller ones, a college and public baths. The houses are of stone, two stories high. Beyond the walls of the city, west and south, are suburbs consisting of low houses, yards, gardens and planta...
screen of iron filigree, at the south side of
which the pilgrim goes through its devotions,
for all of which he pays, but is consolded with
the assurance that one prayer here is as good
as a thousand elsewhere. The tombs of Fatima
(Mohammed's daughter) and Abu Bekr
(father of his wife Ayesha), and of Omar, the
first calif, are also here. The mosque dates
from the period of Mohammed, but has been
twice burned and reconstructed. Omar and
Othman both enlarged the original simple brick
structure. It was again enlarged by the Calif
Walds, so that it enclosed the three tombs. It
was destroyed by lightning, probably about
850, and the graves almost forgotten. In 892
the place was cleared up, the tombs located and a
fine mosque built, which was destroyed by
fire in 1257 and almost immediately rebuilt. It
was restored by Khaid Bey, the Egyptian ruler,
in 1487. It is estimated that one-third of the
pilgrims to Mecca go on to Medina, the pil-
grimage to which may be performed at any
time of the year. In the time of Prolemy the
town was known as Lathrippa. There never
was much population until the place acquired
fame as a resort for pilgrims. The city has
been built up by acquisitions from visiting pil-
grims, who recognized the opportunities for
making money here by catering to visitors. For
this reason the local people are heterogeneous
and stand for nothing but keeping up the crowd
of pilgrims. Since 1814 Medina has been the
capital of the north pashalic of Arabia. Pop.
40,000. In June 1916 the Grand Sherfet of
Mecca proclaimed his independence of Turkey.
Mecca thus, with the founding of the new king-
dom of Hejaz, was lost to the Turks; Medina
held out, however, until 13 Jan. 1919, when
the Turkish garrison under Phahri Pasha surren-
dered to the Emir Abdullah, the representa-
tive of King Hussein of Hejaz. Consult Bur-
ton, Sir Richard Francis, The Pilgrimage to
Al-Medinah and Mecchah, (London 1855). See
MOHAMMED.

MEDINA, me-din'a, N. Y., village, in Or-
leans County, on Oak Orchard Creek and on
the Erie Canal, and on the New York Central
and Hudson River Railroad, about 35 miles
northeast of Buffalo and 12 miles from Lake
Ontario. The first settlement was made about
1834. In 1852 it was incorporated as a village.
It is in a fertile agricultural region in which
the chief products are grapes, apples, straw-
berries and other fruits and dairy pro-
ducts. In the vicinity are valuable sandstone
quarries from which is obtained excellent building
stone. The water-power is excellent and
has been increased by a storage dam. Elec-
tricity is used as a power in manufacturing as
well as for light. The chief manufactures are
pumps, iron, foundry products, shirts, shoes,
vineyards and furniture. It has a large trade
in fruit and sandstone. The Medina Falls are visited annually by a number of tour-
ists. The government is vested in a president and
board of trustees. Pop. 5,683.

MEDINA, Ohio, village and county-seat of
Medina County, on the Baltimore and Ohio and
Northern Ohio railroads, 10 miles northeast of
Cleveland. Here are located the Sylvestre Li-
brary, the Pythian Sisters' Home and Spring
Grove Cemetery. Its industrial establishments comprise bee-supply works, foundries and bending
works. Pop. 2,734.

MEDINA SERIES, in geology, a term in-
troduced by the New York Geological Surv
for a subdivision of the Upper Silurian series
apparently the base of that system. It is named
from Medina, N.Y.; occurs throughout the At-
lantic States, and includes shales, conglomer-
ates and sandstones. For the Medina sand-
stone see LEVANT.

MEDINA SIDONIA, mä-din'ä-sö-dö-niä
Spain, a city in the province of Cadiz, 20 miles
southeast of Cadiz and 55 miles northwest of
Gibraltar, built in the form of an amphitheater
on a broad eminence, in the middle of an ex-
tensive plain, noted for its agricultural prod-
ucts and cattle rearing, which constitute the
chief occupations of the population. A fine
Gothic church, a town hall and the ancient
palace of the famous dukes of Medina Sidona
are the principal buildings. Pop. about 11,800.

MEDINET EL FAYUM, Egypt, capital
of the province of Fayum, on the Bahit-Yusef
155 miles north of Cairo. It contains a, bazaar and a mosque. It has an extensive trade
in grain, woolens and roses. Woolens are manu-
factured. An American mission is established
here. Pop. 37,320.

MEDITATIONS OF LAMARTINE
The 'Meditations' (1820) and 'Nouvelles Méditations' (1825) of Lamartine should be
counted rather as heralds of the Romanz
School of French poetry than as products of
it. The former, its author's first publication—it
was then 30—appeared five years after Water-
loo. Its sentimentalized melancholy is **) ad-
mirably the temper of that fatal day; its
reaction and moral exhaustion that it achieved
success in its day hardly paralleled. Its appeal
was to the cultured only, but 40,000 copies of
the Méditations were sold in four months.
The modern reader must strive to realize the
temper of 1820 if he would comprehend the
poet's bitter and always superficial reflec-
tions on the relations of man to 'Nature—
its creation of the poet's morbidity, with little
relation to reality—rather than to his fellow-
men. His found admiration so ardently written volumes of verses, in his own phrase, 'fell free
my pen like drops of evening dew,' while the
poet found himself 'incapable of the exac-
labor of the file and of criticism. The 'rev-
olution of the poet,' he writes in one of his
epistles, 'is a running brook which writes
murmurs and sings them, but we write with
human notes and Nature with the notes of
God.'

The Méditations were the work of a
army officer, but it was the army of the Re-
toration, more responsive to Rousseau's call for
a return to nature and to Chateaubriand's call for
a return to religious emotionalism than it was to
any summons to action. When that moved
and France recovered the energy that showed itself in politics by the Revolution of
1830 and in literature by the Romantic School,
the Méditations soon came to be little read
though still conventionally admired. Unques-
tionably, however, they were the most com-
promising literary efforts to emerge from the
literary aspirations of the generation of 1820. This gives them a lasting value, greater than their merit of content
or of form.

Lamartine's verses preserve much of the
MEDITATIONS OF MARCUS AURELIUS — MEDITERRANEAN SEA

verbal mannerisms of the earlier period. They are harmonious, refined, delicate, graceful, sincere, spontaneous, the indolent pleasure of a too-rich and2 fretted mind. They are, on the one side, they are conventional in expression, monotonous in feeling, elusive in development. The themes are throughout those of the true lyric — nature, love, death. The essence of all Lamartine's best poem, in Loneliness (L'Isolément), and in the vague pantheistic melancholy of Frayer (La Prière). In the 'Nouvelles Méditations' the poet's conjugal marriage is reflected in the happier vein of the Love Song (Chant d'Amour), Wisdom (La Sagesse), Ischia and The Preludes (Les Préludes), but the poet soon resumes the melancholy pose. The Ode on Bonaparte in this collection goes deeper and rises higher than is usual in Lamartine; as indeed there is unwo ned grace in Ischia and force in The Crucifix. Never so popular as the earlier book, 'Nouvelles Méditations' and its sequel Jean-Baptiste and Brunetti even pronounced them 'at once the noblest and the most voluptueux in French poetry.' It is juster to say, with Lanson, that if, and so far as, poetry is essentially sentiment, disengaged from the ideas and facts that produce or accompany sentiment, the 'Méditations' are great poetry and Lamartine is among the most poetic of poets. Consult 'Life of Lamartine' by H. R. Whitehouse (New York 1919).

BENJAMIN W. WELLS, Author of 'Modern French Literature.'

MEDITATIONS OF MARCUS AURELIUS, The. There is probably no more romantic story of a book in the history of literature than that of the volume known as the 'Meditations of Marcus Aurelius.' It is merely the commonplace book or diary of a Roman emperor (121-180 A.D.), who at the end of a very busy and troubled reign, just when worries were thickest, jotted down all the serious thoughts that came to him with regard to the meaning of life and the way it should be lived. He called his little book simply 'To Himself.' It was probably meant only for his own perusal when he was in meditative mood. He so loved the Greek Stoic philosophers whose writings had been his inspiration and consolation that he wrote in Greek. It is not good Greek any more than the 'Imitation of Christ' is good Latin. He paid little attention to the style of it, and yet Headmaster Rendall of Charterhouse in his Introduction to the 'Meditations' does not hesitate to say that 'in the whole range of Greek literature, no work (excepting the New Testament) has wider vogue and currency than these unadorned meditations of the imperial moralist.'

The book created a furor in the Renaissance when it was first edited and printed, but it has never ceased to be the favorite reading of the thoughtful. Accordingly to Professor Arnold, according to Professor Arnold, the 'Meditations' are "almost equal in ethical elevation to the Sermon on the Mount." Matthew Arnold went so far as to say that "Marcus Aurelius remains the especial friend and comforter of all clearedhead and scrupulous, yet pure hearted and upward striving men in those ages most especially that walk by sight, not by faith, but yet have no open vision." Americans will be interested to know that the 'Meditations' of Marcus Aurelius was read and quoted by Machiavelli's 'Art of War'; the daily study of Capt. John Smith, the Virginia pioneer whose romantic history might seem to indicate some less stern and stoic reading. The Roman emperor's little book has often since been the daily resource or even the boon companion of men of action in the field as well as of statesmen worried over matters of politics, and of scholars with time on their hands.

It has been suggested that perhaps this last of those Spanish Caesars, under whose rule for 80 years Gibbon thinks that the world was happier than it has ever been before or since, had the idea while he was jotting down these scattered thoughts on life that some time or other they might be of service to his son Commodus. If that were so, the book might serve as the contrast to Chesterfield's letters. The modern English nobleman wrote an epitome of worldliness; the ancient emperor a manual of other-worldliness. But if Marcus Aurelius wrote for the eye for his son, he also wrote for himself; for Commodus was probably one of the worst rulers of history. For his weak selfishness no advice would have availed.

The 12 books treat of: I. The debts that he owes for all that has come to him in life — there are tributes to his grandfather — his father died when he was very young — to his wife so docile, so affectionate, so simple, and to many dear friends; II. On doing what you do; III. That to obey God is liberty; IV. That there is no such thing as chance; V. On the real goods of life; VI. That the inner life is all that counts; VII. On repressing impulse and finding self-content; VIII. On equanimity; IX. Fate leads the willing man, but drags the unwilling; X. Look around you, look behind you, look ahead of you; XI. Unselveshness; XII. (In conclusion) "Depart then satisfied for he who also releases thee is satisfied."

When the Emperor Julian whom the modern world knows as the Apostle would sum up the life of Marcus Aurelius in a single phrase he gave an excerpt from a dialogue supposed to take place not long before his predecessor's death: "Then Hermas, looking at Marcus, said, 'And to you, Verus [Marcus'] family name, what seemed the noblest end of life?" Quietly and gravely he replied, 'The imitation of God.'"

Consult Watson, 'Life of Marcus Aurelius' (New York 1884); 'Marcus Aurelius,' in Matthew Arnold's 'Essays in Criticism'; Rendall, 'Marcus Aurelius Antoninus' (London 1901); Long, 'The Meditations of Marcus Aurelius Antoninus' (London 1862); Camon Farrar, 'Marcus Aurelius,' in 'Seekers After God.'

JAMES J. WALSH.

MEDITERRANEAN (med'i-tè-râ'ne-ân) SEA, the great inland sea between the continents of Europe, Africa and Asia, the remnant of the Tethys Sea. According to Professor Arnold, "of a great ocean which at an early geological epoch, before the formation of the Atlantic, encircled half the globe along a line of latitude." From its eastern extremity in Syria to the Strait of Gibraltar it is about 2,300 miles long; its maximum width from Venice to the Bay of Sidra.
is 1,200 miles; its average width 300 miles. Its area is variously estimated as from 815,000 square miles to 1,145,000 square miles. The shores of Europe are on the north and northwest, those of Africa on the south and those of Asia on the east. The Mediterranean is connected with the Atlantic by the Strait of Gibraltar, and on the northeast with the Black Sea through the Dardanelles, Sea of Marmora and the Bosphorus, which form a continuous waterway. It is irregular in shape and by the projection of the south part of Italy, and of Cape Bon in Africa and the interposition of the island of Sicily, is divided, near its centre, into two distinct portions, an east and a west. In addition to these, the other important subdivisions are the Tyrrhenian or Tuscan Sea, between the west coast of Italy and the islands of Sardinia and Corsica; the Adriatic Sea or Gulf of Venice, between the east coast of Italy and the west coast of Turkey in Europe, through Dalmatia; the Ionian Sea, between the west coasts of Turkey in Europe and Greece, and the south part of Italy and the island of Sicily; the Aegean Sea or Archipelago, between Turkey in Europe and Greece on the west, and Turkey in Asia on the east; and the Levant, which is usually understood to include the whole sea east of the island of Crete. The largest gulfs are, on the shores of Europe, those of Lion or Lyons, Genoa, Taranto, Lepanto, Koron, Kolokythia and Salonica; on the shores of Asia, Adramyt, Smyrna, Adalia, and Skanderoon; and on the shores of Africa, Sidra and Cabes. The largest and most important islands are Sicily, Sardinia, Corsica and the Balearic Isles, in the west division; and Cyprus, Rhodes, Cretan, the Ionian Isles and Malta, in the east division. The principal rivers which discharge themselves into the Mediterranean are the Ebro, Rhone, Po and Nile; but its communication with the Black Sea entitles it to claim it as part of its basin, and, consequently, also the great rivers Don, Dnieper, Dniester and Danube. Between Cape Bon and the Sicilian coast, where the sea is shallower, the depth varies from 30 to 250 fathoms; but in almost all other places, particularly at a depth of from 60 to 250 fathoms, the depth is very much greater, the maximum depth in the eastern division being 2,150 fathoms, in the western division, 2,040 fathoms. The mean depth is practically equal in the east and west divisions, about 883 fathoms. However, half the area is less than 500 fathoms deep. The depth temperatures are very much warmer than in the Atlantic. Owing to the very narrow channel which connects the Mediterranean with the main ocean, there is very little tide; though in some places, as in the Ionian Sea, the Adriatic, on parts of the African coast, etc., a rise of more than six feet sometimes occurs. The prevailing winds are the southeast and southwest in spring, and the northeast and northwest during the rest of the year. They often rise suddenly and with great violence. The most remarkable are the historic Euroclydon or Leverant, mentioned in Acts xxvii, 14, a northeast wind of dangerous whirlwind characteristics; the Bora in the Adriatic; and the Sirocco, and the burning Sirocco from the African desert. The Mediterranean abounds with fish, some 400 species having been noted, and also furnishes the finest coral and sponge. The evidences of volcanic action along its shores are present in the active volcanoes of Vesuvius, Etna and Stromboli (q.v.). Consult Playfair, The Mediterranean, Physical and Historical (1809); Cook, J. W. The Mediterranean and Its Borderlands (Philadelphia 1910).

MEDITERRANEAN SUBREGION, a zoogeographical district of the Nearctic Region, embracing the basin of the Mediterranean and the plains of Syria. Faunistically this region is allied to Europe rather than to Africa or Asia, from which it is separated by deserts. It includes many sub-tropical forms, rarely or never seen north of the Alps or south of the Atlas Mountains. See Zoogeography.

MEDJIDIE, mé-jéd'ë, a Turkish order equivalent to knighthood, instituted by the Sultan in 1852. It has been conferred on numerous foreign officers, soldiers, and seamen, who have taken part in wars on behalf of Turkey. It is divided into five classes, indicated by the difference in size of the decoration. Recipients of the first order, in addition to the large gold and red decoration, receive a ribbon on the left breast. The accompanying ribbon is red and green. The name is also given to a modern Turkish silver coin, value about 8 cents.

MEDLAR, a small tree or shrub (Mespilus germanica) of the apple family and native of southern Europe where in the wild state it has thorns, but in cultivation it is thornless. It differs from various near relatives such as apple and pear, in bearing solitary large, white, terminal flowers upon leaf growths of the current season, and, like the quince, in having no detachable peduncle to the fruit in which the receptacles do not completely overgrow the ovaries. It is widely grown in Europe but much less in America. In Central New York, it is usually hardy and produces with no special care. The fruit is shaped like a pear which is about the size of a small pear, should be allowed to hang until after a frost, which mellow's its austerity and assists the process of "bletting," as ripening in cool dry rooms is called. The fruit is soft and the softened fruits are eaten by those who enjoy tart flavors, or are made into preserves.

MÉDOC, mä-dök', a wine which derives its name from a district of France, in the ancient province of Gascony. The modern locality termed Charente-Inférieure, it is most covered with vineyards, which are cultivated with great care, and the wines produced from them have a high reputation. They are dry and delicate, resembling Bordeaux wines which territory is immediately south of Médoc. See Wine and Wine-making.

MÉDULLA, in botany, the pith of a plant stem. See Pith.

MÉDULLA OBLONGATA, the brainstem, or that part of the nervous system that lies between the pons, or pons Varoli, at the upper end, and the spinal cord proper, with which it is continuous, at its lower end. It is the very old part of the nervous system, jaded from the passage of ages, and contains the important centres of the cranial nerves, including the centres that govern the nerves of the heart and of respiration. It
is a triangular cone-like portion of the nerve-axis, about an inch in length and one-half to three-quarters of an inch thick, being tubular below and flattened above. Below, it closely resembles the cervical cord in its internal construction, but above great changes take place to accommodate important new structures. One of the most conspicuous features of the medulla consists of a triangular enlargement of the central canal of the cerebro-spinal axis, constituting what is known as the fourth ventricle. The lower seven cranial nerves have their apparent origin in the medulla, and the first spinal nerve also originates in the medulla proper. The internal anatomy of the medulla is complicated. At the lower end the chief motor tracts, the pyramidal tracts that come from the motor area (q.v.) in the brain cross one another to pass down on opposite sides of the spinal cord. It is because of this decussation that a hemorrhage of the brain of the right side causes a paralysis of the muscles of the left side of the body, and vice versa. Just above the decussation of the pyramids the end-stations (nuclei) of the sensory tracts are located. It is into these nuclei— the gracilis and the cuneatus—that all of the sense-impressions from the body below the head are collected, to be passed to higher cerebral centres through the lemniscus or sensory fillet. The chief gray masses in this part of the brain are the nuclei of the cranial nerves referred to, and of the olives, two structures of undetermined function. The best description of the oblongata at present is that of the model of the medulla and pons by Dr. Florence Sabin, which is figured in Barker's 'Nervous System.' Consult also Buck, 'Reference Handbook of the Medical Sciences,' article 'Brain,' and Johns Hopkins Hospital Reports, Welch Memorial Volume. See Brain.

MEDUM, Egypt, village on the Nile, 40 miles south of Cairo, near the Pyramids. See Pyramid.

MEDUSA, me-doo'sa. See Gorgo.

MEDUSA, a disk-bearing jellyfish (q.v.).

MEDWAY, England, a river which rises in the county of Sussex and flows northeast in a winding course through Essex, Cambridgeshire, and Middlesex, to the Thames at Chatham. Below Chatham it spreads out into a broad tidal estuary, in which are several islets, and joins the Thames at Sheerness. It is 70 miles long and is navigable to Faversham, 20 miles above Chatham.

MEEHAN, me'an, Thomas, American botanist: b. Potter's Bar, near London, England, 21 March 1826; d. Philadelphia, 19 Nov. 1901. From his father, a gardener, he learned facts of natural history when a child; at eight made and recorded an original discovery in herpetology; taught himself from books read at night after daily tasks; at 12 began to publish scientific papers; soon after produced the first hybrid fuchsia; and was nominated to membership in the Royal Wernertian Society. For two years he held a position in the Horticultural Society. In 1848 he came to America and took charge of Bartram's Gardens in Philadelphia. In 1854 he established the Germantown Nurseries, which he conducted until the end of his life. For 30 years (1859-89) he edited the Gardener's Monthly, and contributed papers to many other periodicals and to scientific societies. For 23 years he was senior vice-president of the Philadelphia Academy of Natural Sciences, in whose proceedings were published his important 'Contributions to the Life History of Plants.' In 1875 he was elected a fellow of the American Academy for the Advancement of Science, before which, among other expositions, he read 'A Contribution to the Doctrine of Evolution and the Theory of Natural Selection,' which showed him as a co-worker with Darwin and other evolutionary scientists, in whose field he also was a discoverer. From the creation of the office until his death he served as State botanist of Pennsylvania, at one time was a member of the board of visitors of Harvard, and was one of the American editors of the 'Encyclopædia Britannica.' His travels and researches extended throughout the country, including Alaska. In 1878 he began the publication of 'Native Flowers and Ferns of the United States,' an illustrated serial covering a wide field of floral distribution, the main features of which he continued in the American Flora Monthly, founded in 1891. Many learned societies abroad enrolled him, and he held intimate relations with nearly all the leading scientists of his time. Among his closest friends was the Comte de Paris, a devotee of plant-study. Meek was the third American to receive the Veitch medal, awarded to him for distinguished services in botany and horticulture. Apart from scientific work he devoted himself to public labors; was a member of the Philadelphia common council from 1865 until his death; during the same period served on the local school board; in both capacities introduced many reforms; and chiefly through his efforts nearly 30 small parks were added to the city: A work of permanent value is his 'American Hand-book of Ornamental Trees' (1853).

MEEK, mek, Alexander Beaufort, American jurist: b. Columbia, S. C., 17 July 1814; d. Columbus, Miss., 30 Nov. 1865. He was graduated from the University of Alabama in 1833 and admitted to the bar two years later. He served in the Seminole War in 1835-36; was secretary of the state of Alabama 1836; judge of Tuscaloosa County 1842-44; and member of the legislature in 1853. While there he established the free-school system of Alabama. In addition to a legal digest (1842) he wrote: 'The Red Eagle' (1855); 'Songs and Poems of the South' (1857); 'Romantic Passages in Southwestern History' (1857), etc. His best-known poem is 'The Charge at Balaclava.'

MEEK, Fielding Bradford, American paleontologist: b. Madison, Ind., 10 Dec. 1817; d. Washington, D. C., 28 Dec. 1876. His educational advantages were limited, but his interest in natural history made study imperative to him, and in 1848 he became assistant to David D. Owen in a geological survey of Iowa, Minnesota and Wisconsin. He assisted James Hall at Albany in 1852-58, spending several summers in a geological survey of Minnesota and Nebraska, and in 1858 went to Washington, where he devoted the remainder of his life to paleontologic investigations under the government. He was elected in 1870 to the National Academy of Sciences, and was a member of
other scientific organizations. Among his writings are 'Check List of the Invertebrate Fossils of North America' (1864); 'Report on Invertebrate Cretaceous and Tertiary Fossils' (1865), etc. For a complete list of his works, see bibliography published by the Smithsonian Institution.

**MEEEKER, Royal**, American statistician: b. Silver Lake, Susquehanna County, Pa., 23 Feb. 1873. In 1898 he was graduated at Iowa State College and in 1906 took the degree of D.P.H. at Columbia University. He also studied at Leipzig. In 1904-05 he was professor of history, politics and economics at Ursinus College, Collegeville, Pa. In 1905 he became preceptor at Princeton and from 1908 to 1913 was assistant professor of political economy there. On 12 Aug. 1913 Dr. Meeker was appointed commissioner of labor statistics by President Wilson. In 1918 he was appointed member of the United States meat commission. He published 'History and Theory of Shipping Subsidies' (1905).

**MEEKINS, Mēkinz, Lynn Roby**, American journalist: b. Salem, Md., 14 Nov. 1862. He was graduated from Western Maryland College, Westminster, Md., in 1882, and devoted himself to journalism. He was literary editor of the Baltimore American 1882-89, when he became editor of the Philadelphia Saturday Evening Post, and since 1903 has been editor of the Baltimore Herald. He has published 'The Robb's Island Wreck' (1894); 'Adam Rush' (1902), etc.

**MEERANE, Saxony, town, 10 miles north of Zwickau and 36 miles south of Leipzig. It contains a medieval church. Meerane is one of the largest textile-producing centres of Germany, turning out vast quantities of woolen and mixed cloths. It has also extensive dyeing establishments, machine works, tanneries, boiler works, motor factories, button, paper box and cement works. The town has a Realschule, a textile school and a school of commerce. Pop. 26,005. Consult Leopold, 'Chronik und Beschreibung der Fabrik-und Handelsstadt Meerane' (1863).

**MEERKAT. See SUDICATE.**

**MEERSCHAUM (Sepiolite), mēr'sham or -shum, a name given to one of the silicates of magnesium; it is a mineral of a whitish or creamy color, and received its name from its appearance and the position in which it is sometimes found suggesting that it was petrified foam of the sea. It is obtained from various places, but the best quality comes from Asia Minor, rich deposits of it existing about 20 miles southeast of Eschachehr, at a place called Sepedje. Here are some 20,000 pits in a space of six miles, of which only 150 are worked, all the others being exhausted. It is said that these mines were opened 1,000 years ago, which is not incredible, as it is well known that magnesia was formerly used for many purposes, other than the fabrication of pipes; moreover, fuller's earth was once worked on a vast scale by the ancients. The meerschaum mines are worked by some 500 miners, who live in the surrounding villages. At Gehlert, in the neighborhood of Sepedje, there are 3,000 pits, of which only 100 are worked, giving employment to 400 miners. The mineral is mined in blocks, which are taken to Eschachehr, where the blocks are cleaned, the operation consisting of scraping and cutting the blocks with a sharp instrument or knife, the meerschaum being still soft and easily cleaved. Persons are occupied in cleaning and shaping these blocks, which, after being thoroughly cleaned, are separated into four classes, according to size and quality. These blocks being ready for sale, a bargain is struck between the pipe manufacturers and the owners or Asiatic merchants at Eschachehr, of whom there are about a dozen. The latter then pack the blocks of these four classes with very great care into boxes of equal size, each block being wrapped in cotton to avoid any friction or shock between the pieces. The actual annual output of these mines varies from 120 to 150 tons. It is soft when dug up, but becomes hard when dry. Most of it is sent to Vienna, where it is chiefly made into tobacco-pipes, many of them highly artistic. Similar pipes are also made in Paris, London and elsewhere.

**MEERUT, India, the capital of the district and division of the same name, in the United Provinces, situated 40 miles northeast of Delhi on the North Western Railway. The city is irregularly built, with narrow, dirty streets. It contains several mosques, a fire-town hall, a college, normal school and church schools. At Meerut is one of the largest cantonments in India. Flour and soap are the principal manufactures. The first outbreak of the Indian Mutiny of 1857 occurred at Meerut. The city has a good water supply and an excellent drainage system. Pop. 116,227.

**MEES, Arthur**, American musical director: b. Columbus, Ohio, 13 Feb. 1850. He was graduated from Concordia College, Fort Wayne, Ind., and studied music in Berlin. He has been assistant director, and later director, of some of the leading opera and musical associations, and has published, in addition to his annotated programs for the New York Philharmonic Society and the Chicago Orchestra, 'Chorus and Choral Music.'

**MEGACLES. The most illustrious Greek of this name was the head of the family of the Alcmaonidae at Athens in the time of Solon. After twice expelling Pisistratus, who in 507 B.C. had made himself Tyrant of Athens, he was himself exiled by the latter together with all his family.

**MEGALESIA, or MEGALESIA, an annual festival at Rome (4-10 April) in connection with the foreign cult of Cybele, the Magna Mater or Great Mother of the Gods, celebrated by a procession of her eunuch-priests, by circensian and theatrical shows, and at the close a carnival.

**MEGALITHIC MONUMENTS. See DOLMEN; MENHIR; STONES, STANDING; STONE CIRCLES.

**MEGALONYX. See GROUND-SLOTHS.**

**MEGALOPOLIS, mēg-əlōp'ə-lis, or SI-NANON, Greece, a ruined city on the ancient Helisson, in the nomarchy of Gortynia, 5 miles north of Leonardi. It was founded 370 B.C. by Epanthiodas (n.v.) as the capital of the Arcadian district of Arcadia and was a magnificent walled city, five and one-half miles in circumference; it was frequently but unsuccessfully attacked by the
MEGALOSAURUS — MEGAPODES

Spartans. In 222 B.C. it was captured and partially destroyed by Cleomenes III. From 1800-93 the British School at Athens excavated the site and revealed the Precinct of Zeus Soter, the Agora, the Stoa of Attalos, and the Stoa of Myopolis on the right bank of the river, and on the left bank, the hemispherical Theatre 400 feet in diameter, and the Scanotheca, the Therian or great assembly hall, altars and remains of other buildings described by Pausanias. Consult Schiitz and Loring, 'Excavations at Megalopolis' (1892); Haigh, A. E., 'The Attic Theatre' (Oxford 1907).

MEGALOSAURUS, mēg'-ə-lō-sār'-əs, a genus of huge carnivorous dinosaurs of the group Theropoda. Their remains occur frequently in the European oolitic rocks. The extreme length was about 50 feet. They were covered with scales and built like lizards, but with proportionally longer, heavier legs. See DINOSAURIA.

MEGAPHONE (a Greek word meaning 'great sound'), an instrument magnifying the sound of the voice many times, so that one can be heard at a considerable distance. In its simplest form it is a cone-shaped trumpet, and the speaker shouts into the small end, the instrument directing the sound wherever it is aimed. This form is used by announcers at base ball games, etc. The form invented by Thomas A. Edison consists of two large funnel-shaped receivers in which the waves of sound are collected and concentrically carried by means of flexible tubes held to the ears of the person using the instrument. In the instrument called telephone-megaphone, the mouthpiece of the telephone is connected with four transmitters which multiply the usual telephone sound of the voice by loud wire, so increased, that the megaphone, which sends it forth into space with sufficient intensity to carry it with perfect distinctness throughout a large church or hall. One form of megaphone is largely used by deaf persons.

MEGAPODES, a general name for the brush-turkeys or mound-birds of Australia constituting the gallinaceous family Megapodiidae, so named in reference to the disproportionately large size of the feet; and remarkable for their breeding habits. The family, although mainly Australian, is represented in many of the South Sea Islands and in the Philippines, replacing the pheasants, which are absent from that region. There are 7 genera and 20 or more species, mostly with restricted individual ranges, and varying in size from that of a turkey to that of a large pigeon, the sexes being always alike in plumage. The general colors are browns and yellows with the naked wattled parts brightly colored. They have a short, strong bill; the head and neck almost naked and wattled; the wings short and round; the tail large; the legs and feet large, strong, and provided with great claws. Megapodes are terrestrial birds found in hill-valleys, among thickets or along river and sea beaches. They run well, but if hard pressed will take to trees where they hop about awkwardly; their flight is heavy, but may be long sustained. Hoarse, chuckling, cackling or mewing cries express the utterances of the different species, which are often heard at night. The food consists of fallen fruit, seeds, berries, worms, snails, insects and even small crabs. The flesh is dark-colored and not good, though palatable to the Australian aborigines.

One of the best known species is the brush-turkey or mound-turkey (Catheturus lahtami), also known as the wattled talleagalla and the New Holland vulture, the latter name being given to it on account of its yellow, naked head and neck, covered in part with fleshy wattles. It is rather common in New South Wales, inhabiting the most thickly wooded parts. It is a large bird, about the size of a turkey, with blackish-brown plumage. It is shy, and when pursued, endeavors to escape by running through the thickest brush, or by leaping to the lowest branches of a tree, and thus avoids the dingoes or native dogs, which, however, often hunt it down on open ground. It is easy game to the sportsman, who finds it roosting under shelter of the branches of trees during the day, and although several of a flock are shot, the rest keep their place undisturbed. They are generally seen in small flocks, and make their nests together, the females heaping up, by means of their feet, mound of several cubic yards, and depositing bits of earth and decayed leaves which are used from year to year, new materials being added every year. The eggs are separately buried, often by several females, within the mass, where they are hatched by the heat of the fermenting mound. The parent birds partially uncover them during the day. Nearly a bushel of eggs may sometimes be found in a single heap. The male bird pays great attention to the young after they are hatched, carrying them up partially in the mound at night for warmth. The flesh of the talleagalla is excellent, and the eggs are also very delicate and eagerly sought after. Two other species occur in New Guinea.

South and West Australia have another familiar megapode in the mallee-heen or native pheasant* (Lipoa occellata) — a large gray-brown bird with eye-like markings on the wings and back, and the naked neck and wattles blue; its mounds are comparatively small and often made individually. A bird is confused with this in holos because of similarity of name is the maleo (Megacephalon maleo) of North Celebes, which has the singular habit of making a general migration in the breeding season to the sea-beach, where small groups of females dig large holes in the sand just above high-water mark, and day by day bury eggs there until the quota of each is laid; these gradually hatch under the influence of the hot sand. The largest genus is Megapodius, whose 15 species are scattered over all the island region between Samoa, the Philippines and the Micohars, each group having a distinct species. The most widely distributed and best known is M. tamariscinus, the common mound-bird or scrub-turkey of Northern Australia and the European archipelago, which fashion mounds 10 or 11 feet high in the densest woods, continues to use them year after year, and lays pale, coffee-colored, thin-shelled eggs in straight burrows penetrating the mound. In some islands the eggs of these birds are a prime food resource. The young are well fledged when they emerge from the egg and scramble out of the mound, but are attended to by their parents for some time. Consult Newton, 'Dictionary of
MEGAPOLENSIS — MEGIDO

Birds (1869); (Proceedings,) Zoological Society of London, 1876, 1888, etc., and works on the ornithology of Australia and Oceania.

MEGAPOLENSIS, Joannaes, Dutch Protestant missionary to the North American Indians; b. Koedijk, Holland, 1603; d. New York, 24 Jan. 1650. His family name, van Meckelenburg, he Hellenized to Megapoloensis. In 1642 Van Rensselaer, the first Patroon, brought him to New York from Holland, and he soon learned the Mohawk tongue and penetrated successfully among the Indians near Albany, several years before John Eliot's mission or any other Protestant preaching to the Indians. From 1649 until his death he was pastor of the Dutch church in New York, where he showed little tolerance to Lutherans and Independents. He advised peaceable surrender to the English in 1664. His account of the Mohawks is published in the third volume of the New York Historical Society's 'Collections' (1870).

MEGARA, Greece, the capital of ancient Megaris (q.v.), between Attica and Corinth; also a modern town in the eparchy of Megaris, of 6,500 population.

MEGARION SCHOOL OF PHILOSOPHY, a Greek school of philosophy based on and developed from a part of the Socratic system. Euclid of Megara was the first to give definite form to its teaching. Eubulus was also a prominent member of this school, which confined itself mainly to dialectic methods, and sought to unite the Socratic ethical principle and the Eleatic theory of the One, to whom only true being might be attributed.

MEGARIS, még's-ris, Greece, the name of an ancient state or small district bounded north by Beotia, east by Attica, south by the Saronic Gulf and the territory of Corinth, west by the Corinthian territory and the Corinthian Gulf; area, about 143 square miles. It is a mountainous country, the only plain being that on which the capital was situated. Mount Citharon was on the north boundary, separating it from Beotia. The people were traders and sold their textiles over a large area. The only important town was Megara, situated a mile from the sea, opposite the island of Salamis. It contained a Pelasgian citadel, called Carra, on a hill northwest of the city, with a temple to Demeter called Megaron, from which the name of the town is supposed to be derived. It had flourishing colonies at an early period, and its navy was so powerful that it was only after a long struggle with it that Athens obtained possession of Salamis. It afterward became annexed to Attica, of which Megaris formed one of the four ancient divisions. It was successively conquered by the Dorians and the Corinthians, but afterward asserted its independence, and became wealthy and powerful.

MEGASTHENES, a Greek historian, who about the year 300 B.C., as ambassador of King Seleucus Nicator at the court of the Indian king Sandracottos, gathered the material for a geographical and historical account of India that, reaching us in the form of fragments and works by other writers, such as Strabo, Herodotus and Arrian, is our chief source of knowledge of that country in antiquity. There is an edition of the fragments by E. A. Schwanbeck (Bonn 1840); also a translation by McCrindle, 'Ancient India as Described by Megasthenes and Arrian' (Calcutta 1877).

MEGATHERIUM, a gigantic fossil ground-sloth, the largest known edentate, representing the family Megatheriidae, and especially the species M. americanum. Remains are found plentifully in the Pleistocene strata of Argentina and Patagonia. These edentates were so generalized, that, as compared with modern forms, they exhibit the head and teeth of a sloth, associated with the vertebral columns and tail of the ant-eater. Some of the attain a gigantic size, at least as large as an elephant, but with shorter limbs and a bigger tail, and the latest species are the most bulky. Megatherium, according to Woodward, seem to have been entirely destitute of dental armor. The only one of its allies in which bony plates have been discovered is Mylodon, and they are very small and not fused together. The pelvis and hind limbs are heavily formed, showing that the animal was in the habit of standing on them, steadied by the powerful tail, covered with a garo. They fed on the branches of trees. Mylodons were somewhat smaller than the megatheria, with a skull and teeth more like those of the modern sloths, and the three inner digits of the forefoot bear claws, about equal size, instead of the huge middle finger claw of the Megatherium. In both animals the hind foot lacks digit 1, but II and III bear claws. The typical species of mylodon (M. harlan) was about as large and of much the same form as a rhinoceros, and inhabited the southwestern United States, while various other species lived in South America. The long-headed South American genera, Scelidotherium and Megalonyx, are other forms of the same family. See Ground-Sloths. Consult the palaeontological writings of Leidy, Lydekker and Woodward, also Scott, G. B., 'History of Land Mammals' (1913).

MEGIDO, an important fortress city of ancient Canaan. Thothmes III captured it in the 23rd year of his reign, and took therefrom magnificent spoils. The city is mentioned several times in the Tel-el-Amarna correspondence. Though nominally in the territory of Manasseh (Jos. xvii, 12, 13; Judg. i, 27, 28), it remained in possession of the Canaanites. Near the "waters of Megiddo" Barak and Deborah defeated the Canaanites under Sisera (Judges v, 19-21). Solomon restored the fortifications (1 Kings ix, 15) and Ahaziah is said to have died there (2 Kings i, 5). Finally it was at Armageddon (Har-Meged, mountains of Megiddo) that the great conflict of Revelations xvi, 16, was to take place. The site of Megiddo may now be considered as proved to be Tel-el-Mutesellim, a great mound four miles northwest of Tel Taanach. It was evidently of great strategic importance since it commanded the pass from the Plain of Esdraelon, which in all centuries from Thothmes III to Allenby in 1917-18 has been the route of armies. Fortifications preceding 2000 B.C. have been uncovered on the site, together with the remains of several centuries earlier than those of Thothmes and Arrian. Here too was found the seal of Shema, servant of Jeroboam II (I Kings). In Roman times the place was a fortified post—the Legio e
Eusebius, the modern el Lejjun. Consult Schumacher, 'Tell el Mutesellim: Bericht über die 1903 bis 1905 veranstalteten Ausgrabungen' (Leipzig 1908).

MEGNA, meg'en, or MEGHA, India, the estuarine outlet of the Ganges and Brahmaputra (q.v.), in Bengal. There are four principal mouths, producing three islands. The tidal bore is characterized by its velocity, which endangers navigation, advancing at a rate of 15 miles an hour, and frequently attaining a height of nearly 20 feet. As the bottom is loose sand, it shifts continually, making navigation difficult.

MEGRIM. See MIGRAINE.

MEHMET (mäh-met), or MOHAMMED (moh-ham'ed), ALI, viceroy of Egypt: b. Kavala, Macedonia, 1769; d. Cairo, 2 Aug. 1849. An orphan, he was brought up by a janizary captain, governor of Kavala, who married him to a kinswoman and made him a militia officer. When the French invaded Egypt he was sent there, rose rapidly, became the confidant of Koskrew, pasha of Egypt, and, by treachery both to the pashas and the Mamelukes and by the liberal use of his wealth, in July 1805 became pasha of Cairo, whence his power quickly spread over the rest of Egypt. His utterly unscrupulous policy was shown by his massacre of nearly 1,700 Mamelukes in 1811. He extended the limits of Egypt by wars on the Arabian Wahbees, by the possession of Nubia and Kordofan, and by the treacherous conquest of Syria, in which he aimed at independence of the Porte. This first break with Turkey was settled by the Powers; and in 1839 the Sultan was forced to call on the Powers to help him turn Mehmet out of Syria; by the treaty then concluded he surrendered Syria, Candia and Hejaz; but was made hereditary pasha. His internal administration was vigorous; both agriculture and manufactures flourished, thanks to French capital solicited by Mehmet, who also introduced European methods into his army, and established a system of education. He was insane during the latter part of his life, and was succeeded by his grandson, who took his place as regent in September 1848, died in November of that year. Consult Murray, C. A., 'Memoir of Mehmet Ali' (London 1896).

MEHRING, Franz, German historian, critic and socialist philosopher: b. Schlawe, Pomerania, 27 Feb. 1846; d. Berlin, 29 Jan. 1919. He was of middle-class Pomeranian origin, but became interested early in life in the struggles of the poor. His life is an interesting example of the career of a political thinker who passes out of the organizations of his own class, yet remains as a liberal, by natural sympathy, although in Mehring's case this process took a long time. He attended the University of Berlin, where he obtained the Ph.D. degree, simultaneously working for a democratic newspaper, Zeitung für die Arbeit (afterwards, the Freie Zeitung), in the direction of Johann Jacoby and Dr. Guido Weiss. After this paper was suppressed (1871), he became a member of the staff of Die Wage, a weekly edited by Dr. Weiss. In 1873 appeared Mehring's first socialist work, Die Abhängigkeit der Sozialistentätigkeit, und die Enzüge des Liberalismus, which, as its title indicates, is an attack upon Treitschke (q.v.). When the two chief socialist bodies in Germany united at Gotha in 1875, Mehring was sympathetic to the new party but did not become a member, and a rather personal controversy which he had with Leopold Sonnemann, editor of the Freie Zeitung, for which Mehring had been Berlin correspondent, removed him more and more from the activities of the Social-Democratic party. From 1877 to 1882, Mehring was unfavorably disposed toward the leaders of the party, and in his 'Geschichte der deutschen Sozialdemokratie,' which he began writing in those years, he made many attacks upon them, for which he was seriously taken to task at the Dresden Party Congress. He defended himself in a little book 'Meine Rechtfertigung' ('My Justification'), in which he asks forgiveness for having been so foolish as to believe that the monarchical régime might develop into an honest democratic republic, which idea, he explains, has been completely corrected by the anti-socialist laws as administered by the Prussian government. Yet Mehring still hoped that it might be possible to found a bourgeois democratic party in Germany, in which work, which was foredoomed to failure, he was associated with Lenzmann (1884). He was editor of the Berliner Volkszeitung (1885-89), but was forced to resign from that paper because of a controversy with Paul Lindau (q.v.), arising out of the latter's maltreatment of the actress Elsa von Schabelski (by a curious coincidence, Paul Lindau's death in January 1919, coincided almost to a day with that of Mehring). Mehring has written profound historical analyses, among which the best are 'Die Lessing-Legende' (1893) and 'Gustavus Adolphus' (1894). As a man of 70 his hostility to the German Imperial government was still unbroken, and together with Rosa Luxemburg and Karl Liebknecht he wrote, in January 1915, a pamphlet attacking the militaristic system that had plunged Europe into war, known as the 'Junius' pamphlet. This appeared in Switzerland and was secretly circulated in Germany (English translation: 'The Crisis in the German Social-Democracy,' New York 1916). He spent considerable parts of 1916 and 1917 in jail, under 'militarist' arrest, but had to be released because of his failing health. In January 1918 he was elected a member of the Prussian Landtag, on the socialist ticket, and distinguished himself in that body by his biting comments on the inability of the Prussian military leaders; Mehring had always had a sort of amateur interest in military affairs; a number of his pamphlets deal ably with questions of this kind. Shortly before (September 1918) the final defeat of the German armies (October) at the western front, Mehring predicted that the hope of the militarists in the inability of the United States to land sufficient troops in Europe would be disappointed. His death was due to pneumonia, and coming, as it did, close upon the murder by von Lüttwitz of 11 Jan. 1919, it considerably depressed the hopes of the radical element ('The Reds') of the German Social-Democracy. Of the four chief leaders of the so-called 'Spartacus' group, three had therefore met their death in less than six months, and only one. Klara Zetkin (q.v.), an old woman, herself seriously ill, was still alive.
in April 1919. Consult also Die Neue Zeit (1882 et sequitur, Stuttgart); The Class Struggle (New York 1917 et sequitur).

JACOB WITTMER HARTMANN.

MÉHUL, Etienne Henri, d-tè-èn ôn-ré mâ-ùi, French musical composer: b. Givet (Ardennes), 22 June 1763; d. Paris, 18 Oct. 1817. He was the son of a violin-maker. He substituted the name of Nicholas for Henri. He studied at Paris under Gluck; and after the departure of the latter for Vienna, Méhul presented to the Royal Academy of Music the opera of 'Cora and Alonzo,' the representation of which was delayed for six years. He then turned to the Opéra Comique, which gladly received his 'Euphrosine and Coradin' in 1790. His patriotic hymns, 'Chant du Départ,' 'Chant de Victoire,' and 'Chant Retour,' greatly increased his fame. He was chosen a member of the Institute in 1796, of the Academy of Fine Arts in 1816, and a knight of the Legion of Honor in 1802. His chief operatic work is 'Joseph' (1807). His style as a composer is remarkable for dramatic force and coloring. There is a 'Life' by Pougin (1899). A statue was erected in his native town in 1892.

MEIBOMIA, a genus of erect perennial herbs of the pea family, of which about 150 species are natives of warm and temperate America, Africa and Australia. More than 40 species belong to the United States, some of the more familiar of which are called tick-seeds.

MEIDERICH, Prussia, town of the Rhine province, 15 miles northeast of Krefeld. It contains several large iron and steel mills, machine shops, brickyards, phosphate works and saw mills. Coal deposits are worked in the vicinity and there is a large cattle trade. Its history as an industrial centre began in 1850. It was annexed to Duisburg in 1905. Pop. 40,000.

Consul Graf, Graefeb, Tausendjährige Geschichte von Meiderich' (1933).

MEIER, Edward Daniel, American mechanical engineer: b. Saint Louis, Mo., 1841; d. 1914. In 1858 he was graduated at Washington University and subsequently studied four years at the Royal Polytechnic College at Hanover, Germany. In 1863 he enlisted in the 391 Pennsylvania Volunteers; served later in the artillery and in the engineers and was a cavalry lieutenant at the close of the war. He entered locomotive works at Paterson, N. J., after the war, became superintendent of machinery of the Kansas Pacific Railroad in 1867; chief engineer of the Illinois Coke Company in 1870; and two years later constructing engineer of the Meier Iron Company. He founded the Heine Safety Boiler Company of St. Louis in 1884, of which he was president in 1914. For many years Mr. Meier was president of the American Diesel Engine Company. In 1908–14 he was president of the American Association of Boiler Manufacturers and of the Machinery and Metal Trades Association. In 1913 he was president of the American Society of Mechanical Engineers.

MEIGS, meégz, Henry, American contractor: b. Catskill, N. Y., 7 July 1811; d. Lima, Peru, September 1877. He was engaged in the lumber business in New York and other places but met with financial reverses and in 1845 went to California, where he again took to the lumber business and gained an immense fortune. Reverses, however, once more swept away his wealth, leaving him with an indebtedness of more than $1,000,000. He fled with his family to Peru, where he soon embarked upon a sense of bridge- and railway-building enterprises which won for him immense wealth and a world-wide fame as a railway contractor. His engineering achievements in South America comprise some of the most daring feats in the history of the profession. The construction of the Callao, Lima and Oroya road, which crosses the Andes and ascends to a height only 130 feet lower than the summit of Mount Blanc, was his crowning achievement, and was practically completed at his death. He paid in full the enormous obligations incurred by his failure in San Francisco, contributed generously to charities in the United States and Peru, and by the laying out of a beautiful park, which he presented to the city of Lima, materially changed for the better the appearance of the city.

MEIGS, Charles Delucena, American physician: b. Saint George, Bermuda, 1792; d. 1869. In 1809 he was graduated at the University of Georgia, and in 1813 he entered the college of the University of Pennsylvania. In the same year he established his practice in Philadelphia and became prominent as an obstetrician. He was professor of obstetrics and diseases of women and children at the Jefferson Medical College from 1841 to 1861. He was one of the editors of the North American Medical and Surgical Journal, which he helped to found in 1826. Dr. Meigs published 'The Philadelphia Practice of Midwifery' (1838; 2 ed., 1842); 'Lectures on Some of the distinguishing Characteristics of the Female' (1847); 'Females and their Diseases' (1848); 2 ed. with title 'Woman; Her Diseases and Remedies,' 1851; 3d ed., 1854); 'Remarks on Syphilitic Cholera' (1849); 'Obstetrics' (1849); 2 ed., 1855); 'Observations on Certain Diseases of Children' (1850); 'Treatise on Acute and Chronic Diseases of the Neck of the Uterus' (1854); 'On the Nature, Signs and Treatment of Childbed Fevers' (1854); 2 ed., 1857); 'Remarks on the Translations of Hufeland's 'Treatise on the Disease of the Nervous System' (1829); Velpeau's 'Elementary Treatise on Midwifery' (1831); Colombat de L'Ile's 'Treatise on the Diseases and Special Hysteria of Females' (1845). Consult Meigs, John f. 'Memoir of Charles D. Meigs' (Philadelphia 1872).

MEIGS, Montgomery, American civil engineer: b. Detroit, Mich., 27 Feb. 1847. He was educated at Harvard and in Germany, and was for several years in the employ of the Northern Pacific Railroad. Since 1882 he has had charge of the Des Moines Rapids Canal under the government. He is the inventor of a 'trench coffer-dam.' He also constructed the United States dry dock at Keokuk. In 1898 he proposed a new method of improving country roads by using oil with a sprinkler to make a water-tight surface and lay dust, which attracted little attention and has since been adopted. He built and designed many steamboats and steam dredge tenders for the United States. In 1910–13 he was the government local inspecting engineer in the construction of the great lock, dry dock and power developments in the Mississippi River at Keokuk, Iowa.
MEIGS, Montgomery Cunningham, American military officer: b. Augusta, Ga., 3 May 1816; d. Washington, D. C., 2 Jan. 1892. He was graduated from West Point in 1836 and entering the engineering corps the next year was engaged in the construction of forts Delaware, Wayne, Porter, Niagara, Pulaski, and Montgomery until 1852, when he took charge of the building of the great Potomac aqueduct. In 1860 he built Fort Pickens in Florida, and in 1861 was appointed quartermaster-general of the United States army and held that office until 1864. He was promoted major-general in 1864, and in 1875–76 he was sent by the government to Europe to make an inspection of various staff-departments, the quartermaster's in particular. After his retirement in 1882 he was engaged in preparing plans for various public buildings in Washington. He was a regent of the Smithsonian Institution and of many scientific societies, and was at his death architect of the Pension building.

MEIGS, Return Jonathan, American soldier and politician: b. Middletown, Conn., December 1734; d. at the Cherokee agency, Ga., 28 Jan. 1823. At the commencement of the Revolutionary War he raised a company of men and marched to the American camp at Cambridge, subsequently accompanied Arnold on his expedition against Montreal, was taken prisoner, and after his release was commissioned a colonel in the Continental army. He signalized himself by a brilliant expedition against a British post at Sag Harbor on Long Island, for which he received the thanks of Congress and a sword, and took a distinguished part in the capture of Stony Point under General Wayne, and elsewhere in the course of the war. In 1788 he emigrated to Ohio, and established himself at Marietta. In 1801 he was appointed by President Jefferson Indian agent of the Cherokees, among whom he passed the remainder of his life.

MEIGS, William Montgomery, American lawyer and biographer: b. Philadelphia, 12 Aug. 1852. He was graduated from the University of Pennsylvania in 1872, studied law and was admitted to the bar in 1879. In addition to his law practice he has devoted much time to literary work and is author of 'Life of Joseph Meigs' (1887); 'Life of Charles Jared Ingersoll' (1897); 'The Growth of the Constitution' (1900); 'The Life of Thomas Hart Benton' (1904), etc.

MEIJI, may-ee-jee, the name of the most famous era in the history of Japan (1868–1912). From the introduction of almanacs and chronology from China, 645 a.d., it has been customary to select a nengo, or year-period, from certain words, mostly of happy augury, contained in the Chinese cycle of 60 years (a "cycle of Cathy"). The two words united in Meiji mean Enlightened Government. Of old, it was customary to change the nengo for arbitrary reasons, but from 1883 the rule was fixed to have each year-period begin and end with the emperor's reign. Succeeding the Meiji era, in 1912, was that of Tai-sho, or Great Righteousness. All the dates in Japanese historical records, before 1868, are given in year-periods and the 40 days and days according to the lunar calendar. In 1880, Mr. William Bransen, in Tokio, after elaborate investigation, published his great work, which enables one to express all the Japanese dates, of the 243 year-periods, from 645 a.d., in terms of the Gregorian or European calendar, which in 1875 was adopted in Japan. Consult Clement, 'Handbook of Modern Japan' (1913), and Bransen, 'Japanese Chronological Tables' (Tokio 1880).

MEIKLEJOHN, mi-k'l-jon, Alexander, American educator: b. Rochdale, England, 3 Feb. 1872. He came to America in 1880; was graduated from Brown University in 1893 and from Cornell in 1897. In 1897–99 he was instructor in philosophy at Brown University; was associate professor 1899–1903. In 1900–12 he was professor of logic and metaphysics there, and in the latter year was called to Amherst as president and professor of logic and metaphysics.

MEIKLEJOHN, mi-k'l-jon, George D., American lawyer: b. Weymouth, Mass., 22 Aug. 1857. He was graduated from the University of Michigan in 1880 and established himself in a law practice at Fullerton, Neb., in that year. He held several public offices and in 1884 and 1886 was elected State senator. In 1889 he was elected lieutenant-governor of Nebraska and in 1893–97 served as member of Congress. He was appointed Assistant Secretary of War in 1897 and filled that post through the war with Spain, retaining his office after the resignation of Secretary Alger, until 1901, since which time he has been engaged in his law practice at Fullerton.

MEILHAC, Henri, ön-ré má-yák, French playwright: b. Paris, 25 Feb. 1831; d. there, 6 July 1897. His work as a dramatist, begun in 1855, was attended at first by scant success, but he finally became a favorite playwright. Much of his work was done with Halévy (q.v.). He furnished the book for Offenbach's 'Grande Duchesse,' 'La Périchole,' and 'Les Brigands,' and other works of that composer. Among his independent plays are 'Petite Marquise' and 'Décoré.' In 1888 he was elected to the Académie Française.

MEILLEUR, Jean Baptiste, Canadian author and educator: b. Saint Laurent, near Montreal, 1795; d. 1878. He received his education at the Collège Saint Sulpice de Montreal; studied for the bar, but later took up the study of medicine at the Carleton Medical College, Vermont, where he was graduated in 1825. He became editorial writer on the 'Tessier Journal' and was elected to the Legislative Assembly of Lower Canada in 1834. In 1842 he became superintendent of public instruction and retained this post until 1857. Several educational in-
sitions were founded during his administration which was eminently successful. Meillier became rector of the college in 1802. He was a founder of the Collège de l'Assomption. His published works included textbooks on chemistry, education and grammar, all in French.

MEININGEN, mi'ning-en, Germany, the capital of the small Duchy of Saxe-Meiningen, in a narrow, well-wooded valley, on the Werra, 40 miles southeast of Erfurt. It is an attractive modern town with regular and handsome streets, having been practically rebuilt since the disastrous fire in 1874 which destroyed the old town. The round palace, the large and ducal palace with a church, private and public library of 55,000 volumes, picture gallery, museum, etc., attached. The stock company of the local theatre which for 16 years enjoyed a European reputation for the excellence of its acting and staging, was dissolved in 1890. The industries are only of domestic importance and include brewing, woolen and cotton-weaving. Pop. 17,180.

MEISSEN, mi'sen, Germany, a town of Saxony; founded by Henry I in 922-33, 14 miles northeast of Dresden, on the left bank of the Elbe, at the confluence of the Meisse and Triebisch. It has a noble old castle originally built in the 10th century and rebuilt in the 15th century on a precipitous rock above the town, recently restored. Here is a fine old Gothic cathedral, 500 to 600 years old. Also the Franciscan church, a large and magnificent edifice, used as the custom-house; the church of Our Lady, or city church; the ancient church of Saint Nicholas; and other public buildings. The porcelain factory, first established by Böttcher (q.v.), and now at some distance from the town, is the great industrial establishment of the place; there are also manufactures of matches, stoves, iron foundries and machine-works, a jute-mill, breweries, etc. Meissen is the seat of a see of an archbishop. Pop. about 35,805.

MEISSONIER, Jean Louis Ernest, zhohn loo-é ér-ná má-só-nyá, French painter; b. Lyons, France, 21 Feb. 1815; d. Paris, 31 Jan. 1891. He came to Paris in early youth and entered the studio of Cogniet, meanwhile forming his style on the Dutch masters as represented in the Louvre. He first attracted attention by his illustrations of the Bible, Bossuet's 'Universal History,' Orlando Furioso,' 'Paul and Virginìa,' etc. His earliest paintings in genre to be exhibited in the Salon were 'The Little Messenger' and 'The Chess Player' (1836). His reputation grew rapidly on the successive appearance of 'The Monk' (1838); 'The English Doctor' (1839); 'The Chess Party' (1841). The times of Louis XVI and Louis XV with all the accessory richness and variety of costumes, weapons and domestic luxury, began to find in him their most successful delineator. In the many canvases which he produced in this narrow department of genre he showed a keen and sagacious but not too florid power of characterization, which was accompanied with a marvelous technique in the handling of stuffs, metals, etc. But modern history eventually claimed his attention and he found a congenial field for the exercise of his special gifts in the campaigns of Napoleon. His pictures were often small, but finished with minute and delicate virtuosity, a good example of which may be seen in his 'Marais Prison,' but he is perhaps less successful in large canvases and elaborate figures compositions than in his small paintings. Among his most famous pictures of the Napoleonic cycle are 'Napoleon I with his Staff' and 'Napoleon III at Solferino' (1864); 'Napoleon I at Friedland' (1875), now in the Metropolitan Museum of New York. In his latter days he painted Venetian scenery and architectural views with his usual dash, thoroughness and originality. In his works he shows the best qualities of the Dutch school with all its life-like expression, truthfulness and spirit combined with the delicacy of French sentiment and abandon. His water colors, etchings and lithographs bear admirable witness to his versatility and vigorous industry. His pictures have always fetched a high price, 'Friedland or 1807' having been sold for $60,000, a sum scarcely disproportionate to that given for smaller canvases. He is to be looked upon as the founder of the new school of military painters. It was Gian Francesco Meissonier, and Eduard Detaille, his most illustrious pupil. Consult Claretie, 'Meissonier' (1881); Larroutur, 'Meissonier' (1893).

MEISTERMANN, Barnabas Francis Joseph, German archaeologist and missionary; b. Pforzheim, Alsä, 27 March 1835. He received his education in the seminary of Strasbourg and in 1873 was ordained to the priesthood of the Roman Catholic Church. In 1873 he joined the Franciscan Order, was sent to France and England for a time, and from 1893 to 1893 labored as a missionary among the Chinese. Since 1893 he has resided in Jerusalem, engaged in teaching, writing and research work. His works include 'La Portioncule' (1884); 'Le Mont Thabor' (1900); 'La Montagne & la Galfée ou le Siegeur apparût aux Apôtres' (1901); 'Deux questions d'archéologie palestiniene' (1902); 'Le prétoire de Pilate et la forteresse Antonia' (1902); 'Questions et topographie palestiniene' (1903); 'Le tombeau de la Sainte Vierge à Jérusalem'; 'La ville de David' (1903); 'La patrie & Saint Jean-Baptiste' (1904); 'New Guide to the Holy Land' (London 1907); 'Guide de Nil au Jourdain par le Sinaï et Pétra' (1909). He contributed to the 'Catholic Encyclopedia.'

MEISTERSINGERS, mist'er-sing-érr, a society of German singers formed in the 14th century. During the long evenings of winter the worthy burghers of the German cities assembled to read the poems of the minstrel. Some of the hearers were naturally led to try their own skill in verse; others followed, and the spirit of the age soon embodied these vocations of the muse into societies after the fashion of corporations. Charles IV gave them a charter and a coat of arms. They met on certain days and criticized each other's productions, in which they found an idea of the difference between poetic and prosaical ideas or expressions. Their attempts in the lyric style were chiefly limited to spiritual songs; in the epic to rhymed versions of the scriptural narratives. They were also
fond of the didactic style. The rules by which the members of the societies were to be guided as to the choice of their compositions were written on a table, and called tabulatur, for the sake of enforcing a strict observance of purity in language and prosody. The chief faults to be avoided were collected; they were 32 in number, and distinguished by particular names. He who invented a new metre, invented also a new tune, the names of which were the drollest and sometimes the most senseless imaginable. Besides their stated meetings they held public meetings, generally on Sundays and festivals in the afternoon in churches. In Nuremberg, where the master-singers flourished particularly, such meetings were opened with free singing, in which anybody might sing, though not belonging to the corporation. In this choice the subjects of the works was left comparatively uncontrolled; then followed the chief singing, when only those who belonged to the corporation were allowed to sing, and only on scriptural subjects. The judges were called Merker, and sat behind a curtain. There were four: one watched whether the song was according to the text of the Bible, which lay open before him; the second whether the prosody was correct; the third criticized the rhymes; the fourth the tunes. Every fault was marked, and he who had the fewest reprimands was declared the victor with medals. Whoever had won a chain was allowed to take apprentices, to have many of whom was a great honor. Money was never taken from apprentices. After the expiration of his period of apprenticeship the young poet was admitted to the corporation, and declared a master after having sung for some time with acceptance. These strange societies originated toward the end of the 14th century at Mainz, Strassburg, Augsburg and continued in several free cities of the empire until the 17th, in Nuremberg to the 18th century, where probably the renown of Hans Sachs (q.v.), the famous shoemaker and poet, kept them longer in existence. The last society of the kind was that of Ulm, which was dissolved in 1839. Richard Wagner, in his musical drama, 'Die Meistersinger' satirized the art of these early masters, 'Consult Mey., K.,' 'Der Meistersang in Geschichte und Kunst' (1892); 'Nagel, W.,' 'Studien zur Geschichte der Meistersanger' (1909).

**MEJERDA, or MEJERDA, me-ye'rd'a, the ancient Bagrada, a river of North Africa, formed by the union of several head-streams rising in the Atlas Mountains in Algeria, and flowing through Tunis to its outlet in the Mediterranean, 24 miles north of the city of Tunis. The mass of sediment which it brings down has enlarged its delta and changed the coast line, its mouth formerly being at Bu-Chateau, seven miles southward. Its whole course is about 200 miles.**

**MEKONG, mä-kông', or CAMBODIA, a river of Indo-China. See CAMBODIA.**

**MELA, mel'a, Pomponius, a geographer who flourished during the 1st century of the Christian era, was the pupil of Claudius. Little more is known of him than that he was a native of Spain, and the author of a treatise in three books in the Latin language, 'De Situ Orbis,' containing a concise view of the state of the world so far as it was known to the ancient Romans. Mela is edited by Tschacke (1807), Parthey (1867), and Frick (1880).**

**MELACONITE. A black copper ore consisting of oxide carrying 79.7 per cent of copper. Occurs in many mines.**

**MELAMPUS, in Greek mythology, son of Amythaon, who was the first mortal endowed with the gift of prophecy, and who first practised the medical art. He is said to have introduced the worship of Bacchus into Greece. According to the legend, he could converse with animals, and was favored by Apollo, who taught him divination. His powers saved his life when he was imprisoned in Thessaly. The worms in the wall informed him that the structure would soon fall, and he told his jailers, who withdrew, taking him with them. They informed the king and Melampus was at once in demand, courted and feted. He married one of the king's daughters and was given large estates. In ancient Megaris, he was worshipped and a temple erected in his honor.**

**MELANCHOLIA. See INSANITY.**

**MELANCHTHON, Hellenized name of Philipp Schwarzerd (Eng. 'black earth'), German reformer: b. Bretten, in the Palatinate, 16 Feb. 1497; d. Wittenberg, 19 April 1560. He was left an orphan in his 10th year and taken into the house of his grandmother, a sister of Reuchlin (see Reuchlin), a great German humanist, by whom he was affectionately treated and encouraged in his studies. In his 12th year he entered the University of Heidelberg and two years later was graduated bachelor. While he was occupied with a son of Count von Löwenstein, he continued to give attention to his own progress in Greek; in 1514 was made master of arts at Tübingen and henceforth devoted himself to humanism, lecturing on Cicero, Terence and Greek grammar. He also gave much time to the study of theology, jurisprudence and medicine. Here he first became acquainted with Erasmus' edition of the New Testament, and was through the influence of Reuchlin elected professor of Greek in the newly founded University of Wittenberg. He delivered an inaugural address (29 Aug. 1518), 'De Corrigendis Adolescentiae Studiis,' which produced a revolution in German educational methods and above all met with the approval of Luther, professor of philosophy at Wittenberg. From this time Melanchthon became 'Preceptor Germaniae' (The Schoolmaster of Germany), and the 'Ally of Luther.' These two champions of the Reformation were brought still closer together by their union at the 'Leipzig Disputation' (1519), in which they were confronted by Dr. Eck (see ECK, JOHANN von) the great opponent of Luther and the movement he was inspiring. In his handling of this adversary, both orally and by his writings, Melanchthon showed himself to be the leader of Protestant controversialists and the most learned, judicious and ready of Protestant disputants.**

In 1520 he married Katharina Krapp, daughter of the burgomaster of Wittenberg, and 'Master Philip,' as he was familiarly called, as he settled down to domestic life, was placed on the theological faculty of the university, and the first fruit of his increased application to the theological study and teaching was his 'Lois Communis Rerum Theologicarum,' which was
the first declaration of the Protestant position delivered in formal terms of dogmatic theology. The volume ran through 60 editions in his lifetime and established his author's position as Luther's complement — in some respects the lessor spirit of the Reformation movement, but the scientific talent which supported on the intellectual side the genius and the faith of Luther. Melanchthon, by his historic learning, by his use of the classic languages, was enabled to communicate to the learned world the real principles of the new movement and the facts of the past on which it was founded. He brought to bear his deep knowledge of theological philosophy, his acquaintance with the precise terms in Greek and Latin of scriptural, patristic and scholastic statement on the main question of the dispute, and he had the calmness of the well-balanced humanist which enabled him to direct with cool and even mind the movements of his party and to keep it free as possible from the fury and blindness of intolerance. His knowledge of Greek made him as useful to Luther in translating the Bible as Parnell was to Pope in the production of his Catechismus. His pen had a more permanent influence in securing the after success of the initiative taken by bolder but less cautious and reasonable spirits, and left a mark on the German Reformation deeper, more permanent and characteristic than that of any among his most enthusiastic contemporaries. His 'Epitome Doctrina Christianae' became from the first an influence which establishes its claim to be called the pandect and code of European Protestantism.

The spirit of Melanchthon was distinctly ironic. The Reformation had resulted not only in a German revolt from the papacy, but in the creation of a host of jarring Protestant sects. Melanchthon's broad and far-seeing spirit was averse to division of any kind. The Augsburg Confession which was presented to the diet in 1530 surprised even the Roman Catholics by its moderate tone. It was drawn up by Melanchthon in accordance with memoranda supplied by Luther and it has all the breadth, calmness and judicial cautiousness of Luther's friend and good genius. But this spirit of compromise, however, was not out of harmony with the passion for controversy which made Wittenberg a centre of storm and strife. Melanchthon, however, stuck to his post at Wittenberg long after the great power and influence he once wielded had passed from him into the hands of more positive, violent and aggressive leaders. There occurred a breach between the Philippians, the followers of Melanchthon and the Lutherans, who adhered to the extreme views of his friend on the subject of free will and irresistible grace, on the doctrine of the Lord's Supper, and on the "adiephora" indifferent matters, as the former was inclined to term the ceremonies of the Roman Catholic Church. He and his followers were assailed as "rogues" and "worshippers of Baal." Luther stated his own views on the sacrament with such violence that the recollection of his 'Short Confession respecting the Lord's Supper' filled him with remorse on his death bed, where he acknowledged to his friend "Dear Philip, I confess to have gone too far in the affair of the Sacrament." The death of Luther left Melanchthon to the mercy of such zealous and fiery sectaries as had been engaged in that teeming period of intellectual and theological movement, which the monk of Wittenberg had inaugurated. He survived Luther four years, waiting for death, he said "as a refuge from the frenzy of theologians," and praying that the Protestant world might find its way at last to reunion, a prayer which as yet remains unfilled.

Melanchthon's important part in the Reformation movement has often been lost sight of in the blaze of Luther's more striking and popular personality. Yet he may with some reason be called the brains of the Reformation. More than that, he was a man who, while he stood for the acquisitive spirit of his age, was ready to make personal change. In one sense he was the Mirabeau of a religious revolution, a constructive rather than a destructive reformer, a man born in generation, which he could only affect by presenting an example of intellectual refinement, moderation, tolerance and conservatism, which the warring giants of the Reformation refused to follow. In 1865 a statue was raised to him at Wittenberg and in 1883 a group comprising Melanchthon and Luther at Leipzig.

MELANESIA. (Greek, melas, black; nētos, island), in which the reference is to the extreme blackness of the people rather than to the islands themselves, is the designation applied to the islands of the western Pacific Ocean. They extend northeastward like three interlacing chains, from New Caledonia on the south to the Bismarck Archipelago on the north. East of New Caledonia lie the Loyalty Islands, northeast of the Loyalty Islands begin the New Hebrides, and these are succeeded by the Santa Cruz, the Banks and Swallow groups. A little to the west of these, the Eastern Polynesians begin the Solomon Islands, and considerable east of this archipelago lies a chain of small islands which are considered Polynesian in Melanesia, but ethnologically are distinct Polynesians. In the partition of the Pacific among the European powers New Caledonia and the Loyalty Islands belong to France, the New Hebrides are held jointly by France and Great Britain, the Santa Cruz and the Solomon Islands form a British protectorate. Bougainville and Buka, the northernmost of the Solomon Islands, joined for purposes of administration with the Bismarck Archipelago, form a part of the German colony of Kaiser Wilhelm Land; this colony was captured in September and October 1914, by the Australian contingent, on its way to the World War. Economically, Melanesia has been but little explored. The French in New Caledonia have worked with considerable success extensive mining operations, the garnierite being the richest known ore of nickel and being found in beds which in general may be worked as open quarries. In the New Hebrides the French have established extensive plantations with the promise of future industrial success. The other islands of Melanesia remain in almost unmodified savagery, and only within the last few
years has any considerable attempt been made to utilize their extensive groves of coconut. Missionary effort in Melanesia has for the most part followed the flag; Catholic missionaries are engaged upon the conversion of the New Caledonians; Presbyterian missions have engaged with the southern New Hebrides, the Melanesian Mission of the Church of England is active in the New Hebrides and the Solomon, and in the Bismarck Archipelago the Australian Wesleyan Connection had a flourishing station at Mioko before the German annexation. After the collapse of the missions, the efforts of German missions, both Catholic and Protestant. The inhabitants of Melanesia vary so considerably in form and language as to lead to the conclusion that probably three distinct racial types are to be found in the area, in addition to a certain admixture of Papuan characters which have filtered into the northern areas of the region. Between island and island, even between village and village on the same small island, the difference of speech is so marked as to prevent a natural communication. In general it is to be said that the Melanesians are very close to the lowest level of savagery; polygamy, infanticide and cannibalism are constantly practised, yet the people are of an agreeable disposition which they are attractive to all such as are brought into contact with them. The cultural position of the Melanesians is markedly distinct from that of the Polynesians in several important particulars: The bow is in use; the art of pottery is very generally practised, the loom is found in one area, the taboo does not exist in any sense of moral control, the authority of chiefs is very limited and scantily invested with the idea of hereditary succession, shell money is used as a circulating medium, and over a large and increasing area of Melanesia sirih (betel) chewing is extensively practised. Consult Codrington, R. H., 'Melanesian Languages' (Oxford 1885); id., 'The Melanesians: Studies in their Anthropology and Folk-Lore' (Oxford 1891); Head-Hunters, Black, White and Brown' (London 1902); Guppy, 'Solomon Islands and their Natives' (ib. 1887); Imhaus, 'Les Nouvelles-Hebrides' (Nancy 1890); Seligmann, 'The Melanesians of British New Guinea' (Cambridge 1910).

MELANESIA. See MELANIA.

MELANISM, an excess of pigment in the skin and its appendages, producing real or comparative blackness; the opposite of albinism (q.v.). Melanism is less frequent than albinism, but more inclined to affect large numbers of individuals of a species, forming melanistic varieties and is seen not only in man but in other mammals and in birds, reptiles, fishes, and in insects as, for example, certain moths which are found in Labrador and in the White Mountains of New Hampshire, showing a possible connection between melanism and cold or high altitudes. Moisture is also considered to be a determining factor, as is indicated by the fact that the species of most insects inhabit the warmest and dampest regions of the earth. A conspicuous example of melanism is afforded by the American 'black' squirrels, which are melanistic varieties of several species, especially the fox-squirrel (Sciurus niger) and the gray squirrel (S. carolinensis). These varieties prevail in certain parts of the country, as the region of the Great Lakes and upper Mississippi Valley, and rarely occur elsewhere. Thus a black squirrel is almost unknown in New England or the Hudson Valley. Another familiar example is found in the black leopards, which in a direct light seem absolutely black, but under reflected light betray a pattern of spots similar to those of the ordinary leopard. Such examples, as is the case with other melanistic animals, often occur in the same litter of young with normal forms. In many of the lower animals, as butterflies, melanistic tendencies have developed under certain conditions, especially of excessive moisture. The pigments in the skin are mainly of the class called Melanins, which produce dark hues. Total abnormal melanism in man is unknown, but cases of partial melanism are on record. In one instance one-half of the face was white, the other black. A case is on record of a 16-year-old girl, a laundress, whose neck, face and upper chest became blue on certain occasions. She was otherwise apparently healthy but the skin was so pigmented that when she blushed her color was blue instead of red, the change appearing with chameleonic rapidity and being associated with the accession of blood to the skin. A white towel, which had been rubbed over her skin. Other cases of skin discoloration are that of a man who became black in places and yellowish brown in others, and that of an unmarried woman white until she was 21 and thereafter black as a negro. The cause of this condition is unknown. Melanoderma, chloasma, and liver-spots are terms applied to irregularly shaped yellow, brown, and black colorations of the skin. Some of these spots are due to scratching following the bites of body-vermin, to prolonged pressure upon a portion of the skin, prolonged use internally of preparations of silver, to racial admixture, general diseases, such as cancer or tuberculosis, etc. See COLOURING MATTERS; COLORATION, PROTECTIVE.

MELANITE (Gr. μέλανίτης), a very black variety of garnet, especially the lime-iron variety, in which lime largely replaces magnesia in the protoides. Melanite occupies a place midway between schorlomite and the garnets pure and simple; this is notably true of the sort containing the rare element titanite (q.v.). The group includes all the darkish garnets, with the exception (made by Dana) of the precious garnet, technically the pyrolite, which varies from red to black. With the green demantoids the blackish melanites make up the greater part of Dana's second class of garnets, the iron garnets.

MELANORRHGEA, mel'ə-nō-rě'ä. See VARNISH TREE.

MELANOSIS. See TUMOR.

MELANTERITE (Gr. μελαντερίτης, μέλανης), in mineralogy, the native hydrous sulphate of iron; iron vitriol. It is the native form in which copperas occurs, is green in color and has a glassy lustre.

MELASMA (Gr. μέλανης, μέλανα), a disease marked by discoloration of the skin. The term is rightly used in connection with a pigmentation of the skin, sometimes diffuse (color varying—dusky yellow, greenish brown, or even
black), and believed to be dependent upon degeneration of the suprarenal capsules or the seminal ganglia. (See Addison's Disease). Sometimes the teeth are replaced by the conditions known as liver-spots and "moth-patches."

**MELASTOMACEAE.** See DEER GRASS.

**MELBA, Nellie,** Australian prima donna; b. Melbourne, about 1860. She studied there in the Presbyterian Ladies' College; then took up music under Marchesi in Paris. On 15 Oct. 1887 she made her début in Brussels in 'Rigoletto'; at that time gave up her family name Mitchell and took the stage name Melba, which is said to have been suggested by the name of her native city; in 1889 she appeared in Paris at the opera, where she stayed for three years, during which she appeared in London in Italian repertoire; and after 1892 toured Europe and America. Her best rôles are Ophelia, Juliette, Lucia and Nedda in 'I Pagliacci.' She was married to Charles Armstrong in 1882. Consult Murphy, G. A., 'Nellie Melba' (London 1909).

**MELBOURNE, mēlˈbərn,** William Lamb, Viscount Melbourne, English statesman: b. 15 March 1779; d. 24 Nov. 1848. Carefully trained by his mother, he entered Eton in 1790, Trinity College, Cambridge, in 1796, and Lincoln's Inn in 1797; studied law in Glasgow; was called to the bar in 1804; and in 1805 was elected to the House of Commons, where he followed Fox, leader of the opposition. He lost his seat in 1812 because of his vote for Catholic emancipation; was returned in 1816; served as chief secretary in Ireland in 1827; and in 1828 entered the House of Lords upon his father's death. Only then did he begin to figure in politics, and that only because of his popularity, for he had no official ability, being neither diligent nor brilliant. As home secretary under Grey in 1830 he was a failure; but in July 1834 the king induced him to form a ministry, and again in 1835, in spite of the king's effort to foist Peel on the country in November 1834, he became Premier. He remained in office until August 1841, thus covering the early years of the reign of Victoria, in whose household Melbourne was instructed in the duties of her position. His tuition of the young queen seems, however, the only event of his long administration, and he must be classed rather as a politician than as a great statesman, since he was scarcely more than indifferent to the reform measures of the day. He was a man of much learning, of a rather attractive, though coarse and habitually profane, wit and of a strange admixture of constitutional conservatism and political liberalism. His wife, Lady Caroline Ponsleby, whom he married in 1805, was separated from him in 1825; she wrote several novels and was a friend of Lord Byron. See NORTH, CAROLINE ELIZABETH; and consult Torrens, W. M., 'Memoirs.'

**MELBOURNE, Australia,** the capital of the State of Victoria, and the largest city of Australia, situated around Hobson's Bay, at the northern extremity of Port Phillip, 40 miles north of its entrance from the ocean between Points Lonsdale and Nepean. The city and its numerous suburbs occupy an extensive undulating area, with the Yarra River, a stream of moderate size, winding through it. The central and most important business part of the city is on the north bank of the Yarra, two miles by a direct railway line from the river's outlet in Hobson's Bay, but nine miles by the meandering water route. The city is built on a rectangular plan with streets laid out in the conditions known as "liver-spots" and "moth-patches." Numerous lines of railway connect with the interior and the extensive suburban districts, which include such important places as Collingwood, North Melbourne, Fitzroy, Carlton, Brunswick, South Melbourne, Richmond, Prahran, Saint Kilda, Port Melbourne, etc. The city is well lighted, and paved, and is abundantly supplied with water, but the drainage, although much has been done toward its improvement, is still defective. Street railways traverse all the principal city and suburban thoroughfares.

The public buildings of Melbourne are noteworthy. The Houses of Parliament form a remarkable pile with a splendid west façade. Government House is a palatial building conspicuous from every part of the city and 25 feet high. Other public buildings include the law courts, forming an extensive square, the post-office, the custom-house, the treasury, the land and mining offices, the mint, the free library, and with an admirable museum belonging to it and a splendid hall (the Wilson Hall) in the Gothic style; the Ormond Presbyterian College; the town hall, with a large assembly room containing a splendid organ; the exchange observatory, meteorological station, and art museum. The ecclesiastical buildings include an Anglican Cathedral, a Roman Catholic Cathedral and the Scots church, with a fine steeple. There are several "sky-scraper" office and store buildings; many banks and business premises are attractive; and the Exhibition building deserves notice. At the head of the educational institutions is Melbourne University (about 930 male, 320 female students annually), which are affiliated the three denominational colleges, Trinity (Episcopal), Ormond (Presbyterian), and Queen's (Methodist). Charitable and benevolent institutions are numerous. There are several parks and other grounds for public recreation, and among these the Botanic Gardens, a preserve, Melbourne on 2,185,440 acres, beyond the latter manufactured goods. Most imports are subject to a heavy duty. Vessels of 26 feet draught can ascend the Yarra. Its navigation has been much improved, and the Coode canal shortens the passage. The largest vessels accommodated at Port Melbourne and Williamstown, worth of about 100 feet, both on Hobson's Bay; Port Phillip Bay affords unlimited anchorage for the largest vessels. The tonnage of vessels entered 1915-16 was 5,290,118. Pop. of Melbourne, including the suburban municipalities, 684,000, nearly half the population of the state.

The first settlements on the site of Melbourne were made in 1835, and a year or two
1 Parliament Building, Melbourne

2 Public Library, Melbourne
after it received its present name, being so
called after Lord Melbourne, who was then
British prime minister. It was incorporated
in 1842 and became a bishop's See in 1849. In
1851 it became capital of Victoria (then estab-
lished as a separate colony), and received an
immense impetus from the discovery of gold
fields.

A centennial exhibition was held in 1888 in
celebration of the founding (in 1788) of the
Australian colonies. A great conflict between
labor and capital took place in 1890, and a
strike by the labor-unionists took place on a
very extensive scale both in Victoria and New
South Wales. In 1892-93 Melbourne suffered
severely from commercial depression, financial
crises and banking disasters. The first Parlia-
ment of the Commonwealth of Australia was
opened in the Exhibition Building on 9 May
1901 by the Duke of Cornwall and York (after-
ward George V). Consult 'Victoria and its
Metropolis, Past and Present' (1899); Gordon
and Gotch, 'Australian Handbook' (1906).

MELCHERS, Paulus, German cardinal: b.
Mplies, Westphalia, 28 Dec. 1811; d. Rome, 14
Dec. 1895. He studied law at Bonn and the-
ology at Munich and Münster; was ordained
priest in 1841; in 1857 became bishop of Osna-
brück, and in 1865 Pope Pius IX nominated
him archbishop of Cologne. At first opposing
the doctrine of papal infallibility at the Vatican
Council, Melchers afterward accepted it, in
agreement with the majority, and dealt severely
with professors who sought to prevent its de-
claration. In the Kulturkampf (q.v.) his con-
ception of national rights brought him into colli-
sion with the representatives of government, and in
1876 he was removed from his archbishopric.
His writings include 'Eine Unterweisung für
das heilige Altarsakrament' (1878); 'Die
katholische Lehr des Herrn' (1883), and 'Das
Leben der allerliebsten Jungfrau und Gottes-
mutter' (1884).

MELCHITES, mel'kìts, those Christians of
western Asia and of the Levant who acknowled-
ged the supremacy of the Roman Pontiff and
accept the dogmas of the Roman Catholic
Church. The Syriac and Egyptian congrega-
tions in which the name in the main belong to the
Greek Church though in some unimportant matters of
ceremony and discipline they take an independent course. They are, however, under a chief bishop of their own, who is
styled patriarch of Antioch. The term Mel-
chites is a nickname. It means 'Royalists' and
was given to them by the orthodox Greeks with
the implication that they accepted the decrees of the Council of Chalcedon merely at the dic-
tation or in conformity with the example of the
emperor. Celibacy is imposed upon their
bishops, but their priests are at liberty to marry.
Their liturgy is in the Arabic language; they
use unleavened bread in the Eucharist and in
their monastic houses they follow the Basilian
rule. There are said to be 100,000 of them.
Consult Neale, 'History of the Eastern Church'.

MELCHIZEDEK, mel'kìz'dèk ('king
of righteousness,' that is, righteous king), in the
story of Genesis, king of Salem and priest of
'Supreme God.' He met Abram on his re-
turn from the victorious expedition against
Chedorlaomer, gave him his blessing and re-
cieved tithes from him. The antilegal king-
priest stands in Psalm cx as a figure typical of the
Messiah the viceroyer of Jehovah, and in
Hebrews vii, 3, of the kingly priesthood of
Jesus. There are various views as to the
identity of Melchizedek, as he is named in
many ancient writings. Rabbi Kaufmann
Kohler of the Hebrew Union College, Cin-
cinnati, states in the 'Jewish Encyclopedia'
that the personality of Melchizedek rests upon
ancient Jewish tradition, and identifies him
with Malki-Zedek, first king of Zedek, the
ancient name of Jerusalem. Philo speaks of him
as the *Logos*; others believe he was Shem,
ancestor of Abraham. The chapter in Genesis
containing his story is a unique passage of the
Pentateuch, and according to Wellhausen is
one of its latest additions. Ewald counts it
the earliest portion of the history and based on
old Canaanitish records; others, as Nöldeke,
explain it as utterly unhistorical.

MELCHTHAL, mel'h'tål, Arnold von
(ARNOLD AN DER HALDEN), Swiss patriot. He
is considered by some authorities to be a
mythical character, but was supposed to have
lived in the 14th century. He inveigled the
wrath of the governor and was compelled to
flee to escape punishment, whereupon the gov-
ernor seized Arnold's aged father and had his
eyes put out. The son, enraged at this bar-
barity, with two friends planned a revolt
against the Austrian power which they suc-
cessfully conducted. Consult AEGIDIIUS TSCHUDI,
'Chronicon Helveticum' (1505-72).

MELDOMETER. See MELTING POINT.

MELEAGER, according to Greek legend,
the hero of the Calydonian boar hunt. The
earliest form of the story is found in the
'Iliad,' according to which Meleager is son
of Aeneus, a king of Aetolia, and Althaea,
daughter of Theseus. When the boar had
devastated the land Meleager gathered a band
about him and after a great struggle and with
considerable loss of life slew the monster. A
quarrel over the spoils arose between the
Aetolians and the Curetes, the latter being un-
der the leadership of Meleager's maternal
uncles. In the quarrel the latter were killed
by Meleager, who was not aware his mother, who prayed the Furies and gods of the nether
world to destroy him. The hero withdrew from the fight until the Curetes stormed the
town when he launched forth to save his
people and was slain, according to some, by
the Furies, according to others by the hand of
Apollo. Other versions of the story were cur-
rent in later times, one of which is preserved
in an ode of Bacchylides. The Calydonian
Hunt was a favorite subject with artists from
early times, and a copy of a work by Scopas,
executed originally for one of the pediments of the temple of Athena Alea at Tegea, is now
in the Vatican, Rome. In the Fogg Art Mu-
seum of Harvard University is an excellent
replica of the Vatican copy.

MELEDA, Austria, an island off the
southern coast of Dalmatia in the Adriatic. It
is about 25 miles long and the Austrian name
is Babinopolis. It is believed by some to be
identical with Melita on which Saint Paul was
stranded.
MELENDEZ VALDES, Juan, hoo-án’ mèlén-dèth vál-dàs’. Dow. Spanish poet: b. Ribera del Fresno, Badajoz, 11 March 1754; d. Montpellier, France, 24 May 1817. He studied law at Salamanca, where he attracted attention by his poems in the old ballad manner and was taken up by the poet Cadalso. In 1780 he received first prize in a competition under the control of the Spanish Academy for his pastoral Batilo, and, in 1784, his comedy, Las Bodas de Camacho, won a prize from the city of Madrid, although unsuccessful on the stage. In Madrid he won the favor of Jovellanos, who appointed him professor of the classics in the University of Salamanca and urged him to enter upon an unfortunate political career; he became judge in 1789, a judicial chancellor at Valladolid in 1791, and fiscal in the Supreme Court in Madrid in 1797. He suffered brief exile after the fall of Jovellanos (q.v.) in 1798; but in 1802 returned to Salamanca. His sympathy with France, however, made him more than ever unpopular, and after the expulsion of Joseph Bonaparte, he went into exile in France. He was one of the most prominent figures in Spanish literary life during the 18th century.

MELETIUS, (1) founder of the sect of Meletians. He was bishop of Lycopolis in the 4th century, and antagonized Peter, patriarch of Alexandria, by refusing absolute and communion to the lapsed, that is, those who under the stress of persecution had renounced their faith. A schism resulted from the dispute and Meletius traveled through Egypt and Syria gathering thousands of followers, until the Council of Nicea, 325, deprived him of authority and he died soon after, a merely titular bishop. (2) Another Greek ecclesiastic of the same name and century, who was made bishop of Antioch in 360, when the Arian controversy was at its height.

MELGAREJO, Mariano, mà-ré-à’ño màl-gà-ðáh. Bolivian soldier: b. Cochabamba, Bolivia, 18 April 1818; d. Lima, Peru, 23 Nov. 1872. He entered the army at an early age and by his courageous though somewhat unprincipled conduct in the many revolutions in his country, rose to be chief adviser of General Acha in 1862 and was made a general. In 1864 he turned against Acha who was then President, instigated a revolution and seated himself in the presidential chair. During a brief absence of Melgarejo the ex-President Belzu returned and reinstated himself in the presidency only to be shot by Melgarejo himself, who then became dictator. He crushed a revolution in 1866 and in that year formed an alliance with Spain against Peru and Chile. Revolutions followed and he was compelled to flee the country in 1871 and was killed in a quarrel at Lima.

MELIC GRASS (mel, honey), delicate genius of grasses growing in the shade of woods, of the order Gramineae, having a lax panicle and spikelets of 2-5 small florets, of which one generally is imperfect. M. uniflorum is of graceful and delicate appearance; cattle are fond of it. This species is common in Europe. M. nutans is common in the United States west of the Rockies. M. altissima, a Siberian species, growing to the height of three or four feet, has been introduced in parts of Europe and yields a considerable bulk of herbage. It is perennial.

MELICERTES, son of Athamas and Ino. In fear of Athamas, whose children by Nephele, Phrixus and Helle, she had tried to kill, Ino jumped into the sea with Melicertes. She became the sea divinity Leucothea, he Palemon, whom the Romans identified with their god of harbors. Fortunately some identified him with Moloch. It is recorded that children were sacrificed to him at Tenedos.

MELICOCCA (mu’là-kà, honey — kókko, berry), genus of trees or shrubs of the natural order Sapindaceae, comprising about six species, one of which M. bijuga, native of the West Indies, is there universally cultivated for its fruit. It is called the honeyberry and the Jamaica bulrush; by the Spaniards, Monos; by the Dutch, Knippee. It is 16 to 20 feet high. The fruit has an agreeable flavor and varies in color from yellow to jet black. It is now grown in California and Florida. When roasted the seeds may be eaten after the manner of chestnuts. Some other species also yield edible fruits.

MELIHAH, the salting of meat according to Jewish ceremonial, that it may be without blood and ritually fit for eating, thus complying with the law (Gen. ix. 4).

MELIKOFF. See LORIS-MELIKOFF.

MELLILITE, or MELLILITE, a native silicate of sodium, calcium, magnesium, aluminum and iron. Potassium is also commonly present to some extent. Melilitite crystallizes in the tetragonal system and has a vitreous or resinosus lustre and usually a honey-yellow color, from which circumstance it derives its name (Greek, ὑπόλυς, "honey"). It is brittle, translucent (at least in thin layers), and distinctly pleochroic. It has a hardness of about 5 in a specific gravity of 3. The mineral occurs in basic eruptive rocks and is also observed, quite frequently, in the slag from furnaces. It is sometimes called mellilit.

MELILLA, Africa, a port of Spain in Morocco, about 150 miles east of the Straits of Gibraltar. The exports in 1915 totaled $1686. A Spanish military command is located there, a wireless station and an armory, the latter having a range of 320 miles. It has been used by Spain also as a penal settlement. Pop. about 9,000.

MELILOT, a genus (Melilotus) of annual biennial and perennial herbs of the family Fabaceae. The species of which there are about a dozen, are natives of western Asia and the Mediterranean region and have become widely distributed in temperate and sub-tropical climates. They are upright, alfalfa-like plants with small yellow or white flowers which are borne from late spring until frost. The pods are few-seeded and not twisted as in the closely related genus Medicago (q.v.). The two best known species are yellow melilot (M. officinalis), an annual, and white melilot (M. albus), a perennial, which are common weeds in waste places, the former especially upon dry, clayey soils, the latter in damp situations. Like other members of the genus they are sweet-scented particularly while drying, and their flowers are used to some extent for perfumery.

MELINE, James Florant, American lawyer and author: b. Sacket's Harbor, N. Y.; 4
MÉLINITE — MELL 606

Brooklyn, N. Y., 14 Aug. 1873. He was graduated at Mount Saint Mary's College, Emmetsburg, Md., and went to Cincinnati, where he was one of the professors at the Athenaeum, and engaged in teaching, and established a practical creed sufficient to inspire ardent and prolonged endeavor. The opponents of meliorism have connected it with the theory of evolution. Evolution by them is presented in a semi-religious light, inasmuch as they believe in a gradual abatement of evil through progressive evolution. This view is not confined to philosophers of this school, however, but is now the view of many agnostics, who unwarly have assumed this unconsciously religious conception of the universe. Consult Fraser, 'Theism.'

MELISSA, a plant. See BALM.

MELISSUS, MELISS-ös, Greek philosopher: b. Samos, about 480 B.C. He was the son of Ithagenes, and is said to have been a friend of Heraclitus and to have commanded the fleet opposed to Pericles in 440 B.C. in the Samian War. Some fragments of a prose work of his, written in the Ionic dialect, have come down and have been collected and published by Brandis and by Mullach (1846). From these he appears to have been a philosopher of the Eleatic school and to have reached more definiteness and consistency than Parmenides. He reasoned that being was eternal, and could not have a beginning, else it would start with non-being; by like reasoning, there can be no destruction of being, for it would have to become another and opposite thing. Void he holds to be nothing, which is not, and therefore unknowable. He concluded that being was incorporeal, because a body has size and parts.

MELITA, MELIT-a, the island on which Saint Paul, on his voyage to Rome, was cast away. This has generally been considered to be the Island of Malta, the ancient name of which was Melita, and one of whose bays has from immemorial time borne the name of Saint Paul; but some critics have attempted to prove that it was an island, the modern Meleda (q.v.), on the coast of Dalmatia, in the Adriatic.

MELKART (Phoenician, Baal of the City), name of the presiding deity of the seas of Tyre and of the whole Tyrian nation, namely, Baal (q.v.), the sun god. He is sometimes identified with the Heracles or Hercules of the Greeks. He was the patron god of mariners and the Phoenician colonies of the West, in Africa and Spain, were under his protection. To him has been ascribed the subjugation of the savage races who recently peopled these regions and the building of early Phoenician towns. The institution of order and legislation in these cities was also said to have been his work. Many are the voyages which he is related to have made. One of his exploits was the rescue of Astarte from the darkness in which the moon had imprisoned her in the West; he afterward married her, and bore her off. For an account of the Temples of Melkart at Tyre consult Jeremias, 'Tyris bis zur Zeit Nebukadnezzar' (1891).

MELKITES. See MELCHITES.

MELL, Patrick Hues, American educator: b. Walthourville, Ga., 19 July 1814; d. Athens, Ga., 26 Jan. 1888. He was educated at Amherst and after teaching for several years was appointed professor of ancient languages at Mer-
MELL—MELODEON

cer University in 1842 and was also ordained a Baptist minister in that year. In 1856 he was appointed to the same chair in the University of Georgia, and in 1870 he became vice-chancellor, which post he resigned in 1872. In 1876 he was appointed chancellor and in 1880 was elected to the chair of metaphysics and ethics, which offices he occupied at his death. He held several pastoral charges and was president of different conventions in addition to his educational work and published 'Baptism' (1864); 'Parliamentary Practice' (1868); 'Church Polity' (1878).

MELL, Patrick Hues, American scientist: b. Penfield, Ga., 24 May 1850. He was a son of the preceding, was graduated at the University of Georgia in 1871 and was State chemist in 1874-77. In 1878 he was called to the chair of geology and botany at the Alabama Polytechnic Institute and continued in that position until 1902, when he accepted the presidency of the South Carolina Agricultural and Mechanical College. In addition to his work in the university, he was connected in 1884-1902 with the Alabama Weather Bureau and the Agricultural Experiment Station and he invented a system of weather bureau signals which has been adopted by the United States Weather Bureau. He has published 'Southern Soapstones and Fireclays' (1882); 'Study of Cotton Plant' (1890); 'Life of Patrick Hues Mell, Sr.' (1895); 'Biological Laboratory Methods' (1902); etc.

MELLLEN, Charles Sanger, American railroad president, b. Lowell, Mass., 16 Aug. 1851. He was educated in the public grammar and high school of Concord, N. H. He began his railroad service 22 Sept. 1869 as clerk in the cashier's office of the Northern New Hampshire Railroad. In 1872-73 he was clerk to the chief engineer of the Central Vermont Railroad, in 1873-75 superintendent's clerk to the chief clerk and assistant treasurer of the Northern New Hampshire; assistant to the manager of the Boston and Lowell Railroad in 1880-81; auditor 1881-83; superintendent 1883-84; general superintendent 1884-88 of the Boston and Lowell and Concord railroads. In 1888 Mr. Mellen became general purchasing agent, in 1889 assistant general manager, in 1889-92 general traffic manager of the Union Pacific system. In 1892 he became general manager of the New York and New England Railroad at Boston; from 1892 to 1896 he was second vice-president of the New York, New Haven and Hartford; from 1896 to 1903 president of the Northern Pacific and from 1903 to 1913 president of the New York, New Haven and Hartford Railroad. From 1910 to 1913 he also served as president of the Boston and Maine Railroad. Mr. Mellen's administration of the New Haven road was severely criticized because of the efforts to secure a monopoly of transportation in New England. Trunk and short line rates were brought out and the equipment of the parent road was depreciated to such an extent that numerous wrecks resulted. Mr. Mellen retired from business in 1915.

MELLITE. See Mellilite.

MELO, Custodio José de, koos-tô'dô-ké do'sa'da mál'é, Brazilian admiral: b. about 1845; d. 16 March 1902. In 1889 he took a prominent part in the revolution, was promoted to be admiral and was appointed Minister of the Navy. Four years later he formed a plot in behalf of the Federal party and the navy, against the party of the army and its candidate for re-election, President Pires; bombarded and blockaded Rio de Janeiro; and when forced out of the harbor by vessels of foreign navies, notably American, occupied Rio Grande do Sul. He could not agree with his lieutenant, Saraiva, however, and so surrendered to the government of Argentina. In 1901 he was accused, in spite of his former republicanism, of plotting to establish an empire and was interned upon the island of Cobras.

MELONI, Macedonio, mách-chá'dô-né, Italian physicist: b. Parma, 11 Apr. 1798; d. Portici, near Naples, 11 Aug. 1854. He became professor of natural philosophy at the University of Parma, where between 1824 and 1831 he taught hygrometry. Political events having compelled him in the latter year to expatriate himself, he went to Geneva, where he made several important discoveries respecting the radiation of heat, and in 1833 to the French Academy of Sciences. Later discoveries won him the Rumford medal from the Royal Society of London. Through the influence of his friends, Arago and Humboldt, he was enabled to return to Italy, and was appointed by the king of Naples director of the meteorological observatory on Mount Vesuvius. Among the results of his labors at this institution was the discovery of heat in lunar light which led to the determination of the analog of radiant heat to light. Political troubles again interrupted his labors, and for his presumed sympathy with liberal principles he was in 1849 ejected from his post. In 1850 he published the first volume of a work entitled 'La termocrazi, o la colorazione calorifica,' containing an account of his theory of the 'coloration of light,' and of his experiments on the diffusion of heat by radiation, and particularly of transmission through transparent media. Subsequently he gave much attention to the study of electricity and combated the conclusions of Faraday with regard to the transmission of currents over submarine wires.

MELOCACTUS, a cactus typical of the tropical American melon-cactus family, Melocactae. It consists of a globose or conical stem, having rows of spines at intervals and flowers at the top on a hemispherical or cylindrical head. There are more than 20 species: M. communis of the West Indies is the Turk's Englishman's or Pope's head cactus. The head bearing the flower is red and like a Turkish fez in form.

MELODEON, a musical wind instrument with a row of reeds and operated by keys. The rocking melodeon, known in America since about 1825, was unsightly, tardy in sounding and of harsh tone. Jeremiah Carhart in 1813 conceived the plan of acting on the reeds by suction instead of blowing, and reversed, to this end, the bellows and reeds, inventing the present instrument in 1836. He thus obtained prompt sounding and a flute-like quality of tone; "voiced" the note by curving the reeds and made many other improvements. In a single year 22,000 of these instruments were manufactured in the United States, and they
were popular until the cheap parlor organ displaced them.

**MELODRAMA** (from the Greek *melos*, song, and *drama*, action), originally and properly a half-musical drama, or that species of drama in which the declamation of certain passages is interrupted by music. It is usually a tragedy of common life, filled with surprises, acts of violence and all that excites and sustains the attention of the audience, mixed up with dancing and music and sometimes with scenes of a rudely comic character. Probability is freely sacrificed for the sake of striking situations. The object is to be sensational and to catch the applause of the gallery. See **DRAMA**.

**MELODY, in music,** a succession of single tones so arranged as to express a musical thought. A solo for one instrument or voice with or without accompaniment is the most typical example of a melody.

Melody is one of the most comprehensive terms employed in music, being properly applicable to as few as two notes or to as many as the entire principal vocal or instrumental part of a composition. An example of the first is the motif of woe in Wagner's *Der Ring des Nibelungen.*

Examples of the latter are too numerous to require mention.

The term is also appropriately applied to a phrase or portion of a phrase in a part that has been subordinate to the principal one and which for a moment gains importance on account of its greater melodic significance. In concerted music, vocal or instrumental, the highest part is usually the melody, though as stated above an inner one may temporarily assume it. In polyphonic music all the parts are equally melodic.

Melody is the outgrowth of the improvised recitative. The early Greek singer standing before his audiences holding his four-stringed lyre or chelys, plucked a string and recited his poem on that note until fancy impelled him to change it. From this crude ancestor has sprung melody as we understand it to-day, which with rhythm and harmony form the great triad necessary for the complete expression of music. Melody is the only one of the three capable of suggesting enough of the other two to be satisfactory by itself. The folk-song of old and the popular song of to-day may be sung by a single voice without any accompaniment and yet convey a very definite idea of the rhythm and something of the harmony that would naturally accompany the tune. Such a performance is, of course, incomplete and only effective in music of the simplest character. Yet it conveys much more than the mere rhythm of the tune played on a drum would give and still more than the mere harmony played without either the melody or the rhythm. It is curious that the Greeks with all their extraordinary achievements in all other forms of art should have advanced so little in music. No doubt they used music in their religious feasts and the cross flutes — *pyxioncarda* — and lyres supplied what they must have thought melody, but they do not seem to have ever dreamed of musical accent or rhythm, without which we cannot to-day call a succession of sounds melody, while harmony was unthought of for many centuries.

Melody is greatly affected by the harmony that the composer has wedded to it, and it is to this fact perhaps more than any other that originality continues possible, for with but 12 different notes from which to form a melody it is evident that even with all the variations that rhythm can add the melodic material is capable of exhaustion in the enormous and growing number of compositions. The following phrases of melody, especially the first, have no particular suggestion played alone:

-but with the harmony that the composers have added they have an entirely different signification, the one of the great solemnity and foreboding, the other of harsh cynicism and sneering.

**HENRY GORDON THUNDER,**

**MELON-CACTUS, or MELON-THISTLE.** See **MELOCACTUS.**

**MELON-PEAR, or SHRUB.** See **MELONS.**

**MELONS, a popular name for several unrelated plants, but more particularly for two members of the family **Cucurbiteae,** the muskmelon (**Cucumis melo**) and the watermelon (**Citrullus vulgaris**). The more important other fruits similarly known are the Chinese preserving melon (**Benincasa hispida**) of the same family; the melon papaw (**Carica papaya**) of the family **Caricaceae,** and the melon-shrub or melon-peal (**Solanum muricatum**) of the family **Solanaceae.**

The muskmelon is an annual trailing herb which has been introduced by man into all tropical, subtropical and many temperate climates from southern Asia where it is native. It is characterized by long, running, hairy and somewhat prickly vines, roundish heart-shaped leaves, yellow monocious flowers — and usually edible fruits of very various forms and sizes. The following are the principal varieties: Variety **cantaloupe,** the cantaloupes, or rock-melons, which have hard, warty or scaly rinds more or less furrowed, and flesh of various colors from white to red, green or yellow. In the United States the name **cantaloupe** is loosely applied to horticultural varieties of
other groups. Variety reticulatus includes the
nutmeg or netted melons which have softer
rinds, sometimes smooth, but usually more or
less netted. To this group belong the larger part
of the so-called cantaloupes in American
markets. Variety vacciniana comprises the
pineapple melons which have very sweet flesh,
but are not clearly distinct from the preceding
group. Variety inodorus, the winter musk-
melons, which have less hairy, lighter-colored
vines and foliage and whose long-keeping fruits
are deficient or entirely lack the characteristic
muskmelon odor. This variety is less tolerated
in the United States than in the Mediterranean
region, but because the fruits can be kept until
Christmas or later when properly grown,
gathered before frost and slowly ripened in a
cool, rather dry room, they should become more
widely popular where the seasons are long
enough to permit their reaching such a stage
of maturity. Variety flexuosus, the snake-
melons or cucumbers, have very long, narrow,
greenish, contorted fruits, prized more as odd-
tities than for culinary use and hence be
sued for making preserves. They are distinct from
the snake-gourds which belong to the genus
Lagenaria. A variety chito, called orange-
melon, melon-apple, garden-lemon and many
other popular names, bears orange- or lemon-
like sweet scentless fruits with white or pale
yellow flesh, which is grown to some extent
for preserving. Variety dudaim, the pomegran-
ate-melon, Queen Anne’s pocket-melon, dudaim
melon, etc., has small brown and yellow fruits
valued solely for their exquisite perfume.
Melons are propagated wholly by means of
seeds, which may be sown directly in the field
or started under glass upon sown beds, in
flower-pots, berry-boxes, etc., and transplanted
to the field as soon as danger of frost has
passed. The former method is practised most
extensively in the South and in other warm
climates where the seasons are long; the latter
in the North because the shortness of the
season demands that the plants obtain an early
start. The soil best suited to melons is a light,
sandy loam well drained, well exposed to the
sun and well supplied with plant-food. It
should be deeply plowed, thoroughly harrowed
and kept clean of weeds, especially before the
plants are set and until the vines cover the
ground. After growing, the ground is
marked in checks about five feet square and
10 or 12 seeds, or five or six plants, are set in
each "hill," from which all but the two or three
strongest vines are removed after the insects
have had their share. Often, especially upon
rather poor or tenacious soils, two or three
shovelfuls of well rotted manure is mixed with
the earth of the hills to give the plants a little
impetus. The fruits are gathered when they
will readily separate from the stems, preferably
in the early morning.
During the closing decade of the 19th cen-
tury the demand for highly flavored melons was
greatly increased by the appearance in the east-
ern markets of the Rockyford melon, a small
fruit grown in Colorado. Its appearance in
large quantities drew public attention to numer-
ous other high flavored melons grown in other
sections. As a consequence many inferior varie-
ties have nearly disappeared from cultivation.
Besides the Colorado melon fields there are
large areas devoted to melon-growing in New
Mexico and California. New Jersey, Mary-
land and Delaware produce immense quantities,
the first-mentioned State especially; and the
product is consumed largely in the cities of
Pennsylvania and New York. The Mississippi
Valley States also send considerable quantities
to Northern markets.
The watermelon is an annual trailing herb,
a native of tropical and southern Africa,
whence it has been introduced by man into all
tropical, subtropical and many temperate
climates for its watery sweet fruits, which
sometimes are 75 pounds or more. The water-
melons usually range between 20 and 50 pounds.
The vines are more hairy, lighter green, longer run-
ning than those of the muskmelon and the
leaves are deeply notched, in some cases ap-
proaching the compound form. Except for a
horticultural group of firm-fleshed varieties
known as preserving watermelons or more pop-
ularly as citrons, the watermelon seems to have
no varieties worthy the name of sub-species or
botanical varieties, and even this group appears
not to be true to type, though often used for
making preserves.
In general, the watermelon requires the same
treatment as the muskmelon, the soil being, if
anything, lighter and more sandy, and the dis-
tances between hills about double, except for
the smaller growing sorts. The principal pro-
ducing regions are Georgia and Colorado, but
the watermelon is grown largely in all the
southern States, and some of the short-season
varieties as far north as Michigan and Ontario.
The watermelon is more easily shipped than the
muskmelon, since the tough-rinded kinds may
be placed in cars two or more feet deep, the
smaller specimens upon the bottom, and shipped
long distances. Muskemelons, being more deli-
cate, must be barreled or crated. The fruits
are used exclusively in the raw state and have
no by-products such as vinegar, sugar, syrup or
brandy. The rinds, however, when deprived
of the hard exterior, are often preserved with
raisins, etc.
Both muskmelons and watermelons are sub-
ject to the attacks of several insects, among
which the small, black, striped cucumber-beetle
(Anasa reticulata), the squash vine borer
(Mellisia cephalotes), the melon-caterpillar
(Margaronia hyalinata), the cucumber flea-beetle
(Crepidoidea cucumeris), the squash bug
(Ambus Harris), and the melon-louse and leaf
sawfly (Aphistogaster gossypi) are the most important. Tobacco dust
and plant protectors are largely used to prevent
the attacks of the first, the adults of which feed
upon the under sides of the leaves and the
larvae upon the roots. The melon-louse is
fought with kerosene emulsion sprayed upon
the under sides of the leaves or by fumigation
with carbon disulfide. No effective remedy
has been suggested for the borer. Arsenical
sprays have been recommended for the cater-
pillars and other chewing insects. Since the
insects are believed to spread diseases from
plant to plant, melon-growers seek to prevent
insect injury as far as possible and practicable.
The diseases, of which a large number have
been described, are chiefly cucumbers, and may be similarly controlled
where control has been found possible. Some
diseases, as wilt, have defied all tried remedies.
This disease generally ruins the vines a week
or 10 days before the fruits would be ready
to harvest. Many of the complaints as to the

poor quality of eastern-grown muskelons results from the sale of melons that have been gathered from blighted fields.

M. K. KAIS, Crop Expert.

MELOPANO, an invention by which sustained sounds can be produced on a pianoforte. It consists of a series of small hammers set into very rapid vibration by the winding up of a spring. See MUSICAL INSTRUMENTS, MECHANICS.

MELOS, mēˈlos, MILO, or MILOS, Greece, an island in the Ægean Sea, in the southwestern portion of the Cyclades, about 65 miles east of the mainland. Its length, east to west, is about 14 miles and it is about eight miles in extreme breadth; area, 64 square miles. It is mountainous, Mount Ilias rising 2,543 feet, of volcanic formation, has hot mineral springs and mines of sulphur. The island was once famous for its riches, fertility and population, and corn, wine, cotton, oranges and other fruits are still grown. Sulphur, manganese ore, millstone, gypsum, etc., are exported. Plaka is the principal town and nearby are the ruins of Melos, the ancient capital. Kastron is a large village on the north coast. The island of Melos was first colonized by Phoenicians and afterward by Dorians. During the Peloponnesian War it was the faithful ally of Sparta till 416 B.C., when it was taken by the Athenians and its inhabitants massacred or sold as slaves. From 1204 till 1537 it formed part of the Venetian duchy of the archipelago. At the latter date it was taken by the Turks, with whom it remained till the epoch of Greek independence. Its ancient prosperity is claimed to be due largely to the fact that obsidian was found there, which was quarried and sold for making knives, hatchets and tools. In 1520 a peasant discovered here the celebrated statue known as the Venus of Milo now placed in the Louvre at Paris; the Poseidon in the National Museum at Athens was also discovered here. There are numerous interesting archeological remains, chief of which are those of the Hall of the Mysterion on the site of the ancient capital near the village of Klima, and those of prehistoric Phylakopi, which were excavated by the British School at Athens from 1896 to 1899.

MELOPOMENE, mēˈlōpəmˈe-nē, one of the Muses, daughter of Zeus and Mnemosyne. She presided over tragedy and was generally represented as a young woman with vine leaves surrounding her head, and a tragic mask covering her face.

MELROSE, Mass., city in Middlesex County, on the Boston and Maine Railroad, about eight miles north of Boston. It was settled about 1632, and until 1649 it was a part of Charlestown. It remained a part of Malden until the next year (1650), when it became a separate municipality. It was chartered as a city in 1900 and includes the towns of Peabody, Stoneham, and Melrose Highlands. It is a residential suburb of Boston, but has considerable manufacturing. The chief manufactures are rubber boots and shoes. There are 25 factories of all sorts, employing about 12,000 persons, with a total capitalization of $2,000,000 and annual gross products of $2,825,000. The State Reservation, Middlesex Fells, 1,800 acres, and Spot Pond, a natural reservoir, are attractive features. It has municipal waterworks and a lighting system. The government is vested in a mayor, elected annually, and a council. The subordinate officials are chosen by the mayor and council; the school board by election. Pop. 18,000. Consult Drake, 'History of Middlesex County'; Goss, E. H., 'History of Melrose' (1902).

MELROSE, Minn., city in Stearns County, on the Great Northern Railroad, 100 miles northwest of Saint Paul. It contains flour mills, granite works, planing and saw mills. The municipality owns and operates the electric-lighting plant and the water-supply system. Pop. 2,600.

MELROSE, Scotland, a village of Roxburghshire, on the south bank of the Tweed at the base of the Eildon Hills, two miles east of Abbotsford, the home of Sir Walter Scott, whose 'Lay of the Last Minstrel' gave Melrose and its ruined abbey world-wide celebrity. The village had a population of 2,166. The famous abbey, now the property of the Buccleuch family, is admitted to be the most beautiful of all the ecclesiastical ruins in Scotland. The architecture is in the late flamboyant Gothic style, and the chief remains are part of the nave, the transept, choir and the southern aisle with several chapels, of the abbey church and fragments of the cloister. The church originally was 258 feet long, with a width at the transepts of 137 feet. It was founded by King David I in 1136, destroyed by Edward II in 1322 and rebuilt by Bruce in 1326. It is the burial place of the heart of Robert Bruce, the good Lord James Douglas and the Knight of Liddesdale. It was partly demolished by the English in 1545.

MELROSE PARK, Ill., village of Cook County, about 10 miles west of Chicago, on the Chicago and Northwestern Railroad. It contains iron works, can factories and stone quarries, but is best known as a residential suburb of the Windy City. The water-supply system is the property of the municipality. Pop. 4,800.

MELTING POINT, the temperature at which the solid and liquid states of a body can coexist, without the fluid part of the mixture solidifying, nor the solid part melting. The melting point of a body which is crystalline in nature (like ice) is usually quite definite, and a body of this kind, when it melts, passes at once from a state of perfect solidity into a state of perfect fluidity. The melting point of an amorphous body, such as wax or pitch, is often very indefinite; and when a solid of this sort is gradually heated it grows soft and passes into the fluid state by a process which is practically (or even absolutely) continuous. The phenomena of the fusion and solidification of amorphous bodies like wax are not yet understood as well as those that attend the change of state of a crystalline body; in fact, it is said that what follows in the present article is stated with particular reference to the crystalline class of substances, in which the melting point is definite.

In general, solid bodies expand upon melting, the original solid having a greater density than the liquid that results from its fusion. In
the case of water, as is well known, the reverse is true; the fact that ice floats in water proving that the water is denser. The fact that the denser of a substance changes upon fusion implies (as may be proved by the mechanical theory of heat) that the melting point of the substance cannot be entirely independent of the pressure. This fact was discovered in 1849 by James Thomson, who showed that the melting point of a substance like ice, which contracts upon melting, must be lowered by pressure; while the melting point of one which expands upon melting must be raised by pressure. These theoretical conclusions have since been abundantly verified by experiment. In the case of ice, for example, it has been found by Dewar, that the melting point is lowered by 0.010° F. per atmosphere of increase of pressure, up to 700 atmospheres.

When a substance passes from the solid to the liquid state, it absorbs a very considerable amount of heat, which is known as the latent heat of liquefaction; and the liquid which is formed cannot be all reduced to the solid state again until an exactly equal quantity of heat has been added to it. When heat is added to a mixture composed of a solid and its liquid (pounded ice and water, for example), it does not increase the temperature of the mixture, but merely causes a certain amount of the solid to melt. This continues so long as any of the unmelted solid remains; each addition of heat merely bringing about a corresponding amount of liquefaction, while the temperature of the mixture remains unchanged. It is only after all of the solid has melted that the further addition of heat will produce elevation of temperature. The melting points of compounds undoubtedly depend, in some manner, upon their molecular constitutions, but we have, as yet, no definite knowledge of the nature of the dependence. We know that in a homologous series of organic compounds, the melting points show a strong tendency to increase, as the molecular weights of the members of the series increase; but the change in the melting points is irregular as we proceed from member to member, and no law has been discovered which takes the changes fully into account. The melting point of a mixture (such as an alloy) is often lower than that of any one of the constituents, and the effect of the presence of an impurity in a given substance upon the melting point of that substance is often out of all apparent proportion to the quantity of impurity present. This fact implies that in the determination of a melting point it is highly important that the substance under examination shall be as nearly pure as possible. The presence of slight, unrecognized and apparently negligible impurities has sometimes led to entirely erroneous conclusions. In 1860, for example, Kolbe announced the discovery of an azo isomeric with benzoic acid, but having a lower melting point; but Befstein afterward proved that the substance in question was merely ordinary benzoic acid contaminated with a quantity of chlorobenzoic acid so small as to be barely recognizable by analysis.

For determining the melting point of minerals, a instrument devised by Joly and known as the melsometer, is sometimes very convenient. It consists essentially of a strip of platinum foil, upon which small fragments of the minerals are laid. The platinum is then gradually heated by the passage of an electric current, until the mineral melts; the temperature of the foil being obtained by a circulation based upon the resistance of the platinum, the observed strength of the current and the rate at which heat is radiated from the foil, as determined by separate observations. This method is especially useful for minerals which can be melted within a few minutes.

The term fusing point is often used instead of melting point, where a high temperature is required to melt. Following are the melting or fusing points of a few familiar elements in degrees F.: Mercury, 38; ice, 32; potash, 145.5; soda, 204; sulphur, 233; bisnath, 917; tin, 551; lead, 850; aluminium, 1,160; flint, 1,600; silver, 1,750; gold, 1,913; copper, 1,931; nickel, 2,642; iron, 2,912; platinum, 3,225; carbon, fusible. Alloys show vastly different melting points; thus 93 per cent bismuth with 7 per cent zinc melted at 479° F.; 44 per cent lead and 56 per cent bismuth at 233°. See FREEZING POINT.

MELTON nowbray, mûbrè, England, an ancient market town in Leicestershire, 14 miles northeast of Leicester, on the right bank of the Wreak, at the junction of the Eye, 105 miles north by west of London. Nowbray is famous for its pork pies and Stilton cheese. It owes its prosperity chiefly to being the seat of the Melton Hunt, which attracts the sporting world in great numbers during the winter months, extensive and luxurious hunting establishments being maintained there. Pop. (urban district) about 8,000.

MELTZER, Charles Henry, Anglo-American playwright and journalist; b. London, England, July 6, 1853. He was educated in London and Paris, where he became correspondent of the Chicago Tribune and later of the New York Herald, for which paper he traveled over Europe and Egypt. In 1888 he was appointed dramatic and musical critic of the New York Herald, holding that position for four seasons. From 1893 to 1896 he was dramatic reviewer of the New York World, also for seven years New York correspondent of the London Daily Chronicle. His experience was utilized as literary associate in connection with a course of modern plays at Carnegie Lyceum, New York, and in Washington. Boston and Chicago. In 1907 he became musical critic and special writer, in the United States and abroad, of the New York American and the Cosmopolitan Magazine. In 1914 he was appointed dramatic critic, New York American. Among his plays are The Story of Rodin, the Student (original, founded on Dostoievsky, novel); Monon Lescaut (original, founded on the romance of Abbé Prévost); The First Duchess of Marlborough (original, historic comedy); besides English versions of Haupmann's Mme. Sans Gêne (Sandou and Moreau); L'Arlesienne (Daudet); The Sunken Bell (Hauptmann); and a farce, His Honor the Mayor (with A. E. Lancaster). From 1902 to 1907 he was secretary and librarian to the management of the Metropolitan Opera Company. He has made English versions of Das Rheingold; Die Walküre; Kongoñskinder; Les Contes d'Hoffmann; Das Heimchen am Herd; and Orfeo (Monteverde).

MELTZER, Samuel James, American physiologist: b. Russia, March 22, 1851. He
received a general education at Königsberg, Prussia; studied philosophy and medicine at the University of Berlin, and was graduated in 1875-76 and removed to the United States in 1883 since when he has practised his profession in New York. Since 1906 Dr. Meltzer has been head of the department of physiology and pharmacology at the Rockefeller Institute for Medical Research, and is attending physician at Harlem Hospital. In 1917 he was commissioned major in the Medical Reserve Corps. Dr. Meltzer is a member of many medical and surgical societies. He is the author of over 200 papers on biology, physiology, scientific medicine, etc.

**MELUSINA, mel-o-soo’na, or MELUSINE, in French myths, a beautiful nymph or fairy, who is represented as the daughter of Helias, king of Albania, and the fairy Persine; and as having married Raymond, Count of Toulouse, who built the magnificent castle of Lusignan. Like most of the nymphs of that period, she was doomed to a periodical metamorphosis during which the lower part of her body assumed the form of a fish or serpent. On these occasions she exerted all her ingenuity to elude the clutches of her husband. One day she was accidentally seen by her husband in this condition, she swooned away, and soon afterward disappeared. Her form is said to be seen from time to time on the tower of Lusignan, clad in mourning and uttering deep lamentations. Her appearance is believed to indicate an impending calamity to the royal family.**

**MELVILLE, mel’vil, or MELVILL, Andrew, Scottish reformer: b. Baldovie, near Montrose, Forfarshire, 1 Aug. 1543; d. 1622. He was educated at the grammar school of Montrose and the University of Saint Andrews; studied two years (1564-66) at the University of Paris; went to Poitiers to pursue his studies in the law; there became regent in the College of Saint Marcon; and through the influence of Beza received an appointment to the chair of law in the University of Geneva. Returning to Scotland in 1574, he was at once appointed principal of the University of Glasgow, and in 1580 was made principal of Saint Mary's College, Saint Andrews. In 1582 he gave up his college duties and went to Geneva, to avoid the undue interference of the court in ecclesiastical affairs, for which he escaped imprisonment by going into England. Returning in 1585, he resumed his duties at Saint Andrews, and was moderator of the General Assembly in 1587, 1589, 1594. In 1600 he was summoned to London by the king to confer on Church matters, but because of his outspokenness he was committed to the Tower, and there remained until 1611. He was then released upon the solicitation of the Duke of Bouillon, retired to France and became professor in the university at Sedan, which, according to some accounts (others say London), was the place of his death. Consult 'Lives' by McCrie (1819); Morrison (1900).**

**MELVILLE, Sir George, British administrator: b. Aberdeen, Scotland, 1 July 1842. He was educated by private tutors and at Edinburgh Academy. He entered the imperial service in 1862; and was employed in the colonial civil service from 1874-1905. Between 1899 and 1903 he acted successively as administrator of British Honduras, the Falkland, Bahamas and Leeward islands, Saint Lucia and Windward Islands. He was created K.C.M.G. in 1900.**

**MELVILLE, George Wallace, American naval engineer: b. New York, 10 Jan. 1841; d. 17 March 1912. Educated Brooklyn Polytechnic; entered the navy as assistant engineer 1861; served through the war; and in 1879 accompanied the De Long expedition on the Jeanette to discover the northeast passage. Of this party he was one of the few survivors; most of the others owed their lives to his indomitable courage and herculean strength—he carried a brother officer, weighing 175 pounds, upon his back, through ice and snow, at the same time superintending all movements of the crew and on occasion helping with the boat. He also commanded the subsequent search expeditions which recovered the Jeanette's records and De Long's body. In 1887 he was made chief engineer of the navy, a post from which he retired in August 1903, having entirely reformed the service, put navy engineers on a professional rather than an artisan footing, introduced the triple screw on such successful ships as the Colorado, and invented and patented the 'Meltzer' streamer, which saved the department a tremendous sum by his refusal to adopt a boiler which had proved unsatisfactory in the British navy and designed 120 ships of over 700,000 horse power. Melville was made rear-admiral and retired in 1903. His book, 'In the Lena Delta' (1885), describes his experiences in the Jeanette expedition.**

**MELVILLE, Herman, American novelist: b. New York, 1 Aug. 1819; d. there, 28 Sept. 1891. His grandfather was the original of Holmes' Last Leaf. His father, a fur-trading merchant, died when Herman was a boy; and in 1837 his education in the Albany Classical School and in New York City having been completed, he shipped as a cabin boy. Then he taught school for several years, but in 1841 sailed on a New Bedford whaler, from which in 1842 he made his escape with a comrade on one of the Marquesas. His experiences among the warlike natives and his rescue by an Australian whaler are described in 'Typee, a Peep at Polynesian Life' (1846), and his subsequent return to the whalemen and an excellent portrayal of life in the South Seas. In 1847 he married the daughter of Justice Lemuel Shaw of Massachusetts; from 1850 to 1863 lived in Pittsfield; was employed in the New York custom-house from 1866 to 1885; and then retired because of ill-health. Melville's writings apart from a few small volumes of verse are mostly taken up with the life of the sailor; some of his better known titles are 'Omoo, Adventures in the South Seas' (1847); 'White Jacket, or the World in a Man-of-War' (1850), which effected the abolition of flogging in the United States navy; 'Moby Dick, or the White Whale' (1851), and 'Pierre, or the Ambiguities' (1852). These stories were justly popular. Several philosophical romances met with little success. 'Battle Pieces, and Aspects of the War' (1866) is Melville's best verse. His four best romances of the sea were re-edited in 1892. See Moby Dick.**

**MELVILLE ISLAND, (1) an uninhabited island of the Arctic regions crossed by lat. 75° N., long. 110° W., and separated on the**
west by Fitzwilliam Strait from Prince Patrick Island. Its greatest length is 200 miles; greatest breadth 130 miles. It lies north of Melville Sound, and was discovered in 1819 by Parry, who gave the island its name and wintered there. The formation is mainly sandstone with lime and coal beds. It was visited by Bernier in 1808. (2) An island at the entrance to Van Diemen Gulf, off the shore of the Northern Territory of Australia, with an area of about 1,800 square miles. It is hilly and densely wooded, especially with several species of eucalyptus. The earliest British settlement was made in 1824.

**Melville Peninsula**, North America, a northeastern projection of Keewatin in the Northeast Territories of Canada, about 400 miles north of Hudson Bay. Bounded on the north by Fury and Hecla Strait and on the east by Fox Channel. It is about 250 miles long by about 100 miles broad.

**Melville Sound**, North America, a channel about 250 miles long by 200 miles broad, extending southeast of Melville Island, and communicating with the Arctic Ocean on the west by Banks' Strait, and with Baffin Bay on the east by Barrow Strait and Lancaster Sound. Much of its contour was measured by Hansen in 1903.

**Membran**, a subdivision of a formation (q.v.) not usually considered of sufficient importance to map separately, but given a separate description or mention in the text of a report.

**Membrane, in anatomy and physiology**, a thin sheet-like tissue, more or less elastic, varying in structure and vital properties. Membranes absorb or secrete fluids, connect certain parts of the body, separate, envelop or form certain organs or act as partitions between two fluids or gases, permitting them to mingle. Mucous membranes line the canals, cavities and hollow organs which communicate externally by different apertures on the skin; for example, the digestive, respiratory and genito-urinary tracts. These membranes are soft and velvety and have on their free surface cells for absorption or motion and in their substance follicles, which secrete mucous for lubricating and other purposes. Such secretions are saliva, gastric juice and pancreatic juice. Serous membranes, such as the peritoneum, pleura, the unica vaginales and pericardium, facilitate the motion of the organs they envelop (abdominal digestive organs, the lungs and heart) by reason of the serum they secrete, and also maintain the shape of these organs. Allied to the serous membranes are the synovial membranes lining movable joints. By reason of their smoothness and by aid of their lubricating serum the ends of bones move readily upon one another. Fibrous membranes (for example, periosteum, dura mater and perimyseum), not moistened by any particular fluid, augment the solidity of organs they envelop, retain them in position, favor their motion and form canals and rings for the passage of different organs. The membranes which envelop the brain and are extended to cover the spinal cord are called meninges. (See Meninx.) The membranes enclosing the fetus are called the placenta (q.v.). Other special membranes are Descemet's membrane, which is the fourth layer of the cornea of the eye, and Bowman's membrane which is the second.

**Membre, mōn-brā**, *Zenobius*, French missionary in America: b. Bapaume, France, 1645; d. Fort Saint Louis, Tex., 1687. He became a member of the Recollect Order; was sent as a missionary to Canada in 1675, accompanied La Salle in his western expeditions and was with Tonti at Crévecœur, where he helped bring about peace between the Iroquois and the Illinois; in 1682 went down the Mississippi with La Salle, and in the same year returned to France. For a time he was a warder of a convent in his birthplace. But in 1684 he set out again with La Salle for the mouth of the Mississippi. He was left by La Salle at Fort Saint Louis and there massacred by the Indians. He wrote a description of his trip down the Mississippi, which was incorporated into a book by his cousin, Christian le Clerq, into his 'Etablissement de la Foi dans la Nouvelle France' (1691), and which was later unscrupulously copied by Hennepin (q.v.). This narrative he sometimes attributed to La Salle.

**Memel, mā'mēl**, Germany, an important seaport of Prussia, near the Russian frontier, at the north extremity of the Kurisches Haff, at its opening into the Baltic, 70 miles north by east of Königsberg. It was almost wholly destroyed by fire in 1854, and was rebuilt in modern style. It has a large harbor and exports from Lithuania and Russia great quantities of timber, also flax and linseed, coal, manure, grain and herring; has also manufactures of brandy, soap and chemicals, sawmills, iron foundries, breweries and yards. Memel was founded in 1252 by the Livonian order, who gave it to the Teutonic Knights, by whom it was fortified in 1404. It suffered severely in the Lithuanian wars (13th and 15th centuries). Here in 1807 Frederick William III of Prussia took refuge and a treaty with England was signed. It was seized by Russia in 1812 and again in 1914, but each occasion they were obliged to give it up. The town gives its name locally to the Niemen River (q.v.). Pop. 21,470.

**Meling, or Memling, Hans, Flemish painter about 1430; d. Bruges, 1495. He settled at Bruges 1478, of which town he was a prosperous citizen until his death. While all that is handed down of his biography is apocryphal, it is evident, from his works, that he was imitator of Roger Van de Weyden, although he avoided the harshness and ungraceful drawing of that artist's style. He stood alone among the Flemish painters of his day in the religious tenderness of his pictures, their life-like expression, their exquisite coloring and modeling. His chief works are to be found in Saint John's Hospital, Bruges, namely, the altarpiece, 'Marriage of Saint Catherine' (1479); 'Portrait of Marie Moreel as Sybilla Persica' (1480), and the 11 scenes illustrating the legend of Saint Ursula and the 11,000 Virgins of Cologne (1589). In the Academy of Bruges is a triptych of his in the central panel of which are Saints Christopher, Maurus and Ansgarius, and on the wings Burtgsmaster Moreel (who offered the picture) with his family. In the Pinakothek at Munich a companion
ion picture, 'The Seven Joys of Mary,' Consulting, 'Memling, sa Vie et ses Œuvres' (1883); Wauters, 'Sept Études pour Servir à l'Histoire de Hans Memlinc' (1894).

MEMMI, mem'mé, Simone. See Martini, Simone.

MEMMINGER, mem'min-ger, Christoph-Gustavus, American politician, secretary of the Union League in Pennsylvania, born in Württemberg, Germany, 17 Jan. 1803; d. 7 March 1888. He was brought to America in infancy, and was educated at South Carolina College. He studied law; began to practise in Charleston in 1825; entered politics as a leader of the Union party; attacked the States' Rights party in a satire called 'The Book of Nullification' (1832); reformed the public school system of the State, and for 20 years was in the State legislature, much of the time as head of the finance committee. In 1859, after John Brown's raid, he was commissioned by South Carolina to consult with other delegates in Virginia as to the best method of warding off attacks of Abolitionists. From the formation of the Confederacy until June 1864 he was the Secretary of Treasury, and his mistaken policy in that office did much to ruin the Confederacy financially.

MEMNON, in Greek mythology, the son of Eos (Dawn), an Ethiopian prince, nephew of Priam, for whom he fought at Troy. After he had killed Antilochus he was defeated by Achilles. The post-Homeric legend adds that his mother wept bitterly for him, even after he had been made immortal. Memnon's kingdom was localized on the west bank of the Nile, and one of the colossal statues of Amenophis III, as early as the 1st century A.D., became connected with the myth. It was said to portray Memnon, and the musical note emitted when the sun's rays struck the statue in the early morning (probably due to the action of sudden heat on the chilled granite) was wrongly explained as Memnon's greeting to his mother. The statue, rehabilitated by Severus, is still sonorous. The name Memnonium was applied in the Ptolemaic period not only to the west bank of the Nile, but the whole of Egypt, until the time of Augustus. It was a name applied to the banks of the Nile from Memphis to Thebes, which contains the famous 'gallery of kings.' This has a list of 76 Egyptian kings, and dates from the time of Seti I and his son, Rameses II. This Memnonium contains many other important sculptured documents.

MEMOIRS OF CARLO GOLDONI ('Memoires de Carlo Goldoni') This work is celebrated among the many of this class in literature, and yet, in a general way, is comparatively little known. The 'Memoirs' were written in French, when Goldoni was 80 years old, and first appeared in Paris in 1787 (3 vols.). An excellent edition, reproducing them entire and accurately, was published on the second centenary of the author's birth 1907, by the Florentine firm Barbèra, edited with Italian notes by Guido Mazzoni. It was in 1700, a year before Goldoni was called to Paris, that he conceived, as he states in the preface to the 'Memoirs,' the idea of an autobiography. On seeing that the first Florentine edition of his plays had become the subject of universal pillage, no less than 15 editions having been published without his knowledge and very incorrectly, he resolved to publish a second edition at his own expense and insert in each volume a part of his life, imagining that in this way the history of his person and his work might be completed together. Moreover, it occurred to him that possibly a collection of his works might some day be discovered in a corner of some old library and awaken curiosity to know something about the writer who took to reform the Italian theatre and wrote 150 comedies of character and intrigue. But as the years rolled on and the work which was to extend to 30 volumes and become completed in eight years had only reached the seventeenth volume, Goldoni realized that his project would not be completed during his life. So setting to work six years before his death, abridging and translating into French the contents of the historical prefaces of his 17 volumes of the 'Venice edition of the plays which related mostly his early life, and continuing with an account of the reformation of the Italian theatre, due largely to the author's theatrical genius, he completed the first part of the 'Memoirs.' The second part gives an account of the composition and outcome of his many plays, together with the criticism of them and rivalry excited by them. The third and final part of the 'Memoirs' relates the author's personal experiences in France from 1762 to their close in 1787.

The 'Memoirs' of Goldoni have been called his most amusing comedy and pronounced by no less a literary light than Gibbon, 'more truly dramatic than his Italian Comedies.' They have been the subject of admiration of some of the most distinguished literates not only in Italy but in England, France and Germany, is proven by such testimony as that of Byron, Voltaire and Goethe. But to appreciate and enjoy Goldoni's entertaining personal reminiscences, no such extra discrimination is necessary,—far from it, for the average reader can hardly fail to get enjoyment from them, especially if he be at all interested in 18th century life in Italy. As a faithful picture of the life of this period, especially the life of the humbler classes, the 'Memoirs' is unrivalled and his plays are unexcelled. The parts that relate to Venice, Chioggia and to life in the Italian cities where Goldoni had his many and varied youthful experiences have that genuine ring found in his best plays in Italian dialect depicting life among the common people. The portions relating to the author's life in France, although far from lacking in interest, have not the charm that the parts of the 'Memoirs' have which relate to Italy. There is an English translation of the 'Memoirs' by John Black (2 vols., London 1827). The same, abridged and edited, together with a luminous introduction by William Dean Howells (Boston 1877). For everything concerning Goldoni and his works, consult H. C. Chatfield-Taylor's masterly work 'Goldoni, a Biography' (New York 1913).

JAMES GEDDES, Jr.

MEMORIAL ARCH, an arch usually built across an avenue or street, or at an entrance to a park, garden or other public place, to commemorate some person or event. The
MEMORIAL ARCHITECTURE—MEMORY AND ITS DISORDERS

Washington Arch in Washington Square, New York City, is a well-known American example of the memorial arch. It is built of marble and is adorned with elaborately carved figures.

MEMORIAL ARCHITECTURE. See SEPULCHRAL ARCHITECTURE.

MEMORIAL DAY. See Decoration Day.

MEMORY IN ANIMALS is to be studied in the light of comparative psychology, as between the mind of man and the animal mind. To one class of thinkers this difference seems only one of degree; the mind of the animal to them is of the same nature as that of man, but is less developed by reason of limited experience. Lack of stimulus because of comparatively small means of intercommunication of ideas, and general inferiority in complexity of brain structure. To another class of thinkers there is an essential difference—a permanent gulf between the mental processes and powers of brute and human animals. Memory is one of the most important attributes of mind and must vary with varying mental abilities. Thus it is hardly, if at all, perceivable in animals of low organization, but is more and more recognizable as we ascend the scale of animal life and finally reach the human mind. In the top its operation is clearly visible. In studying it as regards animals we are met, however, with that initial and constant difficulty, that while we are able not only to question ourselves and report what we find for comparison with and discussion of the self-examination by other men, we cannot see into an animal's mind and must judge of its processes by their outward signs. Thus we may assure each other that we possess imagination, which is a high function of memory, but how are we to discover whether an animal indulges itself in such a mental exercise? When a horse goes slowly and with hanging head on an outward journey but becomes instantly animated and brisk in his gait when he is turned toward home, is that because he pictures in his mind the comfortable stable and good food awaiting him? If so, is that not an example of imagination? It has been customary to attribute all such acts as nest-building and the like, to instinct, but many cases of both faulty and beneficial work of this kind discourage faith in so simple a solution; and when a bee ingeniously stays a falling comb by a new brace or guy of wax, or a beaver overcomes a change in his pool by altering the direction of his dam or by building another in a new place, must these creatures not exercise imagination in order to plan and carry out the new way of meeting an unexpected difficulty? Each is applying his experience called by memory, in the way he pictures (must picture) to himself the result of what he purposes to do, or he could not carry out his intention. That the animals we know best, horses, dogs, cats and so forth, have a very retentive memory, at least in certain directions, every one knows. The theory of many students of the matter is that this is purely "associative," that something they see or smell or hear recalls a group of facts connected with it; and that it is impossible for them to recall all this group without such a concrete suggestion. Much evidence may be produced throwing doubt on this limitation of their power.

EVENST INGERSOLL.

MEMORY AND ITS DISORDERS

Locke has defined memory as the power to a mind has to revive perceptions which it once had, with the additional perception that it has had them before. Ribot distinguishes the functions of memory: (1) the preservation of certain states, (2) their reproduction and (3) their recognition. In view of the fact that the collection of gray matter in the cerebro-spinal axis below the cortex is capable of storing impressions and of probably controlling in some manner the sensory nervous system are concerned in mind action and in memory, it will be necessary to speak not merely of memory but of memories in the sense of reproductions of like sense quality with the original impressions. Modern psychology accepts the concept of unconscious memory, which would imply that all impressions upon all sense organs are permanently retained in the organism. In this case the question arises as to how the unconditioned instinct, or primary stimulus, whether of touch, taste, hearing or sight, undergoes certain molecular changes. Repetition of similar impulses induces similar reactions and a habitual response in the affected cells results. A line of least resistance is established and these habitual responses the germ of the idea of memory is to be found.

From this point of view the nerve-cells retain something as a result of a previous experience, and the repetition of the stimuli constitutes a memory and in this sense the training of a certain mechanism has bound up in it this mechanical theory of memory. Thus a muscular effect, as in tennis, or skating, or piano-playing, becomes an automatic response, the simplest example of both faculty and benefit of work of this kind. The normal faculties of sight, hearing, and smell in the usual sense, the association of ideas, play an important part in this action, frequently without consciousness. It is the usual rule that many muscular acts which in their acquisition have called for consciousness memories soon become automatic, and the effect no longer rises into consciousness, perhaps because of its diminished intensity. A similar point of view may be held for sound-impressions, for taste, for touch, for sight, in each individual case a different series of nerve-cells and nerve-fibres being the path. Thus memory for a poem may mean a habit-response to a series of sight or sound impressions, or of the muscular memories of the speech mechanism that has learned to repeat the phrases. The actor who automatically says his lines, often not conscious of what he is saying, the pianist who mechanically plays, or the golfer who unconsciously drives true, all show the same class of memory adaptations, involving different nervous chains.

There are thus not only a visual memory, but an auditory memory, or memory for sounds, a gustatory memory for tastes, an olfactory memory for smells, and special memories for the other special classes of sensation. Older psychology
MEMORY AND ITS DISORDERS

was concerned with the question as to the fidelity and longevity of these special memories or types of memory, as related to each other, and with the discovery of laws according to which their reproduction in consciousness is possible. But with the introduction of the unconscious as a dynamic factor, the recalling of a previous experience is explained on a new principle. Memories are thus seen in the form of ideas to be reproduced into consciousness by virtue of forces which are mainly unconscious, and over which consciousness has only an indirect control, and the study of memory as such requires to an importance secondary to the study of the causes why some things tend to be remembered and others tend to be forgotten. This trend or tendency on the one hand to be forgotten or on the other to be remembered is now known to be determined by the unconscious wish, a force which is termed the libido and which is the prime, and very often the only, organized, unrecognized, of all the activities of the ego, both conscious and unconscious.

The mental mechanisms by which the unconscious pervades and indirectly controls all the activities of the mind, and the unconscious thoughts, will be discussed under the title PSYCHOANALYSIS. In connection with memory it is necessary here only to point out that what we remember is only the residua after the work accomplished by the processes of repression, during which most of our former experiences are forgotten. On the fundamental principle that what is unpleasant in experience is from earliest infancy rejected by the individual ego, and regarded as if it did not exist, we may regard the ego as similarly rejecting or repressing the memories of impressions associated with the unpleasant or painful incidents. This explains why some things are forgotten and others are remembered. The unconscious, which functions solely on the principle of accepting or striving for the pleasurable and rejecting or repressing the painful, therefore furnishes the motive force for injecting certain ideas into consciousness, and restraining other ideas from entering. Of course this depends upon the fundamental phenomenon that the dynamic force called the libido is becoming attached to certain ideas which are thrust out of consciousness, may be converted and its force applied to vegetative functions of the body producing in many cases certain forms of disease. See PSIHYANALYSIS.

Memory, however, does not depend on repetition of stimulus alone. There are variations in intensity and duration of stimuli, modifications in plasticity of the nerve-cells themselves, the quality of the impulse, and, we are the native individual character of health of the nerve-tissue itself—all of which factors enter into the everyday variations in memory that are familiar to all. The fixity and enduring quality of the memories of childhood are proverbial, and are due to the great plasticity of the youthful nerve-cells, as well as to the intensity of the early pictures. That one person should have a good visual memory and a poor auditory memory, and vice-versa, must naturally be interpreted as due to variations in individual capacity. Modern pedagogy has slowly recognized these variations, and the greater prominence given to play, and to methods of precision, be they manual, lingual, auditory or visual, and less to distinctly-formal methods of memorizing as a purely visual process from a printed page, may be regarded as evidence of this wider recognition that memory should be a generalized function, and not a pedagogy. A well-trained muscular system may be of far greater use to a man than any of his acquired knowledge. It is impossible to train certain children to do certain things, whereas in other directions training may result in great proficiency.

Disorders of Memory.—The classifications of disorders of memory into those of defect and those of excess is based on the old psychology which laid most of the defects to lesions in the cortex of the brain. The newer view, while admitting the loss of memory evinced by the physical defect in the brain or nerve substance, admits also a purely functional deficiency in various memories which is determined by the unconscious wish and is entirely unrelated to any organic lesion or defect. It is agreed by most psychologists that the native retentiveness in any given individual does not itself alter, although there may be in one individual a finer nerve and brain activity than another, enabling one to perceive and therefore retain finer distinctions. But the ability to recall will, which is the essential quality of a good memory in the ordinary sense, is dependent solely upon the proper alignment of the unconscious wish with the desires of the conscious life, which are determined by the social environment of the individual.

The general term for deficiency or loss of memory is amnesia, although this term fails to express the various distortions of memory, the illusions or slight absences; and there are no technical words to distinguish temporary or permanent, periodic or progressive stages of the amnesic process. Inasmuch as memory is not one thing, but a great assemblage of processes which reflect a vast variety of psychological functions, situated not in the brain alone, but almost anywhere in the nervous system, a "defect in memory," as defined by Jastrow, is an expression of the incapacity of a group (or of certain groups) of central processes to perform their normal functions; or a tendency which they show to function in an abnormal manner. Defects of memory may be general or special. General defects may be due to an incapacity on the part of nervous centers to establish residua. This type is found in those people who never remember what they see, and, notwithstanding frequent repetition of an act, never acquire procidity in it. Occasionally a reverse general condition is manifest wherein the power of memorative activity is increased. Special defective may arise in which particular isolated experiences are cut out of the mind. Thus alcoholic amnesia, that may forget even a committed crime, is an illustration. Somnambulism and other hysterical states are characterized by defects of this special type. Another form of defect is observed in individuals whose groups are blown out, as in the special disorder aphasia. (See APHASIA; SPEECH, DEFECTS OF.) Memory may be falsely localized in time, or in order; imaginary additions to
real events may be present; or illusory remembrances of what has never been experienced occur. Disorders of memory are never primary conditions but depend upon either the physical nerve or brain defect for which there must always be a corresponding deficiency in memory or amnesia. Psychological conditions referred to above, where the specific memories are inhibited by associations with unpleasant or painful situations. Through the technique of psychoanalysis a great amount of forgotten material can be restored to memory by means of living over again the situations in which occurred the events responsible for the apparent obliteration of the memory.

Psychologically considered, memory defects may occur either in the storing or retentive part of the nerve-cells, or they may involve the much more complicated and associated process of reproduction of the retained images. Both processes may be involved at the same time. In imbecility, idiocy, dementia, etc., a born or acquired defective real power is present, and pianists — for example, Paderewski or chess-players — Morphy, Pillsbury, etc., a state of localized hyperamnesia is present. This group would include all such prodigies. Occasionally one sees these two groups represented in one individual, as in an imbecile who has great power for mathematical calculation, etc. A case of this kind proves that the old assumption of closely localized memory-centres is false. Memory may be said to reside in all parts of the sensory nervous system. In another group the ordinary amnesias may be placed. These vary with each individual and depend largely on the healthy tone of the nervous system. A third group would include the paramnesias, or illusions of memory. In this condition (1) there is a loss of distinction between memory of things which really did happen and an imagination of things which never did or could. The so-called "constitutional liar" is an example of this inability to distinguish between real and imaginary, and many types of insane persons are similarly affected in an extreme degree. The reverse of taking an imagination for a real thing is (2) taking a real thing experienced for the first time as an imaginary one, and experienced only as a thought of having seen, heard or felt "just that same thing before," also called "deja vu." Such a feeling has nothing to do with native retentiveness, but only with the "feeling of familiarity," which is essentially the presence of an organic sensation which is absent in the simple paramnesia. In some insanities this form of double memory is very prominent and leads to the belief on the part of the person so affected that he is prophesying when he is only recalling what he experienced before. (3) There is also an associated paramnesia in which things actually experienced suggest ideas falsely taken as memories of other things never experienced. This condition is seen in children and often leads to false testimony. It is also responsible for many "presentiments" or alleged antecedent knowledge of what has happened. Examples of such memories of the actually non-existent are seen in the stories of faith cures, where all the healing is that of ills that never really existed, saved as associated false memories. On these false memories erected much of the complicated structure of spiritualism, second sight and other similar phenomena. See IMPO: PERSONALITY AND ITS DISORDERS; SPEECH, DEFECTS OF; AND RETENTIVENESS.

SMITH ELY JELLINEK, M.D.

MEMPHIS, mëm'fis, Egypt, an ancient city near the apex of the Nile Delta, 121½ miles south of Cairo, according to Herodotus, founded by Menes, the first king of Egypt. It was a large, rich and splendid city, and the second capital of Egypt. After the fall of Thebes it became the sole capital. Among its buildings were temples of Ptah, Osiris, Serapis, etc., and its palaces were described as remarkable. At the time of the conquest of Egypt by Cambyses (524 B.C.) it was the chief commercial centre of the country and was connected by canals with the Lakes of Merosis and Mareotis. With the rise of Alexandria the importance of Memphis declined, and it was finally destroyed by the Arabs in the 7th century. In Strabo's time (20 A.D.) it was, in population and size, next to Alexandria; in biblical history it is mentioned as Moph and Noph. The name Memphis is a corruption of Men-nofer, "good above." Edrisi, in the 12th century, describes it as extant in his time. Among the works specified by him are a monolithic temple of granite 13½ feet high, 12 long and 12 feet broad, entirely covered within and without with inscriptions, and statues of great beauty and dimensions, one of which was 45 feet high, of a single block of red granite. These ruins then extended about nine miles in every direction, but the destruction has since been so great, chiefly for the construction of Fostat, an Arabic city on the opposite bank of the Nile, that although Pococke and Bruce fixed upon the village of Mitrahineh as the site (where prone on a mound are two colossal statues of Memnon) this was not accurate. It was ascertained until the French expedition to Egypt, when the discoveries of numerous heaps of rubbish, of blocks of granite covered with hieroglyphics and sculpture, and of colossal fragments scattered over a space of three leagues in circumference, decided the matter. The views of the great temple of Ptah, the palace of Apis, the sepulchre of the Apis bulls, portions of the White Wall and of pyramids have been identified. Consult Petrie and Walker ('Memphis,' Egyptian Research Account, London 1908).

MEMPHIS, Mo., city, county-seat of Scotland County, on the Keokuk and Western Railroad, about 160 miles north by west of Saint Louis. It is in an agricultural region, and is the trade centre for a large part of Scotland and adjacent counties. The principal outgoing shipments are farm products and stock. There are bituminous coal fields in the vicinity. Pop. 2,400.

MEMPHIS, Tenn., city, county-seat of Shelby County, on the Mississippi River, at the
MEMPHIS, TENN.

1 Court Square, showing Exchange Building
2 Down on the Levee
3 Memphis Terminal Corporation Plant, covering an area of 170 acres of ground, and handling annually 1,000,000 bales of cotton
head of all-year-round navigation, is the largest city in Tennessee, the fifth in size of the cities on the Mississippi River and the most important commercial centre and distributing point between New Orleans and Saint Louis.

Communications—Steamer transportation on the Mississippi River and its tributaries reaches all the river and gulf ports, connecting with New Orleans, 394 miles; Mobile, 383 miles; Galveston, 661 miles; Savannah, 665 miles; Charleston, 726 miles; Norfolk, 961 miles; New York, 1,153 miles. Ten trunk lines operating 17 railroads, with two bridges over the Mississippi River, include the Illinois Central; Frisco Railroad; Louisville and Nashville; Nashville, Chattanooga and Saint Louis; Yazoo and Mississippi Valley Railroad; Southern Railway; Missouri Pacific Railway; Saint Louis and Southwestern Railway; Mobile and Ohio Railway; and the Rock Island Railroad. The principal inland cities reached by direct lines are Birmingham, 251 miles; Saint Louis, 309; successfully as before but most all of the rest, 394 miles; Atlanta, 417 miles; Kansas City, 484 miles; Cincinnati, 497 miles; Chicago, 534 miles; Washington, 931 miles. The Cumberland Telephone and Telegraph Company (Bell System) has 18,547 telephones in Memphis served by three exchanges. There are a total of 133 long distance circuits connected with the Memphis exchange, and subscribers are connected with the lines of the Bell System, which covers the entire United States and Canada.

Topographical Conditions—Memphis is located in the most rapidly developing agricultural section of the country. It is the trade centre from the famous Mississippi Delta, and Saint Francis Basin, the combined area of which is in excess of some of the Eastern States. It is the home of the first successful Farm Development Bureau, which is doing great work in bringing about diversification of crops. The Memphis territory is no longer a one crop country. It now not only grows cotton but tobacco, soybeans, cottonseed, and other crops that are grown anywhere in the temperate zone. Suburban truck routes are operated whereby merchandise of various kinds and produce are handled between Memphis and suburban towns and farms in the Memphis district. The tendency is toward a solution of the long-felt national problem of handling freight on short hauls. The food conservation problem is far better taken care of in this territory, farmers not only feeding themselves but being enabled to make convenient and prompt deliveries of their farm products to the city; this being especially true in connection with dairy products, fruits and vegetables.

Industries, Commerce, Banking.—Memphis is the largest inland cotton market handling actual cotton in the world. The receipts run between 700,000 and over a million bales per year, according to the size of the crop. These receipts will be very materially increased when the opening of the 10,000,000 acres of land in Mississippi is finished. The cotton gin is finished and will be in operation next season. This basin has been protected by strong levees and is being rapidly developed. As a market for short fibre cotton, such as linters and cotton hull fibre, there is no market that can compare with Memphis. There are more fibre mills in Memphis than in any other city and the trade in linters is far above the trade of any other market. Over one-half of the total crop of the country is sold through Memphis concerns. This city is the greatest centre for the manufacturing of cotton seed products in the country, including crude and refined cotton-seed oil, meal, hulls and fibre. Memphis also is the largest hardwood producing lumber market. There are in this city 28 hardwood saw mills, with an annual capacity of 370,000,000 feet; 15 lumber yards and 32 woodworking plants. Just outside of the city there are 46 hardwood mills operated by Memphis firms, the capacity of which is 500,000,000 feet. In addition there are many other hardwood mills in the timber districts surrounding Memphis, producing an amount of hardwood lumber equal to the amount manufactured by Memphis firms. Therefore, Memphis may properly be considered as the centre of a production of approximately 2,000,000,000 feet of hardwood annually. A forest products mill has been established in the city, which utilizes slabs, culls and unmerchantable timber into the manufacture of large quantities of wood alcohol and similar products. Charcoal is also produced in large quantities by this mill. The manufacture of sweet feeds is becoming an important industry in Memphis. Cotton-seed products, alfalfa and molasses are produced abundantly in this territory. This industry is being rapidly advanced by the present system of diversified farming. Foreign exports aggregate approximately $100,000,000 yearly, including three-quarter million bales of cotton and 5,000 cars of lumber.

There are 800 manufacturing industries of all kinds in Memphis and its suburbs. These include cotton-seed oil mills, ice factories, grain elevators, wholesale grocery houses, wholesale dry goods houses, wholesale drug houses, furniture factories, woodworking establishments of all kinds, foundries, machine shops, flour mills, pulp and paper mills, fibre plants, saddlery and harness factories, potteries, car works, pump works, wagon and carriage shops, pure food products, bread, cracker and candy factories, patent medicine works, printing machinery works, barrel and skewer factories, spoke factories, golf stick works, shuttle block works, trunk, screen door and window factories, basket and box factories, egg case works, horse collar factories, eyebrow factories, electric supplies, refrigerator and cold storage machinery works, cotton gins, stove and range factories, handle and coffin factories, shaft and pole works, cider presses, distilleries and breweries. Memphis has the largest automobile wheel factory in the world. Memphis also is one of the great horse and mule markets of the world.

There are 18 commercial and savings banks in Memphis; also two industrial loan banks and two private banks. The deposits in the 18 commercial banks at the time of the last report amounted to $75,000,000. The total amount of transactions for the year 1918 amounted to $3,441,112,365. The two largest banks carry deposits of $23,500,000 and $17,000,000 respectively.

Civic Conditions.—The city is well laid out and well built. The wide, well-shaded and well-paved streets, the fine public and private buildings, the parks with numerous large trees, all make the city one of the most attractive. The streets are paved with asphalt, vitrified brick, macadam
and gravel. There are 1,056 miles of paved roads in Shelby County. The steel cantilever bridge 1,895 feet in length across the Mississippi, costing $3,000,000, opened 12 May 1892, has been supplemented by another bridge costing $5,000,000, which combines an interurban trolley service, double railroad tracks, pedestrians' walks and a free wagon way. Memphis has 160 churches. Its superior educational advantages include three departments of the University of Tennessee, the State Normal School, Christian Brothers College, business colleges, 7 high schools, 40 public schools, vocational schools, art galleries, libraries and museums, free endowed circulating library (Cossitt) with 15 branches; endowed (Goodwyn) Institute, with auditorium and reference library. Its free lyceum lecture course attracts the world's leading artists, thinkers, men and women of letters. Outside of the public schools, there are 19 parochial and miscellaneous schools and a number of private schools for boys and girls; coeducational, such as the University School, The Memphis Country Day School and others.

The largest hospitals are the Baptist Memorial, the new Methodist hospital (built in 1919), Saint Joseph's, Presbyterian, Lucy Brinkley, the United States Marine Hospital and numerous small hospitals, sanitoria and homes. The Y.M.C.A. occupies its own building, which is the largest in the central South. This building is equipped with a splendid library, gymnasium, swimming pool, club-rooms, dining-rooms and all other features going with the highest class of Y.M.C.A. work. The largest church is the Orpheus (capacity 2,250), Lyric (capacity 1,780), Lyceum (capacity 1,400). There are numerous other show houses and film theatres in the heart of the city and in the suburbs of various capacities from 200 to 900. The leading clubs are the Tennessee, the Chickasaw, the Rex, the old Business Men's Club, which is now the Memphis Chamber of Commerce — The Memphis Chamber of Commerce continues the club features. The country clubs are The Memphis Country Club, with a membership of 450, and the Colonial Country Club, with a membership of 300. The B. P. O. Elks occupy a very fine home here, centrally located. The Khaki Club for the exclusive use of soldiers is located in spacious rooms on Second street in the heart of the city, and there are numerous smaller clubs. The leading hotels in Memphis are Gayoso, 300 rooms; Peabody, 310 rooms and Chisca, 400 rooms. There are about 50 hotels in all, mostly located in the down town district — a few in the vicinity of the depots.

Parks, Public Buildings, Etc.—Memphis has 1,200 acres in improved parks, and has highly improved fair grounds containing 111 acres. Belting the city on three sides is a magnificent parkway system — the most extensive in the South. The largest park is Riverside Park on the east bank of the Mississippi River, just below the confluence. A mile containing 320 acres are highly improved and a splendid specimen of landscape gardener's skill. Next to the largest is Overton Park, the finest park in the South, in the northeastern portion of the city, containing 333 acres. Within its boundaries is located the Memphis Zoological Gardens which is complete as that of Chicago, and the largest free zoological garden in the United States. Both Overton and Riverside parks have the municipal golf links. There are several other parks scattered throughout the city. Memphis has more space in proportion to its total area in parks and playgrounds than any other city in the South. Adding to recreation afforded by the parks may be mentioned the Alaskan Rose Garden with a capacity of 1,500 and pleasure-exursion boats up and down the Mississippi River. Notable among the city's fine buildings are the union station and the all-service hotel, the police station, the exchange building, custom-house and post office, Goodwyn Institute, Masonic temple and Scotch cathedral.

Modern sanitary methods obtain in Memphis, the sewer system being the Waring, the same as in New York. The water supply of the city is obtained from 64 artesian wells, to a depth of which reaches 600 feet. The present pumping capacity of the water supply is 3,000,000 gallons per day, and the daily consumption is 1,000,000 gallons. From the United States with a population of 100 per 1,000 or over, Memphis ranks second in general healthfulness. The death rate is 13.07.

History.—The history of Memphis is almost with the history of the United States. It was a landing and tenting place for the explorers and missionaries. It was the home of the Chickasaw Indians, and the bluffs on which the city is located, 40 feet above the water and 80 feet above low water, have always been known as the Chickasaw Bluffs. In 1868 the French built forts on the site of the city, now the city, and in 1794 the Spanish erected forts at a time when Spain was gaining exclusive rights to lower Mississippi. Of the foremost men in the United States, owned lands in this vicinity and were interested in holding for their own country a right of free navigation on the Mississippi to the Gulf. Andrew Jackson, James Winchester and Overton sent to Memphis in 1819 a colony who established the first permanent settlement. In 1826 there were 500 persons in the city. The city with a number was 150,000 in 1880. The city was a town, and in 1849 a city charter was granted. The Union and Confederate forces tried to gain possession of the city at the beginning of the Civil War. On 6 June 1862 the Federal fleet under Commodore Dauconquered a Confederate fleet under Commodore Montgomery, thus placing Memphis in possession of the Union forces. General Forrest in command of Confederate forces entered the city in August 1864 and took several hundred prisoners. Memphis has also progressed commercially except during the Civil War, and when visited formerly by yellow fever epidemics. The great growth industrially has come within the last three decades. The location has made the city a great railroad centre; the surrounding forests made it a great lumbering centre; lumber, coal, oil, Saint Francis Basin, Yazoo Delta and the valley of the Mississippi River will always make it a great commercial centre. In 1855 yellow fever attacked the city, and again in 1867, 1878 and 1879. The epidemic in 1878 and 1879 so paralyzed the industries of the city that in 1879 Memphis was unable to liquidate the out
rent indebtedness and the charter as a city was revoked. The former city was designated by the State legislature as "the taxing district of Shelby County." The control of the district was vested in a board of public works composed of five members, and a governing council composed of three commissioners. The council instituted the sewerage system, which practically eliminated the recurrence of yellow fever, improved civic conditions, liquidated the debts and in 1891 the place was reincorporated and again chartered as a city.

Population.—After the Federal census of 1890 the city limits were extended; but the population as given in 1890 included both urban and suburban districts, and the increase from 1890 to 1900 was remarkable. The growth of the city may be seen from the Federal census reports. Pop. (1850) 8,841; (1860) 22,623; (1870) 40,226; (1880) 33,592; (1890) 64,495; (1900) 102,320; (1910) 131,105; (1918) 175,000. Within a radius of 50 miles of Memphis there is a population of 1,300,000, according to Dunt's 1917 report. The foreign born population does not amount to over 1 per cent throughout the whole territory and a careful estimate of the white race is 54 per cent and of blacks 45 per cent. Consult Davis, 'History of the City of Memphis' (1873); Keating and Vedder, 'History of the City of Memphis' (1888).

GEORGE W. FOOSHER,
Memphis Chamber of Commerce.

MEMPHIS (Tenn.), Capture of. At dusk 5 June 1862 the Union flotilla under command of Com. C. H. Davis appeared near Memphis and anchored two miles above the city. The Confederate flotilla, Capt. J. E. Montgomery, commanding, was lying at the Memphis levee. At daylight the Union fleet began to drop down toward the city, and the Confederates advanced to meet it. There were no troops protecting the city. The flotillas were composed of the following vessels:

<table>

Besides having more than twice the number of guns, the Union ordnance was much superior to that of the Confederates. The latter, however, made a desperate fight, which finally ended 10 miles below the city, with the result that the Little Rebel, Beauvoir, and Thompson were destroyed; and the Little Rebel, Price, Sumter and Bragg captured. The Van Dorn escaped. On the Union side only the Queen of the West was disabled.

Immediately after the fight the mayor, in reply to a summons to surrender, informed Commodore Davis that there were no troops with which to oppose him. The next morning detachments from troops under Col. C. N. Fitch, who accompanied the fleet, landed and took possession of the city.

General Grant arrived at Memphis 23 June and established the headquarters of the District of West Tennessee. He was recalled to Corinth 15 July and General Sherman was ordered to Memphis, reaching the city 21 July. He restored the mayor and the city government, and made them responsible for civil order. He continued in command at Memphis until his forces left to join General Grant in the final campaign for Vicksburg, having previously participated in the first move against that city.

The raid of Gen. N. B. Forrest, of Confederate cavalry fame, into Memphis occurred 21 Aug. 1864. The Union forces and commanding officers were completely surprised and barely escaped capture. Gen. C. C. Washburn, in command of the District of West Tennessee; Gen. R. P. Buckland of the District of Memphis, and Gen. S. A. Hurlbut were asleep in the city. General Forrest left the vicinity of Oxford 18 August, with three brigades, making a forced march of nearly 100 miles. A strong detachment rode into the city at 4 o'clock in the morning, running over a regiment of 100-days men on picket, and capturing about 400 of them. This force divided into three and at once surrounded the quarters of the three officers named. Each, however, escaped. General Buckland succeeded in reaching his troops and promptly directing offensive operations. With the exception of considerable skirmishes in its vicinity, Memphis thereafter remained in undisturbed Union control.

MEMPHREMAQOGO, mem-fré-má-gog, a lake in the southern part of the province of Quebec, Canada, extending into Orleans County, in Vermont. It is about 30 miles long, north and south, and from three-quarters of a mile to three miles wide. It is irregular in shape, and along its shores are several striking indentations, in some places low and in some other parts high and rocky. The land on the west shore is mountainous, the altitude of the highest points being about 2,800 feet. The outlet is the Magog River, which flows into the Saint Francis River. Along the shore are a number of villages, and in summer a steamer plies daily on the lake, connecting the chief towns and villages.

MENA, Juan de, Spanish poet: b. Cordova, Spain, about 1411; d. 1456. He was educated at Salamanca and at Rome and afterward was appointed secretary and court historian to John II, king of Castile. His allegorical poems, 'Coplas de los Siete Pecados Mortales,' 'El Coronacion,' and 'El Laberinto' (The Labyrinth), a poem founded on the 'Divina Commedia' and published in the year 1496, all show the influence of Dante, for whom he held great respect and admiration. They were very popular, but possessed little literary merit. His collected works were published in 1528, entitled 'Copilacion de todas las obras de Juan de Menas.'

MENA, Ark., city and county-seat of Polk County, 85 miles south of Fort Smith, on the Kansas City Southern Railroad. It is the seat of Saint Joseph's Academy, contains a public library, a splendid park and is also of good repute as a summer resort. The lumber industry is the city's largest interest, although there is a good trade in cotton and fruit. The water-
works are the property of the municipality. Pop. 3,953.

MENABREA, Luigi Federigo, Count, Italian soldier and statesman: b. Chambréy, in Savoy, 4 Sept. 1809; d. there, 25 May 1896. After completing a course in mathematics at the University of Turin and joining the engineers in the Sardinian army, he accepted the professorship of technical science at the military academy and at the University of Turin. Having been promoted to the rank of captain, he was used in the diplomatic corps for some time; was then elected deputy, serving both under the Minister of War and the Minister of the Interior; and upon the outbreak of the war of Sardinia and France against Austria in 1859 he was appointed chief of the engineer corps. After Savoy was ceded to France, Menabrea was made a senator by Victor Emmanuel, and chief of the department of engineers, and as such planned the fortifications of Bologna, Piacenza and Pavia; in 1860 he was created a lieutenant-general, in that year laying siege to and after three months of fighting taking Genoa. In 1861 he joined the Cabinet of Garibaldi as Minister of Marine, in 1862 also taking over the portfolio of Minister of Public Works. In 1866 he was Italian ambassador to the council which brought about the Treaty of Prague and ceded Venice to Italy. In 1867, when Garibaldi resigned, he formed a new ministry, himself becoming Minister of Foreign Affairs. As Premier he did much to place Italy in cordial relations with the outside world, and to settle internal dissensions, but his imprisonment of Garibaldi and the prevalent financial straits of the nation lost to him the confidence of the House of Deputies, and on 16 Nov. 1869 he resigned. In 1870 he became Italian Ambassador at Vienna, was appointed to the same post at London in 1876 and in 1882 went to Paris, where he was stationed for 10 years. The most important of his works are 'Études sur la série de Lagrange' (Turin 1844-47); 'Le génoise italien dans la campagne d'Ancone et de la Basse-Italie' (Paris 1866) and 'République et Monarchie dans l'état actuel de la France' (1871).

MENAGE, Gilles, French philologist and satirist: b. Angers, 15 Aug. 1613; d. Paris, 23 July 1692. After completing his early studies he became an advocate, practising for some time at Paris, but, having conceived a profound disgust for that profession and all its adherents, he became an ecclesiastic, and for some time was a member of the household of the Cardinal de Retz, but subsequently took up his residence in the cloister of Notre Dame. A witty satirist, entitled 'Requête des Dictionnaires,' published shortly after this time and aimed at the 'Dictionary' of the French Academy, prevented his becoming a member of that society. His most important works are 'Dictionnaire étymologique ou Origines de la Langue' (1658-94); 'Origines de la Langue Italienne' (1669); 'Miscellanea'; 'Remarques sur la Langue Française'; 'Histoire Mullerum Philosphorum'; 'Poésies Latines, Italiennes, Grecques, et Francaises,' and 'Anti-Baillet.'

MENAGERIE, a collection of wild animals, exhibited in zoological gardens, in museums and by circus companies traveling from city to city. The term is now confined almost wholly to a collection exhibited in connection with a traveling circus, a permanent collection being styled a zoological park or "zoo." The menagerie of the typical circus is usually shown in a separate tent, so arranged that the public can make the round of the cages before taking their seats. The principal exhibits are usually elephants, a giraffe (when one is to be had), hippopotamus, rhinoceros, tapir, lions, tigers, bears, leopards (and others of the cat family), lynx, kangaroo, varieties of deer, monkeys, a few cages of snakes, and minor animals. See CIRCUS; ZOOLOGICAL GARDENS.

MENAI (mén'i) STRAIT, the channel between Wales and the island of Anglesey, is 12 miles long, and varies in width from 250 yards to two miles. A suspension bridge and the celebrated Britannia Tubular Bridge connect Anglesey with the mainland. The tides and current are very strong at times, so that large vessels avoid the strait. See Bridge.

MENAM, mā-nām', or MEBINAM, the chief river of Siam, rising in the Laos country, and flowing generally south into the Gulf of Siam below Bangkok. The headwaters are named the Nam Nan. Its length is about 1,000 miles, and for a considerable portion of its course it is navigable for small craft. It is subject to periodical overflows on which the crops of the rice fields along its banks are dependent.

MENANDER, the name of two Greek writers, (1) the comic dramatist: b. Athens 342 B.C.; d. there, 290 B.C. He was the pupil of Theophratus, himself the pupil and successor of Aristotle as head of the Peripatetics, and author of 'Characteres,' a somewhat more literary and popular enlargement of some ruling ideas of the Nicomaehian Ethics; he was by such a teacher well trained for his dramatic vocations. He was, moreover, a friend of Epicurus free early life, and may thus have been imbued with that bonhomie which renders him so great an interpreter of manners. He wrote a hundred comedies which are distinguished from those of Aristophanes by their refinement, the freedom from personal and political virulence and their graceful, sometimes beautiful, delineation of feminine character. He was, however, overrivalled in popular favor by his contemporary Philemon, whose ribaldry was irresistible to the Athenian playgoers. Only some fragments of his works survive in the original, the most important of these relics having come to light in Egypt (1898). He was, however, closely imitated by Plautus and Terence, and in the 'Bacchides,' 'Stichus' and 'Poenulus' of the former, and the 'Andria,' 'Eunuchus,' 'Hecatontimoromenos,' and 'Adelphi' of the latter we have very good representatives of the Greek dramatist's method and spirit. A fine antique statue of Menander is to be seen in the Vatican (2) A Greek rhetorician who flourished in the latter half of the 3d century B.C. He has left the rhetorical treatise 'De Encomiasticis,' and his analyses of the orations of Demosthenes, most of the scholia on that orator have been compiled. Consult (on Menander the dramatist), Guiot, 'Ménandre' (1855); Horst, 'Lebenswahrheit des Komikers Menander' (1857); (on Menander the rhetorician), Rissei,
his petition, and in 1655 the legal restrictions were removed. Among his most notable works is 'Vindiciae J udaeorum,' which was translated into German by Mendelssohn, 1782. Consult Kayserling, 'Menasse Ben Israel' (1861).

MEIMCUIS, mën-shī-uś, the Latinized name of Meng-te, that is, Meng the Teacher, a Chinese philosopher and recluse; b. province of Shan-Tung, about 372 B.C.; d. about 289 B.C. He was educated by his mother with such success that the approbation contained in the phrase 'the mother of Meng' has become proverbial. Mencius was one of the greatest of the early Confucians. During his time the governments of China were oppressive, and Mencius for many years wandered about in search of a prince who would consent to govern in accordance with true and just principles. Failing to find any such, he retired to his former seclusion, and spent the rest of his life in perfecting his system and training disciples. His works contain some enlightened views on man and society. He believed in the moral nature of man and had unbounded faith in the possibilities of progress under a good social and political system. He regarded life as granted by God, but at the same time he believed in the responsibility of rulers to their people and the people's right to depose or even put to death unworthy rulers. In a nation the people are the most important element, second comes the government and third the monarch. The aim of a government, according to him, should be the happiness and education of the people, and any ruler who was content to leave his subjects in ignorance and misery deserved to be deposed. The teachings of Mencius were written out by his disciples in dialogue form, under the title 'The Book of Mencius,' which has been translated into Latin by Julien (1824) and into English by Collin (1828). Consult Legge, 'Life and Works of Mencius' (1875); Faber, 'Lehrbergriff des Philosophen Mencius' (1877); Watters, 'A Guide to the Tablets in a Temple of Confucius' (1879).

MENDAITEs. See NAZARENES.

MENDEANS. See NAZARENES.

MENDEL, Johann Gregory, abbot of Brunn, now known as the discoverer of the law named after him (see HEREDITY): b. Heinzendorf bei Adrau, Austrian Silesia, 22 July 1822, of peasant parents; d. 6 Jan. 1884. In 1843 he entered the Königskloster, an Augustinian foundation in Allbrunn, as a novice; and was ordained priest in 1847. From 1851–53 he studied natural science at Vienna; and, on his return to the cloister, taught in the Realschule. About 1869 he became abbot of Brunn; and later took part in the Ultramontane movement. It was in 1854 that he began his researches on Pisum, in the cloister gardens, that, after the lapse of half a century, have brought him posthumous fame. In 1865 he contributed his now memorable paper, 'Versuche über Pflanzenhybriden,' to the Society of Naturalists of Brunn; and, in 1869, mastered, on Hieracium hybrids. After 1869 he seems to have discontinued his work in hybridizing, and died unrecognized by science. This seems inexplicable, as his researches were of a nature to commend them to his studious contemporaries, among them Darwin, who entirely missed his
contribution, even though the Brünn society exchanged with the Royal Society of London. But Mendel had the satisfaction of realizing that he had established a law in heredity as to the hybridization — the grand fact for which we now prize his unobtrusive labors. His theories have given us the word Mendelism. He called himself a student of Kollár; and for some time he was president of the Brünn society. Since the publication of his experiments, simultaneously, in 1900, by De Vries, in Holland, in Correns, in Germany, and Tschermak, in Austria, and of the translation of his paper appearing in the 'Journal of the Royal Horticultural Society of England' (1901), the literature has been full of 'Mendel's Law.' Consult Bateson, W., 'Mendel's Principles of Heredity' (Cambridge 1902).

MENDELEEFF, Dimitri Ivanovitch, Russian chemist: b. Tobolsk, Siberia, 7 Feb. 1834; d. Saint Petersburg, 2 Feb. 1907. He studied at the Institute of Saint Petersburg, where he gave special attention to natural science; in 1856 became docent at the University of Saint Petersburg; was at Heidelberg in 1859-61, where he published his monograph 'On the Capillaryity of Gases,' soon followed by 'Organic Chemistry.' In 1863 he became professor of chemistry at the Saint Petersburg Institute of Technology, and in 1866 was appointed to a similar professorship in the University of Saint Petersburg. The results of his researches on the compression of gases, which he closely pursued from 1871 to 1875, were set forth in his work 'On the Elasticity of Gases.' He was commissioned in 1876 to report upon the petroleum industry in the Caucasus regions and in Pennsylvania. His 'Aqueous Solutions' (1886), a work on experimental chemistry, has taken its place among the most important contributions to that branch of science. In 1890 his 'Tariff Elucidated' presented the protectionist views of which he had already become a well-known advocate. As a member of the Board of Commerce and Industries, he actively propagated. When the Chamber of Weights and Measures was established by the Department of Finance, in 1893, he was appointed conservator of the weights and measures. His proof of the periodic law (q.v.), first presented in 'Elements of Chemistry' (1868-70), is his crowning achievement in pure science. Consult Thorpe, 'Essays in Historical Chemistry' (1894).

MENDELEEFF, the law of heredity discovered by Johann Gregor Mendel (q.v.) and first published in 1865 under the title 'Versuche über Pflanzenhybriden' in the Proceedings of the Society of Natural History of Brünn, Austria. Mendel made prolonged experiments in crossing varieties of the pea (Pisum sativum). His paper was overlooked until attention to his remarkable results was called by De Vries in 1900; he and also Correns and Tschermak at the same time independently rediscovered Mendel's law. Mendel selected seven pairs of characters, such as the shape of the ripe seed, of the variety of color of the seed-skin, length of stem, etc. Large numbers of crosses were made between peas differing in respect of one of each of these pairs of characters. It was found, says Bateson, that in each case the offspring of the cross exhibited the character of one of the parents in almost undiminished intensity, and intermediates which the hybrid did not exhibit. It proved impossible to get characters from either of the parental forms were not found. "In the case of each pair of characters there is thus one which in the first cross prevails to the exclusion of the other." This prevailing character Mendel called the dominant character, and to the other he gave the name of recessive character.

This law of dominance has been found by Bateson and by Castle to apply to animals as well as plants, and thus is a most important biological law. Thus when mating occurs between two organisms, whether vegetable or animal, differing in some character, the offspring frequently all exhibit the character of one parent only, in which case that character is said to be dominant. For example, on crossing the white mouse with gray mice, Castle found that the offspring were all gray, that color-character being dominant. The character which is not seen in the immediate offspring is called recessive, for though unseen it is still present in the young, white in the experiment being the recessive color.

The law of dominance has its exceptions: the hybrid often possesses a character of its own, instead of the pure character of one parent, as is true in cases of complete dominance. The hybrid form often resembles a supposed ancestral condition, when it is usually regarded as a reversion. Examples are the gray hybrid mice, which are indistinguishable in appearance from the house mouse; also slate-colored pigeons resulting from crossing white with buff pigeons.

The one result of Mendel's discovery is the purity of the germ-cells. As stated by Castle: "The hybrid, whatever its own character, produces ripe germ-cells which bear only the pure character of one parent or the other." To breeders Mendel's law is of great importance because it provides a basis for making sure that the offspring is the result of an exact science the art of breeding in the case most carefully studied by him, that of entire dominance. "No animal or plant is pure simply because it is descended from a long line of ancestors possessing a desired combination of characters, but any animal is pure if it produces gametes (germ-cells) of only one sort, even though its grandparents may among themselves have possessed opposite characters."

The workings of Mendel's discovery, confirmed by De Vries' experiments, on the origin of species are most important. It is whether aberrations, sports or discontinuous variations may not sometimes result in the formation of new species and types, or whether species are all the result of slow, continuous variations. As stated by Castle, a sport having once arisen affecting some one character of a species, may by crossing with the parent form be the cause of no end of disintegration on the part of any or all of the characters of the species, and the disintegrated characters may, indeed must, form a great variety of new combinations of characters, some of which will prove stable and self-perpetuating.

Mendel's discoveries also explain the principle that new types of organisms are extremely
variable, whereas old types are subject to little variation. A new type which has arisen as a sport will cross with the parent form. The offspring, says Castle, will then inherit some dominant character, others latent, and this will result in polymorphism of the race. Thus the suggestion of Galton at sport may arise from sports is confirmed, while added cases are afforded by the recent remarkable experiments of De Vries, resulting in the originates of seven new species of primrose by sudden variation. In his "De Generations," and "De Variation," Bateson, W., 'Mendel's Principles of Heredity' (Cambridge 1913); Castle, W. E., 'Mendel's Law of Heredity' (Cambridge 1903); Morgan, T. H., 'The Mechanism of Mendelian Heredity' (New York 1915). See HEREDITY; SEX.

MENDELSSOHN, mend'sél-són, Moses, German Jewish philosopher. b. Dessau, Germany, 6 Sept. 1800; d. Berlin, 4 Jan. 1868. His father, Mendel, a schoolmaster, though very poor, gave him a careful education. He lived several years on the charity of persons of his own religion, devoting his time to study, chiefly in Hebrew and Hebrew literature, but also in mathematics and modern languages. In 1750 he was appointed by a silk manufacturer named Bernhard, a Jew, tutor of his children. At a later period Bernhard took him as a partner in his business. In 1754 he became acquainted with Lessing, with whom he contracted a close intimacy, which had a great influence on his mind. Intellectual philosophy now became his chief study. His "Briefe über die Empfindungen," were the first-fruit of his labors in this branch. Mendelssohn contributed to several of the first periodicals, and now and then appeared before the public with philosophical works, which brought him fame, not only in Germany, but also in foreign countries. The most celebrated of these is "Phaedon," a treatise on the immortality of the soul, first published in 1767. It has been translated into European languages. He established a new system, but was, nevertheless, one of the most profound and patient thinkers of his age, and the excellence of his character was enhanced by his modesty, uprightness and amiable disposition. He knew how to elude with delicacy the zealous efforts of Lavater to induce him to declare himself a Christian. To this encounter between Lavater and Mendelssohn German literature owes one of its greatest dramas, Lessing's "Nathaniel der Weise," in which the author, in the person of the hero, commemorates the virtues, the tolerant spirit and comprehensive mind of his friend Mendelssohn. His "Jerusalem, oder über religiöse Macht und Judenethun" (1783) was much misunderstood, partly because he attacked many deep-rooted prejudices of his race. "Morgenstunden" (Morgenstunden) was published in 1785. The last work of Mendelssohn was in defense of his friend Lessing, of whom Jacobi had asserted that he was a Spinozist, was entitled "Moses Mendelssohn und die Freunde Lessings" (1786). Consult Kaysen, "Moses Mendelssohn" (1882).

MENDELSSOHN-BARTHOLDY, Jakob Ludwig Felix, German composer: b. Hamburg, 5 Feb. 1809; d. Leipzig, 4 Nov. 1847. The kindly influences which, like a halo, encircled the life of the illustrious man, are reflected in many of his best compositions. He was born in prosperity, reared in plenty and at nearly all times was surrounded by conditions conducive to success. It has been said that in no way was Mendelssohn's naturalness and naïveté more evident than in his constant reference to his own foibles; and further, that the bearty way in which he enjoyed idleness and boasted of it were delightful in a man who got through so much work, who was singularly temperate and whose only weakness for the products of the kitchen was for rice, milk and cherry pies. "I do not in the least concern myself," he said, "as to what people will praise or pay for; but solely as to what I myself consider good."

It is doubtful whether the history of any other great musician discloses so wide a combination of qualities. Some of his biographers have expressed the thought that his happy disposition prevented his work from attaining that degree of depth which it might have done had his genius been subjected to fiery trials. Be this as it may, the fact remains that among all the German composers there is none who has enjoyed such universal popularity, certainly in America and England, as Mendelssohn. His oratorios, "Saint Paul" and "Elijah," are sung everywhere, while his "Hymn of Praise," the "Overture to the Hebrides," his symphonies, sonatas, concert- overtures, settings for certain Psalms and "Songs without Words" are familiar to all.

Seventy-two of Mendelssohn's numbered works were published before his death and 47 later, while 23 of his compositions, many of them including two or more pieces, had no "opus" numbers assigned to them. Six other of his published compositions have been recorded, while his unpublished pieces, mostly in autograph and principally composed before he was of age, are quite numerous, including 12 symphonies, several fugues, concertos, sonatas, studies, fantasies, etc. Felix was the second child and eldest son of Abraham Mendelssohn, a Jewish banker of Hamburg, and Lea (or Leah) Salomon, a resident of Berlin, and a Jewish lady of considerable property and attainments, to whom he was married on 26 Dec. 1804. The grandfather of Felix was Moses Mendelssohn (q.v.), who settled in Berlin in 1762 and was the son of Abraham Gugenheim, of Hamburg. Moses' father was named Mendel, a poor Jewish schoolmaster of Dessau, on the Elbe. Thus the name Mendelssohn (son of Mendel) simply perpetuates the Oriental method of name-making.

When not three years old Felix was taken to Berlin, and five years later (1816) his father took him and his sister Fanny, four years the senior of Felix, to Paris on a business trip. While there they both received lessons on the piano from Madame Bigot, but it was not till after their return to Berlin that their systematic education commenced. Ludwig Berger became their piano instructor and Zelter taught them thorough-bass and composition. In 1824 Moscheles became acquainted with Felix and while he declined to accept Felix as a pupil consented to offer him suggestions and advice. In the same year Spohr visited Berlin and renewed his friendship with the family, which had been formed at Cassel in the summer of 1822 where the family had gone for
the purpose of introducing Felix to him. In his eighth year Felix played the piano with remark able facility, and about a year later (1818) he made his first formal public appearance. This was at a concert given by Joseph Gugel, a virtuoso on the horn. At 11 he joined the Singakademie as an alto. In 1820 Felix commenced systematic work as a composer, although before that time he had written from 50 to 60 complete movements. The earliest date of which a dated autograph is preserved was attached to a cantata entitled ‘In ruhrend feierlichen Tönen,’ which he completed on 13 January of that year.

The following year was eventful. He composed five symphonies, nine fugues, several pieces for the piano, two operettas and a number of songs. It was in this year, too, that he visited Goethe at Weimar. The poet was delighted with his talent. While at Weimar he played before the Grand Duke and Duchess and improvised before the court and also before Hummel. His compositions in 1822 were very numerous, and during this and the following year he wrote eight symphonies, five concertos, a piano quartet, a violin sonata, a Magnificat and Gloria, and an opera in three acts, entitled ‘Die beiden Neffen, oder der Onkel aus Boston.’ On 31 March he played for the second time in public an Aloys Schmitt’s concerto, taking part in a duo for two pianos, and again, on 5 December, he played at a concert given by Madame Milder-Hauptmann, when he gave one of his own concertos. It was probably in this year, too, that the practice of having informal musical performances on alternating Sunday mornings at the Mendelssohn home was begun. Felix directed, his sister Fanny presided at the piano, his younger brother, Paul, played on the cello, and his second sister, Rebecca, sang.

In 1824 his musical genius showed marked advance, as evidenced in his symphony in C minor, composed between 3 and 31 March. In the summer he was taken to Doberan on the Baltic, a seaside resort, and there received the impressions which later found expression in his ‘Meeresstille Ouverture.’ His wonderful power of extemporizing and his readiness to play the music of other composers are noteworthy features, and Hiller, who was with him in Frankfort in 1825, was carried away with his performances. In this year he met Cherubini in Paris, whither he accompanied his father on a visit. Toward the end of 1825 Mendelssohn’s father purchased a large mansion, surrounded by spacious grounds, and under the influence of this charming home he became more and more devoted to his work. The beauties of Shakespeare were here unfolded to him. Felix was especially charmed with the ‘Midsummer Night’s Dream,’ and probably then conceived the idea of the exquisite composition bearing that name, which forms opus 61 and was first produced in Potsdam 14 Oct. 1843. The overture to a ‘Midsummer Night’s Dream’ appeared earlier, and as a piano duet, its first public performance being given at Stettin in February 1827. Either during this or the previous year, Felix entered the University of Berlin, where he showed evidences of decided literary powers. On his return from Stettin he made preparations for his opera ‘Die Hochzeit des Camacho,’ but owing to the opposition of the director, Spontini, it was performed only once at that time, although, strange to relate, a complete performance was given at Boston, Mass., on 19 March 1855.

The principal compositions during 1828 were a cantata for the Tercentenary Festival of Albrecht Dürer, a cantata for a Congress of Science, an autophona for four voices, and a concert overture. He also completed his overture to Goethe’s ‘Calm Sea and Prosperous Voyage.’ During this year he organized a choir of 16 voices for practising Bach’s Passion music. The year 1829 was an important one for Felix. Hitherto his father had not permitted him to regard himself as a professional musician, but this now being determined on, arrangements were made for him to visit some of the great capitals, with a view of gaining materials for his greatest works. His first journey was to England, where he arrived on 21 April 1829. He was received with much enthusiasm and also scored a success in society. His delightful manners and unfailing animation charmed every one. In November he was again in Berlin, and in the course of the following year he wrote ‘Reformation Symphony’ for the Tercentenary Festival of the Augsburg Confession. He declined the professorship of music in the university, preferring to carry out the program which his father had mapped out for him. In May 1830 he visited Weimar, where he again met Goethe, afterward going to Munich, and later to Italy. Preparations for his return began in June 1831, and after visiting many cities he arrived in Munich where his concerto in G minor was performed for the first time on 17 October.

Another visit to London was made in the spring of 1832, during which he composed with unabated vigor. Among the more important productions of this time were his musical representation of Goethe’s ‘Walpurgis Night,’ and the ‘Fingal Overture,’ which was finished in Rome. Again in Berlin in July 1832, he gave several concerts, producing the ‘Walpurgis Night’ at one of them. His time was fully occupied in composing, playing and conducting. His ‘Italian’ symphony was completed in March 1833, and sent to London where it was produced on 13 May under his personal direction. Later in the month, we find him conducting the Lowe’s festival in Düsseldorf, where, as a result of his success, he was engaged as director of all the public and private establishments of the town for three years with a salary of 600 thalers. He resigned, however, during the second year to accept the position of conductor of the famous Gewandhaus Concerts at Leipzig, then considered the highest position in the musical world of Germany. Thither he proceeded in August 1835, to make arrangements for the season which began on the 4th of October following. Seven concerts were given between the 4th and 24th of the month, when he was shocked by the news of his father’s death which had occurred the day before. For the first time his radiant disposition forsook him and he fell into a despondent mood. During this season of sadness, however, he was able to finish the oratorio of ‘Saint Paul’ while he also maintained the excellence of the concerts for which he was responsible. The great oratorio was first produced at the Lower Rhine Festival at Düsseldorf 22 May
1836. About this time he took charge of the Frankfort Cäcilien-Verein during the illness of the cellist, Heiss, and the Sheratonship of Madame Jean-Renaud and her family. He became devotedly attached to her youngest daughter, Cécile, to whom he was married on 28 March 1837. Returning to Leipzig he conducted another successful season, closing with a performance of 'Saint Paul,' for the first time produced in that city. In August 1837, he left his bride for the purpose of conducting 'Saint Paul' at the Birmingham Festival. This was his fifth journey to England, and before he returned he held conferences with his friend, Klingermann, over the plan of a new oratorio having the prophet Elijah as the central figure. He reached Leipzig on 1 October in time to conduct the first concert of the Gewandhaus on the same evening.

The year 1839 was notable for the composition of the 'Ruy Blas' overture for the Leipzig Theatre and the setting of the 114th Psalm to music. In the following year the invention of printing was celebrated in Leipzig by a festival, and the 'Friedliche Weihnacht,' 'Lobgesang,' or 'Hymn of Praise,' were composed for the occasion. During this year Mendelssohn accepted the direction of the musical department of the Berlin National Academy of Arts, but before entering his duties he made another visit to Birmingham to conduct a performance of the 'Hymn of Praise.' On his return he was installed as General-Musik-Direktor in Berlin, but having the privilege of living where he pleased, he returned to Leipzig. About this time he composed the music for the 'Antigone' and 'Edipus Colonus' of Sophocles, Racine's 'Athalie' and Shakespeare's 'Tempest' and 'Midsummer Night's Dream.'

Another sad trial now befell him in the death of his mother, 12 Dec. 1842, and in November of the following year he removed to Berlin. The king of Saxony had recently established a conservatory of music, a plan which Mendelssohn had long cherished, and he and Schumann were appointed professors of composition and the piano. Meanwhile the Gewandhaus concerts were left in charge of Hillel. In 1844 he visited London for the eighth time in response to an invitation to direct several concerts of the London Philharmonic Society. He held a position as General-Musik-Direktor in Berlin and took a much-needed rest until the autumn of 1845 when he again assumed charge of the Gewandhaus orchestra.

Early in 1846 he was back in Leipzig where he took charge of two classes in piano and composition, and among his pupils were Goldschmidt, De Sensi, Tausch and others. The season of 1845-46 was unusually brilliant in concert work and the program showed a great breadth of selection. At the eighth concert he brought with him Jenny Lind, who was then heard for the first time in Leipzig. On 5 Aug. 1846, a preliminary rehearsal of 'Elijah' was held in Leipzig and soon after he started for England (1846); also Benedict, 'Life of Mozart,' having been sent over a month earlier for translation. First there was a rehearsal with piano accompaniment at Moscheles' house, followed by two full rehearsals at the Hanover Square Rooms, and later by rehearsals in Birmingham, where on 26 August the oratorio was performed for the first time in public. One of his biographers states that 'there was a mad rush at the close of the performance to overtake the hand of the hero of the day, who thanked all present for their share in the performance with which he was so deeply gratified.' Returning to Leipzig he remodeled the oratorio, however, making so many changes that scarcely a movement stands to-day as it was originally written. The complete edition was published in July 1847. The Sacred Harmonic Society of London now invited Mendelssohn to give a production of 'Elijah' in its revised form in Exeter Hall, and for the tenth and last time he visited London in April 1847. Four performances were given, Queen Victoria and the Prince Consort being present at the second of the series. After giving other productions of the 'Elijah' in Manchester and Birmingham, followed by a performance with the Philharmonic Society, he returned to Frankfort, weary and utterly worn out. To add to his now unhappy condition, his sister Fanny, whom he had loved devotedly, was stricken with paralysis and died 14 May 1847. On the day before he fell fainting and for several weeks was utterly prostrated. Seeking diversion, he revisited Switzerland during the summer, where, it is said, he applied himself to water-color painting and made excellent progress in that direction. Later he resumed composition, numbering among his productions at that time the beautiful quartet in F minor (Opus 80), and he also wrote some parts of a newly commenced oratorio, 'Christian,' which he left unfinished. He returned to Leipzig in September, but attempted nothing serious in a musical way. His spirit was broken and he dreaded to appear in public. The beginning of the end came on 9 October while calling on Madame Frege, whom he was accompanying in his last set of songs. She left the room to order lights, says one of his biographers, and on her return found him shivering and suffering violent pains in the head. He rallied somewhat, but another relapse occurred on 3 November and he never spoke again. He died the following day and on Sunday, the 7th, was borne to the Paulinen-Kirche, preceded by a band playing one of his 'Lieder ohne Worte' (Book V, No. 3), which Moscheles had scored for the occasion. Hence the coffin was taken to the Aegidienkirche and Kirchhof in Berlin, where it was deposited in its last resting place.

A cross on the grave bears this inscription: 'Jakob Ludwig Felix Mendelssohn-Bartholdy: geboren zu Hamburg, am 3. Feb. 1809; gestorben zu Leipzig am 4 Nov. 1847.'

MENDENHALL, men-dén-hál, Thomas Corwin, American physicist: b. near Hanover-town, Ohio, 4 Oct. 1841. He was educated in the public schools and by his own efforts obtained a knowledge of physics and higher mathematics. In 1873 he became professor of physics and mechanics in the Ohio University, where he remained until 1878, when he accepted a call to the chair of physics at the Imperial University in Tokio, Japan. There he founded a laboratory, an observatory, a scientific society, inaugurated a system of lectures, which work was highly approved by the Japanese government. In 1881 he returned to the Ohio University, and in 1884 accepted a position in the Signal Service at Washington. In 1886 he was elected president of the Rose Polytechnic Institute, but resigned in 1889 to become the superintendant of the United States Coast and Geodetic Survey, and from 1894–1901 was president of the Worcester Polytechnic Institute. He has published several scientific papers and a book entitled 'A Century of Electricity' (1887).

MENDENHALL, Walter Curran, American geologist: b. Marlboro, Stark County, Ohio, 20 Feb. 1871. In 1895 he was graduated at Ohio Normal University; studied at Harvard in 1896–97 and at Heidelberg, Germany, in 1899–1900. In 1894–96 he was geologic aid, in 1896–97 geologist and since 1901 geologist on the United States Geological Survey. He has charge of the ground-water investigations of the survey in 1907–10 and since the latter year has served as chief of the Land Classification Board. He is the author of various memoirs and articles on professional topics.

MENDES, Catulle, kă-tūl môⁿ-dâs, French writer: b. Bordeaux, 22 May 1841; d. Paris 8 Feb. 1909. His name is marked by extreme devotion to form. He also wrote a great deal of prose — short stories, longer works of fiction, dramas. There is much affection about them all. Among his books are 'Poésies' (1888); 'Monsaires Parisiens' (1882); 'La Rose et la Noix' (1885); 'Grande Maguet' (1888). Of his plays may be cited 'Le Capitaine Fracasse' (1872) and 'Fiamette' (1889).

MENDES LEAL DA SILVA, José, b. 145 Mâng'â-dash lâ-lâ' da sêlvâ, Portuguese statesman and poet: b. Lisbon, 18 Oct. 1818; d. Cintra, 14 Aug. 1883. He was Minister of the Navy and of Foreign Affairs; Ambassador to France, 1874–83; and to Spain, 1883–86. His vogue as a poet has been very great in his own country and his 'Songs' ('Canicos') were first collected in 1838. He wrote also a large number of plays, some of them very popular on the Portuguese stage, as 'Uncle Andrew from Brazil'; and 'The Sportsman' and also several romances. He became a member of the Portuguese Academy in 1861.

MENDEZ-PINTO, män'dê-boô'roo, Fermân, or Fernam, Portuguese traveler: b. Montemor-o-Velho, near Coimbra, Portugal, about 1510; d. Almada, near Lisbon, Portugal, 8 July 1583. He departed for the Indies in 1537, returning in 1558, and after his death a very curious relation of his life, 'Perigrinacao de Fernam Mendez-Pinto' was published, which has been translated into French, English and other European tongues. Congreve, in his 'Love for Love,' called him 'the liar of the first magnitude,' and from this his narrative was considered as a romance; but his good faith and veracity are now generally admitted.

MENDEBURU, mân-de-boô'roo, Manuel, Peruvian soldier and historian: b. Lima, 1805; d. there, 21 Jan. 1885. While a student he joined the patriot forces in 1821, was captured by the Spanish and held prisoner till the close of the war. Among various civil and military posts afterward held by him were those of Minister of War and Finance. He published a 'Dicionario historico-geografico del Peru,' a work of great value and highly prized by scholars. The first part, in eight volumes, deals with the Inca and colonial periods, and its publication, begun in 1874, was concluded after General Mendiburu's death. The second part was not published.

MENDICANCY, a condition of permanently pauperism, where professional beggars are so numerous that government laws are necessary to remove or control them. A population of mendicants naturally results in a criminal community and all countries containing this element have endeavored to remove this evil by legislation. There were beggars in biblical times. As early as 1351 France was compelled to pass laws against "Lazy persons, truants, and able-bodied beggars." Laws were passed in England on this subject as early as the reign of Henry VIII. Mendicity has been found to exist to a greater extent in South European countries than elsewhere, and in Spain and Italy the professional beggar has been one of the greatest evils, the standard of prosperity, morality and intelligence declining as mendicity increased.

According to the census statistics of 1809 there were 91,227 professional beggars in Spain, of whom 51,948 were women. In some of the cities beggars are licensed to carry on their trade. Seeking alms is recognized as a legi-
MENDICANT ORDERS — MENDOZA

mate business, and the municipality demands a percentage upon the collections. Seville is the only city in the kingdom which forbids begging. In Madrid there is no restriction and no license, and the streets are lined with them.

The United States gathers no figures of beggars as their existence is illegal. If paupers, they are supposed to go to the almshouses. The 1910 census showed 72,645 so cared for, 9,500 in New England, 10,272 in New York, 8,653 in Pennsylvania, 7,400 in Ohio, 5,395 in Illinois, 2,927 in Indiana, 2,641 in Wisconsin, 2,600 in California, etc.

In Mexico, both Indians and native Mexicans to the number of thousands make up the army of professional beggars, and Mexico appears to have no laws to regulate them. In the Mexican cities and at fairs and festivals the mendicants are to be seen in astonishing variety; some blind and able-bodied fellows with most artistic "make-ups" of tattered garments and unkempt hair and beards. Some of these stand before one silently with a dumb appealing look in their eyes. Others kneel in the midst of the way and fill the air with their dolorous stereotyped appeals for charity. These beggars are humbugs after the manner of their kind the world over.

In the United States, where labor is in greater demand and better paid than abroad, there seems to be no excuse for mendicity, and yet there are many professional beggars here, largely able-bodied foreigners. The laws of Massachusetts, New York and some other States make vagrancy a crime and authorize the commitment of tramps to the workhouse, house of correction and common jail for varying periods. In the Atlantic Coast States the evil is a serious one.

New York City is a beggars' paradise. Between 6,000 and 8,000 professional mendicants make it their home. Every other city in the United States suffers from the professional beggar, but not to the same extent as New York. The outdoor officer of the Charity Organization Society says that mendicants from all parts of the country flock to New York because the indiscriminate giving there is so common. Cities and States ship their beggar population to New York. About 10 per cent of these beggars are women.

MENDIVÉ, mán-dé-và, Rafael María de, Cuban poet; b. Havana, Cuba, 24 Oct. 1821; d. Matanzas, Cuba, 1886. His first collection of poems (1847), entitled "Passion-Flowers," is widely popular. Banned in 1869, he lived alternately in New York and Nassau, writing legends and stories in verse. He was one of the most noble of Spanish-American poets; and many of his verses received English, French and Italian translations.

MENDOCINO. See CAPE MENDOCINO.

MENDOTA, Ill., city of La Salle County, 80 miles west of Chicago, on the Chicago, Milwaukwe and Saint Paul, the Illinois Central and the Chicago, Burlington and Quincy railroads. The city contains the Blackstone School, Lincoln School, a public library, agricultural implement works, machine works, water-tank heater works, etc. The municipality owns the water-supply system and the sewage system. Pop. 3,806.

MENDOZA LAKE, See FOUR LAKES.

MENDOZA, mén-dō-thá, Antonio de, Spanish administrator; b. about 1485; d. Lima, Peru, 21 July 1552. In 1535 he was appointed by the Emperor Charles V, with whom he was in great personal favor, viceroy of New Spain (Mexico), being the first of 64 viceroys, with the longest administration and that which shows the best record in the history of that provincial government. He made many reforms, especially in relieving the oppressed natives; developed agriculture and mining; established the first Mexican mint; founded the first college; and introduced the first printing press. In 1551 he became viceroy of Peru where he caused to be prepared a code of laws that has been the basis of the colonial and, to a large extent, of the present legal system of the republic. It was under Mendoza's administration in Mexico that Francisco Vasquez de Coronado (q.v.) undertook his famous exploring expedition.

MENDOZA, Diego Hurtado, dé-á'go hoor-tá'do, Spanish author and statesman, great-grandson of the Marques de Santillana (q.v.): b. Granada, 1503; d. Madrid, 15 April 1575. He was educated, as a younger son, for the Church, but, after studying Arabic at Granada and the humanities at Salamanca, entered the army and in 1525 fought at Pavia. He acted as Charles V's Ambassador to England in 1537, to Venice in 1538, to the Council of Trent in 1545 and to the Papal See in 1547, when he became governor of Siena. With Philip II he quarreled and in 1564 was interned in Granada, only returning to court in 1574, soon before his death. To his stay in Italy was due his influence in making the Spanish lyric thoroughly Italianate; and from Italy he brought an unusual knowledge of the classics as well as a fine collection of Greek manuscripts. Mendoza also perfected the Spanish poetic epistle. The famous romance, "Lazarillo de Tormes," has been ascribed to him. His greatest work is his history of the Moorish insurrection, "Guerra de Granada," a model of historical impartiality and on a theme for which knowledge of Arabic particularly fitted him. So impartial was this work that it was not published complete for many years, and even now a good edition is a desideratum. Consult the biography in German by Fesemair (1882).

MENDOZA, Pedro de, Spanish explorer in America, founder of Buenos Aires: b. Guadix, Granada, about 1487; d. at sea, 1537. He was a favorite of Charles V; fought bravely in Italy; and in April 1535 left Spain with 12 ships and 800 men, sailed up the Plata River and founded the city then called "Nuestra Señora de Buenos Ayres." His further movements were unfortunate; Indians and disease attacked his men, three-fourths of whom, including his own brother, were killed. The survivors captured and burned the city, and Mendoza, rescued none too soon by his brother, who came with reinforcements, set sail for
MENDOZA — MENENDEZ Y PELAYO

home. But his health and reason were undermined and he died on board ship.

MENDOZA, Argentina, a province in the western part, on the eastern slope of the Andes Mountains; area, 56,502 square miles. Mount Aconcagua, 22,427 feet, is on the northwestern boundary. The western part of the province is mountainous, the eastern part pampa land and fertile where watered by the streams or by irrigation, but the climate is hot and dry. There are four important rivers, the Mendoza, Atuel, Diamante and Tunuyan. The Transandean Railway which extends from Valparaiso to Buenos Aires divides the territory. There is also a railway to San Juan and San Carlos, and a southern line from San Rafael east. It is rich in minerals, especially silver and copper. Coal and petroleum abound. Grapes grow luxuriantly and a large quantity of wine is shipped to the other provinces. Cattle, hides and wool are the chief exports. Wheat and corn are increasing in importance. Pop. 277,535.

MENDOZA, Argentina, city, capital of the province of Mendoza, at the base of the Andes, on the eastern side of the mountains, on the railroad which extends from Buenos Aires to Valparaiso, Chile, about 600 miles west by north from Buenos Aires and 165 miles east of Valparaiso. It is about 2,400 feet above the sea. The city was founded in 1559. It belonged to Chile previous to 1776. In 1861 it suffered from an earthquake which killed about 10,000 people and destroyed a great part of the city. The Transandean Railway connects the city via Villa Mercedes with all the large cities of the eastern coast, also with Santa Fe and Corrientes. It has eight banks, seven department stores and is an important trade centre. It is the seat of two national normal schools, a national college and an agricultural institute. Pop. about 58,790.

MENE, me'né (numbered); TEKEL (weighed); UPHAR SIN (divided), the Chaldean words traced on the wall at Belshazzar's feast, signifying the weight of his impending doom (Dan. v). The astrologers could not read them, because they were written in antique Hebrew characters, but Daniel understood their awful meaning; and the same night witnessed their fulfilment.

MENEMEDUS, founder of the school of philosophy called Eretian from his native city Eretia: b. about 351; d. about 277 B.C. Traditions vary as to whether he turned to philosophy under the influence of Plato, or under that of Stilpo of Megara, but his tenets seem to have most resembled those of the Megarian school.

MENELAUS, mên-e-laüs, in Greek legendary history, the son or grandson of Atreus and brother of Agamemnon (q.v.). From his father-in-law, Tyndareus, whose daughter Helen he married, he received the kingdom of Sparta and Lacedaemon. Paris, son of Priam, king of Troy, having carried off his wife, Helen, with a present of gift to Iphigenia and some female slaves, and conveyed them to Troy (q.v.), Menelaus, accompanied by Ulysses (q.v.), went thither to demand the restitution of his wife and property, and this being refused, he summoned the Greek princes to revenge the affront according to their promise.

After the conquest of Troy, Menelaus took Helen to return with her to his native land. Eight years he wandered before he reached home. On the island of Pharos (q.v.) he surprised Proteus asleep and compelled him to disclose the means which he must take to reach home. See Trojan War.

MENELEK, emperor (negus) of Abyssinia; b. 1842; d. December 1913. He was the son of a king of Shoam and secured the throne with some fighting in 1889, in which year he signed the Treaty of Uccialli with Italy. The text of the treaty he was bound to conduct his foreign affairs through the Italian government, while the Amharian text made the thing a national. He accordingly wrote to Queen Victoria in 1893 and protested against the treaty as infringing upon his sovereign rights. In 1896 he fought a war with the Italians and severely defeated them in the battle of Adwa. His complete independence was then recognized by Italy and the other European powers. He concluded treaties of commerce with the British and other countries and co-operated with the British army against the Sudanese. A humane and just ruler, he endeavored to apply the arts of civilization to his backward country. He was succeeded by Léopold Yussi, who was deposed in 1917.

MENENDEZ DE AVILES Y MARQUIS, mán-né'de-zó á-vi-lez 'é már-kés, Spanish captain, founder of the city of San Augustine, Fla.; b. Aviles, Austria, 1559; d. Santander, 17 Sept. 1574. In June 1565 sailed with 1,500 men in 19 vessels to dissolve the French in Florida; landed there 28 Aug. and 6 September began a fort, the nucleus of the present town. He attacked the French garrison at Fort Caroline, during the absence of part of the force, which had set out to attack him but was storm-stayed and not wrecked. Menendez slaughtered the entire garrison at the fort and those saved from shipwreck. He returned to Spain in 1567; visited once again, strengthening Saint Augustine 1568, and in 1570 sending a party of colonists to the Chesapeake and up the Mississippi River, where they were massacred by the natives. He was recalled to Spain shortly before his death. During the last two years of his life he was governor of Cuba. Consult Winsor, J. Narrative and Critical History of America (New York 1886).

MENENDEZ Y PELAYO, e pê-lâ'yo, Marcellino, Spanish critic; b. Santander, 17 May 1856; d. there, 19 May 1912. He was educated at Madrid and Paris; in 1878 became professor of philosophy and letters in Madrid; several years later was elected to the Spanish Academy; and in the late nineties became director of the Biblioteca Nacional. He lectured especially at the Athenaeum in Madrid. He was dean of the faculty of letters at the University of Madrid, and in this capacity was a color prominent and efficient literary critic. He received many honors, including the grand cross of the Order of Alfonso XII. His literary style was finished and elegant and was an accomplished defender of classical methods. He wrote 'Estudios criticos sobre poetas y filósofos' (1875); 'Hercio en España' (1876); 'Hercio en España' (1876).
(1877); 'Historia de los Heterodoxos Españoles' (1880-81); 'Calderon y su Teatro' (1881); 'Odas, Epistolás y Tragedías' (1883); 'Historia de las Ideas estéticas en España' (1884-91).

MENENDEZ PIDAL, Ramón, Spanish critic, philologist, educationalist and general literary man: b. Coruña, 13 March 1899. Educated at the universities of Madrid and Toulouse he became professor of Romanic philology at the University of Madrid (1899). See PIDAL RAMON MENENDEZ.

MENEPHTAH, or MERNEPTAH, king of Egypt about 1250 B.C. He succeeded his father, Rameses II, and reigned for a period of 20 years. His reign was troubled by an invasion from Libya, but he succeeded in crushing it and thereafter set about the construction of numerous buildings and monuments, especially at Tanis. In 1898 his mummy was discovered at Thebes and now reposés in the Cairo Museum. Previous to 1896 it was thought that Menephtah was identical with the Pharaoh of the Exodus, but in that year an inscription was uncovered in which it was stated that Israel was settled in Palestine in the fifth year of Menephtah. This inscription is of prime historic interest as fixing the period of the settlement of Israel in Palestine and as the only mention of Israel on Egyptian monuments. For the inscription consult 'Der Sieges-hymnus des Menephtah auf der Flinders Petrie Stele' in Zeitschrift für ägyptische Sprache, Vol. XXIV (1896). Consult also Breasted, J. H., 'History of Egypt' (2d ed., New York 1909) and Budge, E. A. W., 'History of Egypt' (New York 1902).

MENES, mē-nez, according to Egyptian traditions, the first king of Egypt. Herodotus relates that he was the founder of Memphis, which he built on a piece of ground which he had recovered from the Nile by altering the river's course. According to Diodorus, Menes introduced into Egypt the worship of the gods, as well as a more elegant style of living. He has been identified by some with the Mirzim mentioned in Gen. x, 6. A tomb supposed to be that of Menes was discovered near Nakada by De Morgan in 1897. Consult Sethe, K., 'Menes und Grundung von Memphis'; Breasted, J. H., 'History of the Ancient Egyptians' (New York 1908). See EGYPT.

MENG-TSE, men-tshê. See MENCNIUS.

MENGER, Karl, Austrian political economist; b. Neu-Sanáez, Galicia, 1840. He was educated at the universities of Vienna and Prague, where he gave special attention to law and political economy. In 1872 he began his long connection with the University of Vienna, being appointed full professor of political economy in 1875. He was elected member of the Austrian House of Peers in 1900. As an economist he is undisputed leader of the new school of economics in his country and is opposed to the traditional system hitherto followed. He has published several important works including 'Kritik der Volkswirtschaftslehre' (1871); 'Untersuchungen über die Methode der Sozialwissenschaften und der politischen Oekonomie insbesondere' (1883); 'Die Irrtümer des Historismus in der deutschen Nationalökonomie' (1884); 'Beitrag zur Währungsfrage in Oesterreich-Ungarn' (1892) and the article "Geld" in 'Handwörterbuch der Staatswissenschaften,' 3d ed. (1909).

MENGs, Anton Raphael, German painter: b. Aussig, Bohemia, 12 March 1728; d. Rome, 29 June 1779. In early childhood his father, Ismail Mengs, a miniature painter of little talent, who was settled at Dresden, took him in hand to make a painter of him, and in 1741 carried him to Rome and set him to study the antique and to copy Michaelangelo and Raphael. He was compelled to do a certain task in painting every day; his day's work subjected to severe criticism; and he was even punished if it was not satisfactory. From this constant practice he early gained skill as an artist, and when he returned to Dresden his talent and proficiency were at once recognized by August III, who appointed him court painter and gave him permission to return to Rome. At Rome he attended the Academy and in 1748 produced a large and elaborate composition, 'The Holy Family,' taking as model for the Mother of Jesus a beautiful peasant girl, whom he afterward married. On his return to Dresden he was commissioned to paint 'The Ascension of Christ,' for the high altar of the Chapel Royal, and was given permission to return to Rome for the purpose of doing so. A new academy of painting having been opened in the capitol he was appointed director and painted for the Celimenses the ceiling of their church, San Eusebio, for Cardinal Alhani the 'Parnassus' in the ceiling of his villa, and several oil paintings, including 'Cleopatra,' 'The Holy Family' and 'The Magdalene' for private persons. When King Charles III of Spain summoned him to Madrid he executed for him in fresco there 'The Assembly of the Gods' and 'The Descent from the Cross'; he also completed the altar-piece for Dresden. He returned to Italy in 1769, stayed eight months at Florence and painted for the Pope a calligraphy fresco for the Vatican Library. In 1772 he went to Spain and produced for the king the fresco 'Apotheosis of Trajan,' his finest work, but returned to Rome in 1775. On his death the Cavalier d'Arzara set up a monument to him, and Catherine II of Russia raised a splendid tomb for him in Saint Peter's. He was certainly one of the most prominent painters of his day, and if he possessed none of the free and living originality of genius he was a master of noble composition and design. He was catholic in taste and eclectic in style, drawing inspiration from the antique, as well as imitating Raphael, Titian and Correggio, whose styles he tried to blend. Consult Woermann, 'Ismail und Raphael Mengs' (in the Zeitschrift für bildende Kunst, No. 5, 1893).

MENHADEN, a species of fish (Brevoortia tyrannus) of the herring family (Clupeidae), appearing in vast schools along the Atlantic Coast of America. Owing to the large number of local names applied to this species much confusion concerning its identity and distribution exists in the minds of fishermen and others. The name "menhaden" (Indian) is used chiefly in southern New England. North of Cape Cod the fish is called pogy, or occasionally hardhead; in New York and New Jersey, bunker or marshbunker; the fishermen of Delaware
and Chesapeake bays know it as bay alewife, and in the latter region and southward also as bug-fish or bug-head; still farther south it becomes the fat-back herring. From the other herring the menhaden is readily distinguished by its very large head, large mouth, complex gill strainers and crenulated scales. The body is deep, the fins small, the mouth toothless and the color bluish and silvery, with one large and several small black spots.

Like some other pelagic and migratory fishes the menhaden is exceedingly irregular in its movements and variable in abundance and distribution from year to year, but its general range is from Nova Scotia to Brazil and oceanward, so far as observed, to the Gulf Stream. In spring it approaches the coasts and extends northward with the alewives and other species, probably for the purpose of spawning in brackish water, though little is actually known of its spawning habits. In winter Cape Hatteras marks the northern limit of its abundance. The menhaden swims in compact schools of large size, the movements of which, at the surface, or sunken to a greater depth, are extremely irregular.

These irregularities are owing, no doubt, to corresponding variation in its food-supply, which consists wholly of the minute organisms, both vegetable and animal (plankton), that are caught as the fish swims with open mouth, straining the water through its lips and gillarches as it goes. Owing to its strong oily taste and extreme bonyness its value as human food is very slight, but as furnishing food for other fishes, as bait, and for the manufacture of oil, fertilizer and other products, it has a very great economic importance. Large companies control its capture for the latter purposes and, besides pound nets, utilize many steamers provided with purse seines and dericks, by means of which entire schools are taken at a haul and lifted on deck. The oil is extracted and the solid parts ground up for fertilizer at factories on shores. The product varies from year to year, but the total weight of fish taken runs into the hundreds of millions pounds. The meshes of fish and industries involved reached their highest level of importance in the latter part of the last century, since which both have much diminished, whether by reason of over-fishing or because the menhaden no longer come to the northern part of the coast in so great abundance, is not determined. Consult Goode, 'History of the Menhaden,' Report United States Fish Commission, 1879, and recent reports of the United States Bureau of Fisheries.

MENHIRS, elongated, rough-hewn monoliths standing with one end in the ground. They are found of various sizes, from about 6 to as much as 67 feet high, the latter being the height of that at Locmariague in Brittany. Singular superstitions naturally attach to some of them. See STONES, STANDING.

MENIERE'S DISEASE, a disease of the ear first described by the French physician, Edouard Armand Meniere, in 1861. It is one form of auditory vertigo and usually attacks persons of middle age. The principal causes are sunstroke, influenza, rheumatism, anemia and venereal diseases. The attack is usually very sudden and appears to be due to hemorrhage into the labyrinth. The seizures may occur at irregular intervals of days or even weeks. While the symptoms of dizziness, vertigo, nausea, gradually disappear the deafness is generally permanent. Potassium iodide is most serviceable in reducing the dizziness. See EAR.

MENIN, Belgium, town in the province of West Flanders, on the Lys and on the Belgo-French frontier here demarcated by the river seven miles southwest of Courtrai, and 30 miles southwest of Ghent. It contains lace and cotton mills, tobacco factories, etc. In the neighborhood there were extensive tobacco plantations previous to the war of 1914-18, in which Britain suffered severely. It fell to the Germans during the great rush of both armies northward to the sea; was taken by the British in a spirited attack, but was subsequently evacuated by them for strategic reasons. The British having noted a German concentration of troops and materiel in Menin made an aerial attack upon it which brought damage to a great number of buildings. Pop. 18,600.

MENINGITIS. The brain is enveloped by three membranes called the meninges. Next to the skull comes the dura mater, the arachnoid and innermost is the pia mater. These three membranes are prolonged from the brain in three envelopes of the spinal cord. Meningitis is an inflammation of the meninges of the brain or of the spinal cord. It is very rarely a primary condition, but is usually secondary to infection from micro-organisms of many types, or results from chronic poisonings such as lead, alcohol, etc. Hence modern medicine speaks of various meningitides rather than one meningitis. When the surface of the dura mater becomes inflamed by some object breaking through the skull, or a piece of broken bone of the skull, thrust inward by some blow, an artery is ruptured and the blood flows between the membranes. Such a condition is called traumatic meningeal hemorrhage. When the dura mater becomes inflamed after a wound, or after inflammation of other parts of the head, as the ears, teeth, etc., there results a condition called pachymeningitis externa. Inflammation of the meninges, however, is generally confined to the pia mater and arachnoid and is then called leptomeningitis. Pachymeningitis, inflammation alone or chiefly of the dura mater, may extend to the other membranes. Inflammation of the cerebral meninges is cerebral meningitis; of the spinal meninges, spinal meningitis; of those of the brain and spinal cord together, cerebro-spinal meningitis. Ascending meningitis is a meningitis ascending from the lower part of the spinal cord.

Pachymeningitis has one form involving the external surface of the dura mater and resulting from blows or other injuries, and from osseous growths. There may be no well-defined symptoms, but usually is local headache and tenderness on pressure. The onset is usually sudden. Many cases of meningitis of the type called 'serous' are not other than pachymeningitis. If the dura mater, which is normally free, is bound to the skull by fibrous exudation, and especially if pus forms and hemorrhages occur, there are symptoms of pressure. Inflammation of the internal portion
of the dura mater may result from the extension of inflammation from adjacent parts, such as the ear, or it may attend cases of pernicious anemia, chronic syphilis, tuberculosis and chronic wasting diseases. It occurs chiefly in old age, but has been seen in children. There are fibrinous deposits and extravasation of blood in cysts (harmatoma), and occasionally pus forms. The brain is anemic, sometimes softened. The symptoms are those of irritation — convulsions, vomiting, dilated pupils which are not affected by exposure to light, a slow irregular pulse, etc. — and those of compression or pressure — coma, etc. Pachymeningitis is usually fatal.

Cerebral meningitis (simple or cerebral meningitis), in the acute form, is not common, and is most apt to occur in men engaged in hard mental pursuits. It may be caused by injuries, by universal fibrin or lymph, and its superficial layer is softened. There is almost always watery effusion into the brain-cavities. The symptoms are those of three stages: (1) Headache; (2) delirium; (3) coma. At first there may be slight fever, some photophobia, frequency and irregularity of the pulse and some contraction of the pupils. There is a disposition to vomit, a slowness in movements of the bowels and often hyperesthesia. Then comes delirium, which may or may not be active; the patient talks much and tries to get out of bed; does not obey readily. There is more or less trembling of the limbs, with difficulty in moving them. One pupil is likely to be dilated. Sometimes strabismus occurs; the pulse is very irregular; and paralysis begins. Then follows coma, loss of sense, sensation and of voluntary motion; there is sighing, the pulse is frequent and weak; the pupils do not respond readily to light and the capillaries of the skin and eye are congested. Recovery from this disease cannot occur after the period of coma begins.

Sub-acute or chronic cerebral meningitis is a secondary disease, sometimes associated with chronic syphilis, Bright's disease, alcoholism, etc., though the cause is not always ascertainable. The lesions are similar to those of acute meningitis, but less pronounced. There is less of serum and pus, and the exudated fibrin is more circumscribed. The symptoms are insidious and vague. Headache, vomiting and photophobia are rare. The slight delirium is followed, it may be, by somnolency, irregular pulse, strabismus and slowing respiration. With coma the pulse is rapid, 120 or more, and the patient dies as in acute meningitis.

Tuberculous meningitis, also known as acute hydrocephalous granular meningitis and basilar meningitis, is an acute tuberculous inflammation of the pia mater, caused by a deposit of miliary granules over the surface of the brain, but most numerous at the base, in the track of the cerebral vessels, and in their sheaths. There is a noticeable vascularity, especially in the ventricles. The pia mater is thickened and opaque and covered with a semi-purulent exudation. Serum fills the ventricles and foramina, pressing upon the convolutions, and assists in softening portions of the brain. The lesions in this disease are rarely limited to the brain; tubercles are found in other organs, especially the lungs. The disease is a phase of that protean meningitis, though the cerebral lesions may first be noticed. The primary causes are a hereditary diathesis (scrofulous or tuberculous), foci of caseous degeneration in some organ, a suppurating joint, or a scrofulous inflammation of bone. The physically weak children of tuberculous parents are most subject to this disease, and in cases where strong children are attacked there is generally found a tubercular relative. Though the disease is essentially a disease of early life (from three months to 10 years), it also attacks adults. Most of those affected die in from two to six weeks. The symptoms may be classed under three heads: (1) Obscure symptoms; (2) those of rapid development; (3) those of coma. There are seen listlessness, loss of appetite, occasional vomiting, slowness of the bowels and somewhat frequent pulse. Sometimes there is headache, a remittent form of fever and then rapid development of diagnostic symptoms. The patient talks a good deal. One of the most important symptoms is a change in the disposition through which the child, although bright and lively before, suddenly becomes listless, or excessively emotional, a condition which may continue for several weeks. There are irregularity of the pupils and pulse, a sharp "epileptiform" cry, severe headache, insensitivity to light and sound, grinding of teeth, a flushed face in paroxysms, usually before convulsions, rolling and drawing back of head, urine scanty and high-colored, oscillation of the eyes, ophthalmia constipation, etc. With coma comes strabismus; the pupils do not contract under the influence of light, but will contract and expand when the bowels rumble or the patient is moved. There are convulsions, paralysis and automatic movements of the feet and hands, it may be for hours. The thumb may be turned in. There is a hollowed abdomen (boat-shaped) and congestion of the eyes, a puri form secretion sticking the eyelids together; involuntary discharge of bowels and bladder, etc. For treatment of this affection place patient in bed, in a quiet room; give easily digested food; apply an ice-cap to the head and warmth to the feet. Further treatment should be in the hands of a physician. Much can be done by parents and guardians to prevent the onset, by not developing the nervous system at the expense of the muscular and digestive systems. Precocious children are to be judiciously restrained, and outdoor life encouraged. Tuberculous meningitis in adults is commoner in men than in women, and most frequently occurs between 17 and 30. It is generally fatal in 2 to 14 days, about one in 200 cases recovering.

Spinal meningitis is not common; it is usually caused by injuries, is liable to occur in children with spina bifida and is rarely amenable to treatment. Death occurs usually in from 8 to 10 days, either from extension of inflammation to the brain and pressure there by fluid, or from asphyxia due to spasms of the respiratory muscles. The lesions are similar to those of cerebral meningitis. The chief symptoms are pain in the spine and extremities, increased by movements.
of the body, great sensibility of the surface of the body, spasms of muscles, opisthotonus and dyspnnea.

Epidemic cerebro-spinal meningitis, or spotted fever, is due to a special micro-organism, the diplococcus intra-cellularis. Death frequently occurs in a few hours; recovery usually requires 30 or more days. The disease has spread over sections of this country two or three times, mainly in the winter and spring. The exact manner of its transmission is not known. One form is characterized by fever with no eruption; the other by fever and an eruption. The symptoms are a chill or chilliness, followed by nausea and vomiting, fever, violent headache, sometimes with pain down the spinal column, general hyperaesthesia, great prostration, vertigo, tetanic rigidity of muscles, irritability or apathy, delirium and other symptoms of meningeal irritation, followed more or less rapidly by those of coma. In the majority of patients the head is raised when the patient is lying on his back, the knees are involuntarily flexed. When there is an eruption it usually appears early and consists of dark blottches, from the size of a pinhead to that of a nickel, and is not marked on the extremities.

Where death occurs within 12 hours from the time of attack only a congestion of blood-vessels of the brain and, it may be, of the spinal cord, is generally found. Almost always there is lymph or pus beneath the pia mater, and sometimes serous effusion in the pleura, pericardium or peritoneum. The blood urinates, goes a change, ecchymoses are found sometimes in the muscles, or in connection with the pericardium or pleura. This disease is best treated with a serum, which was first produced in the monkey but now is successfully derived from the horse. The serum is given in frequent doses depending on the severity of the case, from 12 to 24 hours apart; this treatment has reduced the mortality to 30 per cent. In 20 chronic variety serum therapy is of no avail; the application of cold to the head should depend upon the desires of the patient. Pain has to be reduced by morphine. Consult Jelliffe and White, 'Diseases of the Nervous System' (3d ed., 1919).

SMITH Ely JELLIFFE, M.D.

MENIPPUSS, më-nëp'ës, Greek cynic philosopher, a native of Gadara in Palestine, and supposed to have flourished about 260 B.C. His writings were chiefly of a satirical kind. Lucian styles him "the most snarling of cynics," and in two or three of his dialogues introduces him as the vehicle of his own sarcasms. It appears that his satires were composed in verse and prose, on which account those of Varro were denounced Menippian, and for the same reason the name of Satyr Menippus was given in France to the celebrated piece written against the League and Philip II of Spain, its head. His writings are lost.

MENKEN, Adah Isaacs (originally DOROTHEA AHNES FUERTES), American actress: b. near New Orleans, La., 15 June 1835; d. Paris, France, 10 Aug. 1868. Making her début with her sister as danseuses, at the New Orleans French Opera House, she was received with much favor. She visited Cuba, Texas and Mexico. On her return to New Orleans, she published a volume of verse and tales in French and Latin at a girls' academy in the city. In 1858 she appeared in 'Fazio' in New Orleans, and went to England in 1863-64, assuming the role of Maizetta at Astley's which won her popularity. On 30 Dec. 1866 she married in Paris for 10 nights, and later in Vienna and London. Her last appearance was in Paris in May 1868. She was famous for her fine form, and many marriages and divorces: Alexander I. Menken, John C. Heenan, J. H. Newell and James Barclay being her successive husbands. Her mind seems to have been as winning as her physical beauty, for among her friends were numbered Charles Reade, Dickens, Swinburne and the elder Dumas.

MENNO SIMONS, Dutch religious reformer: b. Witmarsum, Friesland, 1492; d. Oldesloe, Holstein, 19 Jan. 1559. He was ordained priest in the Roman Catholic Church and took pastoral work in the village of Pingium (1524), and from a study of the New Testament, undertaken (1530) to solve his doubts about transubstantiation, he was induced to become an evangelical preacher and finally left the church of his ordination. The marauding of Sickie Snyder at Leeuwarden for Anabaptism impelled him to consider the Scriptural grounds for infant baptism. He was finally converted to the cause of the Anabaptists, but never sympathized with the excesses of Mennonites and wrote a diatribe against John of Leyden (1535). In 1537 at the request of a number of Anabaptists of Groningen he assumed the functions of an Anabaptist preacher and exercised, by his moderation, a most salutary influence on his fellow-ministers. He now married, his change in faith having superseded his vow of celibacy, and began to travel as an evangelist not only in Friesland but throughout Holland and Germany as far as Livonia. Being persecuted from place to place he finally settled in Oldesloe in Holstein, where he closed his ministry with the happy consequence of having founded a large and flourishing sect, whose subsequent history is related under the title Mennonites (q.v.)

Views of Menno Simons.—Menno was a rather a preacher of salvation than either a dogmatist or a violent fanatic like some of the Anabaptists. He was a man of pure moral and devotion and enthusiastic, whose account of his own conversion says like a passage from the 'Confessions' of Augustine: He sums up the results of his labors by confessing in the conversion and recovery of the wicked. Yet he formulated a somewhat vague profession of faith. He believed in the divinity of Christ, who was born on earth in Mary that is without taking upon him human flesh and blood. He rejected infant baptism, and baptized those only who made a personal profession of faith in Christ. He particularly emphasized the power of excommunication possessed by the Church, without which the "Spiritual Kingdom [of God] is not," he said, "exist in purity and piety." He believed in the coming millennium (q.v.); he excluded civil magistrates from church membership on the ground that the church was a "theocracy" whose magistrate is John of Leyden. He declared that war and all taking and administering of oaths were unlawful, and e-
MENNONITES, a body consisting of a dozen or more branches of followers of Menno Simons, akin to Baptists in faith and practice. Menno Simons (1492-1559), a Holland Anabaptist, was not the founder of the body that bears his name, but was a convert to it several years after it began and became its chief leader. He left the priesthood of the Roman Catholic Church, espousing the views of the Anabaptists, but opposing the Fanatical extremists of Münster. His books were his chief contribution to the movement, which formed the division of Protestantism which is called by the name Anabaptist. The Anabaptists were opposed to the baptism of infants, baptizing only on confession of faith. The followers of Menno Simons became numerous in Holland, Germany and Switzerland, and were persecuted to death, particularly in Holland, because of their views in regard to the temporal power. Rising in the first half of the 17th century (they were first called Mennonites in 1559), though the name was never generally adopted in Europe as it was in America) they increased under persecution and emigrated to Russia and the United States to escape it, to the former country near the close of the 18th century and to the latter from 1640 on, coming from Holland, and Germany to New York and New Jersey. They were then sent to Pennsylvania by William Penn's announcement that those settling in that colony would enjoy freedom in the practice of their religious faith. The Society of Friends in England assisted the Mennonites of Holland to emigrate. The first Mennonite colony was formed at Germantown, near Philadelphia, in 1683. Thence they spread to Lancaster, Bucks, Berks and other counties in Pennsylvania and from that State to other States and to the Canadian provinces. They came in constant contact, in colonial and post-colonial days, with the Indians, but like the Friends, being opposed to bearing arms and inclined to peace they suffered little from attacks by the savages. It is worthy of note that a Mennonite meeting at Germantown as early as 1688 adopted a protest against the traffic in slaves, saying that those "who steal or rob men and those who buy or purchase them" are all alike.
gates elected by the State conferences. The Amish body is represented in this conference— the two churches are practically one—and cooperates in the conduct of the general missionary, educational and benevolent work. The board of missions has missionaries in India and in America, with a department of city missions. The chief educational institution is at Goshen, Ind. Two unincorporated organizations help members who sustain losses by fire, storm, etc., one for Mennonites and Amish, the other for Mennonites and Old Mennonites. The property listed for this purpose aggregates more than $12,000,000. The Mennonite Church is growing in numbers. In 1906 it returned, according to the government census, 18,674 members; in 1916 that number had almost doubled—34,965. There are 509 ministers and 307 churches in the Middle Western and a few of the Southern States, by far the larger number being in Pennsylvania. The Mennonite, of Berne, Ind., is the weekly organ of the denomination in English. There is also a German weekly at the same place.

5. Old Order Mennonite Church. —This is a small body of the Amish type, with only one conference, 14 churches, 30 ministers and 1,066 members, census of 1916. The Amish Mennonites date from 1690, separating from the Mennonites in Switzerland and Alsace, on account of their laxness of discipline. The name is derived from Jacob Ammon or Amen, who insisted that the doctrines set forth in the Dort Confession of Faith should be interpreted literally and accepted strictly. In later years, this strictness has been relaxed and the main body of Amish is practically reunited with the Old Mennonites in the Mennonite Church.

Old Order Amish Mennonite Church. —This body represents the stricter descendants of Jacob Amen and the Swiss Amish of the 18th century. While the main body of Amish were approaching agreement with the main body of Mennonites, the stricter wing were holding the older position resulting in the organization in 1853 of the Old Order Church. This body is opposed to building churches, holding that one place is as sacred as any other and that separate church buildings favor ritualism. They therefore hold their meetings in private houses, which necessarily makes their congregations small. A Sunday service usually continues about four hours, and is exclusively in German. They use the old hymnal, Ausbund, first published for the Swiss brethren in 1571 and reprinted many times in America. The tunes supposed to be the original have never been committed to musical notation and of course never printed. The sermon is without text, and traces God's dealing with the race from Adam down, setting forth the sinfulness of sin and God's love and care for his obedient children. On some Sundays service is continued from morning till night without intermission, several ministers being in attendance to keep them going. There is no church property, except hymnbooks, plain benches and the sacred articles. The Lord's Supper is observed weekly, sometimes accompanied with the Lord's Supper. As a result, the Amish have a head covering during prayers and worship. Its platform of union is acceptance of the Dort Confession, salvation by grace through faith in the Spirit, baptism in Confession of faith, and refusal to take oaths, peace, non-resistance and practice of scriptural discipline. The General Conference, which is gaining in numbers, has according to the census of 1916, 194 ministers, 117 churches and 15,407 members.
8. Mennonite Brethren in Christ.—This branch grew out of an evangelistic effort in Pennsylvania, in 1853. The first conference was formed in 1858. The movement spread and the groups came into existence, which united in 1879; subsequently other groups joined the body which took its present form and name in 1883. There is a general conference which meets every four years, and five district conferences in the United States and two in Canada. The weekly newspaper, The Gospel Banner, is published in New Carlisle, Ohio. The General Conference has 95 ministers, 110 churches and 4,737 members.

9. Defianceless Mennonite Church.—A small body of 854 members, which consists upon a definite experience of conversion, organized under the leadership of Henry Egli, in 1860, an offshoot of the Amish branch. It has a mission in Africa and is akin to the conference of Defianceless Mennonites known, until recently, as the Minnesota and Nebraska Conference of Mennonites and now affiliating with the Mennonite Church. (See 1. Mennonite Church, supra.)

10. Mennonite Brethren Church.—This body, which was not reported by the census of 1860, was formed by district conferences in the United States and one in Canada. It conducts home and foreign missions and has a college at Hillsboro, Kan., where it publishes the Zion's Bote. The census of 1916 gives this church 81 ministers, 53 churches and 5,127 members.

11. Krimmer Brueder Gemeinde.—A union of two bodies of Brueder Gemeinde, which came originally from Russia, where they separated from the main body of Mennonites, because they were thought to be licentious in religious life and discipline. They differ from other Mennonites in baptism by immersion and not by pouring, and they formerly differed among themselves as to the mode, one group baptizing with a forward, the other with a backward movement. There are 894 members, with 34 ministers and 13 churches.

12. Hutterian Brethren.—These are descendents of the Hutter Brethren of South Russia. Their leader was Jacob Hutter who was burned at the stake at Innsbruck in the Tyrol, in 1536. The Hutterian Brethren are not strictly Mennonites, but agree with them and are so classified. They formerly observed community life in South Dakota, and have sometimes been called Bruderhof Mennonites. They have (census of 1916) 982 members, with 32 ministers and 17 churches.

The Kleine Gemeinde, the Stauffer Mennonites and the Central Conference are small groups, differing in minor particulars among themselves and from other Mennonite bodies. They have 894 members and 840 churches and 79,591 members. The increase in 10 years was nearly 25,000 members.

Author of 'Religious Forces in the United States,' etc.

MENOBRANCHUS, an alternative designation of Necturus. See Proteidae.

MENOCAL, Aniceto Garcia, American civil engineer: b. Cuba, 1 Sept. 1836; d. 20 July 1906. He was educated in Havana and was graduated from the Knesselaar Polytechnic Institute in 1862. In 1863-69 he was engaged as sub-chief engineer of the Havana waterworks and in 1870 returned to New York, where he was two years in the engineering of the waterworks department. He was chief engineer of all the surveys made for the Isthmian Canal by the United States government and was sent to Paris in 1879 as member of the Canal Congress. He furnished the estimates of the cost of the canal and was a member of the boards for selecting crossing stations at the Philippines, Porto Rico and on the coast of Liberia, Africa. He was a member of several scientific societies and published many of his official reports, etc.

MENOMINEE, the French Folles Avoines, a tribe of North American Indians of Algonquian stock, formerly known in upper Michigan and Wisconsin, along the Menominee River and Green Bay, and ranging west to the Mississippi and south to the Fox River. Their name signifying "wild-rice men," hence the French translation is derived from their use as a staple food of the abundant wild rice of the region. Their descendants numbering about 1,400, civilized and Roman Catholics, inhabit Green Bay Reservation, Wisconsin. Consult Hoffman, J. W., 'The Menominee' (in Bureau of American Ethnology, 14th Annual Report, Washington, 1886).

MENOMINEE, mě nō'mē-ně, Mich., city, county-seat of Menominee County, on the mouth of Menominee River, on Green Bay, and on the Chicago, Milwaukee and Saint Paul, the Wisconsin and Missouri and the Chicago and Northwestern railroads, opposite Marinette (q.v.), at the southern point of the Northern Peninsula, and about 46 miles northeast of the city of Green Bay, Wis. The first settlement was made in 1799 by Louis Chappieu, a French fur trader. The first lumber mill was built in 1832, but the town was not incorporated until 1853. It is situated in an extensive lumbering region, and it is one of the largest lumbering ports on the Great Lakes. Its chief industries are connected with the lumbering interests, and its great sawmills have an annual capacity of 275,000,000 feet. The principal manufactures are lumber in all forms, paper, shoes, boxes, machinery, telephones, steam-boilers, beet-sugar, electrical machinery, auto trucks and lumbering camp outfits. The city has an agricultural college, a fine high school, public and parish schools and a public library which contains about 3,000 volumes. It has Saint Joseph's Hospital, the county buildings and several fine churches. The government is vested in a mayor and council elected annually. The city treasurer and the justice of the peace are elected by the people; the other adminis-
Menommee Range — Mensural Music

Menommee Range. See Iron Ore, Iron Ore Districts.

Menomonie, Wis., city, county-seat of Dunn County, on the Red Cedar River, and on the Chicago, Saint Paul, Missouri and Ohio and the Chicago, Milwaukee and Saint Paul railroads, about 65 miles east of Saint Paul, Minn. It is in an agricultural region and near the lumber section of the State. The chief manufactures are lumber, wagons, carriages, machinery, foundry products, bricks, pianos and flour. The trade is principally in lumber, pianos, flour, brick. Menomonie is the seat of the Stout Institute, a State institution for the teaching of trades and for the preparation of teachers of industrial arts and household arts. It has a county training school for the preparation of rural school teachers, and a County Agricultural School. It has the Mabel Tainter Memorial Library, which contains about 18,000 volumes. The Dunn County Asylum is near, but just outside the city limits. Pop. 5,036.

Menopause, the cessation of menstrual flow in women; climacteric. This epoch is reached generally between the 45th and 52d years, and is frequently marked by nervous disturbances. The power of child-bearing terminates at the menopause. It is popularly termed the "change of life." A woman who begins child-bearing early and gives birth to a large family usually has her menopause earlier than a childless woman. The approach of the menopause is marked by irregular — usually delayed — menstruation, and sometimes the latter flows are very profuse and weakening. See Climacteric; Menstruation, Disorders of.

Menopome, a giant salamander of the genus Cryptobranchus (formerly Menopoma). See Hellbender.

Menpes, Mortimer, English artist: b. Adelaide, South Australia, 1859. He went to London when 19, studied at South Kensington; spent three years in Brittany at Pont Aven; traveled in Japan, where he learned something from Kyosai, in India, Burma and Cashmere, then through southern Europe and Mexico; and wherever he went continued his early experiments in color and his attempts to reproduce the atmosphere of various localities. Originally he used the color as dry as possible, then mixed it with petroleum and finally used poppy-oil as a medium. He revived the lost art of printing in color from etched plates; made some excellent dry paint etchings, notably one of Hals' 'Archers of Saint Adrian,' and published several volumes of pictures. His English house was made in the East, and is a wonderful piece of oriental workmanship in gold and black. He has published 'World Pictures' (1902); 'Whistler as I Knew Him' (1904); 'India' (1905); 'Sir Henry Irving' (1906).

Mensa, or Mons, in astronomy, one of the footstool elevations where Lacaille discovered at the Cape of Good Hope. It is named from the mountain which is a conspicuous feature of the landscape at the Cape. The constellation is a very inconspicuous one near the South Pole, its brightest star being only of 5.3 magnitude.

Mensuration, the periodic discharge of the menses or bloody fluid from the female generative organs. In women it normally occurs at intervals of one lunar month, or 13 times a year (hence the term menses, Latin plural of menstrua, month). Its first appearance marks the stage of puberty, and is usually attended by definite changes — enlargement of the breasts, showing development of the mammary glands, growth of the ovaries, of the uterus and external genital organs, etc., and by other signs, physical and mental, of approaching womanhood and maturity. It usually begins in temperate climates between the 13th and 15th year; in hot climates it is apt to commence as young as 12 years, and in very cold climates as late as 17 years; in periodic recurrences continue until the menopause (q.v.) or final cessation of the discharges which ordinarily arrives somewhere between the 45th and 52d years. The recurrent period of its appearance, as well as its duration, vary with different females, and not infrequently in the same individual; the variation, however, not always indicating abnormal pathological causes. The immediate cause of menstruation is the breaking away of an ovum or egg from one of the ovaries. (See Ovary.) Menstruation is often at first, and in many persons throughout the catamenial age, attended by characteristic pains and symptoms, with pathological and psychological conditions of disturbance or depression which require some form of special hygienic treatment. During pregnancy (with exceptional cases) there is a menstrual flow, its cessation being one of the earliest signs of conception. Observation of wholesome rules of exercise, rest, etc., helps maintain normal conditions of body and mind, the reverse of which, owing to neglect of said rules, so often makes the menstrual function visitation of dread and distress.

Disorders of Menstruation. — These include amenorrhea, dysmenorrhea, metrorrhagia, and metrorrhagia. Amenorrhea is an absence of the menstrual flow from some cause other than the pregnancy or the approach of the menopause (q.v.) or tardy establishment of the menstrual function. It is a symptom of anemia (q.v.) or may be due to a constitutional condition such as profound nerve-fag or tuberculosis. Straining, iron and ergot may be administered internally or the physician may apply local treatment. (See Dysmenorrhea.) Menorrhagia is an abnormally profuse flow during the menstrual period, due to one of several conditions. If not checked by rest, a physician is necessary as also in metrorrhagia, which is a sanguineous flow between the menstrual periods.

Mensural Music. Mensural or measured music is a term applied to a historical style of composition in which there are exact relations to each other in regard to length or time. Such a designation and the occasion for it may appear strange, as precise rhythm seems to belong to the essence of music. This, however, is not the case; there was a period when notes were not exactly measured, and mensural music is a subsequent development from this early practice.

All European music of a higher character
was originally cultivated in connection with speech or poetry. This is true of the music of the Greeks as well as the early Christian. But speech is not necessarily rhetorical. Ordinary speech is not so at all, and even poetry is not always characterized by the exact time relations typical of strictly measured music. A trochee can be delivered either in two or three part time, the accented syllable matching the unaccented in duration or requiring double or much time. And in impassioned utterance rhetorical relations are apt to be lost sight of altogether. Moreover, any rhythm which the accompanying tones may possess would be theirs only by virtue of the words to which they are added; it would be a rhythm of the poetry, not of the music.

Such was the case in Greek music. Although instrumental performances were also in vogue among the Greeks, music with them, as we have said, was primarily vocal. We know little of its exact character, but are probably justified in regarding it as a species of recitative, the words guiding the course of the tones. In the earliest fixed type of the art was the Ambrosian chant, formulated by Saint Ambrose of Milan in the 4th century. This, too, was similar to Greek music in its adherence to the rhythm of the words. A change was wrought by Pope Gregory the Great, two centuries later. What distinguishes his chant from the Ambrosian is supposed to be the uniform length of its tones, giving it a character similar to that of our choral. However, this is probably true only in part. According to the historian Ambros, the length of the chant which were sung by many voices may have been measured and regular, but the utterances of the priest must have retained much rhetorical variety. The real difference is formulated by him as follows: "The Ambrosian chant was based essentially on the poetical metre, the Gregorian on the musical." Whatever the exact nature of the difference, however, there is no doubt that Gregory effected a liberation of the tones from the rhetorical shadow of the words. And this was a gain of far-reaching importance. Music had now won its independence, and the way was prepared for the development of mensural composition.

The more immediate occasion for this development was the introduction of harmony. Just as music had primarily been vocal, so also it had been unisonal in character. Though a second tone may occasionally have been added to the principal part, nothing like the later polyphony was attempted. In the 9th century, however, the so-called Organum of Hucbald makes its appearance. In this the theme is systematically accompanied by one, two or three other voices, singing intervals of a fourth, fifth and octave in parallel motion. The point was now reached beyond which no further advance was possible without an exact designation of the length of the notes. As long as the singing had been confined to a single person this was not necessary. Nor was it necessary in the case of parallel parts, the so-called "organum" which the length of the notes was regulated by the natural accent of the words, or if all the tones were of equal length. In the Organum, however, a certain care was already required. The singers had to stand so that they could see as well as hear each other, and one among them acted as leader, introducing the new notes at the proper moment. The Organum now developed in various directions. There was a more independent progression of parts, contrary alternating with parallel motion, and the tones no longer coincided with each other note for note, but one voice sang two or more tones while the other sang one. Manifestly this required an understanding as to the relative duration of the tones, and a method of designating the differences graphically. The first person to formulate the solution of this problem was Franco of Cologne, who lived about the year 1200. Previous to him tones of two lengths, the longa and brevis, had already been recognized. He also admitted the duplex longa or maxima,— twice as long as the longa, and the semi-brevis,— half as long as the brevis. The notes in question were represented as follows:

maxima

longa

brevis

semi-brevis

Rests were also indicated by Franco, by means of appropriate signs. The bar-line was not yet in use, but measure was recognized, being at first confined to triple or "perfect" time. Duple or "imperfect" time was only permitted at a later date.

There were many complexities in the system as promulgated by Franco and his followers. Thus the length of the notes was not only determined by their own character and appearance, but also depended on the neighboring notes. There were also "inversions," "prolapses" and "ligatures," but space will not permit us to enter into all these involved details, which have only a remote historical interest. The rules governing mensural music were further elaborated—among other writers—by Marchettus of Padua, who lived about a century after Franco; and Jean de Muris, a celebrated theoretician of the 14th century. Notes of shorter duration were gradually introduced, such as the minima, semiminima, fusa and semisemis, and the notation too was modified, until it finally assumed the appearance to which we are accustomed to-day. Together with the Organum, mensural music furnished the basis for all subsequent advances in the art. It was the indispensable prerequisite for the growth of rhythmic and contrapuntal variety. It made possible the wonderful development in part writing which was soon to take place in the Netherlands, and which was eventually to lead to the glories of modern instrumental and choral music. In fine, it may be regarded as one of the two or three great elementary contributions to the art, on which the dazzling superstructure of modern beauty and inspiration has been erected.

Author of "The Basis of Musical Pleasure," etc.

MENSIURATION. Mensuration is that branch of applied mathematics which treats of the metrical relations of geometric figures, in particular of the length of lines, the magnitude of plane and solid angles, the area of surfaces and the volume of solids. The term is used both for the act and for the art of measuring geometric magnitudes. Mensuration is not usually treated as a separate branch of math-
Mensuration, but occurs as an integral part of various subjects, such as plane geometry, solid geometry, trigonometry and integral calculus. For a discussion of the measurement of plane, dihedral, spherical and solid angles and of the relations between the sides and angles of a triangle (plane or spherical) the reader is referred to the article on Trigonometry. The present article will give formulas for lengths, areas and volumes of the simpler and the regular figures and methods of approximation for the more complex or irregular figures.

The measure of a geometric magnitude is its ratio to a fixed magnitude of the same kind selected as the unit of measurement. Throughout this article the unit of area is assumed to be a square each side of which is equal to the unit of length, and the unit of volume is a cube whose edges are likewise of unit length. The purpose of a formula is to show how one of these numbers (ratios) may be found from certain others which are supposed to be known or obtainable. Thus formula (XIX) says that the ratio of the area of a circle to that of a square each side of which is a foot long (that is, the area of the circle measured in square feet) may be obtained by multiplying together the ratio of the circumference to the unit of length known as a foot, the ratio of the radius to the same unit of length, and the number \( \frac{1}{2} \).

It is important to recognize that in using any formula the units must all be of the same system. The number of acres in a field cannot be found directly from formula (X) by multiplying together the number of rods in two adjacent sides; this would give the number of square rods in the field. Nor is the number of gallons in a barrel given by formula (LXV) when the radii are measured in feet or inches, but the number of cubic feet or cubic inches, as the case may be. In order to change any measure from one system of units to another the following table may be found useful:

<table>
<thead>
<tr>
<th>To change</th>
<th>Multiply by</th>
<th>Inverse</th>
</tr>
</thead>
<tbody>
<tr>
<td>in. to cm.</td>
<td>2.54998</td>
<td>0.393704</td>
</tr>
<tr>
<td>ft. to m.</td>
<td>0.30480</td>
<td>3.28087</td>
</tr>
<tr>
<td>miles to km.</td>
<td>1.60934</td>
<td>0.62137</td>
</tr>
<tr>
<td>sq. in. to sq. cm.</td>
<td>0.0007854</td>
<td>1296.0</td>

<td>0.000264150</td>
<td>3785.238</td>
</tr>
</tbody>
</table>

(in. = inches, ft. = feet, yds. = yards, sq. = square, cu. = cubic, m. = meters, cm. = centimeters, km. = kilometers).

(For other multipliers see Weights and Measures). The second column of figures serves to change the unit in the opposite way to that indicated by the rest of the table: thus to change meters to feet multiply the number of meters by 3.28087; for instance, 10 meters is equal to 32.8087 feet.

In many cases the computation of area or of volume may be accomplished most easily by mechanical means. For the measurement of the area of plane figures ingenious and effective instruments known as planimeters have been invented. Two historic instances are the finding by Galileo of an approximate value for the area of a cycloid by cutting it out of a sheet of copper and weighing the model, and the discovery by Archimedes of a fraud in Hiero’s new crown through measuring its volume by submerging it in water and measuring the water displaced. To apply this last method, multiply the number of ounces of water by 1.73, or less accurately by \( \frac{7}{4} \), and the result will be the number of cubic inches in the object; or, measure directly the volume of the water displaced.

**Length of Lines.**

**Circle.** The circumference of a circle is equal to the diameter multiplied by 
\[
3.14159265358979323846264338328 \ldots
\]

This constant is usually denoted by the Greek letter \( \pi \) (pi) and is approximately equal to 3.1416.

Use the first if an error of one two-thousandth of the final result may be neglected, and the last if an error of one four-hundred-thousandth is negligible.

The above theorem may be written
\[
l = \pi d, \quad l = 2\pi r,
\]
where \( l \) = length of circumference, \( d \) = diameter and \( r \) = radius.

The length \( l \) of the arc \( AMB \) in Fig. 1 is which \( MD \) is the perpendicular at the middle point of the chord \( AB \), \( AE \) is tangent to the circle at \( A \) or perpendicular to the radius \( OA \). \( OE \) is perpendicular to \( AM \), the chord of half the arc or the angle \( AOE \) is one-fourth of the angle \( AOB \), may be found by any one of the formulas
\[
l = \frac{\pi}{180} dr, \quad \frac{\pi}{180} \approx 0.017453
\]

\[ l = c + \frac{5}{3} \frac{h}{c}, \]
\[ l = 2k + \frac{1}{2}(2k - c), \]
\[ l = (k - c), \]
\[ l = s + \frac{h}{c}, \]
\[ l = \frac{1}{2}s, \]
in which \( d \) = number of degrees in the angle \( AOB \), \( r \) = radius \( OA \), \( c \) = chord \( AB \), \( h \) = height \( MD \), \( k \) = chord of half the arc \( AM \), \( t \) = length of \( AE \), and \( s \) = length of \( BE \). Formulas (III), (IV) and (V) are only approximate, the error being small only if the angle \( AOB \) or the ratio of \( h \) to \( c \) be small. Thus for an angle of \( d = 90^\circ \) the arc is 1.5708 \ldots, whereas formulas (III), (IV) and (V) give 1.576 \ldots, 1.5696 \ldots, 1.572 \ldots, respectively.

**Fig. 1.**

of \( AE \), and \( s \) = length of \( BE \). Formulas (III), (IV) and (V) are only approximate, the error being small only if the angle \( AOB \) or the ratio of \( h \) to \( c \) be small. Thus for an angle of \( d = 90^\circ \) the arc is 1.5708 \ldots, whereas formulas (III), (IV) and (V) give 1.576 \ldots, 1.5696 \ldots, 1.572 \ldots, respectively.
MENSURATION

Parabola.—The length \( l \) of the arc \( AVB \) of the parabola in Fig. 2 is

\[
l = \sqrt{y' + 4x} + \frac{y'}{2} \left( \log \frac{2x + \sqrt{y' + 4x}}{y} \right),
\]

where \( x = VD \), \( y = AD \), and the logarithm is taken to the base \( e \).

\[\text{Fig. 2.}\]

Ellipse.—The length \( l \) of the circumference \( ABA'B' \) of ellipse in the next figure (Fig. 3), in which \( F \) and \( F' \) are the foci (\( OF = BF = \frac{1}{2} \text{OA} \)), is

\[l = 2a \left( 1 - e^2 - \log \frac{1 + e}{1 - e} \right),\]  
VII

or approximately

\[l = \pi \sqrt{a^2 + b^2},\]  
VIII

where \( e \) is the eccentricity \( \frac{OF}{OA} = \frac{1}{a} \sqrt{a^2 - b^2} \).

\( a = OA \), one-half the longest diameter; \( b = OB \), one-half the shortest diameter; \( d = AB = \sqrt{a^2 + b^2} \).

\[\text{Fig. 3.}\]

General Methods of Approximating the Length of Any Curved Line.—Divide the line into parts each of which differs but little

from a small circular arc. Then each portion may be found by any one of the formulas (III), (IV) or (V). A convenient method for the

use of formula (IV) is indicated by the diagram herewith (Fig. 4) and formula (IX). The only restrictions upon the location of the points 1, 2, 3, 4, \ldots, in addition to that given above is that the odd-numbered ones must be half-way between the others and that there should be an odd number of points in all.

\[l = (a1 + 12 + 23 + \ldots) + \frac{1}{2}[(a1 + 12 + 23 + \ldots) - (a2 + 24 + 46 + \ldots)].\]  
IX

Area of Plane Figures.

Rectangle.—The area \( a \) of a rectangle, the lengths of two adjacent sides of which are \( b \) and \( c \) respectively, is

\[a = bc.\]  
X

Triangle.—The area \( a \) of the triangle \( ABC \) (Fig. 5) is

\[a = \frac{1}{2}bh,\]  
XI

\[a = \frac{1}{2}bc \sin A,\]  
XII

\[a = \sqrt{s(s-a)(s-b)(s-c)},\]  
XIII

or

\[a = \frac{1}{2}bs \sin \frac{A}{2} \sin \frac{B}{2} \sin \frac{C}{2},\]  
XIV

where \( a, b, c \) are the lengths of the sides \( BC, CA, AB, \) respectively; \( h \) is the perpendicular distance (height) of \( B \) from \( AC \); \( s \) is one-half of the sum of the sides:

\[s = \frac{1}{2}(a + b + c).\]

If one angle of the triangle (say \( A \)) is a right angle, both formulas (XI) and (XII) simplify; namely, the area is one-half the product of the area of the two sides which enclose the right angle (\( a = \frac{1}{2}bc \)). For a simple method of finding the area of an equilateral triangle, \( (a = b = c) \) multiply the square on one side by \( \frac{1}{2} \) \((a = \frac{1}{2}b, \text{approximately}), \text{see formula (XVIII)}.\)

\[\text{Fig. 5.}\]

Parallelogram.—The area \( a \) of the parallelogram \( ABED \) (Fig. 5) is

\[a = dh,\]  
XV

or

\[a = cd \sin D,\]  
XVI

where \( c \) and \( d \) are the lengths of two adjacent sides, \( D \) is the angle between them, and \( h \) is the perpendicular distance between the two parallel sides whose length is \( d \).

Trapezoid.—The area \( a \) of the trapezoid \( CBED \) (Fig. 5), any four-sided figure with two of the opposite sides \( (BE \text{ and } DC) \) parallel, is

\[a = \frac{1}{2}(d+e),\]  
XVII

where \( h \) is the perpendicular distance between the two parallel sides and \( d \) and \( e \) are the lengths of the parallel sides \( (d = BE, e = DC) \).

Regular Polygon.—The area \( a \) of a polygon bounded by \( n \) equal sides each of length \( s \) and having its \( n \) angles all equal is

\[a = ns^2 \cot \frac{180^\circ}{n},\]  
XVIII

from a small circular arc. Then each portion may be found by any one of the formulas (III), (IV) or (V). A convenient method for the
The following table gives (approximately) the value of the multiplier in the simpler cases:

<table>
<thead>
<tr>
<th>NAME</th>
<th>( n )</th>
<th>( n ) ( \cos 180^\circ ) ( \approx \frac{1}{n} )</th>
</tr>
</thead>
<tbody>
<tr>

<td>12</td>
<td>1.00000</td>
</tr>
</tbody>
</table>

Thus, for instance, if the side of a regular hexagon be 9 feet, its area is \( 81 \times 2.59808 = 210.4445 \) feet.

Irregular Polygon.—The area of an irregular polygon may be found by dividing it into parts each of which is a triangle, parallelogram, rectangle, or trapezoid. Thus if we draw a system of parallel lines across the polygon, one through each vertex, each part will be a triangle or trapezoid and its area may be found by formulas (XV) or (XVI).

Circle.—The area \( a \) of a circle, whose radius is \( r \) and whose circumference is \( l \), is

\[
a = \frac{1}{2}lr, \quad (XIX)
\]
or

\[
a = \pi r^2, \quad \pi = 3.1416 \approx \frac{22}{7} \quad \text{(nearly)}. \quad (XX)
\]
The area \( a \) of the sector OAMB (Fig. 1), in which \( l \) is the length of the arc \( AMB \) and \( d \) is the number of degrees in the angle \( AOB \), is

\[
a = \frac{1}{2}lr, \quad (XXI)
\]
or

\[
a = \frac{\pi}{90}dr, \quad \pi = \frac{0.34906585}{90} = \frac{\pi}{90} \quad \text{(nearly).} \quad (XXI)
\]
The area \( a \) of the segment \( AMBD \) (Fig. 1) is

\[
a = \frac{1}{2}ch = \frac{1}{2}d \quad (XXII)
\]
or

\[
a = \frac{1}{2}ch \quad \text{(approximately),} \quad (XXIII)
\]
where \( r, l, c, h, d \) have the same meanings as in formulas (II), (III), (IV) and (V).

Parabola.—In Fig. 2 the area \( a \) of the segment \( VABD \) with base \( AB = 2y \) and height \( DVD = x \) is

\[
a = \frac{1}{2}xy. \quad (XXV)
\]

Ellipse.—In Fig. 3 the total area \( a' \) of the ellipse \( ABA'B' \), of which the length of the longest diameter \( AA' \) is \( 2a \) and the length of the shortest diameter \( BB' \) is \( 2b \), is

\[
a' = \pi ab, \quad \pi = 3.1416 \quad (XXVI)
\]

General Methods of Approximation.—Any plane area can be divided into parts each of which is a rectangle or differs from a rectangle in that one side is a simple curve as in Fig. 6. It is therefore sufficient to give methods by which an area, such as \( ABA' \) following, may be measured.

1. The Trapezoidal Method.—Divide the base line \( AB \) into any number of equal parts, \( AP, PQ, QR, \ldots, TB \) and erect the perpendiculars \( PP', QQ', \ldots, TT' \). Then if each portion \( A'P, P'O, \ldots, T'B' \) of the curve \( A'B' \) is nearly coincident with its chord, the area \( a \) is

\[
a = \frac{1}{2}(AA' + BB') \cdot \frac{1}{n} \cdot \left( QO' + SS' + \ldots \right) \quad (XXVII)
\]

2. Simpson's Rule.—Divide the base line into any even number of parts (in Fig. 6 it is divided into six parts); erect the perpendiculars as before. Then

\[
a = \frac{1}{3} \cdot \left(AA' + BB' + 2(OQ' + SS' + \ldots) + 4(PP' + RR' + TT' + \ldots) \right). \quad (XXVIII)
\]

3. Weddle's Rule.—Divide the base into exactly six equal parts (as in Fig. 6), then

\[
a = \frac{1}{18} \cdot \left( AP + PP' + RR' + TT' + AA' + QQ' + SS' + BB' \right). \quad (XXIX)
\]

Surface and Volume of Solids.

Prism.—This includes any solid two of whose faces, known as the bases, are equal polygons situated in parallel planes and all the other faces, the lateral faces, are parallelograms. Thus in the following diagram (Fig. 7) the polygons ABC... and A'B'C'... are the bases and the parallelograms AAB'B', BB'C'C'... are the lateral faces. The edges A'A', B'B', C'C'... are the lateral edges. The polygon UVW... lying in a plane perpendicular to one, and so to all, of the lateral edges is called a right section. The right section is equal to the base if and only if the lateral edges are perpendicular to the base.

For the lateral area \( a \) which is the sum of the lateral faces AAB'B', BB'C'C'..., and the volume \( v \) of a prism we have the formulas

\[
a = e(\overline{UV} + \overline{VW} + \ldots), \quad (XXX)
\]
\[
v = es, \quad (XXXI)
\]
\[
v = hb, \quad (XXXII)
\]
in which \( e = \text{length of a lateral edge} \ (A'A' \text{ or } B'B' \ldots), \ s = \text{area of a right section} \ (UVW \ldots), \ h = \text{height, i.e., distance between bases}, \ b = \text{area of a base}. \]

The volume \( v \) of a truncated triangular prism, that is one with three lateral faces and
whose bases are not parallel (therefore the length $a$, $e$, and $f$ of the lateral edges are not equal) is

$$v = bh(e + e + a).$$

(XXXIII)

Any truncated prism may be divided into truncated triangular prisms and its volume thus found. For a four-sided prism whose opposite lateral faces are parallel this gives

$$v = \frac{1}{3}(e + e + e)s,$$

(XXXIV)

where $e$, $e$, $e$ are a pair of opposite edges.

Cylinder.—This includes any solid having two bases which are equal plane figures bounded by curved lines (such as circles, ellipses or irregular figures), and situated in parallel planes, and the rests of the surface of the solid such that it may be thought of as consisting of an infinite number of parallel straight lines.

If we call the length of each of these (equal) parallel lines $e$, the formulas for the prism given above (XXX, XXXI, XXXII) apply also to the cylinder, namely, the lateral area $a$ and the volume $v$ are

$$a = \pi e,$$

(XXXV)

$$v = \pi es,$$

(XXXVI)

$$v = \pi hb,$$

(XXXVII)

where $p$ is the length of the boundary, and $s$ is the area of the section of the cylinder by a plane perpendicular to one of the lines lying on the lateral surface.

If the right section of a cylinder be a circle, the base, unless a circle, is an ellipse and its area is found by formula (XXXVI). If in such a circular cylinder the bases are not parallel and the distance between the centres of the bases is $l$, then the area $a$ and the volume $v$ are

$$a = \pi rl,$$

(XXXVIII)

$$v = \pi l,$$

(XXXIX)

where $r$ is the radius of the right section. These formulas are equivalent to (XXXV) and (XXXVI) when the bases are parallel, since then $l = e$.

Pyramid and Cone.—The volume $v$ of any solid, such as those in Fig. 8, whose surface consists of a base, which is a plane figure of any kind, triangle, polygon, circle, ellipse, etc., and of triangles or curved areas which may be thought of as composed wholly of straight lines, joining the boundary of the base to some point (the vertex) not in the same plane as the base, is

$$v = \frac{1}{3}bh,$$

(XLII)

where $b$ is the area of the base and $h$ is the perpendicular distance (height) of the vertex from the plane of the base.

For a right circular cone, that is one in which the base is a circle and the line joining the vertex to the centre of the base is perpendicular to the plane of the base, the area $a$ of the curved (lateral) surface is

$$a = \pi re,$$

(XXXIII)

$$\pi = 3.1416$$

where $r$ is the radius of the base and $e$ is the distance from the vertex to any point in the circumference of the base.

Prismatoid.—The volume $v$ of any solid, whose total surface consists of two plane figures (the bases), of any character whatever, lying in parallel planes, and a lateral surface made up of triangles, trapezoids, or curved portions which may be thought as made up of straight lines joining the boundaries of the bases, is

$$v = \frac{1}{3}(b_1 + b_2 + 4m),$$

(XLIV)

where $h$ is perpendicular distance (height) between the bases, $b_1$ and $b_2$ are the areas of the bases, and $m$ is the area of a section of the solid by a plane parallel to and half-way between the planes of the bases; or

$$v = \frac{1}{3}(b + 3p),$$

(XLV)

where $b$ is one of the bases and $q$ is the area of a section parallel to and two-thirds of the way from that base to the other.

Solids of Revolution. Sphere.—The area $s$ of the surface and the volume $v$ of a sphere of radius $r$ are

$$s = 4\pi r^2,$$

$$4\pi = 12.56637 \ldots$$

(XLVI)

$$v = \frac{4}{3}\pi r^3,$$

$$4\pi = 4.18879 \ldots$$

(XLVII)

The volume $v$ and lateral area $a$ of a segment of a sphere (that is the part lying between two parallel planes) are

$$v = \frac{\pi}{6}[h(3r + 3r^2)],$$

$$\pi = 0.5236 \ldots$$

(XLVIII)

$$a = 2\pi hr,$$

(XLIX)

where $h$ is the height of the zone (perpendicular distance between the parallel planes of the bases), $r_1$ and $r_2$ are the radii of the bases respectively, $r$ is the radius of the sphere.

Spheroid.—For a prolate spheroid, that is the solid formed by revolving an ellipse about its longest diameter (in Fig. 3, about $AA'$), the area $s$ of the surface and the volume $v$ are

$$s = 2\pi \left(\frac{a}{b} + \frac{ab}{\sin\phi}\right),$$

(L)

or

$$s = 2\pi b(b + fa),$$

(approximately)

(LI)

where $a$, $b$ and $e$ have the same significance as in (VII) and (VIII) and

$$f = 1 + \frac{a^2}{b^2} + \frac{a^2}{e^2} + \frac{b^2}{e^2} + \frac{b^2}{e^2} + \ldots,$$

in which $e = 1 - \frac{b}{a}$. Or less accurately

$$s = \frac{\pi}{3}[7a + b(6 - \frac{b}{a})],$$

$$\frac{\pi}{3} = 1.0472;$$

(LII)

$$v = \frac{4\pi}{3} abh,$$

$$\frac{4\pi}{3} = 4.18879 \ldots$$

(LIII)

The volume $v$ of a segment of a prolate spheroid (part cut off by a plane perpendicular to the axis of revolution) the height of which is $h$, is

$$v = \frac{\pi}{3} \frac{bh}{a^2}(3a - h),$$

$$\frac{\pi}{3} = 1.047198 \ldots$$

(LIV)

For an oblate spheroid, that is the solid formed by revolving an ellipse about its short-
Mental Defectives — Mental Diseases

est diameter (in Fig. 3, about \(BB'\)) the corresponding formulas are

\[
S = \pi \left( 2a + \frac{b^2}{v} \log \frac{1 + e}{1 - e} \right),
\]

(LV)

or

\[
S = 2\pi \left( a + \frac{b^2}{v} \right),
\]

(LVI)

where

\[
\frac{a}{4} + \frac{b^2}{v} + \frac{d+e}{v} + \frac{d^2}{v} + \frac{d^3}{v} + \cdots
\]

in which

\[
d = 1 - \frac{a^2}{b^2}
\]

(VII)

\[
v = \frac{4\pi}{3} \frac{d}{a^3}, \quad \frac{4\pi}{3} = 4.18879 \ldots
\]

(LVIII)

The volume \(v\) of a segment of an oblate spheroid is

\[
v = \frac{\pi}{3} \frac{h^3}{a^2} (3b - h),
\]

(LVI)

Paraboloid.—The volume \(v\) of the solid formed by revolving \(VAD\) in Fig. 2 about \(VD\) as an axis is

\[
v = \frac{\pi}{2} \frac{a}{2}, \quad \frac{\pi}{2} = 1.5708 \ldots
\]

(LIX)

which is just one-half the volume of the circumscribing cylinder.

The General Solid of Revolution.—The volume \(v\) of the solid formed by revolving any curve about a line lying in the same plane and not intersecting it, for instance by revolving \(A'B'B'A\) in Fig. 6 about \(AB\) as an axis, is

\[
v = \frac{\pi}{3} \int \frac{d^3}{a^3} + \int \frac{b^2 + 2(c^2 + \cdots)}{d^3} + \cdots
\]

(LX)

Or, as it is perhaps usually easier to measure the circumferences of the circles generated by \(P'Q'\), etc., than to measure the circumferences generated by \(A'B'\), \(P'Q'\), etc., if we denote the circumferences generated by \(A'B',\ P'Q',\ \ldots,\ B'\) by \(a,\ b,\ c,\ \ldots,\ b\), respectively, the above formula may be written

\[
v = \frac{1}{12\pi} \int \frac{d^3}{a^3} + \int \frac{b^2 + 2(c^2 + \cdots) + \cdots}{d^3} + \cdots
\]

(LXI)

The Regular Solids.—The area of the surface and the volume of the five regular solids may be found by means of the multipliers given in the following table:

<table>
<thead>
<tr>
<th>Name</th>
<th>Area ((\text{edge})^2) (X)</th>
<th>Volume ((\text{edge})^3) (X)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tetrahedron</td>
<td>1.7320508</td>
<td>1.178511</td>
</tr>
<tr>
<td>Cube</td>
<td>0.6</td>
<td>1.</td>
</tr>
<tr>
<td>Octahedron</td>
<td>3.4440106</td>
<td>1.4774043</td>
</tr>
<tr>
<td>Dodecahedron</td>
<td>2.0647758</td>
<td>1.763189</td>
</tr>
<tr>
<td>Icosahedron</td>
<td>3.0602540</td>
<td>2.1816930</td>
</tr>
</tbody>
</table>

(Genral Method.—The volume of solids which do not come under any of the types treated above may be measured by an application of the prismoidal formula (XLIV). Let \(a,\ a_0, a_m, a_0 \ldots, a_m, a_{m+1}\) be the areas of a set of plane sections parallel to a suitably chosen base and dividing the solid into an even number (2m) of portions; \(a, a_0, \ldots, a_m\) being the areas of sections (that is, the solid lies wholly between \(a, a_0, a_m\) and \(a_{m+1}\)). The distance between consecutive cutting planes is to be the same throughout and to be taken so small that between the odd-numbered sections the solid is approximately a prismoid. The area of a section may be found by surrounding it by a rectangle and measuring (by XXVII, XXVIII or XXIX) the portion of the rectangle outside of the section. If the distance between the sections \(b\), then

\[
v = \frac{4\pi}{3} a(a_{m+1} + 2(a_0 + a_m + \ldots) + \ldots)
\]

(LXII)

Barrel.—If \(d\) be the inside diameter of the end of a barrel, \(e\) the inside diameter at the middle, and \(f\) the length (or height) of the barrel, then the prismoidal formula (XLIV) gives as the volume \(v\)

\[
v = \frac{\pi}{3} \frac{d^3}{2} + \frac{e^3}{2}, \quad \frac{\pi}{2} = 0.5236.
\]

(LXIV)

The following is said to be a better approximation:

\[
v = \frac{\pi}{6} \left( \frac{d^3}{2} + \frac{e^3}{2} \right), \quad \frac{\pi}{6} = 0.349.
\]

(LXV)

The volume \(v\) of the smaller portion of a partly filled barrel, that is, of the contents if the barrel is less than half full and of the empty portion if it is more than half full, is

\[
v = 0.000472(d^3 + a + \ldots)
\]

(LXVI)

where \(h\) is the distance of the surface of the contents from the nearest end, \(a\) is the diameter at the surface of the contents, and \(b\) is the diameter half-way between the surface and the nearest end.

William Findlay

Mental Defectives. See Children, Defective; Education of Feeble-Minded or Mental Defectives.

Mental Diseases. These are diseases which show themselves in alteration of conduct or behavior. They are faulty adjustments within the individual which, due to faulty mental functioning, interfere with social values mutually agreed upon by particular groups. Large or small. Such faulty mental functioning may be brought about by a vast variety of causes and be contributed to by a variety of defects or disturbances in many parts of the body. Mental disease may come and go, just as any other type of disease, and mental disease may be due, most frequently is due, to disorders primarily located in other parts of the body than the brain, although a mental disease means that the guiding function of the body as a whole, i.e., the mental functioning, is disturbed by faulty brain functioning.

A mental disease, therefore, only means that the adjustment of the individual as a whole,—the personality,—to his social environment is sufficiently disturbed to interfere with the well-being of that personality. It is primarily because such faulty adjustment tends to exclude the sick individual from his fellow-men,—the group or society,—that mental disease is so much feared by the individual and is looked upon with dread and superstitious awe by the folk in general. In general it may be said that there are two aspects or trends of behavior exhibited by the individual in his reactions to his environment, conscious and unconscious, and so there are two attitudes to be reckoned with in problems of mental disorders. If a man's tongue is cut out he cannot speak, and there are times when he apparently cannot speak, even though he has a whole tongue. Maybe his muscles are paralyzed. That may be
due to some change either in the nerve pathways leading to or from the brain which permit speech, or in the part of the brain to which these nerve pathways lead or in some other part. An attempt has been made to locate the part of the nervous system affected by means of the behavior of the man who cannot speak, both his actions in the use of his voice and his other actions. For, because of the close interaction of all parts of the human being, certain types and groups of behavior will generally be found connected, for instance, a man's inability to speak is due to some affection of the nerves between tongue and brain, there will be certain other physical symptoms, but if it is due to an improperly functioning centre in the brain, some other anatomically more distant activity will be affected. Thus a morbid area at the periphery might affect only one nerve, but if nearer to the centre it might affect two or more nerves, while directly at the centre it might affect all the nerves emanating from that centre and the activities regulated by the disinclined nervical, but is also mental, while the means we have of perceiving that behavior are exclusively physical. That is, the expression of some other person's mind can be reported to me only through the physical actions of others. In man as perceived by me. From this it appears that the diseases known as mental may be the beginning of a process which starts in purely mental conditions or the end of one which starts in purely somatic conditions. Physical traumas may indeed be the result of a lack of co-ordination due to defects of nerve function which in turn may be due to a mental conflict. Adler has brought out the fact that a very unfortunate series of physical injuries to the eye of one patient were the result of a maladaptation in co-ordination of such a nature that the reflex actions that generally operate to protect the eye did not work in this case. From this he deduces his theory of organ inferiority, an interesting corollary to some of the theories of the analysts of psychology. If the condition of this patient did not permit the usual reactions he would not necessarily be awkward because of an unconscious wish, as is the supposition of the majority of psychoanalysts. If a man has an incurable disease of bodily causes, which have been acting for some time, it is most likely that some or all of them will have manifested themselves before the time of the manifestation of the mental disease, and that the presence of these somatic symptoms will be associated with the mental disease and regarded as its causes. But if, on the other hand, the mental disease is itself the beginning and not the end of the process, it will require much more subtle tests to discover it, particularly in its earlier stages. It will be, too, of the utmost importance to detect, as early as possible, these beginnings which are manifested both in mental and in physical behavior, in order that remedial or preventive measures may be adopted at the earliest possible moment. If the diseases of other bodily functions it is the preventive measures that are the most productive of good results. The greatest strides in making a decrease in mental diseases, as well as in those disorders thought not to be bodily not greatly affecting the mental functions, come from taking the disorder in hand as soon as possible. Thus it would be most desirable to have teachers in all schools equipped with a means of detecting very early those early signs of later mental disorders which, although at present extremely elusive, are yet gradually, day by day, becoming clearer through analyses. Those in charge of the young should be the first to observe signs of a possible subsequent mental weakness, even in children apparently normal, and should be in a position to advise parents and guardians by offering the deleterious factors in the child's environment. It is furthermore increasingly clear in what manner the overloading of the nervous system can produce not only mental disease, but, through the effect of the conflict between physical requirements and physical constitution (an effect which is believed to take place in the nerve cells themselves), this overloading of the nervous system produces disorders in the physiological processes, and may therefore in the end produce what has been called an organic arise, namely, an alteration in the manner of working of one or more organs of the body, a condition which sooner or later undermines the general health.

It is noteworthy that a classification of mental diseases based on their relation to physical factors is not satisfactory, for the reason that the disturbances in mentality are not always found associated with lesion or degeneration of any or all parts of the brain and nervous system. In other words, a brain and nervous system which to all tests now applicable prove perfect in every respect may be found in the case of a person whose reactions to environment have been so unsatisfactory in adaptability that he has not been able to act his part in society, which has had either to support him as an otherwise harmless dependent or confine him as a destructive element. From this point of view the modern attitude toward mental disease is that it is a regression, whether from physical or psychological causes, to the condition of a more infantile or primitive type of mentality. It is recognized that the actions of the child resemble those of an earlier grade of human society, such as was the maximum of development in prehistoric ages; furthermore, that the child is not an individual to an environment which is daily becoming more and more complex are demanding of the individual a much more delicate adjustment and adaptation. Whether the failure to adapt is caused solely by a physical lack in the make-up of the cerebral and neural constitution is beyond the present power of physiology and histology to determine. It is therefore quite as useful to classify mental diseases purely from the mental standard, providing, however, that already a certain degree of classification can be made. The discoverable lesions in the neural substance be not ignored. Therefore the present tendency in neurology is to make an analysis upon a purely psychological basis, namely, the mental mechanisms (q.v.) which have been observed to obtain both in the unconscious and in conscious life. It is now known that a phobia, or sudden unreasonable and excessive fear of some definite thing such as snakes, thunderstorms, knives, dogs, horses or what not, is neither to be explained on any conscious basis nor re-
moved by an appeal to reason or to consciousness alone. Similarly the habits of mind named obsessions or compulsions are amenable neither to drugs nor to the conscious adjurations to forget them or avoid them, but only to the education of the character through the freeing of the intellect of the taint of the diseased and habitual habit.

Classification.—Almost every alienist of repute has attempted a classification of the forms of insanity. The subject is one of peculiar difficulty, owing largely to the fact that our intimate knowledge of many of these various forms is far from complete.

A scheme of classification adopted by Jelliffe and White regards the diseases of the nervous system as falling into three general classes: (1) Those of the physico-chemical systems, affecting the neurology of metabolism, and expressed in visceral neuropathology and diseases of the glands with internal secretions; (2) those of the sensory-motor systems, including affections of the cranial nerves, the peripheral neurones, the spinal cord, medulla, cerebrum and cerebral system; and those expressing the pathology of the nervous system itself; and (3) those of the psychical or symbolic systems (neuroses, psychonuroses and psychoses). The last contains the manic-depressive group, the paranoia group, hysteria, dementia paralytica, exhaustion and toxic psychoses and those associated with organic diseases, with senility, arteriosclerosis, and finally idiocy, imbecility and feeble-mindedness.

A more detailed elaboration of this appears as the 1918 classification of the American Medico-Psychological Association. The methods of examination of the nervous system include a questionnaire covering the family history of the patient and his illnesses, and an elaborate physical examination of the vegetative nervous system, of the sensory and motor systems, followed by a thorough mental examination which in many respects is somewhat similar to the questions of the intelligence tests and qualification tests of the army. The alienist comes in contact with a great many diseases whose mental element is no greater in fact than that of the so-called physical diseases. The disorders in the physico-chemical systems produce diseases with mental aspects, but aspects no more mental than those of the diseases affecting the organs, muscles, glands, etc., to which those nerves go. It is only when we come to what are called the neuroses that we find mental behavior alone or predominantly disordered. These affections were called neuroses or nerve troubles on the supposition once accepted that the mental behavior was caused exclusively by some peculiarity, whether called abnormality or merely variation, in the structure of the nerve cells themselves. At the present time, however, scientific thought tends toward the theory that mental disease is determined by the loss of balance between the organism and its physical and psychical environment. Thus there are nervous systems congenitally so weak that they are practically disintegrated by the conflict of the physical and psychical, a conflict which is as often as not, absolutely unconscious, and which occurs in the simplest and least complicated social environment. In such natures mental disease at once appears because of the individual’s inability to adapt himself to the rudimentary requirements imposed upon him from without. On the other hand, there are neural constitutions so strong or elastic that they are equal to a very severe strain of adaptation even to extraordinarily complicated environment. Such constitutions will naturally adapt themselves, retaining their own personal equilibrium and health, to conditions which would completely upset a less strong or, less adaptable constitution. It may be here noted that the European War brought out many such diversities of neural constitution in those subject to “shell shock” or other war psychoses, together with improved methods for congenital neural weaknesses. These tests have resulted in putting in positions of less nervous strain those who are unable to stand the greater. A similar allotment of individuals to the various tasks of life would naturally result in less nervous disease. For it is evident, when both factors are taken into consideration, the constitutional factor and that supplied by the environment, that mental disease is largely a matter of proportion between the nervous system and its ancestry, with the slightest variation in the nervous system and, and thirdly of the psychical or symbolic systems (neuroses, psychonuroses and psychoses). The last contains the manic-depressive group, the paranoia group, hysteria, dementia paralytica, exhaustion and toxic psychoses and those associated with organic diseases, with senility, arteriosclerosis, and finally idiocy, imbecility and feeble-mindedness.

The role of the unconscious in the etiology of mental diseases is a dominant one, and the comparative indefiniteness of the limitations of the various types of mental disorders is due to the newness of any scientific knowledge concerning the unconscious portion of mental functioning. The neurologist should have, though unfortunately comparatively few do, as thorough a knowledge of the unconscious mental mechanisms as can be acquired, in addition to the medical specialist’s knowledge of anatomy, physiology and histology. Recognition of unconsciousness as a factor in the causation of mental disease requires the understanding that the present day unconscious is the direct descendant of the prehistoric consciousness. It is as if the human psyche were like the earth’s surface constructed in strata, the lowest of which was the earliest deposition; much, too, as if the conscious life of successive generations from the earliest human and animal life were retained in the psyche of the present day as are the annual rings of growth in the stems of trees. The part played by the conscious or unconscious mental factor in the vegetative or visceral physiology is less evident to the general student than that played by them in the sensorimotor systems or in the psychical or symbolic systems. Yet there are good reasons to suppose that even so serious a disease as pulmonary tuberculosis may be helped, if not cured, by the patient’s being taught how to secure control of the unconscious portion of his ego. The exciting causes for this disease, as well as for hysterical coughing and asthma, may lie either in the physico-chemical, the sensori-motor or the psychical level. The connection between the diseases of the glands of internal secretion, the thyroid, parathyroid, hypophysis, pineal gland, etc., and the manifest mental condition is shown in the case of cretinism and of
MENTAL DISEASES

exophthalmic goitre. In these diseases it is quite as likely that the cause is mental as that it is physical, and in such event, we should have to regard exophthalmic goitre as a symptom of a mental disease rather than the mental factors accompanying it as symptoms of the physical disease. Similarly the very widespread disorder, migraine, is possibly to be regarded as the projection upon a vegetative system, the vaso-motor, of a conflict which originates in the psychical level. Conflicts at the psychical level, which are usually caused by the adaptation to social environment, referred to above, may be projected upon the sensori-motor systems and produce retinitis, progressive facial hemiatrophy, various facial palsies, vertigo, auditory and visual aphasia, tic douloureux, sciatica, shingles and peripheral palsies, and other diseases, many of which were considered up to recent times to have only physical causes.*

But the conflict, conscious or unconscious, which occurs at the psychical or symbolic level of the ego is manifested in predominantly mental terms, since it has an incidence not upon the world of external reality, as is the case with the average person, but in the shape of work done in some shape or other. On the contrary the incidence of the libido falls upon the physiological functions themselves or upon certain of them through a variety of symbolic mediation. This process, which is known as hysterical conversion, produces very many so-called symptoms, mostly of a bodily nature. There results from this a large number of disorders which the general practitioner is to regard as having only a physical cause, and he prescribes drugs, which rarely have the desired effect. Possibly the commonest form of this is the hysterical headache, which is rarely recognized of psychogenic origin, although it is similar in the sociological respect to the "nine o'clock illness" of school children, who use this gentle form of unconscious malingering as a means for escaping their responsibilities. *An adult ought to make a call upon a recently bereaved friend." This is recognized as a distinct obli-

gation but the patient's infantile necessity of escaping reality and seeking pleasure makes the duty seem a very onerous affair. Thus arises a conflict between duty, born of conscious appreciation of the social obligation, and desire, born of the childish instinct of the necessary sacrifice of personal comfort. As a result the patient develops a headache and so, being ill, does not have to go. While the mechanism in other hysterical conversions is more complicated, it is no less clearly proved, so that the number of what are ordinarily taken as symptoms having a merely somatic cause, and which are through analysis seen to be merely hysterical conversions, is augmented daily. Disturbances of sensibility, such as hemianesthesia or insensitivity to touch and pain on one side of the body only, disturbances of motility such as choreiform movements, tics and certain occupation spasms, disturbances of speech, sometimes including stuttering, visceral disturbances showing vomiting and diarrhoea, vaso-motor disturbances and emotional disturbances, particularly the capacity for depression and fear, are all likely to be caused by the hysterical dissociation before mentioned, in which some mental factor is repressed and therefore driven without the pale of conscious control.

In compulsion neurosis there is no conversion, which implies a shifting of the incidence of the libido power from the external world, which is its natural goal, to the physiological processes of the individual; but there is another kind of shift, namely, from the external world to the mental states themselves. In this condition the numerous physical symptoms mentioned as being found in hysteria are generally absent, but their place is taken by variation from the conventional modes of thinking. Such variations to be sure are far from unpleasant, if they do not become too great, for they add much of piquancy and interest to a person's character. But when the departure from the conventional is excessive and both compulsive and unaccountable, the condition merits the term neurosis and requires treatment from the analyst. There are compulsive thoughts, compulsive doubts, fears, and rituals of dressing and undressing or eating for which this kind of neurotic can give no reason. He generally does not attempt to rationalize them but admits he does not know why he always has to act or think in his own peculiar way. Analysis has convinced Freud that "obsessions are always transformed reproaches, returning from repression, which always refer to a pleasurably accomplished sexual action of childhood" and that "the compulsive ways of thinking and acting are only substitutes for the reproaches which are symbolic distortions formed in order to prevent a recognition on the part of the patient of the real meaning, so as to keep from his consciousness a realization of the circumstances of his guilty conduct."

Paranoia is a group of mental diseases containing the paranoia as defined by Kraepelin and various mixed aberrant forms, some of which are called paraphrenias. In general it is a disease in which there are delusions of persecution that have been pretty well systematized. The disease progresses usually through four rather well-defined stages. In every case the patient is unduly concerned about his health,
MENTAL DISEASES

and particularly about what goes on around him in relation to himself. That is, he considers more things are said and done with reference to himself than does the ordinary person, and he begins to reason it all out that there must be some agreement in the actions of persons or things around him, usually for his benefit. Misinterpretations of hearing are common. The result of his thinking himself to be the victim of persecution is that he sometimes becomes very dangerous, and attacks the persons whom he regards as his persecutors. In advanced cases the system of ideas worked out in justification of the suspicions of persecution or conspiracy is very elaborate, and includes frequently falsifications of early memories, which contribute the grain of truth in some of the projected reproaches.

Another classification of the paranoia group of mental diseases is that into two divisions, the original and the acquired, the first being the inevitable development of a character which was of such a constitution as to develop into exactly this form of mental disease, in spite of the environment and a wholesome life, and the second, the effect of an untoward environment upon a neural constitution which might in more favorable circumstances have escaped this fate. According as hallucinations or are or are not present, these groups are further divided respectively into paranoia hallucinatoria and paranoia combinatoria. Furthermore the individual cases are described as persecutory, expansive, querulous, litigious, inventive, reformatory, religious, and erotic. According to the four prominent mental symptoms show. A third division of the paranoia group is into delirium of interpretation and delirium of revindication. In the first the erratic element is in the interpretation of the factors of the environment of the patient, who remains otherwise quite clear minded, and in the second there is a tendency toward the formation of a fixed idea, either egocentric or altruistic. As paranoia was considered an incurable, progressive and chronic disease, the cases which thorough analysis have been shown to have at the basis of them an idea that could be traced out and corrected, and which therefore have been called acute paranoias, necessitated a further reconstruction of the concepts underlying the classification. The result of this is that the content of the mental states in this form of disease is now not considered so indicative as the mental mechanisms involved. This implies again that it is not so much the delusion, or the suspicion itself, or any other of the symptoms, which used to be considered characteristic of the disease, but it is the inability on the part of the patient to adapt his ego to those ideas which form the so-called content of the paranoid state. The delusion, for example, is found to have been made by the patient for the purpose of making a certain emotion tolerable which he could not get rid of. The removal of the delusion would not in such a case help, for another would have to be supplied in its place, to explain the original emotion, which would itself remain. Therefore control over the emotions is thus seen to be the most fundamental cause of the disease. The explanation of paranoia consists, therefore, in the emotional lack of control, which fixes upon certain ideas and is unable to change them, and furthermore in an exaggeration of the mechanism of projection. (See Mechanisms, Mental). Finally Sigmund Freud states that paranoia is dependent upon a homosexual fixation in the psychosexual development of the individual. Treatment of paranoia has been more or less successful in some and more cases have been handled with great success, but it is to be remembered that incurable cases are now by many regarded as only paranoid forms of other mental diseases, and that the true paranoid is known as paranoid virtually only by the failure of all effort to improve him. Psychoanalysis is the only means by which any satisfactory knowledge can be gained of the unconscious mechanisms dominating any given case, and only by thorough study can it possibly be determined how much or how little can be accomplished in the way of therapeusis. Epilepsy and various convulsive types of reaction including the classical epilepsy, some attenuated forms such as affect epilepsies, and those partly favorable to the epileptic form of mental disease in which there is well-known physiological and anatomical change in the brain itself. The disease is apparently hereditary, in the sense that in the history of all epileptics there is usually to be found some one in the family or in collateral line as the epileptic convulsion of the classical type is spasm with unconsciousness, preceded by a warning called the aura, and followed by gradual waking or a deep sleep. The variations are exceedingly numerous. Modern investigation has shown that there is some association between the epileptic fit and the gratification of an unconscious wish. Epilepsies are likely to be of a low order of intelligence and their reactions to be analogous to those of children or infants. Some cases indeed do not later to be impotent. Treatment is considered to be of avail, except possibly in psychogenic cases, where analysis or sometimes straighten out the complexes of the patient. The best care is secured in the country, where training in healthful outdoor occupation is possible.

The Dementia Praecox (Schizophrenic) group of mental diseases contains the so-called dementia simplex, hebephrenia, catatonia, and paranoid forms and certain mixed or atypical states. The mental symptoms of the dementia praecox group include an emotional dulness which is thought to be due to the fact that the disease the patient shuts himself into his own thoughts and is therefore less moved by external occurrences than are ordinary persons. That is, his thoughts lose their reference to external reality and the result in the worst cases is that nothing in external reality can move or arouse the confirmed dementia praecox patient. Another feature which is an outcome of this segregation from external interests is his so-called negativism, which is shown in his either refusing entirely to do what he is told or doing it as negatively as possible. Thus if he is told to hold out his hand, he puts it behind his back; or if he is ordered to stop he shuts his mouth tight. This segregation of the behavior from all relations with external reality (and in the last analysis reality amounts to little more than the relations of the indi-
MENTAL DISEASES

individual with other persons), is a splitting of the personality, which is the reason for the alternate name of dementia praecox: schizophrenia or "split mind." The detailed features of this separation of the behavior from all that in the average man is in close connection with his behavior are as numerous as all the possible types of relation of the individual with his environment. Some of these are suggestibility, failure of voluntary attention, disturbance of orientation, disorders of memory. The delusions have been shown in many cases to be subjective in origin, and the process of eliminating the unconscious has been successful in the case in institution. The fact that the conflict is unconscious accounts for the difficulty of getting at it and of re-establishing satisfactory relations with the patient. Other symptoms are physical such as the mannerisms, stereotyped mode of action, unusual words or expressions so frequent in dementia praecox, and the rigidity and stupor which characterize some of the patients.

Whatever reactions to the environment remain in the patient are marked by an archaic or re-established prehistoric era. Evolution of human behavior the highest, most complicated and latest acquired types are those first to be lost. In the disease the individual reverts or regresses to a form of behavior which may possibly be supposed to have been valid and current in prehistoric ages. As behavior may be regarded as built outward from a central core, this form of psychosis is what is known as an introversion, one that is, one in which the libido introverts or regresses to a moment in evolution and there find a most archaic form of gratification. There are other physical concomitants sometimes noticed, such as an unusually small heart or a tendency to pulmonary tuberculosis. The onset of the disease is either gradual or sudden. If gradual it may be mistaken at the beginning for other types of mental disease, such as the manic-depressive, hysteria, compulsion neurosis, etc. It is in this disease more difficult than in most others to make any satisfactory statement as to whether it has a physical or a mental origin. As the bodily convulsions so far discovered have been so few and their bearing so uncertain, it is more advantageous at the present time to explain the disorder on a purely psychological basis.

The patient is faced with a situation in which the balance between environment and congenital ability to adapt to it is inevitably lost, whether because of the disproportionate burden placed upon him by his environment or because of his innate weakness rendering him unable to support the average load. In this connection it is to be remembered that many ordinary persons declare their burden is too heavy for them to bear, and that few ever know their extreme abilities; consequently the loss of balance may have a purely psychical cause lying within the unconscious desire of the particular person. When a person says that something will drive him crazy, he is unwittingly expressing an unconscious desire, not to become ill mentally, but to receive the care and symbolic homage which is given to the mentally ill. The several neuroses may be regarded as a measure of how far the unfavorable condition of the environment has driven back the individual patient from reality. There are cases of moderate confusion which appear in almost all respects perfectly natural persons, and only later develop a disorder great enough to dissociate them from their fellows; while in the so-called catatonic cases the inability is generally complete. The cases which have subsequently become well have gradually made an adjustment to reality in some form, either indirectly through the formation of delusions, or directly by a final domination of the reality motive. Cases that do not get well tend to sink to lower levels till they reach one on which they can succeed in maintaining themselves with comparative steadiness. This is not at all the case in institution, where in the minimum life such persons join the ranks of tramps, prostitutes and petty criminals, thus finding their appropriate level.

The treatment of the physical condition is always according to the nature of the bodily symptoms, and the treatment of the mental condition must take into consideration the involvement of the higher or psychological levels of the personality and give as much analysis as possible, in order to reconstruct the social relations involved. The treatment for the disease is one of the most important ends that could be achieved by civilization, and is primarily attained through eugenic methods, lacking which the only means at present known lie in the correction of all irregularities of character as early as they may be observed in childhood and an absolutely frank and scientific handling of the question of sex, the source of much that is abnormal in human character. A division of infection and exhaustion psychoses comprises those results upon union, exhaustion or collapse and upon typhoid fever. While all these diseases have mental aspects, the treatment of them is so essentially in accordance with the disease of which they are themselves virtually only the symptoms that they need not be described here in detail. There is a special form of mental reaction following the over-indulgence in alcohol, in opium, cocaine, bromides, carbon monoxide, lead, mercury or from uremia, diabetes mellitus, pellagra and certain gastro-intestinal diseases. In most of the mental diseases is the mental aspect of individual psychology more important than in alcoholism, as the reasons for drinking which are assigned by people in general are merely rationalizations. (See MECHANISMS, MENTAL). The real cause why people drink to an extent which harms them is that their neutral constitution gratefully the gratification which they get from this source alone. The very fact that a man or woman cannot stop drinking therefore stamps them at once as having a weakness in their nervous constitution. The alcoholic takes his peculiar way in creating an artificial balance, so to speak, in order to make up for the loss of balance between his neutral constitution and the demands made upon it by his environment. It is his way of taking the cash and letting the credit go. Alcohol is the quickest path for some persons to shut out the world of reality, which has been found too arduous, and to open up the world of fantasy, the fact that the individual is unable to face reality being the really important point. It is not surprising to find that ordinarily the alcoholic is in other respects, aside from his alcoholism, an example of general inefficiency. His unconscious appreciation of his essential inferiority is partly what leads him to flee from the world.
of reality to the world of intoxication fantasy. That alcoholism is an indication of a deep physiological weakness, too, is to be inferred from the high mortality in pneumonia and other diseases among alcoholics.

The same remarks could be made about the mental aspects of drug addiction in opium, morphine, cocaine and other poisons. The amount that any given individual can stand depends, as is well known, on the individual’s constitution. The more he can stand, the stronger the constitution; but from another point of view, the greater need he has for some drug to change, through its effect upon himself, the nature of his relations with the external world, the weaker he is as a mechanism and the less suited he is for the field of activity in which he finds himself. In all of these drug indulgences the treatment of the patient by means of other drugs is merely palliative and does not go to the root of the matter. The only hope of doing this is through psychoanalysis, after the acute disturbance has ceased. There are psychoses, too, associated with organic diseases such as apoplexy, chorea, paralysis, multiple sclerosis, polymyelitis and heart disease; also with presenile, senile and arteriosclerotic conditions.

Finally, feeble-mindedness, idiocy, imbecility, regarded as defects in personal endowment or development, have the mental aspect that they cannot live in society acceptably to the degree of being either self-supporting, or of supporting anyone else. The economic importance of these defective classes is being recognized and the more as psychological methods have been devised for grading all individuals into the classes which show characteristic differences parallel with the differences between children of ages between 1 and 14 years of age. Very extensive researches by Binet, Simon, Goddard and Terman have shown that the general intelligence grows steadily up to age 14, while above that age there are roughly three groups, the low, average and high intelligence. What is meant by feeble-mindedness, imbecility and idiocy can be given a very exact form in a table like the following:

<table>
<thead>
<tr>
<th>Mental age</th>
<th>Capabilities</th>
<th>Class</th>
</tr>
</thead>
<tbody>
<tr>
<td>Under 1 year</td>
<td>Helpless</td>
<td>Low class idiot</td>
</tr>
<tr>
<td>2 years</td>
<td>Feels self.</td>
<td>Middle class idiot</td>
</tr>
<tr>
<td>3 years</td>
<td>Eats discriminatingly</td>
<td>High class idiot</td>
</tr>
<tr>
<td>4 years</td>
<td>No work.</td>
<td>Low class imbecile</td>
</tr>
<tr>
<td>5 years</td>
<td>Tries to help.</td>
<td>Middle class imbecile</td>
</tr>
<tr>
<td>6 years</td>
<td>Only simplest tasks.</td>
<td>Low class imbecile</td>
</tr>
<tr>
<td>7 years</td>
<td>Tasks of short duration</td>
<td>Middle class imbecile</td>
</tr>
<tr>
<td>8 years</td>
<td>Errands in house.</td>
<td>High class imbecile</td>
</tr>
<tr>
<td>9 years</td>
<td>Heavy work; must get up early</td>
<td>Low class moron</td>
</tr>
<tr>
<td>10 years</td>
<td>Good institution helpers</td>
<td>Middle class moron</td>
</tr>
<tr>
<td>11 years</td>
<td>Fairly complicated work with only occasional supervision</td>
<td>Middle class moron</td>
</tr>
<tr>
<td>12 years</td>
<td>Uses machinery.</td>
<td>High class moron</td>
</tr>
</tbody>
</table>

The advantages of these so-called intelligence tests, so clearly shown in the organization of the national army, are of further advantage in finding out whether a mental defect is inherent or acquired, because in the inherited mental defects a termination of the individual’s habits to go through the tests is quite even. He can do all of the tests of ages one to seven, for example, but cannot do any of those above that age. On the other hand, the individual with clean cut with acquired defects, the individual being able to do some but not all of those tests several years above his mental age and not all of them below it.

In conclusion it should be emphasized that the mind and body are one unity and whatever affects one is not without effect upon the other, that it is almost if not quite impossible to draw the line between mental and bodily disorders, and that the ultimate truth will be found in the statement that mind is but the function of body and body but the perceptible expression of mind. Therefore few diseases can be regarded as exclusively mental and but few as exclusively physical. Consult Jelliffe and White, ‘Diseases of the Nervous System,’ (3rd ed., 1915); and Jelliffe, ‘Modern Treatment of Nervous and Mental Disease’ (Vol. II, 1915).

SMITH ELY JELLIFFE, M.D.

MENTAL HYGIENE. Hygiene has usually been conceived of as a system of measures for the creation of conditions favorable for maintenance of the body health. Mental hygiene is an effort to create favorable conditions within which will make for mental health. Whereas hygiene heretofore has dealt with external conditions which are favorable to health, such as fresh air, sunlight, pure food, exercise, etc., mental hygiene deals with the principles of right living as they apply to the regulation of our thoughts, our feelings, our activities. In its practical applications mental hygiene attempts to deal with the problem presented by the tremendous demands of our fundamental instincts for adequate expression. It sees in human failures inability to adequately harness these instincts, while in success it sees them adequately expressed in activities that are at once creative and socially acceptable. The principles of mental hygiene receive their formulation as a result of an understanding of the development of the human mind from earliest infancy to adulthood expressed in terms of a constant interplay and compromise between instinctive desires and social repressions. These principles will receive their application along two main lines of endeavor. One by applying them to the scheme of education, modifying it and minimizing the severity of these conflicts, and secondly, in individual instances by an examination of the particular situations under which difficulties have produced disturbing symptoms in the individual.

As soon as the difficulties of the individual are seen as evidences of his endeavor to make his particular instinct-constellation fit in with the social requirements, it is seen that a vast amount of convention, particularly the criminal law, is the reaction of society against instinctive manifestations by an effort at forcible repression, and just as education cannot be complete if it stopped wholly at efforts of repression just so mental hygiene points out that society’s methods of dealing with its delinquents are not complete when measures of repression, censure and condemnation alone are used. As
MENTAL PROCESS—MENTAL TESTS

in dealing with the child it is necessary to search for and help to develop all the positive characters of value, so in dealing with the delinquent it should be society’s effort to search for and develop to their fullest extent all those striving for better things which no one is without.

This new point of view is applicable to every relation which involves the individual and society, and its ideal must be to bring about a state of understanding rather than a blind clashing in children and adults. This does not mean individual indulgence, instead of being met by blind social condemnation, will be met by an intelligent vision which sees the indulgence as a relatively infantile, undeveloped type of reaction and which sets about to bring to pass a different reaction formula by methods of repression where necessary and to the extent necessary carefully checked by adequate controls but which does not neglect those educational procedures without which no repression is safe.

The practical application of the principles of mental hygiene must come about as a result of a more complete understanding of the developmental stages of the human individual and this means specifically a more complete understanding of the development of the child. This is the “century of the child” and in many ways the advances that have been made in child study point the way toward an adequate hygiene of mind. This is so because in all of the defective and delinquent conditions, as we find them either in children or adults, we see evidences of defective psychological development either gross or in detail. In other words, the adult delinquent, or the mentally ill adult, presents distinct evidences of having been arrested at some point in his psychological development, so that in that portion of his behavior which is circumscribed by this limitation there are the outward appearances of infantilism or childishness. The moods, the grouch, the irritabilities, the petty dishonesties, lying and pilfering, the subtle correspondences and deceptions, selfish desires, over-consciousness, prudery, emotionalism and a thousand other traits of character are all the better understood when they are seen to be childish types of reaction, and are almost immediately appreciated as such as soon as the analogy is suggested.

The immediate problem of mental hygiene as addressed to such character traits as have been enumerated above is to approach their study in the individual case with a view to unfolding the causative factors which have, within these certain areas of conduct, prevented the individual from progressing along the usual lines of development and having succeeded in this endeavor, helping the individual to find avenues of expression for this pent-up energy in more useful ways.

All these results have been made possible by a study of the development of the child and realization for the first time that the child is not simply a small adult, but has standards of conduct and sensibility and of mind which is extremely difficult, if not impossible, for the adult to feel himself into. An appreciation of these facts, together with an attitude toward the individual which is truly constructive, the parental attitude in the best sense, is what is needed. So that in the treatment of these sick individuals there is arising in society an attitude which is a development of the parental instinct as a result of better understanding.

The defects in the parental instinct have been that children have been considered the property of the parents, existing only for their use and satisfaction. This has been the history of the child throughout the ages. Now it must be appreciated that a greater sacrifice is demanded of the parent if the child is to grow up to successful adulthood. Only the interests of the child should be considered by the parent, and not the parent’s personal desires. On the other hand the child should be weaned from considering that the parents belong to it and exist for its pleasure, otherwise a dependent attitude upon the love of the parents will persist into adult life. The basic necessity, therefore, for the healthy adult is a healthy relationship between parent and child which results finally in a normal, healthy emancipation of the latter, resulting in the greatest possible attainment of individual efficiency.

WILLIAM A. WHITE, M.D.
Superintendent Saint Elizabeth’s Hospital, Washington, D. C., Professor of Psychiatry, George Washington and Georgetown Universities.

MENTAL PROCESS. A term used in psychology to denote the phenomena of mind viewed as changing rather than as timeless substances. One of the great changes which has come over philosophy in the past century or so is the obsolescence of the notion of substance. It is realized more and more that the unity of phenomena is to be explained by the diversity and homogeneity of a stuff behind them (see PANSYCHISM), but as the persistence of a certain type of change or process. Just as the physicist has ceased to worry much about the nature of matter or the ether and has given himself wholeheartedly over to the study of their laws of change, the psychologist has come to see the utter barrenness of the substantial conception of mind, and now interprets the mind and all phenomena pertaining to it under the category of process. The mind is often treated as the stream of its states, while these are no longer regarded as instantaneous, but rather as undergoing a temporal waxing and waning of their own. Consult James W., ‘Principles of Psychology’ (New York 1890); Stout, G. F., ‘Analytic Psychology’ (London 1896); Titchener, G. B., ‘Textbook of Psychology’ (New York 1910); Wundt, W., ‘Grundzüge der physiologischen Psychologie’ (6th ed., Leipzig 1906–11).

MENTAL SCIENCE, the science of mind: (a) properly, a synonymous term for psychology, or that branch of metaphysics which treats of the aggregate of knowledge concerning the mind and mental operations. (See Psychology; Individual Psychology; Social Psychology; and related references). (b) A term also applied to various empirical systems of religious and philosophical thought, which propound the doctrine that most physical ailments are curable by faith, or rational exertion of the mind, without the aid of medicine. See Christian Science; Emmanuel Movement; Faith; New Thought; Soul.

MENTAL TESTS. In the early eighties the experimental method was developed in the
Mental Tests

study of mental life through the establishment of various psychological laboratories. Certain aspects of this work, though not originally aimed at any practical application, did attract the attention of those interested in abnormal minds, the psychiatrists, and to a lesser extent the attention of those interested in controlling the development of minds, the educators. Gradually there came to be developed in this way methods of investigation somewhat more direct and somewhat simpler than the typical laboratory experiment — methods aimed at probing or measuring mental capacities for diagnostic purposes — and these methods became known as ‘mental tests.’

The things tested were at first mainly sensory vacuity and sensory discrimination, like keenness of vision and ability to notice small differences of pitch; motor ability, like speed of tapping; accuracy of aiming and steadiness; memory in its varied aspects, like memory for nonsense syllables, recognition of forms and colors and capacity to commit to memory; imagination, both passive and active; and especially quickness of association, that is, the speed with which a person, on being given a word, can respond to it with another word related to the first in some prescribed manner. There were also many attempts at measuring capacity to attend, as by the various ‘cancellation’ tests in which the examinee had to cross out, or cancel, designated materials, e.g., every 5 in a page of print; and again by tests in which words, pictures, diagrams, etc., were exposed to view for a very brief time by specially devised instruments. Much was expected, too, from the development in the laboratory of very elaborate apparatus and technique for measuring reaction time, i.e., the speed with which a person could respond by a designated movement to a given signal, e.g., by pressing a telegraph key on seeing a flash of red light — a type of work evidently closely connected with that just mentioned in the measurement of speed of association.

Now, with a few exceptions, these attempts to develop a series of mental tests from the experimental methods of the laboratory psychologist have been worthwhile, but the progress thus made in measuring special aspects of mental life has been entirely overshadowed in the mind of the lay public by developments in another direction — namely, in the determination by mental tests of levels of general intelligence.

About 1905 the French psychologist, Alfred Binet, reported the result of an attempt made by him in conjunction with a physician, Dr. Simon, to devise a system of tests that would serve to select children of subnormal mentality for segregation for special instruction in special classes. In 1908 and again in 1911 the same authors published improved editions of what is now generally referred to as the ‘Binet-Simon Scale for Intelligence Testing’ or, more briefly, as the ‘Binet Tests.’

The root idea of the Binet scale is to assemble a considerable number of relatively simple short tasks of varied character and to classify these into groups which correspond with the average or ‘normal’ performance of children of a given age. Each ‘age’ is represented by five or six tests. Thus, in the recent ‘Stanford Revision’ of the Binet tests, prepared by Dr. L. M. Terman of Stanford University, an eight-year-old child is given the tasks: counting backwards from 1; drawing a circle; finding a simple plan for finding a ball lost in a field; answering certain simple inquiries like ‘What should you do if a playmate should fall accidentally?;’ stating the similarities between things like wood and coal; defining words like ballpen; and ordering the meaning of at least 20 of a set of prepared terms.

Others of these mental tasks, to name just at random, are the counting of pennies, naming of colors, memory for digits, the interpretation of fables, the detection of absurdities in statements, etc.

In addition to the Terman arrangement, American examiners are wont to use editions of the Binet tests prepared by Dr. Goddard, recently of the Yerkes Laboratory of Primate Physical Education at Yale, and by Dr. E. A. Spear, of the University of Chicago.

The American Psychological Association has not yet approved any particular Binet test.

The amount of activity stimulated by the work of Binet has been truly surprising. Beliefs commonly held by Dr. Kohs list 711 books and articles dealing with the Binet tests to 1917. Practical application has been so common in the direction of Binet’s original suggestion, i.e., in detecting subnormal mentality and in measuring its degree. Thus, special classes may be backward or for subnormal or for actual feeble-minded children are now common, recruited with the aid of these tests. Similarly, in juvenile courts the tests have proved valuable in showing the presence of a needed mental development or low degrees of general intelligence in a large proportion of the delinquents brought to trial.

Among other developments from the original Binet scale should be mentioned the York-Bridge “Point Scale,” in which many of the Binet tests are used, but a method of scoring by points is substituted for the Binet age-level principle.

The usefulness of the Binet method, great as it undeniably is, is limited at the present state of our knowledge of the nature of certain limitations. Indeed, differences in degree or type of intelligence are not well revealed for at least 32 adults cannot be so successfully tested; and children cannot be administered simultaneously to a group of persons.
The sporadic efforts of various psychologists to overcome these limitations, to develop a series of group tests to measure the general mental ability of adults, have been powerfully stimulated and co-ordinated by the advent of the war. As a result of preliminary trials in 1917 there has been developed and put into wholesale operation in the army cantonments a system of mental testing that virtually affords a "mental survey" of the distribution of intelligence in all the various groups of men composing a modern army. The system includes, beside the regular group tests, special tests for men who do not speak or write English well, and also various supplementary individual tests for the examination of men who fail to do well in the regular group tests.

It is clear already that the successful use of mental tests in the army, following the success obtained in educational and correctional institutions, will contribute much to the spread of the idea that a measurement of mental ability is as important as it is feasible (even if not always as precise) as a measurement of physical ability. The idea that applicants for positions in commercial and industrial organizations—salesmen, clerks, skilled workers, executives—should demonstrate their mental ability by passing suitable mental tests is bound to make rapid headway; similarly, the idea that in our public schools the most efficient instruction demands the segregation of children into groups of approximately like native ability as well as of approximately like school attainments.

These rapid developments in the use of mental tests will mean the creation of a new profession—that of the consulting or applied psychologist. We may expect that in the not distant future persons of varying degrees of expertise will profit their services in applying mental tests to the solution of various educational, sociological, medical, industrial and commercial problems. It will become necessary for the sake of this new profession of "human engineering" to warn the public against the charlatans who are already trading on the name of "psychologist." In essence, the situation would appear to be this: the mere quasi-mechanical administering of well-known tests, like the Binet tests, may be entrusted to a person of comparatively moderate professional training; but the interpretation of the results of tests demands a fair working knowledge of psychology, a good college training and perhaps a year of special drill in the handling of tests under direction; the devising of tests to meet special needs, the prescription of educational, sociological, psychological and other treatment for the modification of human behavior demands not merely these qualifications but also a well-rounded and intensive knowledge of mental life and a systematic knowledge of psychology. In other words, demands the psychologist as well as the "mental tester." We may expect that eventually some sort of public if not legal recognition will be given to these different uses of mental tests and to the qualifications necessary for undertaking them.

GUY M. WHITTLE,
Author of 'Manual of Mental and Physical Tests.'
the taste of disagreeably flavored drugs. The best-known genera represented in the United States are Nepeta (catnip), Mentha (mint), Origanum (marjoram), Salvia (sage), Thymus (thyme), Marrubium (horehound), Satureia (summer savory), Lavandula (lavender), Monarda (horsemint), Ocimum (basil), Melissa (balm), Scutellaria (skullcap), Lamium (dead nettle), Calamintha (calaminth), Teucrium (germander), and Trichostema (bluecurls).

MENTHENE. See METHANE.

MENTHOL, peppermint camphor, $\text{C}_8\text{H}_8\text{OH}$,
\[
\begin{align*}
\text{CH}_2\text{CH} & \quad \text{CH}_2\text{CHOH} \\
\text{CH} & \quad \text{CH} (\text{CH})_2
\end{align*}
\]
is the chief solid constituent of the Japanese and Chinese peppermint oil (from Mentha piperita Linn., or Mentha Arvensis). American and English oils contain menthol in much smaller quantities, and the menthol obtained from the oil is sometimes used to adulterate the commercial product; among these may be mentioned hydrated magnesium sulphate, paraffin, wax, thymol and various inorganic compounds. The pure substance should possess a sharp melting point and should completely volatilize when heated on a water-bath in an open vessel. Menthol separates in long prismatic crystals. It melts at 43° C, and boils at 212° C. The crystals possess a strong peppermint odor and a cooling taste. It dissolves readily in alcohol, ether, chloroform, carbon bisulphide, strong acetic acid and in a number of oils. Its solubility in water is very slight but the water solution possesses the odor and taste of the substance.

The molecule of menthol contains three asymmetric carbon atoms, and a number of stereo-isomers are possible; the commercial product consists mainly of the laevo modification. Menthol exhibits the properties of a saturated secondary alcohol. Careful oxidation with chromium trioxide converts it into the corresponding ketone, menthone. With acids it yields esters. With phosphorus pentachloride it forms methyl chloride. Heated with phosphoric anhydride or zinc chloride it forms menthene, $\text{C}_8\text{H}_8$. With copper sulphate it yields camphene, and with hydroiodic acid, in the presence of phosphorus, it forms hexahydrocymene.

Menthol acts as a mild local anesthetic. In the form of cones or in solution in various solvents it has been used as a remedy for neuralgie headache, toothache, catarrh of the nose, asthma, diphtheria, diarrhoea, sciatica and tuberculosis of the bone. Sometimes it is also employed as the chief ingredient in atomizers, inhalers, toothpastes, ointments, liniments, and in a number of preparations for internal use.

V. S. BARASINIAN,
Professor of Chemistry, Lehigh University.

MENTONE, měn-tōně (Fr. Menton, měn-tōn). France, a seaport town and health resort on the Mediterranean, in the department of Alpes-Maritimes, near the Italian frontier, and 15 miles northeast of Nice. It is charmingly situated among a promontory about the middle of a bay five miles in circuit, encircled by steeply rising hills. The ancient walls of the feudal town are still standing, and there the streets are dark and crooked. The new part of the town, with numerous fine villas, stretches along the base of the hill on which the old part is situated, parallel to the sea. The climate of Mentone is mild and equable; it is rare that the thermometer descends as low as the freezing point, or rises higher than 86° F, hence making Mentone a favorite resort for persons in delicate health. There is a considerable trade in fruit, in flowers and leaves used in the manufacture of perfumes, and in olive-oil. The town of Mentone belonged to the principality of Monaco from 1346 to 1860, but in the latter year was ceded to France. It is, however, on Italian territory, are the grottoes of Baoussé Rousse, popularly known as the Caves of Mentone, famous for the valuable evidences of prehistoric man that they have yielded. Pop. (of commune) 18,000.

MENTOR, according to Greek legend, the faithful friend of Ulysses, who entrusted to him the care of his domestic affairs during his absence in the war against Troy. The education of the young Telemachus fell to his charge, and when the latter set out on his voyage in search of his father Mentor accompanied him under the form of Mentor (Odyssey, ii, 390; iii, 12, etc.), acting the part of a prudent and experienced counsellor to the young hero. This character of a sage adviser is more fully developed in the Télèmaque of Fénelon, in which Mentor plays a conspicuous part.

MENZALEH, měn-záălě, or MENZALA, Egypt, a large lake or lagoon (one of several at the Nile delta), extending from Damietta to the Suez Canal, and running parallel with the Mediterranean, from which it is divided by a narrow slip of land, from 2 to 12 miles in breadth. Length of the lake from north to southeast, about 50 miles; average breadth, about 20 miles. It receives the Pelusiac and Tanitic branches of the Nile, and communicates with the sea by three openings called Dibeh, Gemileh and Om Parejah. The lake is of comparatively recent origin, and covers what was a fruitful district of the delta, having formed through neglect of the dams. There is a small town of the same name on the south side of the lake. The Suez Canal cuts into its eastern edge from north to south.

MENZEL, měn-zēl, Adolf Friedrich Erdmann von, German artist: b. Breslau, 8 Dec. 1815; d. Berlin, 9 Feb. 1905. In 1830 his parents settled in Berlin, where his father had a lithographic studio, and where the son studied a little in the academy and more by himself. At 18 he published a cycle of lithographs called ‘An Artist’s Wanderings,’ which immediately attracted attention; four years later he had begun to draw historical scenes from the past of Brandenburg and had commenced painting in oils with ‘Continue-Playing’ (1830) and ‘Judgement’ (1837). About the same time his work as an illustrator opened up with the 400 pictures
for Kugler's 'Frederick the Great' (1840), in which Menzel showed himself original, dramatic and historically correct. This vein he followed out in his painting 'The German Lion' (1850). His work on Frederick the Great, and in 600 more accompanying a work on the army of Frederick the Great (1856); as well in his oil paintings, a dozen or more, of various scenes in Frederick's life. A trip to Paris in 1857, so the French critic claimed, altered Menzel's methods, so that he applied himself more to problems of light and shade. After 1890 he used colour less and less and in his pencil drawing broke away from mere line to the use of a cloudy treatment. He was one of the greatest of German artists of his day; and in 1899 he received the Order of the Black Eagle, conferring hereditary nobility. Apart from his historical pictures, mention should be made of the 'Modern Cyclops' (1875), the interior of a Silesian rolling mill, with excellent lights, and of social satires like 'Carnival Morning' (1885). Consult Jordan, 'Das Werk Adolf Menzels' (1895); and lives by Sondermann (1895), and Knackfuß (1897); Singer 'Drawings from Adlon' (1896); (1898).

MENZEL, Wolfgang, German author: b. Waldenburg, Silesia, 21 June 1798; d. Stuttgart, 23 April 1873. He studied at Jena and Bonn, became a follower of F. L. Jahn and the Turnaeus, and was for four years schoolmaster at Aarau in Switzerland. In 1825 he returned to Germany, and immediately made himself known to the literary world by his 'Elastic Verses' (1823). He edited and contributed to magazines, and wrote a very great number of works, poems, romances, histories, criticisms, political points, and Christian theology. From 1826 until 1848, and again later, he was editor of the Litteraturblatt in Stuttgart. His chief writings include histories of Germany (1825), German literature (1827), German poetry (1858) Europe (1859-60), and the world (1 Universal History (1862-72). He also produced a work of mythological research (1842), a book on the pre-Christian doctrine of immortality (1869), and autobiographical memoirs (1876). He was often involved in controversy, assailing with equal rationalists and political radicals. His attacks upon Goethe and others were fully equaled for virulence by the criticisms upon Menzel himself, made by Heine and some of the younger German writers.

MEQUINZEN, or MEKINEZ, Africa, a town of Morocco, 40 miles southwest of Fez. It is one of the capitals and the sultan maintains there a palace. There is a historic mosque and many other fine buildings, especially those of the 18th century, when the town was the preferred residence of Sultan Muley Ismail. There is an ancient city wall with nine gates. There are tanneries and potteries. Pop. 30,380.

MEPHISTOPELES, méf-ís-tóp'élès, a name for the devil, which has been made popular by Goethe's 'Faust.' He was also a chief character in Marlowe's 'Dr. Faustus.' Goethe derived it from an old popular legend, in which it is spelled Mephistophiles or Mephistophelis. Thus in his fight with the good knight as various as the spelling. Some suppose it to be an irregularly formed Greek compound from the negative mé; phós, light; and phílos, loving, thus signifying 'not loving the light.' Others surmise that it may be derived from the Latin mephiticus and the Greek phílos, in which case it will signify literally 'loving the mephitic vapors of hell.' The Mephistoheles of Goethe has little in common with the devil of the popular imagination. He appears, especially in the original form of the drama of Faust, as a real man of flesh and blood, who only preserves those traits of the popular devil of the Middle Ages which are compatible with a true human individuality—such as the companion of Faust, a selfish and malevolent votary of pleasure, always looking to the real, and bringing back Faust by cold and heartless irony, from barren speculation to the enjoyment of the present life.

MER DE GLACE, mār dé glás, France, an Alpine glacier on the northern slope of Mont Blanc, with an area of 16 square miles and an extremely long of about nine miles. It is formed by the confluence of three branches called the Glacier du Géant, the Glacier du Lechaud and the Glacier du Talèfre and is noted for its beautiful scenery. The old town Glacier des Bois where flows the Arveyron River, in the valley of Chamouni. From the village of Chamouni the Mer de Glace is easiest visited and Mont Blanc ascended. The glacier has an average flow of two feet a day during summer and autumn.

MERAMEC SPRING, an unusually large spring in Phelps County, Mo., about seven miles south of Saint James. The water flows as an underground stream in limestone and emerges as a great spring with a flow averaging 125 cubic feet per second.

MERAN, mā-rān', Austria, a celebrated health resort in Tyrol, charmingly situated on the river Passer, near its entrance into the Adige, at the foot of a hill called the Kuchelberg. It is the chief town of a small district of the same name. It consists of an old and a new town, the latter with handsome villas and hotels, and numerous fine residences and old castles in the neighborhood. The old town is mainly on the Laubengasse, which is a long, narrow, winding street. The Polish church and other buildings date from the 14th and 15th centuries. It is believed to have been settled originally in the 9th century. Lying in a sheltered situation on the southern slope of the Alps, it possesses a mild and equable climate, and is much frequented in winter by invalids with pulmonary affections. Permanent population 11,570.

MERCADANTE, Saverio, să-vā'rē-ō mār-kā-dăn'tā, Italian composer: b. Albamara, 26 June 1779; d. Naples, 17 Dec 1870. He studied music at the college of S. Sebastiano in Naples under Zingarelli. From flute and violin he turned to vocal music; won great success with a cantata 'L'Unione delle Belle Arti' in 1818, and with an opera 'L'Apipeta' in 1819; was made chapel-master of the Novara Cathedral (1833) and director of the Naples Conservatory (1840); and in 1862 became totally blind. He wrote many masses and other ecclesiastical music, such as The Seven Last Words; but is best known for his operas which the following, out of a total of 50, should be mentioned: 'Elisa e Claudio,' 'Il Bravo,' 'Il Giuramento,' 'I Briganti,' and 'Le due illustri Rivali.'
MERCANTILE AGENCY — MERCAPTANS

MERCANTILE AGENCY, a business enterprise, usually an incorporated company, which agrees to furnish subscribers who pay a yearly subscription for information as to the business responsibility, financial standing and credit ratings of business houses, whether conducted by private individuals, firms or corporations. They also sometimes have a department for the collection of debts, and sometimes they sell two or three different services, at different prices. The business originated in the United States in 1837, following a financial panic, it being recognized that it was necessary for business houses to obtain better information in the giving of credits. Lewis Tappan was the founder of the first mercantile agency in New York City. The most conspicuous concerns now in the business are R. G. Dun and Company and the Bradstreet Company of New York; a good rating by either is highly prized by business men, as it decreases the cost of credit, and increases the volume of business. The rating is given by the agencies to business houses on the basis of information gathered from a variety of sources, including personal visits, credit reports, public records, and other financial data. The agencies then compile this information into a rating system, which is used by businesses to make informed decisions about whether to extend credit. The ratings are designed to provide a measure of the financial health of a business, and are used by lenders, suppliers, and other businesses as a way to assess the risk of doing business with a particular company. The ratings are typically based on a combination of factors such as the company's financial statements, credit history, and payment performance. The rating system used by Dun & Bradstreet is one of the most well-known and widely used in the United States. Other agencies, such as Moody's Investors Service and Standard & Poor's, also provide similar services. The ratings are an important tool for businesses to assess the risk of doing business with other companies, and are widely used in financial transactions such as loans and investments. The ratings are also used by financial institutions to determine the creditworthiness of borrowers, and by consumers to assess the financial health of companies they may do business with. The ratings are not a guarantee of creditworthiness, as other factors such as the overall economic climate and the specific circumstances of the business may also play a role in determining the creditworthiness of a company. The ratings are continually updated as new information becomes available, and businesses are encouraged to monitor their ratings to ensure that they remain current and accurate. The agencies also provide a variety of other services, such as credit reporting, collections, and consulting, to help businesses manage their credit risk.

MERCANTILE LAW. See LAW, MERCANTILE.

MERCANTILISM. See Economics.

MERCANTINI, Luigi, Italian poet: b. Ripatransone, in the Marches, 20 Sept. 1821; d. Palermo, 18 Nov. 1872. Against his inclinations he was intended by his father for the priesthood, but he deserted that vocation before taking orders and turned to school teaching. For a time he was professor of Italian and Latin literatures in Sinigaglia. He wrote a number of patriotic songs, including "In Colore," but gained his greatest popularity by the song which is now the Italian national anthem or "Inno di Garibaldi." See Garibald HYMN.

MERCAPTANS (Latin, "taking up mercury") or THIO-ALCOHOLS, in chemistry a large class of substances having the same constitution as the alcohols, but differing from them by having the oxygen atom in the hydroxyl replaced by sulphur. They are oily liquids or crystalline solids having an offensive, garlic-like odor, and are all insoluble in water. They possess acid tendencies that are more marked than those of the alcohols, and combine with metallic oxides to form salts which are known as mercaptides. They combine with especial facility with mercuric oxide and take their name from this circumstance. Ethyl mercaptan is the best-known member of the series, and it is this substance that is understood when "mercaptan" is spoken of without further qualification. Ethyl mercaptan, CH₃SH, is prepared by acting upon ethyl chloride, CH₃Cl, with potassium hydroxysulphate, HK₅; the potassium atom and the ethyl radical changing places as indicated by the equation CH₃Cl + HK₅ = CH₃SH + KCl. Ethyl mercaptan is a colorless, mobile liquid, boiling at 99° F. It is very inflammable, burning with a blue flame, and it mixes readily with alcohol and ether, though only to a very slight extent with water. Like the other mercaptans, it forms salts with the oxides of the metals, the hydrogen atom that is associated with the sulphur being the one that is replaced by the metal. The mercury salt, Hg(S, CH₃)₂, can be prepared very readily by agitating the mercaptan (or its alcoholic solution) with red oxide of mercury, HgO. Its formation is attended by the liberation of considerable quantities of heat, and the mercaptide itself is obtained in the form of soapy white scales. All of the metallic mercaptides are decomposed by boiling with hydriodic acid. The mercaptans of red radicals all give a fine green color when treated with a solution of isatin in strong sulphuric acid and this reaction (as well as their insufferable smell) is used as a test for their presence.
MERCATOR, mér-ka-tör. Gerardus (Latinized form of Geraert Kant, a Flemish mathematician and geographer: b. Rupelmonde, Flanders, 5 March 1512; d. Duisburg, 2 Dec. 1594. He studied at Louvain, and became a lecturer on geography and astronomy, making his instruments with his own hands. In 1544 he was arrested for heresy, being declared in his views. He escaped, but 42 of those arrested with him were burnt alive. Recommended to Charles V, Mercator entered into the emperor's service, and executed for him a celestial globe of metal, and a terrestrial globe of wood. In 1589 he retired to Duisburg and received the title of cosmographer to the Duke of Juliers. His last years were devoted to theological studies. He is known as the inventor of a method of projection called by his name, in which meridians and parallels of latitude cut each other at right angles, and are both represented by straight lines, which has the effect of enlarging the degrees of latitude as they recede from the equator. The method is convenient for mapping small areas. His first maps on this projection were published in 1569; the principles were first explained by Edward Wright, in 1599, in his "Corrections of Errors in Navigation," whence the discovery has sometimes been attributed to him. His "Tabula Geographica" (1578) is the best edition of the maps of Ptolemy. See MAP.

MERCATOR'S CHART, or PROJECTION. See Chart.

MERCED, Cal., city and county-seat of Merced County, on the Atchison, Topeka and Santa Fe, the Southern Pacific and the Yosemite Valley railroads, 150 miles southeast of San Francisco. It lies in the valley of the Joaquin and Merced rivers, has a library, sanitarium, county hospital and courthouse. It has extensive farming, dairying, fruit growing and livestock interests. Pop. 3,102.

MERCEDES, mér-sa-dás, Argentina, town in the province of Buenos Aires, on the Pacific Railroad, about 50 miles west of the city of Buenos Aires. In 1779 it was founded as a military station. An Irish colony settled here about 1800. Mercedes is in a region where the chief occupation is raising sheep and cattle. It has several manufacturing establishments among which are flour-mills, soap factories and cattle-yards. The shipments are principally wool, hides and flour. The town has a public library and a college. Pop. about 22,782.

MERCEDES, Uruguay, a town in the district of the Río Negro, about 10 miles from where it empties into La Plata, and about 75 miles north of Buenos Aires. Pop. 15,667.

MERCENARIES, or STIPENDIARIES, foreigners or others who received pay for their services as soldiers, especially as distinguished from government soldiers or those owing military service to the crown or nation. Hired professional soldiers appear very early in the history of military organization. Foreign mercenaries appear in the armies of Alexander the Great, and even in that of Thracia. They were employed in all armies, but generally engaged for a single campaign only. In England, Harold had a body of Danes in his army when he defeated the Norwegian king—the hus-carls, a body originally established by Canute. William III had for some time a body of Dutch troops in his pay after he became king of England; and throughout the 18th century Hessian and Hanoverian regiments were constantly in the pay of the British government for temporary purposes. Hessians fought for Great Britain in the Revolutionary War; and the landgrave of Hesse, who sold his troops at so much a head, received upward of $2,500,000 for Hessian soldiers lost in that struggle. Americans have fought as hired soldiers in China, South Africa and in nearly all the countries of Central and South America. They are generally known as "soldiers of fortune." Most of the officers in the regular Chinese army are either Englishmen or Americans. But most famous of all mercenaries were the Swiss soldiers, who were hired, sometimes by the cantons themselves, over all Europe, and formed many famous body guards. They were long employed by the French monarchs; and the Vatican at Rome still has its Swiss guards.

MERCER, mér-ser, Henry Chapman, American anthropologist: b. Doylestown, Pa., 24 June 1856. He was graduated from Harvard in 1879; was curator from 1894 to 1897 of American and prehistoric archaeology, University of Pennsylvania; honorary member of the United States Archaeological Commission, Madrid, 1893. He was editor for anthropology in American Naturalist, 1893 to 1897; made extensive investigations and studies in anthropology in America, discovering several unknown extinct species, and 1897 to 1917, made and presented to the Historical Society of Bucks County, Pa., an extensive collection of objects illustrating the Colonial and early history of the United States by means of the implements and handiwork of the pioneer settlers. In 1916 he built and presented to the society a fireproof museum for preserving the above collection. He established a pottery at Doylestown, Pa., in 1896, experimented upon and developed the processes of the Pennsylvania Germans for making and decorating pottery, inventing in 1899 a new method of manufacturing tiles for mural decoration and in 1902 a new process for making mosaics; was awarded the Grand Prize at the Louisiana exhibition, 1904, and bronze medal for archaeological work, Madrid, 1983; also bronze medal for tile work, Massachusetts Society of Arts and Crafts. He is a Fellow American Association for the Advancement of Science and member of the American Philosophical Society, the Academy of Natural Sciences of Philadelphia, the Numismatic and Antiquarian Society of Philadelphia, Geographical Society of Philadelphia. He has published "Lenape Stone" (1885); "Hill Caves of Yucatan" (1896); "Researches upon the Antiquity of Man in the Delaware Valley and Eastern United States" (1897); "Tools of the Nation Maker" (1897); "The Bible in Iron or the Pictured Stoves and Stoveplates of the Colonial United States" (1913).

MERCER, Hugh, American general: b. Aberdeen, Scotland, about 1740; d. Newport, R. I., 12 Jan. 1777. Educated as a physician, he served as surgeon's assistant in the army of the Young Pretender at the battle of Culloden. Emigrating in 1747 to America, he settled in Virginia, and resided there, in the
practice of his profession, until 1755, when he volunteered in the expedition led by Braddock to Fort Duquesne. At the outbreak of the Revolution he joined the Continental army, and obtained the rank of brigadier-general. He subsequently accompanied Washington on his retreat through New Jersey, and rendered valuable assistance at the battle of Trenton. In the succeeding action at Princeton he was seriously wounded and died a week later. Mercer County, N. J., was named in his honor.

MERCER UNIVERSITY, Macon, Ga., is an institution having its genesis at a meeting of the Baptist Associations of Georgia, at Powelton, 27 June 1822, held to discuss, among other matters, the question of ministerial education. In 1827, at a similar meeting, held in Washington, Ga., the project was further discussed, and in 1829 Josiah Penfield, of Savannah, bequeathed $2,500 as a fund for education, on condition that the Baptists should raise an equal amount. This was promptly done, and two years later it was resolved to establish "a Classical and Theological School...open only for those preparing for the ministry." It was soon seen, however, that the school could not be so restricted, and in 1832 this bar was removed. Mercer Institute was established on a site of 450 acres, at Penfield, in January 1833, with 39 students,—"Penfield" in memory of Josiah Penfield, and "Mercer," after Dr. Jesse Mercer, early concealer and patron of the school. In 1857 a charter was obtained giving the institution collegiate rank and changing its name to "Mercer University." Thereafter it grew steadily. The successive presidents were B. M. Sanders; Otis Smith; John L. Dagg; N. M. Crawford; H. H. Tucker; A. J. Battle; G. A. Nummally; J. B. Gambrell and P. D. Pickard. President P. D. Pollock was the most efficient president for seven years, and after a lingering illness died in office. Following him, Prof. Charles Lee Smith, of Missouri, was elected president, served one year and then resigned. Following him, Dr. S. Y. Jameson, of Missouri, was elected president and served efficiently for seven years, resigning June 1913. Prof. J. F. Sellers of the department of chemistry of Mercer University was appointed acting president for one year. June 1914 the board of trustees elected Dr. W. L. Pickard president. The registration of Mercer University is now over 400; the departments are college of arts and sciences, law, pharmacy, education and a pre-medical course. The university gives the degrees of bachelor of science, bachelor of arts, master of arts, bachelor of law, pharmaceutical chemist and graduate of pharmacy, accredited certificates in education, receives and gives credit on the pre-medical course for a medical degree, and a B.S. degree. The university has the same requirements for entrance and graduation as all the State universities of the South. The campus has in it about 60 acres and nine large buildings, besides a number of cottages. The working plant is valued at $250,000, and the endowment in round numbers is about one million dollars. The work done in Mercer University is fully accredited by such institutions as the University of Michigan, Columbia University, New York, and leading institutions in America and Europe. It is justly regarded as one of the most potent factors in the educational life of Georgia and the South, and is increasing in its proven force of students and material. Baptists from year to year. The faculty in 1918 numbered 23.

MERCERIZING AND MERCERIZED COTTON.—A process invented by John Mercer, of Lancashire, England, for treating cotton fibre or fabrics. The system was patented in 1851. The process consists of steeping the cloth in a solution of caustic alkali. The cloth shrinks about one-fourth and takes on more brilliant colors in dyeing than unmercerized cotton goods. Cotton may be mercerized either in the yarn or in the cloth, and a variety of machines are made for this purpose. Some of these machines operating on the cloth employ a tension to obviate same after shrinking. This gives a greater yardage, but it reduces the gloss. The name has sometimes been incorrectly extended to sizing of cloth to give it better sheen. True mercerizing gives a lustre to the material cloth, because the fibres are drawn closer and flattened, presenting a glossy surface that reflects the light. A variation in the caustic soda process is employed to give modern crimped or crepe effects. Cook Murphy, 'The Textile Industries' (Loedic 1912).

MERCERSBURG, mér'zérs-burg, Pa., borough, in Franklin County; at the terminus of a branch of the Cumberland Valley line about 70 miles southwest of Harrisburg; was settled in 1730 and was originally called Black Town. It was incorporated in 1857. The borough was enlarged in 1901. It is an agricultural section of the county, but has some coal and iron interests. It was formerly noted for its educational institutions, which were under the auspices of the German Reformed Church in America. It is the seat of the Mercersburg Academy, and was the home of James Buchanan (q.v.). Pop. 1,410.

MERCERSBURG THEOLOGY, a set of religious philosophy founded by F. A. Rue of the German Reformed Church, whose work was taken up by John W. Nevin (q.v.) and Philip Schaff (q.v.). The name comes from the Mercersburg (Pa.) Theological Seminary of the German Reformed Church, where the teaching of this system spread. The Mercersburg theology urged that the Church was not a voluntary society of believers but a historic and spiritual growth—an attitude showing markedly less hostility to the Roman Catholic Church; that old confessions cannot express the modern faith of the Church; that sacraments are more than symbols; that church worship should be orderly—hence the 'Liturgy' (1858) and 'Order of Worship' (1869), and that religious education is of prime importance. The Mercersburg movement infused new life into the German Reformed Church, as Consult Apell, 'Life of John William Nevin' (1889).

MERCHANT, Francis Walter, Cambria county, Pa., educator; b. Oil Springs, Ontario, 1833. He received his education at Toronto University; taught for many years in high schools and collegiate institutes. In 1900-08 he was principal...
of the London (Ontario) Normal School; from 1908 to 1911 was chief inspector of schools in Ontario and in 1911 became director of industrial and technical education in the province of Ontario. He is a senator of Knox College, Toronto.

**MERCHAND MARINE OF THE UNITED STATES.** The merchant marine of the United States—that is to say, the shipping on ocean, lake and river engaged in the carrying of merchandise, mail and passengers—is the second largest shipping in the world, only the fleet of Great Britain exceeding it. By far the larger part of this American shipping has long been employed in domestic navigation between one American port and another. But the shipping registered for foreign commerce, which after a splendid growth began to decline before the Civil War, began again to increase in 1914 with the Great War in Europe.

America throughout most of its history has been distinctively an adventurous and successful maritime country. For many years after the founding of Jamestown and Plymouth the commerce of the seas for coastwise and overseas trade was the chief manufacturing industry pursued upon this continent. There was an abundance of stout timber near the Water's edge, and the pioneers brought a love of the sea from Britain, Sweden and Holland.

Maritime spirit, stirred by necessity, was especially active in the northern colonies. Lord Bellamont, colonial governor, declared in 1698: "I believe I may venture to say there are more good vessels belonging to the town of Boston than to all Scotland and Ireland, unless one should reckon the small craft, such as herring boats." In the colonial era the sea was the easiest highway connecting the long range of settlements that clung to the Atlantic Coast. Small craft—skiffs and schooners—ran along shore and to the West Indies, and brigs and ships to the British Isles, France, Spain, Portugal and the Mediterranean. Colonial shipyards made swift improvement in rigs and models, and found a market for their craft aboard. Out of 332 vessels built in Massachusetts between 1674 and 1714, 239 were sold for British or foreign registry. In 1724 Thames builders complained that their trade was being destroyed by the emigration of their best mechanics to America.

Shipbuilding and navigation were the most energetic and profitable of vocations, and were particularly encouraged by colonial governments. Bounties were granted for the construction of ships, and shipwrights were exempted from compulsory military service. To spirit youth to the sea, royal emissaries appealed. Sir Joshua Child, chairman of the British East India Company, in his discourse on trade lamented that there were "none so apt as the North American colonies for the breeding of seamen, nor more strictly necessary for the breeding of seamen, not only by reason of the natural industry of the people, but principally by reason of their cod and mackerel fisheries, and in my opinion there is nothing more prejudicial to us than the sending to any mother kingdom than the increase of shipping in her colonies, plantations, or provinces."

In response, the British Parliament prohibited the importation of Continental products into the colonies except in English-built ships, and even sought to destroy the colonial trade with the West Indies. The colonists retaliated by forming associations to boycott British manufactures. Against such resistance the impressive British laws failed, and the merchant ships and sailors of America so steadily increased that at the outbreak of the Revolution there were more people in northern New England engaged in shipbuilding and navigation than there were in agriculture.

These merchant ships and sailors proved a powerful resource in the war for independence. The Continental navy as a whole was weak and unsuccessful. In 1781, the seventh year of the war, there survived only nine Continental cruisers carrying 164 guns, while American privateers, converted from merchant ships and owned and managed by merchants, numbered 449, carrying 6,735 guns. These private-armed ships, with merchant officers and crews, in the course of the Revolution served in American and English vessels as many as the privateers did in British vessels, and as many as the regular Continental sloops and frigates. And in the year 1777, when the battles of Bennington and Saratoga were fought, the American merchant seamen aloft in private- armed ships nearly equalled the strength of the army under the immediate command of Washington. These swarming American privateers cruised not only in mid-Atlantic but in the British Channel, the Irish Sea and all around the coasts of the United Kingdom. Their harrying of British commerce brought a stream of arms and supplies to the Continental government and did more than Paul Jones' victories in the Ranger and the Bon Homme Richard to impress the governments of France and Holland with the vigor and audacity of the American people and the probable success of the American cause.

From dread of the maritime strength of the new republic the British government made war on the American merchant marine as soon as the Revolution itself had ended. An Order in Council barred American ships from the British West Indies, and forbade the importation into the United Kingdom of all but a few products if conveyed in American vessels. It being insisted further that these products should bring only the products of the particular States in which they belonged. British shipowners were forbidden to purchase American-built vessels, which in 1775 were supposed to constitute one-third of the British merchant marine. "The ministry," it was declared, "suppose they have now put a finishing stroke to the building and increase of American vessels." Lord Sheffield argued that the Barbary pirates of North Africa, preying on defenseless American merchant craft, were really a blessing to Great Britain, and London merchants told Franklin that "if there were no Algiers it would be worth England's while to build one."

Until the new Federal government was established in 1789, British shipowners dominated American ocean commerce. Our merchant shipping registered for foreign voyages amounted to only 123,893 tons in this year 1789, and 76 per cent of our own imports were conveyed beneath foreign color.  

**Striking Early Growth of American Tonnage.**—Washington and his colleagues felt that this condition was perilous and intolerable, and
Adams, Jefferson and Madison prevailed upon the first Congress under the new Constitution to embody in its very first act, passed on 8 July 1789, "for the support of the government, the discharge of the debts of the United States and the encouragement and protection of manufactures," an important clause allowing a discount of 10 per cent of the tariff duties on all goods imported in ships built and owned by American citizens. Further and heavier rebates were allowed on teas imported direct from the East Indies in American vessels—first of all, encouraging an American East India fleet—and, moreover, a sharp preference in tonnage duties was granted to all American vessels, which practically barred foreign vessels from the coastwise carrying trade.

Five years later, in 1794, the discount of 10 per cent of the tariff duties on goods imported in American vessels was changed to an addition of 10 per cent to the duties on goods imported in foreign vessels. For many years thereafter the powerful government preference for American shipping remained the distinctive national policy of the United States. This was justified not only by commercial considerations but by patriotic regard for the national defense. Jefferson, as Secretary of State, wrote in 1794: "To form shipbuilding is to establish shipyards; is to form magazines; to multiply useful hands; to produce artists and workmen of every kind who may be found at once for the peaceful speculations of commerce and for the terrible wants of war."

What followed this vigorous maritime protectionism of the fathers of the republic was a growth of American shipping well described by a historian of the period as "without parallel in the history of the commercial world." American merchant tonnage registered for overseas voyages rapidly advanced from 123,893 in 1789 to 411,438 in 1792, and to 657,107 in 1800, while the proportion of American imports and exports conveyed in American vessels rose from 13.6 per cent in 1789 to 76.4 per cent in 1792 and to 89 per cent in 1800.

The Napoleonic wars had a double effect upon American shipping. In the first place, these wars gave a great opportunity to America, the chief of neutral carriers. But, on the other hand, and offsetting this advantage, both the British and the French governments began an unscrupulous war of seizure and spoliation on American ships wherever bound, while Great Britain ruthlessly impressed American seamen, native and naturalized, into her naval service. Yet American shipping, in spite of all difficulty and danger, grew and prospered until in 1810 the fleet registered for foreign commerce amounted to 981,019 tons, conveying 91.5 per cent of our imports and exports.

New York, Philadelphia, Boston and Salem were sending ships to the East Indies. In 1789-90 the Columbia made her famous voyage to the Northwest coast and the Orient—the first American merchantman to circumnavigate the globe.

When, tardily, in 1812 the American government declared war on Great Britain, principally to revenge the wrongs of our sailor-citizens, the merchant ships and seamen proved again a tremendously effective weapon, as they had in the first war for independence. The United States navy in the War of 1812 comprised on the ocean only 23 vessels of all classes, mounting 554 guns. These 23 men-of-war captured 254 naval and merchant craft of the enemy. But American merchantmen armed and converted into privateers in 1812-15 numbered 517, mounting 2,893 guns. These privateers, with their merchant crews, took 1,391 prizes, with their freight at nearly $40,000,000, or five times the number of the prizes of our regular ships-of-war. Again Yankee shipowners and sailors carried the conflict right to the coasts of the United Kingdom, convoying American vessels wherever they could be found. The merchants of Glasgow in September 1814 protested to the Admiralty that "a horde of American cruisers should be allowed, unresisted and unmolested, to take, burn or sink our own vessels in our own inlets and almost in sight of our own harbors." It was the exploits of the privateers chiefly, and not the loss of a dozen frigates and sloops in single-ship duels, that quickly made the British mercantile community thoroughly weary of this second war with the Americans.

British diplomacy at the close of the War of 1812 proved more successful than British armed strength. In a commercial convention framed after the Treaty of Ghent, the United States was persuaded to embark upon a plan of mis-called reciprocity in which both governments bound themselves to grant no more preference to their own ships in the direct trade between American ports and the United Kingdom. At the same time, however, the British government, craftily reserved to itself the West India trade and barred American ships out of all but direct trade with British East India possessions. This costly defeat of American diplomacy was sharply resisted by national lawmakers, but the plea prevailed that the terms of the conventions really bound the United States and must be confirmed by Congress. Immediately there came a decline in the American merchant marine, and an increase in British maritime prosperity. Conditions were nominally equal but actually unequal, for British vessels could make major angular voyages to the United States, the West Indies and back to Europe, while American ships could not. American tonnage suffered further by the conclusion of so-called reciprocity agreements with other maritime states of Europe, whose participation in our own carrying trade greatly increased, and whose vessels it was discovered, could be operated at a lower cost because of the lower range of European wages.

But American shippers did not abandon the uneven struggle. When they lost trade in the north Atlantic they turned to the Northwest coast, to the East Indies and to the mid-Pacific archipelagos. They built larger and swifter ships which could make three voyages while dull Europeans were making two. American registered shipping, which had fallen since the War of 1812 to 581,230 tons in 1819, rose steadily to 701,517 tons in 1827. In that year the London Times said:

"It is not our habit to sound the tocsin on light occasions, but we conceive it to be impossible to pass over a year in the history of this country without more than apprehensive observance and concern. Twelve years of peace, and England and Great Britain? The shipping interest, the cradle of our navy, is half ruined. Our commercial monopoly exists no longer; and thousands of our manufacturers are starving, or seeking..."
restitution in distant lands. We have closed the Western
Indies against America from feelings of commercial rivalry.
Its active seamen have already engrossed an important
branch of trade in the Eastern India. Her starred flag is
now conspicuous on every sea, and will soon defy our
thunder."

Of this era Prof. J. R. Soley, the historian, has
written:

"In every respect we may say that this period (1820-28)
represents the first flourishing condition of shipping in
American history. Although since that time commerce has
increased twelve-fold, and although in the year preceding
the Civil War our registered tonnage was three times as large,
yet we have never since 1830 reached the position in respect
to shipping, by far the best, that American ports that was
maintained during this decade, but, on the contrary, have
receded from it further and further."

Success had made our national lawmakers too
confident, for in 1828 Congress took another step in
called miscalled reciprocity by offering to
abandon the preferential duty system, under
which American shipping had grown so
wonderfully, if competing foreign nations
would do the same. This change resulted un-
fortunately, American registered tonnage fall-
ing from 3,908 in 1828 to 537,563 in 1830.
Inland States, or those having no large owner-
ship of ocean carriers, had now come to
dominate the policy of the American govern-
ment. British vessels, of which in 1830 only
78,947 tons had entered the United States, now
rapidly increased to an average of 2,651,611 tons.
While in the decade 1830 to 1840 American
tonnage gained but 40 per cent in all the ports
of the world, British tonnage in American ports
increased nearly 300 per cent. In 1840 the
proportion of the total American tonnage on the
East River, New York City, was 828 per cent.
Yet ship for ship American wooden vessels
were still pre-eminent. Says the British his-
torian, Grantham:

"Previous to the development of steamships, the pre-
ponderance of shipping was falling rapidly into the hands
of American shipowners. Thirty years ago one of the great
objects of interest at the docks in Liverpool was the American
sailing packet, and it was considered that a stranger had
missed one of the lions of the port who had not visited these
celebrated ships. The same prestige was felt everywhere,
and the East River, New York City, and all in the
Atlantic and Pacific oceans, in India, China, and in all
the best trades American ships were most in demand."

Errors of national policy in the too early
reduction and abandonment of the preferential
or protective policy of Washington, Adams,
Jefferson and Madison had hurt American
shipping and checked its normal growth. But,
and on the other hand, the blunders of the law-
makers had been a great extent retrieved by
the persevering and progressive spirit of the
shipbuilders, shipowners and seamen of the
United States.

Steamers, Packets and Clippers.—Steam
shipbuilding and navigation were first made
practicable in America. The Clermont of Rob-
ert Fulton in 1807 was the first successful
steam-driven craft. The Savannah in 1819 had
made the first steam transatlantic passage. In
1823, when the steam merchant fleet of the
United States was first enumerated, it had a
total tonnage of 24,879 — engaged almost en-
tirely in coast and river voyages. By 1833 our
steamer fleet had increased to 3,621,516 tons,
and by 1840 to 1,596,135 tons, of which over
4,155 tons were registered for foreign commerce.
Moreover, American shipbuilders, contrary to
frequent assertions, were quick to recognize
the value of iron, and the first iron sea-going
steamer, the Bangor, was built at Wilmington,
Del., in 1844. Nevertheless, with all this spirit
of energy and progress, American shipping
flattered when it received the degree of
preference from its own government. Our
shipping, still nearly all wood-built and sail,
registered for foreign commerce stood at a
tonnage of 904,476 in 1845 — a handsome total
but less than the 961,019 tons of 1810. The
growth of our merchant shipping had fallen
behind the growth of population. In 1810 the
United States had owned 13,43 cubic feet of
registered tonnage per capita. In 1845 it owned
only 5,4 cubic feet per capita.

In 1840 British steamships launched and
driven by subsidies — a subject considered else-
where — had appeared on the route between
America and Europe, and also in British trade
with the West Indies, South America and the
East Indies. Up to that time the transatlantic
fast freight, passenger and mail service had
been dominated by the American flag. Nearly
all of the lines of sail packets were of United
States ownership and construction. The Black
Ball line, the Swallowtail line, the Clipper
line, the Red Star line, the Williams and Guion
line and others employed vessels comparable in
size with the East Indiamen of Great Britain
and far superior in speed and handiness. These
packets should be carefully distinguished from
the clippers which came afterward. Packets
were swift but capacious vessels, large carriers
for their tonnage, with accommodations in the
cabin for first-class and between decks for
steerage passengers. They were strongly built
of wood, many in New York yards along the
East River and others on the Delaware and
in New England. Their passenger traffic was
carefully regulated by Federal laws. The
packets carried the higher cost freight, and
their rates were above those of ordinary mer-
chantmen. But they were profitable ships be-
cause of the swiftness and regularity of their
voyages, the best of which were from 14 to
20 days from New York to Liverpool. The
packet era began in the early years of the last
century and practically ended by 1860, when
steam became supreme — though a few sail
packet ships remained in transatlantic passen-
ger and freight service long afterward.

The first real clipper ships of a sharper
model, loftier spars and relatively less freight
space appeared in 1843. On the other hand, the
blunders of the lawmakers had been a great extent retrieved by
the persevering and progressive spirit of the
shipbuilders, shipowners and seamen of the
United States.

Steamers, Packets and Clippers.—Steam
shipbuilding and navigation were first made
practicable in America. The Clermont of Rob-
ert Fulton in 1807 was the first successful
steam-driven craft. The Savannah in 1819 had
made the first steam transatlantic passage. In
1823, when the steam merchant fleet of the
United States was first enumerated, it had a
total tonnage of 24,879 — engaged almost en-
tirely in coast and river voyages. By 1833 our
steamer fleet had increased to 3,621,516 tons,
and by 1840 to 1,596,135 tons, of which over
4,155 tons were registered for foreign commerce.
Moreover, American shipbuilders, contrary to
frequent assertions, were quick to recognize
the value of iron, and the first iron sea-going
steamer, the Bangor, was built at Wilmington,
increase was principally due to the California trade and its demand for ships of high speed and heavy armament. It does not represent any proportionate increase in American shipping, for the 75.2 per cent of our imports and exports conveyed in 1849 in American vessels had shrunk in 1860 to 65.5 per cent. Under mischanced reciprocity the American flag in the decade before the Civil War was not holding its own in the overseas commerce of the United States, though its tonnage was apparently mounting. Moreover, this decade before the war was characterized by the sharpest and most disastrous decrease of American shipbuilding in all our national history.

Decline before the Civil War.—In the year 1855 a total of 583,450 tons of shipping had been launched in the United States, but this had fallen off to 156,602 tons in 1859 and stood at only 214,707 tons in 1860. This decline is all the more significant when it is added that the 381 square-rigged ships and barks built for foreign commerce in 1855 had decreased to 89 in 1859 and to 110 in 1860. Revolutionary measures in Europe in 1847 and the Crimean War of 1854-56 had given a temporary impetus to American shipbuilding and navigation because of an exceptional demand for ships for the export of foodstuffs and for immigration and transport service. But when these passing factors had lost their force, an alarming decline set in in our ocean tonnage, in years of peace, under a low tariff policy, before the firing of the first gun of the Civil War.

This decade before the war had witnessed a marvelous change from sail to steam and from wood to iron. But, contrary to frequent assertions, it had not found American shipbuilders and shipowners unprepared. The first British Cunard steamships had appeared in 1840 on the route from Liverpool to Halifax and Boston. They were wooden side-wheel craft, with a speed of from 9 to 10 knots and a tonnage of about 1,200. In fresh breezes they were often beaten by the powerful American packet ships, but there had an advantage in light or contrary weather. These Cunard steamers received at first a British mail subsidy of $425,000 a year, which was subsequently doubled. It was manifestly impossible for American steamships of like cost to compete with them without government encouragement. The subject was actively taken up in Congress, and in 1845 and 1847 laws were enacted providing mail subsidies for American lines. The first United States service was from New York to Havre and Bremen, with $200,000 a year for 20 voyages. Other lines were established from New York to the West Indies, to the Isthmus of Panama and in 1848 northward from the Isthmus to California and Oregon. Like the Cunard ships, the vessels employed were wooden side-wheel steamers, of from 1,000 to 2,400 tons. They were designed and built principally in New York by skilful builders, who had created the famous packet and clipper fleet. In 1847 a contract was concluded with Edward H. Collins and his associates for a first-class steamship line from New York to Liverpool, with a subsidy of $385,000 a year, subsequently increased to $858,000. The Collins steamers were much larger than the Cunard ships, or of 2,900 tons. Under such government encouragement ocean steamship building rapidly increased in the United States. In 1860 our deep-sea steam fleet had amounted to 20,870 tons, but reduced to 11,969 tons — so that our ocean steam fleet and Britain's were practically equal, though America represented by far the more rapid and successful development. The Collins liners uniformlly beat their British rivals on the route to Liverpool and secured the bulk of the first-class passenger and freight traffic.

For reasons set forth in detail elsewhere in the article on steamship subsidies, the mail subventions were taken away from the American lines in the crisis of their rivalry with their British competitors, when every advantage seemed to favor the flag of the United States. One by one the American lines succumbed — except those to the West Indies and the Isthmus of Panama, which came partially within the protection of the coastwise service. The Stars and Stripes had vanished from the regular year-round steam trade of the north Atlantic before the Civil War began. The blow which in 1848, the Irish famine, and the Crimean War of 1854-56 had given a temporary impetus to American shipbuilding and navigation because of an exceptional demand for ships for the export of foodstuffs and for immigration and transport service, hit these lines so severely that the American ship lines was in part responsible for the serious decrease in American shipbuilding that marked the half-decade from 1855 to 1860.

The Civil War did not destroy the American merchant marine. That war found the merchant marine already decreasing. What the war did was to accelerate a tendency that had already developed. Anglo-Confederate cruisers like the Alabama and the Florida destroyed only 110,000 tons of American shipping all told, but created, as it was intended that they should do, such an extraordinary insurance hazard for other American ships that they could not profitably be sailed beneath the Stars and Stripes — so that in the four years of the war 751,595 tons of shipping, or about one-third of our entire fleet registered for deep sea carrying, was sold or European shipowners. In 1861 our shipping registered for foreign commerce amounted to 2,486,894 tons and in 1866 there remained only 1,387,750 tons. Wreck and wear and tear accounted for part of the loss, and many American shipyards had been forced to abandon merchant work for naval construction.

The Geneva award of $15,500,000 against the British government for British complicity in the work of commerce-destroying cruisers was just under the actual value of the ships and cargoes seized by the Alabama and her consorts, but did not make good the vastly larger sums of money lost by those American shipowners who were forced by these depredations to pay excessive insurance rates or accept unremunerative freight rates or lay their ships up in idleness or sell them at one-half or one-third of their cost to foreigners. That award did not make good what American shipowners suffered from the diversion of their accustomed trade to European carriers.

The disastrous consequences of active British sympathy with the Confederacy and British raiding of our maritime commerce far outlasted the Collins and his associates' lines for a first-class steamship line from New York to Liverpool, with a subsidy of $385,000 a year, subsequently increased to $858,000. The Collins steamers were much larger than the Cunard ships, or of 2,900 tons. Under such
MERCHANT MARINE OF THE UNITED STATES

Merchant marine that enabled the United States government to maintain that close blockade of Southern ports that contributed to the final defeat of the Confederacy. More than one-half of the steamships, four-fifths of the officers and five-sixths of the men engaged in this vital work came directly from the merchant service. Masters and mates of American steamships and sail ships gave the navy 7,500 volunteers officers, the best educated and most skilful men of their calling in the world, and these officers were followed into the war fleet, by more than 50,000 merchant seamen. Without the great resources of the American merchant marine of 1861, the quick and sustained expansion of the United States navy would have been impossible. Until new cruisers were built, the fastest and the most efficient steamers of the blockade fleet were vessels from the coastwise and West India lines, and these lines supplied besides an adequate fleet of supply craft and transports.

Stagnation after the War.—For a few years after the Civil War, American ocean shipping seemed to have a fair chance through the treaty lines of 1861 and 1865, and European shipowners utilized the opportunity to strengthen their grip on the chief trade routes of the world. American merchants and shipbuilders fought with energy and courage, and our registered tonnage rose in 1867 to 1,518,648, and remained at or near that figure for a decade thereafter. In 1878 the total registered tonnage was 1,589,348. American steamships without government aid could not compete on the great mail lines with British or French steamships, and our tonnage fell to 400,000 tons. In the case of Great Britain these subsidies, liberally continued for many years, had given a powerful stimulus to iron shipbuilding and engine and boiler construction, and yards which were originally developed by the demands of the mail contracts had turned to building steam freighters of the slow but useful and familiar "tramp" type. Following the apparent line of least resistance, American shipowners and builders swung from the Mail Line to the "Free Ship" and "Free Shipping" Trade, and the Civil War to so-called medium clippers, particularly for the Cape Horn and other long-voyage trades. These medium clippers were not so fast as their racing predecessors, but had a greater range for cargo, with more strength and seaworthiness. For a long time these large American wooden sail ships successfully competed with British iron sail ships, but were finally driven from the seas, first by insurance discriminations enforced against wooden hulls by the British Lloyd's, and then by the liberal subsidies provided for sail ships by the French government. Except for a few inadequate and short-lived mail subsidies like those to the Brazil line and the Oriental service of the Pacific Mail, no national aid whatever was given to American ocean shipping from 1865 until 1891. A subsidy system similar to Great Britain's was strongly urged by the maritime and commercial States, but was regularly defeated by the influence of European steamship interests and the opposition of the agricultural South and West in Congress.

But in 1891 both the Senate and the House passed a cautious mail subsidy measure granting subsidies for postal lines of steamers. This legislation, however, was so seriously crippled by the insistence of Western lawmakers on reducing the original rates in the House of Representatives that tonnage was maintained a fast American mail line to Europe and several other lines to the West Indies and to Australasia, it has failed of any more extended purpose. This is the legislation which, coupled with the admission of the British-built New York and Paris to American registry, made it possible for the International Navigation Company to undertake in 1895-96 a weekly American mail service from New York to England and France. The Ocean Mail Act of 1891 maintains also the Ward line of American steamers from New York to Cuba and Mexico, the Red D line from New York to Venezuela and the Oceanic line from San Francisco to Australasia. Total expenditures under this act in recent fiscal years have been from $1,000,000 to $1,200,000 a year, or less than half of the amount expended for like purposes by the government of Canada, and one-fifth or one-sixth of the total mail subsidy payments to the 30 lines of British postal steamers which constitute the backbone of the British mercantile marine.

President Roosevelt in 1904 earnestly recommended an investigation by Congress of the causes of the decline of the American merchant marine, with a view to recommending remedial legislation. A Merchant Marine Commission of five senators and five representatives, of which Senator J. H. Gallinger of New Hampshire was chairman, was authorized by Congress and published its report in 1905, urging national encouragement of regular steamship services to the West Indies, South America, South Africa, Australasia and the Orient, and the granting of tonnage bounties to cargo vessels. A bill carrying these provisions passed the Senate, but the bounty to cargo ships was eliminated in the House, and every subsequent effort to enact even legislation for mail lines was defeated in the House, though by the slenderest of majorities. Again, as before the Civil War, a large part of the agricultural South and West resisted any federal form of national aid to the ocean shipping industry, and again this opposition was reinforced by the formidable influence of the European steamship organizations which were now monopolizing nine-tenths of the ocean carrying trade of the United States.

A Trial of "Free Ships."—A policy of "free ships," or the free admission of foreign-built vessels to American registry for at least the overseas trade, had found some advocacy for many years in the press and in Congress, and on 24 Aug. 1912, in connection with the Panama Canal Act, the Senate and House changed the traditional policy of the nation by offering free registry for the overseas trade to foreign-built vessels of American ownership not more than five years old, and capable of carrying dry and perishable cargoes. The new expedient absolutely failed. Up to the outbreak of the war in Europe on 1 Aug. 1914, not one foreign-built ship had sought and secured register under this legislation. The reason assigned was the higher cost of operation that would have to be assumed under American laws and regulations. About 1,000,000 tons of ocean shipping, it is estimated, were owned and controlled in 1912 by American capital, but navigated under for-
eign flags to take advantage of foreign mail subsidies or of the lower range of foreign shipboard wages.

But when the European War broke out, many of the American owners of this foreign tonnage, particularly of that part of it under British or German colors, sought the protection of the flag of the United States in order to escape capture by the enemy. Therefore, Congress on 18 Aug. 1914 passed an act to measure an act amending the previous act, broadening its provisions and authorizing the President to suspend the requirement of law that the officers of these foreign-built ships should be American citizens. These foreign-built ships admitted to American registry were further exempted from compliance with our inspection and measurement laws and regulations.

A great many foreign-built craft sought American registration under this measure. It was discovered that the hoisting of the American flag was the signal for a demand from foreign officers and crews for the wage scale and food scale of Americans. The result was an immediate and large increase in the cost of maintaining and maintaining these foreign-built ships, so that they came upon the same basis as American ships of native construction. It was demonstrated, therefore, that a free-ship policy in itself could not suffice to solve the problem of the American merchant marine in overseas trade. Though nearly all maritime governments, as the great war drew on and as the need of ships became more pressing, enacted laws forbidding the transfer of vessels to foreign purchasers, yet before this action was taken a considerable fleet of foreign-built vessels had been converted under the Stars and Stripes. This reinforcement from foreign fleets and the diversion of large coastwise carriers from domestic trade to overseas navigation, due to the high freight rates that had prevailed since the war began, suddenly and greatly increased the tonnage of American tonnage registered for foreign carrying from 1,066,288 on 30 June 1914, to 2,185,008 on 30 June 1916. In these same two years the proportion of American imports and exports carried under the American flag had risen from 9.7 per cent to 16.3 per cent.

A Swift War Growth.—The European War brought to the United States such a sharp realization of the need of a greatly increased fleet of American ships as the “delivery wagons” of American commerce, that immediate and positive action was demanded from Congress. This took the form at first of a proposal for ambitious government ownership and operation of merchant vessels, for the purchase or construction of which it was provided that $30,000,000 should be at once appropriated. But the principle of government participation in the merchant shipping business was so earnestly opposed in Congress and by the mercantile community that the law finally passed on 7 Sept. 1916 contained as its main feature authority for the appointment of a United States Shipping Board, which in 1918 was empowered to supervise ocean freight rates for the purpose of preventing unjust combinations of ocean carriers or the exaction of excessive charges. This Federal Shipping Board was given, moreover, general authority over the merchant marine, and was authorized to devise the best methods to increase it. Government ownership and operation of merchant tonnage were reduced to a minimum, with the stipulation that no ship should be purchased by the government unless it were about to be withdrawn from American commerce without an intention on the part of the owner to return it within a reasonable time. The ships so purchased should be operated by the government unless private capital could not be persuaded to employ it. Moreover, the operation of any vessel on the part of the United States must cease at the end of five years from the conclusion of the European War. The government, however, was authorized by the new law to continue indefinitely to purchase, lease, charter or transfer vessels to be employed by private shipowners, and was even authorized to secure foreign-built vessels for operation in the coastwise trade of the United States Lakes and the Gulf of Mexico.

When on 6 April 1917, the United States itself entered the war, it was recognized that an extraordinary effort must be made to support our Allies with food and munitions, and also to transport our American army to Europe and to sustain our troops with their essential equipment and supplies after they had landed. Therefore, the new Shipping Board, on 6 April 1917, organized the Emergency Fleet Corporation for the carrying out of the vast program of ship construction that had become imperative. There were at that time 37 shipyards building steel vessels and 24 yards building wooden seagoing vessels in the United States. In these yards were 235 shipways. In the presence of war, the previous reluctance to give national aid to the industry suddenly vanished. The Emergency Fleet Corporation advanced generous funds for the expansion of existing shipyards and the creation of new yards, and enormous contracts for new tonnage were distributed to builders on the Atlantic and Gulf coasts. In 1917 and early 1918, nearly 15,000 new ships were launched in the United States. The answer to the question of Lloyd George’s call for “all ships, and yet more ships” for the desperate need of the Allies made the usual expend.
MERCHANT MARINE OF THE UNITED STATES

The total construction added to the American merchant marine during the 19 months of America's participation in the war comprised 875 vessels of 2,941,845 gross tons. In addition, the United States possessed at the end of the war 88 vessels of 562,005 gross tons which had been taken over from enemy nations. Capital had made available for the work of the Shipping Board and the Emergency Fleet Corporation about $4,000,000,000 of national funds, to be expended in the purchase and building of ships, the extension or creation of shipyards, the operation of ships and the training of American officers and seamen. In part the rapidly increased fleet was manned from the Navy and the Naval Reserve.

Before the war, in 1914, good steel cargo steamers could have been built in America for about $5 per deadweight ton. Because of the war increase in materials and wages, the relative inefficiency of many of the new shipyards and their workmen due to inexperience, and the pressure of the war emergency, the Emergency Fleet Corporation was compelled to pay from $150 to $200 per deadweight ton, and even more, for the construction of steel cargo steamers of the same general character. It was very clearly demonstrated that allowing foreign shipowners to carry our imports and exports for so many years had proved in the end not an economy but an extravagance.

On 27 March 1919 Chairman Edward N. Hurley of the United States Shipping Board formally proposed a plan for the future operation of the new government-owned American merchant fleet, which by 1921, including ships bought, built and contracted for, would amount to 2,000 vessels of about 10,000,000 tons gross register. Mr. Hurley urged that the ships should be sold at the world-price to private shipping companies in which the government should be represented by one director, that 25 per cent of the purchase price should be paid down, and the remainder paid in installment through a 10-year period — the government meanwhile to be protected by a mortgage which should have priority above all other liens. Chairman Hurley further recommended a method by which a merchant marine development fund could be provided for, to assist American shipping on routes where the service might at first be unprofitable.

It is in the deep sea or registered tonnage that is embodied the real problem of our merchant marine. The coastwise vessels as enrolled and licensed shipping of the country, as distinguished from the foreign-going or registered shipping, has had a steady, constant growth under the national policy which from 1789 onward had reserved domestic carrying on ocean, lake or river between American ports to ships of the American flag and of American construction. In spite of the unparalleled railroad development of the United States, American domestic shipping had grown from 68,607 tons in 1789 to 6,818,863 tons in 1914 — incomparably the greatest coastwise shipping in the world greater than the entire coastwise and overseas tonnage of the German Empire in 1914, or equivalent to threefold the entire tonnage of France or Norway and fourfold the tonnage of Japan before the war. The progress of this immense domestic shipping has been singularly uneventful, and more than one-third of its tonnage is to be found on the great northern lakes, where an enormous movement of iron ore, coal and grain has demanded carriers of the heaviest dimensions.

Many of the present coastwise steamers on the Atlantic and Pacific have been employed in naval auxiliary service as ammunition ships, fuel ships, general supply ships and transports, and the specific requirement is made in the Ocean Mail Law of 1891 that all subsidized American steamers in the foreign trade shall be built on designs approved by the Navy Department, and be turned over to the government in war.

The new shipping law of 7 Sept. 1916 provides that vessels built, purchased, leased or chartered under this legislation shall be set as possible adapted for use as naval auxiliaries or army transports or for other military or naval purposes.

MERCHAND MARKS. See MONOGRAM; TRADEMARK.

MERCHAND OF VENICE, The. The Merchant of Venice, entered in the stationer’s register in 1598, and published in quarto form in 1600, was written about 1594 or 1595. Several stories that had long had currency in the world—notably the story of the caskets as a device for the choice of suitors by a wealthy heiress, and the bond story of the rich Jew and his debtor—are happily blended in this play, and thereto are added the story of the rings, the romantic minor plot of Lorenzo and Jessica, and the comic character of Launcelot. Shakspere never constructed a better plot, or one better calculated to win popular approval. It meets every demand of stage-management. Although the two main incidents—the choice of the caskets and the pound of flesh—are almost childishly absurd, they are made to seem probable and even natural by the romantic atmosphere in which the characters move. Whether walking the streets of Venice or watching the moonlight sleep sweetly upon the banks of fair Belmont, we breathe the air of the Renaissance in Italy. All the characters fit in perfectly with this background except Shylock. Unquestionably to an Elizabethan audience the impression made by him was partly humorous and not at all typical. With his huge nose and the red wig of the traditional Judas he was fair game, not only for the characters in the play, but for those in the pit. His practice of usury and his Jewish qualities rendered him the legitimate object of hatred and ridicule—his passionate words of rage only increased the laughter of an Elizabethan audience. While Shakspere gave sufficient ground for this interpretation of the character, he has so humanized him as to produce a different effect on a modern audience. His famous words, “Hath not a Jew eyes, etc.,” are an instinctive protest against race hatred and in favor of social sympathy. Whatever may be doubtful in the interpretation of Shylock, there is none in the interpretation of Portia. There is no better illustration of the power with which Shakspere transformed his material than in the change of Portia from a practical and widowed siren, who persuades merchants to stake their all against her hand that they will possess her person, and who then drugs them at supper into one of the most charming characters of all time. Her beauty of person, brilliancy of intellect, nobility of soul, and gift of poetical expression, all combine to produce an effect not surpassed by any other creation of the dramatist. She is the bond of union between the casket story and the pound of flesh story, and all the other characters group themselves naturally about her. The concluding scene of the play at Belmont, after the excitement of the trial scene and the disappearance of the sinister character Shylock, is one of the supreme passages of poetry in the language—almost magical in its beauty of background and expression.

EDWIN MIMS.

MERCHAND VESSELS, Neutral, Rights of. In time of war neutral merchant vessels are entitled to navigate the high seas as in time of peace although in the interest of belligerents they are subjected to certain restrictions such as the liability to search by belligerent cruisers for the purpose of ascertaining whether they are carrying contraband to the enemy or seeking to run a blockade. See BLOCKADE; RIGHT OF SEARCH.

No belligerent may lawfully declare a portion of the high seas to be a war zone within which neutrals shall be excluded from navigating, although he may warn them that a certain portion of the high seas is to be a theater of naval operations and that they will be exposed while traversing it to the dangers incident to the conduct of such operations therein. Within such area belligerent powers may exercise their right of visit, search or capture in respect to neutral vessels than they have anywhere else on the high seas. It is also doubtful whether belligerents have a lawful right to plant mines in the open seas in such a manner as to render the neutral vessels to the danger of destruction while innocently navigating the waters thereof although it is to be regretted that the Second Hague Conference declined to adopt a proposal of the British delegation prohibiting the laying of mines in the open seas. See SUBMARINE MINES.

Neutral vessels have a right to enter the ports of a belligerent so long as they are not blockaded and they may transport supplies to and trade with such ports, subject to the rules governing traffic in contraband goods. (See CONTRABAND.) Whether neutral vessels may in any circumstances be destroyed by a belligerent was much discussed during the World War. The question was first raised during the Russo-Japanese War of 1904-05 on account of the sinking by a Russian cruiser of the Knight Commander, a British merchant vessel, a portion of whose cargo consisted of contraband goods consigned to ports in Japan. The Russian commander justified his act on the ground that on account of lack of coal and trouble to spare a prize crew he could not send the ship into a home port for adjudication by a prize court, hence his only alternative was to allow the prize to go free or destroy it. The act aroused intense indignation in England and was denounced by Lord Lansdowne as a very serious breach of international law. The Russian contention, he asserted, would justify the wholesale destruction of neutral ships taken by a cruiser at a distance from her base for the reason that she could not spare a prize crew or lack a sufficient supply of coal. Several other neutral merchantmen were destroyed by the Russians during their war with Japan. During the recent war German naval commanders have acted on the ground that they have generally destroyed their prizes neutral as well as enemy vessels, because it was impossible to take them in for adjudication. (See the article on CONTRABAND for a discussion of the cases of the Frye and the Maria).
In no war of the past have neutral merchant vessels suffered so heavily as in the present one. More than 800 neutral ships, American, Danish, Dutch, Greek, Italian, Norwegian, Portuguese and Swedish, were sunk while peacefully navigating the high seas—in most cases by German submarines or cruisers. In a few cases the destruction was due to error but in the majority of cases the reason alleged was that the vessels were carrying contraband. The naval regulations of most states authorize the destruction of prizes under certain circumstances and some of them make no distinction between enemy and neutral vessels. Thus the American instructions for blockading vessels and cruisers in 1898 (Art. 28) authorized destruction of prizes which for "controlling reasons" such as unseaworthiness, existence of infectious diseases, and lack of a prize crew could not be sent in for adjudication. Likewise, if there was imminent danger of re-capture the prizes might be destroyed. The prize regulations of many other states contain somewhat similar provisions. The German prize code authorizes destruction of neutral vessels for carrying contraband, for breach of blockade or other unneutral service, if the taking of the ship in would expose the captor to danger or impede the success of his operations; if, for example, the captured vessel is unseaworthy or is unable to follow the captor, or in case the captor cannot spare a prize crew or has an insufficient supply of coal or is near the enemy's coast (Art. 115). Many writers on international law, however, deny the right of belligerents to destroy neutral prizes. The question was discussed at length at the Second Hague Conference but on account of the divergence of views there expressed, no agreement was reached. It was again discussed at the London Naval Conference in 1908-09. The British delegation proposed as it had done at the Hague in 1907 that the right of belligerents to destroy neutral merchant vessels be prohibited in all cases whatsoever and it was supported by the Japanese delegation. The proposals of most of the other powers, however, recognized the right to destroy in certain exceptional cases and this view finally prevailed. The rule adopted affirmed the general principle that a neutral vessel cannot be destroyed but must be taken into a prize court for adjudication. Nevertheless, by way of exception, the right to destroy was admitted in cases where conveyance of the prize to port would involve danger to the captor or to the success of the military operations in which he was at the time engaged (Art. 49). The effort of the British delegation to obtain an express confirmation that inability to spare a prize crew should not constitute a sufficient justification for destruction failed to receive the approval of the Conference. The rules adopted by the Conference provided that a vessel carrying contraband is liable to condemnation, and consequently to destruction, when more than half its cargo consists of contraband goods. Not all vessels carrying contraband therefore may lawfully be destroyed. The rules adopted by the Conference, although representing a compromise between conflicting views, undoubtedly provided some safeguards against arbitrary destruction of neutral vessels. While the Declaration has never been ratified by.any government represented at the Conference the various belligerent countries have put it into effect at the outbreak of the present war with certain modifications, none of which, it appears, altered the rules regarding destruction of neutral vessels. See MINES, SUBMARINE; CONTRABAND; RIGHT OF SEARCH; WAR ZONES.

JAMES W. GARNER.

MERCHANT VESSELS, Transfer of from Belligerent to Neutral Flags. On account of the liability of enemy merchant vessels to capture, their owners frequently at the outbreak of war or when war becomes imminent between their own country and a foreign power seek to withdraw them from the risk of capture by transferring them by sale or otherwise to neutral registry. Are belligerent bound to recognize the lawfulness of such transfers and refrain from capturing enemy vessels so transferred?

The practice of states has not been uniform in respect to such transactions. British and American practice has heretofore admitted the validity of such transfers made during or in contemplation of war provided that there was no intent, that is, if the transfer was a fully perfected transaction, in which the purchase price had passed from the purchaser to the former owner, the ship being actually delivered and duly registered in accordance with the registry laws of the state whose flag it was to fly, the former owner retaining no interests or title in the vessel so transferred. Consult the cases of the Benito Estenger, 176 U.S. 568 (1899); the Sechs Geschwister, 4 c. Rob. (1891); the Baltic, Spinks Prize Cases, 98 (1850); and the Ariel, Moore's Privy Council Cases IX, 128 (1857).

During the American Civil War large numbers of vessels under American registry were transferred to neutral flags in order to avoid capture by Confederate cruisers. During the war between Chile and Peru in 1879 and the conflict between France and China in 1883 many vessels were transferred to American registry for similar reasons. During the Crimean War a number of Russian vessels were transferred to the American flag and the validity of the transfers were generally sustained by the British prize court. The French and Russian rules, however, have heretofore denied the legality of all such transfers made after the outbreak of hostilities. At the London Naval Conference of 1906-09 an attempt was made to harmonize the conflicting views and certain rules governing the validity of such transfers were agreed upon and adopted by the conference. By article 55 of the Declaration of London transfers to neutral flags before the outbreak of war was recognized to be valid unless it was proved that the transfer was made in order to evade the consequences to which an enemy vessel, as such, is exposed. The Declaration laid down certain presumptions of intent to evade the consequences of capture, as where the bill of sale is not on board in case the transfer has been made less than 60 days before the outbreak of war. But these presumptions were not made to be rebuttable by evidence showing the contrary intent. The onus of proving that the transfer was made for the purpose of avoiding capture was placed on the captor, not on the owner. To be valid in any case the sale must be
unconditional, complete and in conformity with the laws of the countries concerned.

By article 56 of the Declaration transfers made during the course of war were declared to be void unless it was proved that they were not made to evade the consequences of capture. Certain absolute and irrefutable presumptions of invalidity were laid down, such as where the transfer was made in a blockaded port or during the course of a voyage or where the right to repurchase the vessel was reserved by the vendor. Unlike the rule governing transfers before the outbreak of war, the rule as to transfers made during the war is based on the presumption that the transfer is void and the onus of proving the contrary is on the owner rather than on the captor.

The Declaration of London, however, never having been ratified, its rules relating to transfers were not legally binding on the belligerents during the War. The War, therefore, applied no general rule as to the right of transfer from belligerent to neutral flags, each belligerent was free to apply its own rule.

The question of the validity of transfers made during the War was raised in the case of the Dacia in 1915. This vessel was a Hamburg-American liner which, while lying in an American port, after the outbreak of the war, was purchased by an American citizen and admitted to American registry in pursuance of a recent act of Congress authorizing the admission to American registry of foreign-built ships. Subsequently while on a voyage from New York to Rotterdam the Dacia was captured by a French cruiser and placed in the custody of a prize court which condemned it and ordered it to be sold. The prize court applied the old French rule which denies the legality of transfers made during war. It might, however, have treated the Declaration of London as binding and then condemned the ship on the ground that the transfer was made with a view to evading the consequences of capture. Had the Dacia been captured by a British cruiser the British prize court could hardly have condemned it without departing from the precedents set by Lord Stowell and Dr. Lushington in the earlier cases. It was doubtful owing to this fact that the Dacia was by prearrangement between the British and French authorities captured by a French cruiser and sent to a French prize court for trial, thus ensuring it certain condemnation.

The Administration Ship Purchase Bill which was before Congress in 1915 raised the question whether the purchase after the outbreak of the war of belligerent merchant vessels by a corporation, a majority of the stock of which was owned by a neutral government, would be an unneutral act and whether the opposing belligerent would be bound to recognize the validity of such transfers. It was the avowed intention of the supporters of the bill that in case it became law purchases of German merchant vessels then laid up in American ports should be made and the vessels so purchased should be admitted to American registry.

The view was expressed by Mr. Lansing, then counsel of the Department of State, and by Senators Lodge, Root, McCumber, Burton and others that such transfers would not have been in accord with the principles of neutrality since neutral governments are forbidden to do many acts which it is permissible for neutral individuals to do. It was unofficially announced in England and France that the British and French governments would not recognize the validity of such transfers and that enemy merchant vessel were purchased by the proposed corporation and appeared on the high seas under the American flag they would be captured and put into a prize court for the purpose of testing the validity of the transfers. The failure of the bill to become law removed what would doubtless have become a source of controversy between the United States and Great Britain and France. Tested by the rule of strict neutrality the proposed purchase by a corporation, controlled by the government of enemy ships which had been driven from the high seas to take refuge in neutral ports to avoid capture and the sending of those vessels on the high seas under the protection of a neutral flag would undoubtedly have been an unneutral act against which injured belligerents could justly have complained.

James W. Garneel

MERCIA, mër-shë-a, England, the largest kingdom of the Saxon heptarchy. It was the scene of the Trent from the North Sea to Wales. Mercia was founded by Cerdic in 585. Like the other Anglo-Saxon kingdoms it had a stormy history, being almost continually at war with some of its neighbors. In 827 it was conquered by Egbert, who united the different kingdoms of England into one. As its frontiers extended to those of the other kingdoms, as well as to Wales, it derived its name from that circumstance (Anglo-Saxon meare = sea). See England, Geographical History.

Antonin, aht-to-nën më-rón, French sculptor and painter; b. Toulouse, 3 Oct. 1845. He studied under Jouffroy and Guiche; won the first Prix de Rome in 1888; and in 1872 obtained a medal of the first class for his bronze statue of the young David, now in the Luxembourg. His masterpieces were 'Gloria victis' (1874), followed by a mounted Juno (1877); a marble statue of 'Paining' (1890); 'William Tell,' now in Lausanne; monuments to Thiers, Meissonier (in front of the Louvre), and Jules Ferry, and 'Napoleon' on the Vendôme Column. He painted a Venus, now in the Luxembourg. In 1871 he was elected an Academician.

MERCIER, Desiré Joseph, Belgian cardinal, archbishop of Malines and primate of Belgium; b. 21 Nov. 1851 at Braine-l'Alleud, province of Brabant. Educated at Louvain, Paris and Leipzig, he was ordained priest in 1874 and became professor of philosophy at the University of Louvain. Here he organized the Institute Supérieure de Philosophie, based on the teaching of Saint Thomas Aquinas, founded under the auspices of Pope Leo XIII. As a distinguished lecturer Professor Mercier—as he then was—earned a high reputation for literary and scientific abilities, united with
HIS EMINENCE CARDINAL DESIRÉ MERCIER
Archbishop of Malines, Belgium
real, leadership and exalted purpose. He wrote several volumes of note, e.g., "Les Origines de la Psychologie Contemporaine" (1897), "Métaphysique Générale" and "Critériologie," which passed through numerous editions, as well as others of a less didactic character. He was also the founder of the Revue Neo-Scholastique when official as head of the school of neo-
scholastic philosophy. On 8 Feb. 1906 it was announced that "Dr. Mercier, president of the Institute of Advanced Philosophy at Louvain," had been appointed archbishop of Malines. Though at first a general surprise, the appro-
priateness of selecting him to the episcopal bench soon became apparent. With energy and
amiability he devoted himself to the admin-
istration of his diocese, and on 15 April 1907 was created and proclaimed cardinal and pri-
mate of Belgium. The German conquest of
Belgium in the early stages of the European
War brought him into world-wide prominence
by the fearless and determined attitude he
adopted toward the ravagers of his country. In
these days of crisis the German death of Pope Pius X, a number of the as-
csembled cardinals decided to give Mercier their
vote in the election for a new pope as a dem-
onstration of sympathy with Catholic Belgium.
He was supported by the French and English
cardinals, while the Germans and Austrians
protested against what they called undue in-
terference of politics in the highest spiritual func-
tions of the Church, and Cardinal Della Chiesa
was ultimately elected. Cardinal Mercier ar-
ived in Rome on 12 Sept. 1901, action the
following day (Sunday), accompanied by the
late Duke of Norfolk, was received in audience
by the King and Queen. In the afternoon he
witnessed a remarkable and enthusiastic dem-
onstration in Westminster, organized by Irish
members of Parliament and attended by many
thousands of people. He returned to Belgium
the same night and exerted himself during the
long period of the German occupation to amel-
iorate the sufferings of his compatriots. He
came into frequent collision with the German
authorities, notably von Bissing (q.v.). The
Cardinal's pastoral letters, collected and pub-
lished by Burns and Oates (London 1918),
form a series of earnest exhortations to the prac-
tice of Christian fortitude and hope amid
the horrors and afflictions of war.

MERCIER, Honoré, Canadian lawyer,
journalist and politician: b. Itherville, Quebec,
was educated at Saint Mary's (Jesuit) College
in Montreal and afterward studied law at Saint
Hyacinthe, being admitted to the bar in 1863.
During his legal studies (1862-64) he was editor of the "Courrier de Saint Hyacinthe,
the Conservative organ of the district; but as
a journalist he was among those who opposed
Canada. This led him to abscond from the
province and to sever his connection with the
Conservative party. During the years
immediately following the confederation of 1867
Mercier devoted himself to his profession, but
in 1871 he reappeared in politics as the leader
of the Nationalists (also called the Parti noir),
whose leading aim was to curtail the power
of the Dominion government in favor of
provincial rights. On this platform he was
elected to the federal Parliament for Rouville
in 1872, but did not stand for re-election to
the Parliament of 1873. After some four years
devoted to the successful practice of law at
Saint Hyacinthe, Mercier was elected (1879)
to the legislative assembly of Quebec, being
appointed solicitor-general of the province in
the ministry of M. Joly. On the defeat of the
Joly administration in the same year, Mercier
passed into the opposition, of which he pres-
tenly became leader. In 1881 he left Saint
Hyacinthe to practise law in Montreal. In
1885 the French Canadian population was
thrown into a ferment by the trial and execu-
tion of Louis Riel, the leader of the North
West Rebellion (q.v.). Mercier, heading the
agitation thus occasioned, declared Riel to have
been a "victim of the fanaticism of Sir John A.
Macdonald." On the strength of the feeling
thus aroused, the Conservative party was de-
feated in the provincial elections of 1886 and
Mercier found himself at the head of the ad-
ministration. In this capacity he carried
through the legislature the famous Jesuit Es-
tates Act, a measure intended to compen-
sate the Jesuits for the property confiscated
by the Crown at the time of the papal dissolu-
tion of the order. In spite of the agitation
throughout Canada against the act the Mercier
government was upheld in the election of 1890.
In the same year grave charges of peculation
were brought against the Premier and his col-
leagues on the ground that a subsidy of $100,-
000, intended for the Baie des Chaleurs Railway,
had been diverted to political uses. Investiga-
tion resulted in the dismissal of the ministry
(13 Dec. 1891), action the following year (Sundiay), accompanied by the
late Duke of Norfolk, was received in audience
by the king and queen. In the afternoon he
witnessed a remarkable and enthusiastic dem-
onstration in Westminster, organized by Irish
members of Parliament and attended by many
thousands of people. He returned to Belgium
the same night and exerted himself during the
long period of the German occupation to ameli-
orate the sufferings of his compatriots. He
came into frequent collision with the German
authorities, notably von Bissing (q.v.). The
Cardinal's pastoral letters, collected and pub-
lished by Burns and Oates (London 1918),
form a series of earnest exhortations to the prac-
tice of Christian fortitude and hope amid
the horrors and afflictions of war.

MERCUR, mër'kär, James, American sol-
dier: b. Towanda, Pa., 25 Nov. 1842; d. West
Point, N. Y., 22 April 1896. He was educated
from West Point in 1866 and commissioned in
the engineering corps. He was engaged in sur-
evays made under the government and in 1867-
72 was assistant professor of natural and ex-
perimental philosophy at West Point, after
which he was in command of an engineering
corps and in 1876-77 assisted in clearing the
New York harbor of the obstruction at Hell
Gate. He was professor of civil and military
engineering at West Point from 1884 until his
death. He published a revised edition of
Mahani's "Permanent Fortification" (1887) and
the original works, "Elements of the Art of
War" (1888); and "Military Mines, Blasting and
Demolitions" (1892).

anIC Acid.

MERCURY, mër'kü-ri, the Roman god
Mercurius who presided over commerce and
gain. See Hermes.

MERCURY, the planet of the solar sys-
tem which is nearest to the sun. Owing to the
position of its orbit, far inside of that of the
earth, it is never seen by us at any great dis-
tance from the sun, but seems to swing back
and forth, first on one side of the central lumi-
nary and then to the other. (See Solar Sys-

The time of revolution is a little less
than three months and therefore less than one-
fourth that of the earth. When, starting from
a point between the earth and the sun, it has
completed a revolution, the earth has moved
forward in its orbit, and, in consequence, nearly
30 days more are required to catch up with the
earth and again come into conjunction with it.
Consequently the time of one synodic or ap-
parent revolution is nearly four months. It
follows that its greatest elongations from the
sun occur at intervals of nearly 60 days, alter-
nately to the east and to the west. When near
its greatest eastern elongations it may be seen
in the west toward the close of twilight. When
west of the sun it may be seen in the morning
before daybreak. To the naked eye it seems to
shine as a star of the first magnitude. But as
it is never seen in a perfectly dark sky except
when very near the horizon, it is not readily
observable in high northern latitudes. It is
said, in fact, that Copernicus died without ever
seeing this planet.

With the aid of a telescope, Mercury may
be seen the greater part of the time—in the
afternoon when it is east of the sun; in the
morning when it is west of it. But it is never
seen fully illuminated unless near the farther
part of its orbit, beyond the sun, when it may
be lost in the effulgence of the sun's rays.
When it approaches nearest to us, only a small
portion of the hemisphere presented to us is
illuminated. Owing to these unfavorable con-
ditions observation on it are extremely diffi-
cult, and it cannot be said that anything is
certainly known of its physical constitution.
The difficulty is increased by its being much
the smallest of all the major planets. The result
is that nothing is positively known as to the time
of the revolution on its axis. About 1800, Schro-
eter, a celebrated observer of the planets,
thought it rotated in a little more than 24
hours. But Herschel found no foundation for
this belief, and could see no evidence whatever
of a rotation. About 1889 Schiaparelli, the
celebrated Italian astronomer, making a very
careful study of the planet, under the favoring
sky of Milan, was led to the conclusion that,
like the moon, Mercury's time of rotation was
the same as its time of revolution in its orbit,
so that it always presented the same face to
the sun. A similar conclusion was reached by
Lowell at the Flagstaff Observatory. But
the difficulty of seeing any well-defined features
on the planet is such that conservative astron-
omers are in doubt on the subject, and regard
the time of rotation as still unknown and not likely
soon to be determined.
The most remarkable feature presented by
the motion of Mercury is that the perihelion of
its orbit is found to move forward considerably
faster than it ought to by virtue of the attrac-
tion of the known bodies of the solar system.
The cause of this motion has perplexed astron-
omers for half a century; it was at first sup-
posed by Leverrier to be due to the attraction
of all other planets; but later it was supposed
that the extremely abstruse mathematical theory
of that body (based upon the law of gravita-
tion), has been so perfected, it is certain do
not exist. Similar discrepancies have been de-
tected in the orbit of Venus and the other
planets, notably in the node of Venus and the
perihelion of Mars. When the disturbing
pull of the exceedingly tenuous, lens-shaped,
cloud of particles known as the Zodiacal Light
is computed and allowed for, it is found that
not only these, but also the historic discrepancy
in the motion of the perihelion of Mercury,
disappear. It is very probable that the true
explanation of them is to be found in this
source.

At varying intervals the motion of Mercury
in its orbit causes the planet to pass between
the earth and the sun; it is then seen as an
intensely black, round dot crossing the sun's
disc. The next four transits will occur on
7 May 1924, 8 Nov. 1927, 10 May 1937 and
12 Nov. 1940. None of these will be visible,
however, from the United States. The first
transit which will be completely visible here
will occur on 13 Nov. 1953 and 6 Nov. 1960.
But little use is made of transits of Mercury.
Attempts have been made to detect traces of
an atmospheric ring about the planet during the
transit, as may be done during a transit of
Venus (q.v.), but these have not been certain
successful. Newcomb subjected 21 transits
from 1677 to 1881 to a critical discussion to
ascertain whether there might be found from
them any indication that the time of rotation
of the earth on its axis,—the unit of time
throughout astronomy,—had changed during
this interval. There was found no conclusive
evidence in any appreciable change in the length
of the day. It has certainly not increased or
diminished by so much as 0.01 second in the
course of the past 2,000 years.

Director Flower Astronomical Observatory,
University of Pennsylvania.

MERCURY, Fulminate of. See Fulmi-
nates.

MERCURY, or MARKERY, a perennial
herb (Chenopodium bonus-henricus) of the
natural order Chenopodiaceae. Like other
members of its genus, it has mealy foliage and
inconspicuous greenish flowers. The tender
shoots which appear in early spring are valued
as a substitute for spinach, for which purpose
the plant is frequently cultivated. In Europe
it is better known as Good King Henry. It
will grow in any garden soil with practically
no attention.

MERCURY, Medical Uses of. Mercury
uncombined is used only for its bulk. As it is
without medicinal effect, at one time as much
as two pounds of uncombined mercury would
be given for the purpose of mechanically dis-
lodging some obstruction in the intestines.
Trituated on or planets between Mercury and the
sun. Another explanation was sought in the assumption that the
sun's gravitation diminishes somewhat more
rapidly than it would according to the law
of the inverse square. If this were so, the perihelion of all the other planets
ought to be effected by a similar motion,
and in particular there should result distur-
bances in the motion of the planets; but it is
now that the extremely abstruse mathematical theory
of that body (based upon the law of gravita-
tion), has been so perfected, it is certain do
not exist. Similar discrepancies have been de-
tected in the orbit of Venus and the other

nates.
over nutrition. This is especially true of salts of mercury, such as mercurous chloride or calomel, mercuric chloride or corrosive sublimate and mercurous iodide or the green iodide of mercury. In small doses, especially in syphilis, mercury has a definite toxic action on the spiroothe which is the known syphilitic organism, and causes syphilis. In large doses mercury acts as a corrosive poison and tends to inflame the mucous membrane of the mouth, stomach and intestines. Calomel and blue pill are largely used as an effectual remedy in the various forms of powder, ointment, lotion and plaster is used to remove body-vermin, relieve itching and as a remedy in certain skin affections. Mercuric chloride, known as corrosive sublimate, is a powerful antiseptic and is taken internally in very minute doses. See Toxicology.

**MERCURY**, or **QUICKSILVER**, a metallic element which has been known for many centuries and which is distinguished from the other metallic elements by the fact that it is liquid at ordinary temperatures. The addition of certain substances to the metallic mercury occurs native in the metallic form, but by far the larger part of it is obtained by distilling the native sulphide, cinnabar (HgS), in a current of air which is regulated so as to burn the sulphur of the sulphide, while leaving the mercury in the metallic state. Cinnabar occurs abundantly at Idria, Austria, at Almaden, Spain, and at New Almaden, near San Francisco Bay, and it is from these sources that the mercury of commerce is chiefly obtained. It occurs as veins and disseminated deposits, the ores of which are believed to have been introduced by hot waters of magmatic (q.v.) origin. Spain is the largest producer and the chief output in the United States comes from California, though deposits are known in Texas and Oregon. Mercury freezes at 37° F. below zero and boils, at the ordinary atmospheric pressure (760 mm.), at 673° F. Its specific gravity at 32° F., when compared with water at 39° F., is 13.964. Its specific heat at ordinary temperatures is about 0.0331, and the average change of temperature of expansion between 32° F. and 212° F. is 0.00010085 (Fahrenheit scale). The ratio of the specific heat of the vapor at constant pressure to its specific heat at constant volume has been found, experimentally, to be 1.666, which indicates that the molecules of the vapor are monatomic and that they behave, so far as their collisions among themselves are concerned, as though they were elastic spheres. (See Gases, kinetic theory of.) Mercury may be freed from dust and dirt by filtering it through leather. To remove tin, lead and other dissolved metals, the mercury may be left for some weeks in contact with concentrated sulphuric acid and subsequently digested with dilute nitric acid; or it may be several times distilled. Various other modes of purification are also known.

The metal is chiefly used, in the arts, for the extraction of gold from crushed ore or fine gravel, the ore being washed by a gentle stream of mercury which is subsequently amalgamated with mercury. The gold particles, being heavy, sink through the water so as to come into contact with the copper plate, where they are held by the mercury in the form of a gold amalgam. (See Gold and AMALGAM.) In physics, mercury is also greatly used for filling thermometers and barometers, and for many other purposes. It is likewise used in medicine, both in the metallic form and in its compounds with other elements. Metallic mercury, when rubbed up in a mortar with confection of roses until its globules are so fine as to be indistinguishable to the eye, which is known as "blue mass," and is administered in the form of pills, as a chalagogue.

Mercury has the chemical symbol Hg (from *hydrargyrum,* its Latin name), and an atomic weight of 200.5 if Q = 16, or 198.8 if H = 1. It forms two oxides, each of which rises to a series of stable salts. The metal does not oxidize upon exposure to air at ordinary temperatures, but when heated nearly to its boiling point in air or in oxygen it slowly oxidizes, with the formation of mercury monoxide (or mercuric oxide), HgO. When prepared in this manner the monoxide is crystalline and red, and for this reason it is familiarly known as the "red oxide." The same substance may be prepared in an allotropic form by precipitating a solution of mercuric oxide with caustic potash, the monoxide then coming down as an amorphous yellow powder. The red oxide turns black when strongly heated, but recovers its color upon cooling. When heated to dryness the monoxide decomposes into metallic mercury and free oxygen. It can, therefore, be used as a source of oxygen; and it was in fact by heating this substance that oxygen was first discovered by Priestley. By acting upon the red oxide or upon metallic mercury by excess of nitric acid, mercuric nitrate, Hg(NO₃)₂, is formed; while if nitric acid is allowed to act upon excess of mercury, mercurous nitrate, Hg(NO₃)₂, is obtained. The corresponding sulphates of the metal are obtained by acting upon metallic mercury with sulphuric acid, mercuric sulphate (HgSO₄), or mercurous sulphate (Hg₂SO₄) being obtained, according to the conditions of the experiment. Mercuric sulphide, Hg₂S, which occurs native as the mineral cinnabar, and which is also known as vermilion, is bright red in color and may be prepared artificially by heating mercury with sulphur, or by passing sulphuretted hydrogen gas through a solution of mercuric salt. When obtained in the latter way it comes down as a black amorphous powder, which may be brought into the normal red crystalline form by sublimation. Mercury forms two chlorides which are extensively used, especially in medicine. Mercurichloride (also known as "bichloride of mercury" or "corrosive sublimate"), HgCl₂, is prepared by heating a mixture of equal parts of mercuric sulphate, HgSO₄, and common salt, NaCl; the reaction being HgSO₄ + 2NaCl = HgCl₂ + Na₂SO₄. The bichloride is fairly soluble in water and dissolves readily in a solution of sal ammoniac. It is also quite soluble in alcohol. It crystallizes in the triclinic system at melts at 500° F. and boils at 563° F. It is intensely poisonous and is one of the most powerful getmicides known. It is used in surgery and medicine as an antiseptic and disinfectant, and is occasionally used in the very smallest doses. Mercuros chloride, HgCl (more familiarly known as "calomel" or as the "mild chloride"), is a white powder, insoluble in water and is greatly used in medicine, both as a chalagogue and otherwise. It may be prepared in various ways, but the usual method is
by heating four parts of corrosive sublimate with three parts of metallic mercury; the mercury combining with half of the chlorine of the corrosive sublimate to form the compound HgCl₂. The equation is HgCl + Hg = 2HgCl₂. The calomel sublimes and must then be ground to a fine powder and thoroughly washed, in order to remove any free soluble corrosive sublimate that may not have been decomposed. The so-called "white precipitate," which is obtained when ammonia is added to a solution of corrosive sublimate, has the composition NH₄HgCl₂. Mercurous oxide, or "black oxide of mercury," Hg₂O, may be obtained as a black powder by digesting calomel with excess of caustic potash. It decomposes into the red oxide and metallic mercury upon exposure to light, or upon being heated to the boiling point of water. Many other compounds of mercury are known, but they are of less importance than the ones here given.

MERCURY VAPOR LAMP. See Vapor Mercury Lamp, The Hewitt.

MERCY, Fathers of, Roman Catholic religious congregation founded on the restoration of Louis XVIII, 1814, and approved of by the Pope (1834) under the title 'Society of the Priests of Mercy.' The object of the society is the formation of sinners by mission preaching and the practice of the corporal works of mercy. In 1839 the order founded houses in New York and Saint Augustine, Fla., and the fathers have churches for the French population in Brooklyn and Manhattan. The mother house was originally at Paris, but was removed to Rome in 1903 as a result of the Association Law. Consult Delaporte, 'Vie de Jean-Baptiste Rauzan' (1857).

MERCY, Sisters of, a name given to members of several religious communities founded for the purpose of nursing the sick at their own homes, visiting prisoners, attending lying-in-hospitals, superintending the education of females and the performance of similar works of charity and mercy. Communities of Sisters of Mercy are now widely distributed over Europe and America. There are also religious orders under the same name of the Anglican Church. The term is applied more particularly to the Order of Our Lady of Mercy, a Roman Catholic order founded for the objects above enumerated in Dublin 1827. The first house in America was established in Pittsburgh, Pa., 1843, and from it have sprung 65 convents. Consult 'Leaves from the Annals of the Sisters of Mercy' (1881). See McAuley, Catherine.

MERCY-SEAT (Heb. Kappo'reth, covering or lid, that is, of the sacred ark in the ancient Jewish tabernacle), an unfortunate and inappropriate term as applied to the cover of the chest or ark containing the two tables of the law and overspread by the wings of the Cherubim. Between these wings appeared the Shekinah or fiery symbol of the divine presence having the likeness of the man in the most probably of a sheet of the finest gold (Ex. xxv, 17, etc.; xxx, 6; xxxi, 7, etc.). The New Testament writers seem to hold that the term contains by implication the idea of the propitiation (q.v.) (Heb. ix, 5; Rom. iii, 24). The high priest sprinkled on it the blood of the yearly atonement, and some writers think that the term covering as applied to it refers more to the covering of or atonement for sins than to its use in covering the treasures of the ark. In any case the idea of a seat, as if the expression in Psalms xcix, 1, 'the sitteth between the cherubim,' does not fit the equation HgCl + Hg = 2HgCl₂. The calomel sublimes and must then be ground to a fine powder and thoroughly washed, in order to remove any free soluble corrosive sublimate that may not have been decomposed. The so-called "white precipitate," which is obtained when ammonia is added to a solution of corrosive sublimate, has the composition NH₄HgCl₂. Mercurous oxide, or "black oxide of mercury," Hg₂O, may be obtained as a black powder by digesting calomel with excess of caustic potash. It decomposes into the red oxide and metallic mercury upon exposure to light, or upon being heated to the boiling point of water. Many other compounds of mercury are known, but they are of less importance than the ones here given.

MERCURY VAPOR LAMP—MEREDITH

MEREDITH, George, English poet and novelist; b. Hampshire, 12 Feb. 1828; d. London, 15 May 1909. Details of Meredith's life are meagre; little is known of his parents or of his education except that he was sent to school in Germany and later studied law. He gave up for literature. For a time he was pupil of T. L. Peacock (q.v.), whose daughter became his first wife. His residence was for some years at Box Hill in Surrey. His first work in literature was a volume of poems published in 1851. This was followed in 1856, by 'The Shaving of Shagpat,' a brilliant, fantastic Oriental tale in which some of the short stories have been made into a political satire in 'The Ordeal of Richard Feverel' (1855), however, he began the course of a man temperament which have made his name famous. The novel, unquestionably one of the most powerful in the language, deals with the ordeal of adjustment to the world of a hotly spirited youth; it is the conflict between temper and desire, represented in the hero and a variety of conventions, most rigidly typified in the *system* of his father, Sir Angus Feverel. The effect of the book is tragic. With 'Evan Harrington' (1861), the next novel, is a wholly comic in character. These are embodied of various "humors," most strikingly represented in the *intriguing Consell*, the plot, as in all of Meredith's novels is quite secondary in interest and springs from the characters. 'Modern Love,' a sequel, was published in 1861. 'Emilia in England' now called 'Sandra Belloni,' appeared in 1863 and its sequel 'Vittoria' three years later. In the story of the young Italian girl of unreflected manners and character and her life in London and American society, the theme of the novel is the conflict between the genuine people, of the genuine with the sentiment character. Between the two novels appears in 1865, 'Rhythm,' perhaps the simplest of all Meredith's novels in style and a powerful study in character. It deals, on the whole, with a conventionally more humble order of society than is usually found in Meredith's novels, and is rather more direct, but few these in fiction are more impressive than the almost instinctive steadfastness of the heroine. The gloomy than the spiritual confusion that she tries to set in order. In 'The Adventures of Harry Richmond' the note is again chiefly comic. Much of Meredith's best work has been written by the hand of the young hero, and in the hero's father is perhaps as typical of the novel perhaps as the typical character of the novelist as can be found, a man who in the adventorous fancy and devotion to son, who is numberless odd and extravagantly acts. Another excellent study is in 'The Hand of Camelot' (1876), it is the analytical, yet lively, story of a young man whose earnestness of character and whose activity caused him, from a conventional point of...
view, to fail in life. Like other of Meredith's novels it is a great contribution to our understanding of the varieties of human temperament and to our sympathy with them.

In 'Beauchamp's Career' perhaps more than in any of his preceding novels Meredith directly explained his aim in drawing character; it was to present a type of motive and to show how it dominates and gives unity to a series of acts. The motive which causes action is, so to speak, temperamental rather than deliberate; in typical examples like the Countess in 'Evan Harrington,' or Beauchamp, for instance, Meredith is interested in the expression of temperament rather than a story. The Countess, on the face of the matter, wished for the social advancement of her family; what she really wanted was scheming for the sake of scheming and her social ambitions were but the medium of expression. This manner of approaching character, indeed, dominated all the character drawing in Meredith's novels, but it was not expressed in the fact that he refuses to give a public education, in 1877, of 'On the Idea of Comedy and the Uses of the Comic Spirit.' The essence of this essay is that comedy is one of the most wholesome and effectual ways of probing and purifying the flesh of the world, that good comedy, or the ways of Molière, really enables the reader to recognize what is genuine and discard what is sentimental; unfortunately, instead of good comedy we often are treated, in most literature, to painful moralizations. Meredith's fullest and finest expression of this idea is in his 'The Egoist' (1879), unquestionably his masterpiece and one of the chief glories of English fiction. Egoism, that love of self which prevents men from seeing things in their true relations, is one of the fundamental failings of mankind and Meredith has drawn it in, in the inimitable Sir Willoughby Patterne, as a figure of colossal proportions. The novelist's skill and dispassionateness as an artist was never better shown than in the fact that he refuses to give conventional rewards and punishments; for the hero's unfailing egoism permits him in the end to turn to the flattering of his vanity what would ordinarily be regarded as humiliation.

As an analysis and a synthesis of the springs which govern action, Meredith in his next novel, 'The Tragic Comedians' (1880) took a story from contemporary European court life and explained it as a piece of dramatic psychology. The comparative shortness of the novel makes it a good study of the author's method. This novel, too, indicated a tendency on his part to depict the motives and the psychology of people actually in existence rather than, as in The Egoist and its predecessors, to draw the embodiment of a type of "humor." This tendency was certainly evident in his next novel, 'Diana of the Crossways' (1885), his greatest popular success, and is shown in the fact that certain of the incidents and characters excited curiosity as, to their originals. It is manifest also in his last three books, 'One of Our Conquerors' (1890), 'Lord Ormont and His Aminta' (1894) and 'The Amazing Marriage' (1895), which are perhaps less broadly representative and more particular than his earlier efforts. These three books also include four short stories, 'The Tale of Chloe,' 'The House on the Beach,' 'Farina,' and 'The Case of General Ople and Lady Camper.'

Meredith, who was one of the last great novelists to hold over, as it were, from the age of Victorian literature, belongs to the so-called psychological school, of which the great popular representative is George Eliot, with whom he is practically contemporary. He differs from her in several important respects: The comedy of character (as the term is understood with Cervantes and Molière) as well as the tragic side of life, is reflected in his pages. His attitude is detached and impersonal and he never allows his sympathies to intrude upon his study of the type he is treating, a characteristic which accounts for the criticism sometimes made that he lacks temperament and which is doubtless one of the reasons for his comparative unpopularity. He is more interested in his characters as types of temperament than as individuals, and in this field he has perhaps represented the greatest range and variety of human motive that is today in circulation. Taking strata of society, on the whole, conventionally above those treated by George Eliot, he has made them representative of a great variety of "comic" motives. As a moralist, his attack has been upon those types which are broadly termed sentimental, and in respect his pictures of such men as Wilfred Pole and Willoughby Patterne are inimitable. The person that he most approves is the simple, considerate, intelligent being, well represented in such minor heroes as Mertby Powys, Vernon Whitford, Dartrey Fennell and Tom Redworth, and pictured to the height of brilliancy in his real heroines. In no other novelist, in no English writer except Shakespeare, can be found so splendid a galaxy of women as Rose Jocelyn, Jane Ilchester, Renée, Cecilia Hillett, Jenny Denham, Clara Middleton, Emilia, Carintha Jane and many others, as well as such older ladies as Lady Jocelyn and Lady Charlotte Eglert, are the best tribute to womankind that English literature possesses, and the creation of them is an achievement of the very first rank. His style is frequently criticized as involved and epigrammatic, but no novel contains passages of greater poetical charm. See DIANA OF THE CROSSWAYS, EGOIST, THE; MODERN LOVE; ORPHEUS IN LISTEN, THE.

Bibliography.—The best complete American edition of the poems and novels is by Messrs. Scribner, in 16 volumes. Commentary is scattering and appears chiefly in the form of contemporary reviews. Consult also, Victorian Prose Masters (1901); Lynch, Hannah, 'George Meredith' (1891); and, for a varied symposium, Le Gallienne, 'George Meredith, Some Characteristics;' with a Bibliography by John Lane; and for his place in history of the novel, Cross, 'The Development of the English Novel' (1899). Consult also Ellis, S. M., 'George Meredith: His Life and Friends' (London 1919).

W. T. BREWSTER,
Professor of English, Columbia University.
she married her cousin Charles Meredith (1839) and removed to Australia, whence they went to Tasmania five years later. She continued her literary activity till the end of her long life and for many years before her death had been the most prominent Tasmanian author. Among her books, many illustrated by herself, are: 'My first Home in Tasmania' (1852); 'Over the Straits' (1860); 'Tasmania: Friends and Foes, Feathered and Furred' (1880). Her prose works were popular in Australia and had also a circulation in England and this country: and her verse, of which she published several collections, was at once pleasing and unpretentious.

**MEREDITH, Owen**, the pseudonym of Bulwer-Lytton. See **LYTTON, Edward Robert Bulwer**.

**MEREDITH, Samuel**, American patriot and first Treasurer of the United States: b. Philadelphia, Pa., 1740; d. 10 March 1817. His father was a Welshman and a friend of George Washington. Meredith became a member of the Pennsylvania colonial legislature, and when the American Revolution broke out he entered the Colonial army as major, took part in several battles and was made brigadier-general for gallant services. He gave £10,000 in silver for carrying on the war, and was exiled from Philadelphia when the British occupied it. Meredith served in Congress in 1785–88 and in 1789 he became the first Treasurer of the United States, advancing to the government, on taking the office, $30,000 and later $120,000, for which he was never reimbursed. He remained in the office of Treasurer until 1801.

**MEREDITH, Sir William Ralph**, Canadian: b. Westminster, Ontario, 31 March 1840. He was educated in Toronto and was admitted to the bar in 1861, when he established a law practice in London, Ontario. He became queen's counsel in 1876 and in 1881 removed to Toronto. In 1872 he entered the provincial legislature of Ontario as member for London, and for 16 years he was leader of the Conservative opposition during the long reign of Mowat as Premier. In that position he showed a disposition to subordinate provincial rights to those of the Dominion; and he was an ardent supporter of the secret ballot, the enlargement of powers of municipalities and workmen's compensation. In 1894 he was appointed chief justice of the Court of Common Pleas and in 1912 chief justice of Ontario. In 1896 he was appointed a commissioner for the revision of the provincial statutes, and in 1905 he was one of the commissions that investigated the affairs of Toronto. He was knighted in 1896, and has been chancellor of the University of Toronto since 1900.

**MEREZHIKOVSKII, Dmitri Sergeevich**, Russian critic and novelist: b. Saint Petersburg, 1865. He was educated in his native city and published his first volume of verse at the age of 23. In 1893 he published an essay on the decadence of Russian literature which attracted general attention. 1901–02 appeared his 'Critical Studies of Tolstoy and Dostoevsky as Men and as Artists' and 'The Religion of Tolstoy and Dostoevsky', which proved him a critic of high order. Next there appeared his trilogy of historical novels dealing with the perennial conflict between Christianity and paganism. Collectively known as 'Christian Antichrist', this work has appeared in modern languages. It includes 'Smert Bogor' (Eng. trans., 'The Death of the Gods,' London 1901), in which the chief character is Julius Apostate; 'Voskresenie Bogor' (Eng. trans., 'The Fororunner,' ib. 1902) with Leonardo Vincent de Vincantu; and 'Antichrist' and 'Pavel Aleksey' (Eng. trans., 'Peter and Alexander,' London 1905). He also wrote the dramas 'Patr' (1908) and 'Alexander I' (2 vols. 1913). Consult collected edition of his works (15 vols., Saint Petersburg 1908–12) and Phelps' 'Contemporary Russian Novelists' (Boxer 1913).

**MERGANSER, or FISH-POWDER**, a bird of the genus *Mergus*, distinguished by a slender cylindrical bill, the upper mandible terminating in a strong hook at the end, and margins presenting the appearance of rows of tooth-like processes. The most widely distributed is the red-breasted (Mergus serrator) known as sheldrake in America where it is more numerous than in the Old World. The goosander (M. merganser) and the sharp-shinned (M. albellus) are Asiatic species, while the hooded merganser (*Lophodytes cucullatus*) or sawbill is found in North America. The mergansers are chiefly upon fishes and swim and dive under their prey with great treachery and dexterity. They are essentially northern in their distribution and breed in the far north and migrate southwards on the approach of the colder season. The nest is built of grass and roots and is lined with down. It is usually placed in a hollow or on a bank near water, but some species precipitate a greater security of a hollow tree. The nest is coarse and rank. Eight or 10 species are known in various parts of the world. The male alone incubates, but the male watches over the nest. From 8 to 14 eggs are laid and a young enter the water as soon as they are hatched.

**Mergenthaler, mér'gän-tä ler**, Os- mar, American inventor: b. Württemberg, Germany, 10 May 1854; d. Baltimore, 28 October 1918. He was a watchmaker by trade; came to the United States at 18, entered the employ of the U.S. Land Office, where he kept clocks and electrical equipment throughout government buildings in order to prove apparatus used in the signal service, as in 1876 removed to Baltimore, where he invented a machine for making fruit preserves, which he patented himself to perfection. On this he spent several years, a scheme going through four stages, the last of which was the linotype (q.y). When he had patented this machine he had much difficulty introducing it. It was perfected by the addition of the Roger's space and numerous minor inventions by Philip T. Dodge and others and brought its inventor large profits and is now in very common use in large printing establishments. Mergenthaler also invented a machine for making fruit gift baskets, which he patented and named. **MERGER, mér' ger**, law, the sinking or obliteration in conveyancing of lesser estate into greater ones, or the consolidation of two or more estates; a term used in finance or business circles, meaning the consolidation or combination of a particular class of manufacturing, railroads or other business interests.
generally in the nature of a trust. Late in the 19th century it became common in the United States for a group of corporations, which it was deemed wise to do for reasons of economy, to "marry" by forming a holding company, which took over the majority stock of each subsidiary company in the merger and gave in exchange the stock of the holding company. To test the validity of such mergers a suit was brought against the Northern Securities Company, and after exhaustive arguments and much delay the United States Supreme Court declared that the procedure was "in restraint of trade." Since then corporation mergers have ceased. The principle still holds good, however, in both civil and criminal law, but the lesser may merge into the greater. In contracts the acceptance of a high grade of security is held to extinguish the lower grade. When a bond is given for the performance of a contract, it is sufficient to fulfill the contract, even though the bond be merged in the bond as the higher obligation.

TRUSTS.

MERGUIS (mér'gë') ARCHIPELAGO, a chain of islands in the Bay of Bengal, off the coast of Tenasserim in Burma, the more northerly ones forming a part of the British district of Mergui. The islands are 10,000 square miles. They are generally covered with trees and present many picturesque features, rising at some points to the height of 3,000 feet. The island is Kings Island, some 25 miles long. Some tin is found here. The chief town is Mergui, with a population of about 5,000. The locality is one of the dampest in the globe, the rainfall exceeding 100 inches annually. The inhabitants belong to a race called Selungo. They give little attention to agriculture, obtaining a sustenance mainly by fishing, pearl gathering and selling edible birds' nests. The Selungs are peaceful and industrious, but few in number. The adjoining seas abound in fish and excellent oysters; pearls of good quality are found. Pop. about 115,000.

MERIDA, Mexico, the capital city of Yucatan. The city was founded in 1542 and is situated on the east side of the bay of Merida. There are railway connections with all important points in the interior and several lines of steamers ply between its port, Progreso, 25 miles distant, and Vera Cruz, New York and other prominent commercial ports. The surrounding country is almost entirely devoted to the sisal hemp industry, which has reached enormous proportions in the state. Hides, sugar, chicle, and indigo are also exported. There are manufactories of cotton goods, cigars, panama hats, earthenware, etc. The principal building is the government palace, the municipal palace, the Casa del Conquistador Montejo (the first Spanish house built in the city), the old cathedral, the School of Arts, the Penitentiary, Literacy Institute, State College of Normal School for Teachers, Meteorological and Astronomical Observatory, Yucatan Museum, Catholic College of San Ildefonso, schools of medicine, surgery, pharmacy, jurisprudence and notarial instruction. The Literary Institute for Girls, the Commerce School for Girls, the Institute de Beneficencia Privado, founded by Leandro de Ayala at an outlay of $1,000,000. There are an asylum for manicats, a lazareto, a maternity hospital, three other hospitals, an asylum for mendigos, two theatres and an arena for bull fights. The Hidalgo Park contains a statue of Gen. Cepeda Peraza, and one symbolizing the peace of the state. Near the great cathedral are also large statues of Sts. Peter and Paul. A body of public security, a jefe politico and an inspector-general preserve order and ensure safety to all. The streets are paved with asphalt. Merida contains two local financial institutions—the Banco Yucateca, with a capital of $8,000,000, and the Banco Mercantil de Yucatan, with a capital of $6,000,000, and a branch of the National Bank and an agency of the Bank of London and Mexico. Pop. about 50,000.

MERIDA, Spain (the Roman Augusta Emerita), a small decayed town of the province of Estremadura, on the Guadiana, 32 miles east of Badajoz. It is unique in Spain, and is in some points a rival of Rome itself on account of the number and magnitude of its remains of Roman antiquity. The Guadiana is here crossed by a Roman bridge of 64 arches (originally 81; 17 destroyed in 1812) and with a length of 2,575 feet and a breadth of 26 feet; it was erected by Trajan and Vespasian. The Roman bridge over the Albarregas, 450 feet long, 25 feet wide, still quite perfect, in spite of the traffic of 18 centuries since its erection. There are also remains of a castle built by the Romans, and among other noteworthy monuments of antiquity are an old half-Roman, half-Moorish palace, the Casa de los Corvos, constructed out of a temple dedicated to Diana, several aqueducts, an ancient amphitheatre and a circus. Merida was founded in 23 B.C., and flourished in great splendour under Roman and Moor until 1228, when it was taken from the Moors, after which it began to decline. Pop. 7,390.

MERIDA, Venezuela, town, capital of the state of Los Andes, 5,290 feet above sea-level, 60 miles south of Lake Maracaibo, at the foot of the Sierra Nevada de Merida, a portion of the Andes, to a height of about 15,000 feet. It was founded in 1558 by Juan Rodriguez Saurez. It was almost wholly destroyed by an earthquake in 1812 and again seriously damaged in 1894. It is the seat of a bishop, contains a fine cathedral, one of the two national universities of Venezuela, and has several high schools. Its manufactures are carpets, woolen and cotton goods. Pop. about 13,000.

MERIDEN, Conn., city, in New Haven County, on branches of the New York, New Haven and Hartford Railroad, about midway between Hartford and New Haven. Originally the town of Meriden was a part of Wallingford until 1806, when the town of Meriden was incorporated. In 1867 it was granted a city charter. It is situated in an agricultural region, but the city is noted for its large number of manufactories. Some of the principal manufactures are cutlery, silver and plated ware, steel pens, hardware, machinery, screws, vises, glassware, cut glass, malleable iron, bronze, firearms, brass castings for ships, carbines, kerosene fixtures, self-playing attachments for pianos and organs, woodenware, tinware, granite, agateware, lamp trimmings, etc. The shipments are principally manufactured arti-
cles, fruit, vegetables and tobacco. The educational institutions are the public and parish schools, a high school and the Curtis Memorial Library. It has the Curtis Home for Orphan Children and Aged Women, the Connecticut School for Boys and the Meriden Hospital. The government is administered under a charter of 1897. The mayor, who holds office two years, appoints fire and park commissioners, board of taxation and apportionment, police and board of health. The council elects the health officer, board of compensation, tax collector, plumbing inspector, boiler inspector and fire marshal. The treasurer, sheriff, clerk and auditor are chosen by popular vote. Pop. 31,000.

MERIDIAN, Miss., city, county-seat of Lauderdale County, on Alabama and Vicksburg, Alabama Great Southern, Meridian and Memphis, Mobile and Ohio, New Orleans and Northeastern and Southern railroads. It is the largest city in Mississippi in population, manufactures and commerce, surrounded by fertile farm land of which cotton and vegetables are the chief agricultural products. Among numerous industrial establishments are lumber mills, fertilizer factories, cotton-seed-oil mills, cotton mills, cotton compresses and railroad shops. The annual wholesale trade is $20,000,000; the average annual bank clearings approximate $17,000,000. Meridian is the seat of the East Mississippi Female College (M. E.), founded in 1867 and opened in 1869, the Lincoln School (Congregational), the Meridian Academy (Methodist Episcopal South), both for colored students, a Catholic high school and Saint Aloysius Academy for Girls. Among prominent features are the municipal building, county courthouse, public library, Scottish Rite Cathedral, Stonewall Club, handsome churches and fine business and banking buildings. The Mississippi-Alabama Fair, held annually at Meridian, is the second largest agricultural and stock exhibition in the South in number of exhibits and attendance. Since 1912 the commission form of government is in operation; the city owns the waterworks and has a modern equipped and salaried fire department. Electric car service, electric and gas lighting are furnished by a company with a plant of sufficient capacity for a city of 100,000 inhabitants. During the Civil War, Meridian was devastated by General Sherman, 14-20 Feb. 1864, and in March 1906 a large portion of the city was destroyed by a tornado. Pop. 30,000.

MERIDIAN (Miss.), Expedition to. In January 1864 General Sherman concentrated two divisions of 10,000 each at Vicksburg under Generals McPherson and Hurlbut, and 3 February marched eastward with the purpose of destroying Meridian, 150 miles distant, as a railroad centre, and possibly penetrating to Selma, Ala., or, if the opposing forces met at Mobile, turn southward from Meridian and attempt the capture of that city. Gen. Sooy Smith was to cooperate with a cavalry force from Memphis; General Dodge, in command at Pulaski, Tenn., was to hold Logan at Meridian, first meeting toward Rome, Ga.; and General Thomas was to demonstrate toward Dalton to prevent troops being sent by General Johnston to Sherman's front. Sherman entered Jackson on the 6th, after heavy skirmishing with cavalry. Decau was reached on the 12th. Meridian was the 14th, the Confederate force, under Gen. Leonidas Polk, being much less than Sherman withdrawing toward Demopolis. The area of extensive storehouses and cantonments was burned. The work of destroying the railroad center at Meridian began on the 10th, 6 miles being rendered utterly useless to north and east and 35 miles toward Mobile Thirsty. The town is of a fine and thorough character; 10,000 men worked it for five days; 61 bridges and culverts or more than a mile of trestles over swamps were burned; all rails were rendered useless. The object of the expedition was fully gained. Meridian was not wholly restored as a railroad center during the war. Thereafter, the transporting of supplies eastward from the State Mississippi was seriously interrupted for a long time and was greatly impeded up to the close of the war, while all military operations which required railroad facilities were rendered extremely difficult.

The expedition, however, was not as successful as had been hoped. The Confederates by the exercise of great energy in the face of many difficulties, so strengthened Mobile as to forbid an advance in that direction. Sherman not receiving the cavalry support under Gen. Sooy Smith which he had reason to expect from Memphis, was unable to push on to Selma, Ala., one of the great manufacturing cities as storehouses for military supplies of the Confederacy. Smith, in turn, had been unavoidably detained, and Sherman returned to Vicksburg reaching its vicinity 26 February. His command had marched between 300 and 400 miles and had crossed Mississippi and inflicted well-deserved irreparable military damage; but had been prevented from carrying out his full program of Confederate activity in assembling forces in the extreme front.

MERIDIAN, one of the imaginary meridians and south lines on the surface of the earth that are the base of the measuring of the longitude, or east-west poles and serving to indicate the longitudinal places, and with a parallel of latitude as their exact position. If one conceive the earth sliced into one of these lines, the result surface is the plane of the meridian. They are also corresponding lines called astronomic meridian, or celestial meridian, which are imaginary circles of the celestial sphere passing through the poles of the heavens and the zenith at any place on the earth's surface. These correspond exactly to the geographical meridians, that is the celestial is exactly above the geographic meridian of any place. Every place on the globe has its meridian, and when the sun arrives at this line it is noon or mideday, where the name (Latin, meridians — medium, middle and day) did not come from having a fixed meridian in different countries is sufficiently obvious to geographers, navigators and astronomers but all found it frequently a source of confusion. After years of fruitless discussion the question of a universal or first meridian was brought before an international conference held at Washington, 1 to 22 Oct. 1884. There although the representatives of France and Brazil dissented, it was agreed to recommend
the meridian of Greenwich both as the astronomical and as the geographical reference meridian of the world, longitude to be reckoned east and west from this up to 180°. At the same time it was advised that the astronomical day should begin at midnight, mean Greenwich time, the hours for astronomical purposes being reckoned as before from 0 to 24. This arrangement began on 1 Jan. 1885. Previously mean time had been used. (At the declination of 50° N. on Greenwich time) the Central, with standard meridian 90° W. (6 hrs. slow); the Mountain, 105° W. (7 hrs. slow); and the Pacific, 120° W. (8 hrs. slow). There are three Australian zones: Queensland, New South Wales, Victoria, with 150° E. (100 hrs. fast) as standard; South Australia, with 135° E. (9 hrs. fast); and Western Australia, with 120° E. (8 hrs. fast). Other standards adopted with reference to Greenwich are: 15° E. (1 hr. fast) for mid-European; 22°/4° E. (1½ hrs. fast) for Cape Colony; 30° E. (2 hrs. fast) for Natal; 135° E. (9 hrs. fast) for Japan; and 172°/2° E. (11½ hrs. fast) for New Zealand. The meridian is also applied to the laying out of the earth, magnetism on a chart, north and south line cutting the magnetic pole, or the vertical plane formed by such line is a magnetic meridian. Consult any map for the meridian lines.

**MERIDIAN CIRCLE, in astronomy**, an instrument used in observatories to combine the functions of a transit instrument and of the old mural circle. It has a telescope mounted to turn in a circle, always in the plane of a meridian. Of course the axis must be accurately laid east and west, and for this purpose solid masonry piers are commonly provided. A vertical circle is carried on the axis of the transit instrument and revolves with it, its divisions being read by micrometer microscopes mounted solidly on one of the piers. In this way both coordinates of the position of a heavenly body, its right ascension and declination, are determined at the same meridian passage—a great saving of time over the old method with the instruments. See Telescope.

**MÉRIMÉE, mā-rē-mā**, Prosper, French author: b. Paris, 28 Sept. 1803; d. Cannes, 23 Sept. 1870. He was educated at the Collège Henri IV and studied law though he never practised it. Under the pseudonym "Joseph Lestrange," he published in 1825 "Théâtre de Clara Gozzi, Comédienne Espagnole," an assumed translation from the Spanish of eight prose comedies, but in reality his own work. From that time onward he continued to publish works at frequent intervals and at the same time had an official career of importance. Following the revolution of July 1830, he was made secretary to the ministers of commerce and marine, in 1831 was appointed inspector of ancient monuments, in 1844 became a member of the Academy, and senator of France in 1853. He was a commander of the Legion of Honor in 1860. Beside publishing several important works connected with his duties as inspector of ancient monuments he was the author of "Colomba" (1840), a very popular novel of the Corsican vendetta; "Carmen" (1847), a romance upon which the famous opera "Carmen" by Bizet is founded; "Lettres à une Inconnue," his most famous work (1873); "Lettres à une autre Inconnue" (1873); "Lettres à Panizzi" (1881); "Une Correspondance Inédite" (1896). The four works last named are Mérimée's most characteristic writings revealing him as a most loyal devoted friend. They differ widely from his other works, which though often brilliant are hard and unsympathetic, while these are tender and romantic. As a master of style Mérimée had few equals in his day. (See Car- men; Combona). Consult Filsón, Mérimée et ses Amis" (1884); Haussois, Mérimée (1888); Tourneux, "Prosper Mérimée, ses Portraits, ses Dessins, etc." (1879).

**MERINO**, a woolen or worsted fabric, introduced about 1826, and so named because made from the wool of merino sheep. The word is originally the title of an inspector of sheep pastures in Spain, and became attached to the short-wool Spanish sheep. The breed did not originate there, however, being imported from Africa by the Moors and bred by the Spanish. The wool was so highly regarded that they have been exported for breeding all over the world, but especially to Australia. See Wool, Manufacture of.

**MERINO SHEEP.** See Sheep.

**MERIT, Order of,** a British order instituted by King Edward VII, 26 June 1902, to confer distinction on persons in military, scientific, artistic and professional circles. The number is limited to 24. In 1917 there were 17 members, and three honorary members (four military).

**MÉRIT SYSTEM, The.** See CIVIL SERV- ICE REFORM.

**MERIVALE, mār′ivāl Charles, English historian and ecclesiastic:** b. Barton Place, Devonshire, 8 March 1808; d. Ely, 27 Dec. 1893. He was educated at Cambridge, took orders in the English Church, was rector of Lawford, Essex, 1848-69, and dean of Ely from 1869. He published 'The Fall of the Roman Repub- lic' (1853), which forms the first part of his popular 'History of the Romans under the Empire' (latest ed., 1890); 'General History of Rome' (1875); 'Lectures on Early Church History' (1879); etc. Consult 'Autobiography and Letters' edited by his daughter (1890).

**MERIVALE, Herman, English statesman and political economist; brother of Charles:** b. Dawlish, Devonshire, 8 Nov. 1806; d. London, 9 Feb. 1874. He was educated at Oxford, where he was professor of political economy 1837-42. He was under-secretary for the colonies, 1848-50, becoming perpetual under-secretary for India in 1859. He wrote 'Colonization and Colonies' (1841), a much valued work; 'Historical Studies' (1865); 'Memoirs of Sir Philip Francis' (1867).

**MERIVALE, Herman Charles, English author:** b. London, 1839; d. 15 Jan. 1906. He
was educated at Harrow and Oxford, became a barrister of the Inner Temple in 1864 and edited the 'Annual Register' 1870-80. Among his publications are: 'The White Pilgrim and Other Sagas' (1872); 'The Orpheus Series' (1882), several plays; 'The Whirl Hand' (1884); 'The Dove' (1888). He was a son of J. H. Meri-
vale.  

MERIWETHER, Lee, American lawyer, social reformer and author; b. Columbus, Miss., 25 Dec. 1862. Having obtained a second-
ary education at Memphis, Tenn., he there published the Free Trader with a brother, Avery, in 1881-83, and in 1885-86 toured Europe afoot from Gibraltar to the Bosporus for study of the condition of Continental working men and of the protective tariff. In 1910, on the 25th anniversary of this "Tramp" trip through Europe, he covered the same route in an automo-
obile; the contrast between walking and motoring abroad, and the changes that had taken place in the manners and customs of the people of Europe between 1885 and 1910, were interestingly set forth in a book entitled 'Seeing Europe By Automobile' (New York 1911). He was appointed by the Secretary of the In-
terior to write for the United States Labor Bureau a Report on the 'Condition of European Labor,' published in the annual report of the bureau for 1886. In 1886-89 he was employed as a special agent of the Department of the Interior for which he made investigations of labor in the United States and the Hawaiian Islands, and in 1891 visited the island prisons of the Mediterranean. He was admitted to the bar in 1892, and in 1893 entered practice at Saint Louis. In 1899-1901 and 1895-96 he was labor commissioner of Missouri. His reports on municipal government and street-railway franchises led to his nomination in 1897 for the mayoralty of Saint Louis on the Democratic ticket. He was defeated at that time and also in 1901, when he was candidate of the Public Ownership party. Besides his various reports, he has published 'A Tramp Trip: How to See Europe on Fifty Cents a Day' (1887); 'The Tramp at Home' (1890); 'Afloat and Ashore on the Mediterranean' (1892); 'Miss Chunk' (1899); 'A Lord's Courtship' (1900); 'Seeing Europe by Automobile' (1911); and other works.  

MERLE D'AUBIGNÉ, Jean Henri. See D'AUBIGNÉ, JEAN HENRI MÉRLE.  

MERLIN, méril, a semi-legendary Brit-
ish prophet and magician, supposed to have flourished toward the end of the 5th century. The accounts of him are hopelessly mixed with fiction. He was said to be the son of a demon and the daughter of a British prince, and was brought up at Caer-Merlin, a city supposed to be the modern Carmarthen. He received from his father the power of working miracles and was in the United States of his time, the counsellor and friend of English kings. Vortigen, according to the legend, on the advice of his mag-
cians, had resolved to build an impregnable tower for security against the Saxons but the foundation was scarcely laid when the earth opened by night and swallowed it up. The magicians informed the king that to give firm-
ness to the foundation he must wet it with the blood of a child born without a father. After much search the young Merlin was brought to the king. Merlin disputed with the magics and showed them that under the foundation of the tower was a great lake, and under the lake two great raging dragons, one red, representing the English, and another grey, representing the Saxons. The earth was dug open, and the dragons began a furious battle; whereas Merlin wept, and uttered prophecies respecting the future state of England. Merlin is a char-
acter in Tennyson's 'Idylls of the King,' a collection of the prophecies attributed to him appeared in Paris in 1498, at London in 1522, and 1533, at Venice, 1554. They can be traced back to about 1360. His prophecies were pub-
lished at Edinburgh in 1613 and contain the those ascribed to the Cambrian or Welsh Mer-
lin. Consult Child, 'Her Book of Mere' (New York 1904); Tennyson, Alfred, 'Idylls of the King.'  

MERLIN. This dramatic narrative poem by Edwin Arlington Robinson is among the most distinguished and significant products of recent American literature, and bids fair to take its place beside the best of its class. Its kind. It is entirely modern in its spirit and treatment, with lines like these that mark its date:  

"Time swings  
A mighty sythe, and some day all your peace  
Goes down before its edge like so much sober."

In Mr. Robinson's poem King Arthur and his knights are not romantic heroes, as other poets have made them, not "our conception of what knighthood should be;" they are a modern poet's conception of what leaders of men should be; they are a merchant, lover, fool; Arthur, Gawaine, Lancelot, Dagenet, Nor is Mr. Robinson's Merlin like Tem-

son's—a magician in his dotage falling a victim to the wiles of a false woman. He is a proper whose 'memories go forward,' he is a man "Who saw himself, a sight no other man ever seen," and he follows Vivian, "a woman who is worth a grave," because Fate wills it so. It is not the age of chivalry but our own time, our own double world of hope and reality, with its loves, faiths, and failures that Mr. Robinson revivifies in Mer-
lin. The philosophy of the poem, that faith and creative love will someday save the world is a histrionic background for the story: "The torch of woman, who, together with the dead That Galahad found, is yet to light the world."

As a tale Merlin is vivid and compelling, with scenes, like that of Merlin's first meeting with Vivian and his final parting, which rival the best in drama for beauty and intensity.
destruction by enticing them into the depths of the sea; and, as a correlative, they are sometimes represented as seeking their own destruction by spitting the sea, through marriage with some favored human husband by which they magically obtain temporarily a complete human form and soul, but always end in bringing disaster to one or both of the sacrilegious pair. Mermen are also occasionally heard of, but take an unimportant part in the legendary lore of the sea.

This medieval notion is doubtless a survival of the primitive fancies, half fearful, half poetic, which created the classic conceptions of tritons, nereids, and the like. Shakespeare wrote (Ant. and Cleop., II, 2, 211):

"Her gentlewomen, like the Nereids,
So many mermaids, tended her."

All of these ideas probably arose from a mixture of observed human resemblances in certain marine animals with purely mystical fancies which peopled the ocean with similitudes to terrestrial creatures. Primitive men have everywhere derived a large part of their sustenance from the natural products of the waters; and always the vastness and mystery of the sea, full of strange creatures and incomprehensible phenomena, have powerfully affected the imagination of the ignorant and superstitious. To this day the ocean is more familiar and more important in the life of many isolated peoples who dwell upon its margin and derive their support almost exclusively from it than is the land; and they invest it and everything it contains with a wondering regard which the inlander can neither share nor understand. To these, even in civilized regions (as on the coast of Ireland or the Hebrides) mermaids remain only one of many present realities, harking sea-cattle and lying in wait for unwary humanity as surely as when sea-horses raced over the Ægean waves with the car of Poseidon or the Sirens tempted the mariners of ancient Greece. In one form or another such stories have been rife in the folk-lore of all maritime peoples since prehistoric times; and, although not so widespread, the belief in mermaids, and the tale of the mermaid, is still a matter of firm faith with hosts of persons in all parts of the world. Folk-lore abounds in evidence of this.

The physical basis for these notions rests upon the resemblance which some marine animals bear to human beings when seen at a distance and in certain attitudes. Such, in northern countries, are various seals, which formerly abounded upon the coasts of western Europe, and still are to be seen in the less frequented spots. They have a way of lifting their round heads and shoulders from the water, with a queer human intellect looking upon their faces, and hugging their young to their bosoms with motherly affection. Impressed with this resemblance, easily turned into a story to beguile a long winter evening or to amuse a child, and growing with imaginative repetitions, the northern peoples were quick to believe the similar and more elaborate stories brought to them by early voyagers from the Mediterranean, and so the tales grew and changed into the rich folklore of the coasts of the North Sea.

The southern stories, embellished by classic culture into the sea-myths of Neptune, Proteus and the sea-nymphs of old, and descending into the mermaids and mermen of medieval folk-lore, yet alive around the Mediterranean and Oriental seas, and among sailors generally, probably have their origin by assimilation not so much from any aspect of the East Indian and African dugongs (q.v.) as from these uncouth monsters would never be mistaken for human beings; but seen at a distance, by fearful and wondering voyages along the coast, such an error might easily happen, for they frequently stand upright among the wavy shallows of the coasts, perhaps draped with loosened vegetation like long hair, and holding to their breasts a young one who nurses from pectoral mammae much as a human baby would do. Such reports, brought back to the enquiring poetic minds of Greece, might easily blossom into the tales of sea-mythology which formed so large and real a part of the popular belief as well as of the legendary lore of the classic age of India, Persia and the Mediterranean peoples. The fish-gods of the Phoenicians and other idolaters are closely related.

From this has come down to us the extensive and varied use of mermaids and mermen in heraldry. "In French heraldry," says Robinson, "the mermaid is called the Siren; in German she has two tails; in other countries it figures a harp; and in many cases in each country she is crowned. In England it is a very ancient crest, and among others the lords Byron, the earls of Portsmouth... and many others display the sea-maiden in their armorial bearing. With her comb and looking glass she smiles at us from the shields of the Holles, Ellises, Lapps; and as a supporter holds up the arms of the Viscounts Boyne and Hood, the earls of Howth and Caledon, and is borne by the heads of the families of Sinclair of Roslyn, and Scott of Harden. Two mermaids crowned are the supporters of the Boston arms."

Artificial mermaids, claiming to be preserved realities, have formed a part of the stock of curiosities of wonder-shows since time immemorial; and most of those exhibited since the days of Barnum have been the products of Japanese ingenuity.

ERNEST INGERSOLL.

MERMAID'S HEAD, a globose seashell, as one of the heart-urchins.

MERMAID'S PURSE, the egg-case of the skate (or shark), which is often cast up empty on the shore.

MERMAN. See Mermaid.

MERO, or MEROU, a West Indian name for a jewfish (q.v.).

MEROBAUDES, Flavia, a Spanish rhetorician and poet of the first half of the 5th century A.D., eminent also as a general, has left us a short hymn in honor of Christ and fragments of five historical poems. L. Jeph in his edition of Claudian (Leipzig 1876-79) publishes four of these poems.

MERODACH, mēr'dāk, or BEL-MERODACH. See BRl.

MEROE, mēr'ō-e, Egyptian Sudan, a city and state of ancient Ethiopia, in the northeastern part of Africa. The city is still represented by ruins and pyramids near Kabari on the Nile north of Khartum and the state forms the district often spoken of as the Isle of Meroë, extending southeast to Abyssinia, and in the
northwest forming a part of Nubia. It was distinguished for its mineral and cereal wealth and at an early date was the centre of an active and varied commerce including the great caravan trade between Ethiopia, Egypt, Arabia, northern Africa and India. The government was in the hands of a caste of priests, who chose a king who was obliged to live and act according to certain prescribed rules. The priests could sentence the king to death in the name of the gods, and he was forced to submit. The priests were of a lighter complexion than the other inhabitants and may have come from India. Ergames, king of Meroë in the 3d century B.C., during the reign of Ptolemy II in Egypt, first made himself independent of this oppressive priesthood by murdering the priests in the golden temple. Meroë and Axum (in Abyssinia), which appears to have been a colony of Meroë, remained the centre of the southern commerce till the time of the Arabians. The existing monuments of their architecture, and many other vestiges, exhibit an advanced religious and social cultivation. The University of Liverpool in 1910-11 financed excavations here, interesting ruins were uncovered and many valuable relics obtained. Consult Budge, 'The Monuments of the Sudan' (London 1907).

MEROPE, the title of an Italian tragedy in blank verse by the Marquis Francesco Scipione Maffei (1675-1755), first performed at Modena in 1713. Appearing just after the dreary period of 17th century stagnation in Italian letters, it obtained a European reputation. More than 60 editions were published and it was widely translated. It attained in Italy an unprecedented success on the stage and is important also for its influence upon the development of the Italian theatre, whose standard Maffei raised perceptibly. The subject of the play is taken from Greek mythology as related by Apollodorus (II, 8-5) and Pausanias (IV, 3-6). Merope is the queen of Messene whose husband, Cresfonte, and two children have been murdered by her brother-in-law, Polifonte, who then usurps the royal power and attempts to force the queen to marry him. On this tragic story Euripides wrote his 'Cresfonte,' which is not extant. Maffei was the first modern dramatist to handle the material and reveal its superb possibilities. He dispenses with the love element so prevalent at that time in the French theatre and proves that without it a play can retain the interest of the spectator. His idea is that such a play shall depict but a single passion, in this case a mother's love for her son. The scene (III, 4) in which Merope, believing that she has in her grasp her son's slavery, discovers in him her own son, the transition from anger and vengeance to surprise and then to the motherly love, is profoundly impressive. The dénouement, the death of the tyrant (V, 6), at the foot of the altar, is equally effective. Notable as are the tragedies of Voltaire and of Alfieri dealing with the same subject with the power characteristic of each of these master minds, nevertheless in intensity of plot interest and in dramatic treatment, Maffei's 'Merope' remains unsurpassed. Consult 'Opuscoli e lettere di Maffei' (Milan 1844), for the text and interesting material. A selected edition, edited by A. C. Clapin was published in London in 1890. The text, with variations and introduction, appeared later in No. 108 of 'Bibliotheca Romana.'

JAMES GEDDES, Jr.

MEROSTOMATA, a sub-class of arthropods, allied to the Crustoidea, and represented by only a single survivor (the horse-foot crab), but including a large series of fossil forms which flourished in the Paleozoic Age from mid-Cambrian onward. They were somewhat scorpion-like in form, although sometimes of gigantic size, and ranked between the superior trilobites and inferior arachnids. The Merostoma are characterized by having six pairs of ambulatory limbs about the mouth, the first of which terminate in some, if not in all, cases in chelicerae. The others serve as organs of locomotion, and their coxal joints for prehension and mastication. The prevailing opinion is that the body is divided into two parts (cephalothorax and abdomen) instead of three (headshield, thorax and abdomen) has been changed by recent discoveries that make the trilobate character of the structure less definite and establish a close relationship with the trilobates. The sub-class comprises three orders, Acipensura, the horse-foot crabs (q.v.), several species of which still exist; the Symphyesura, Silurian and Cambrian fossil forms; and Eurypterae (see Eurypterus). Consult Packard, 'Zoology' (1897), and Zittel-Eastman, 'Textbook of Paleontology' (Vol. 1, 1900), which contains an extensive bibliography.

MEROVINGIANS, mēr-ō-vīn'jī-anz, the first dynasty of Frankish kings which ruled in the northern part of Gaul, since called France. They derived their name from Meroveus, the grandfather of Clovis. They ruled from 496 till 752, when they were supplanted by the Carolingians. Pepin the Short caused the overthrow by deposing Childeric III, and sending him to a monastery. See France.

MERRILL, John Porter, American naval officer: b. Auburn, N. Y., 7 Sept. 1846; d. New London, Conn., 8 Dec. 1916. He was graduated at the United States Naval Academy in 1865, served with the European fleet 1867-70; was on signal duty on the Washington and Darien expedition of 1870-71, was in charge of the naval ordnance proving grounds 1877-79. He was also for a time an instructor at Annapolis and had command of the Atlantic fleet. He also did active work in the Department at Washington. He was retired by operation of law 7 Sept. 1908. In 1895-96 he was a member of the State Department Commission to investigate anti-foreign riots in the province of Szechwan, China.

MERRIAM, Augustus Chapman, American classical scholar: b. Locust Grove, N. Y., 1843; d. Athens, Greece, 1895. He was graduated at Columbia University in 1866 and after 1868 was connected with that institution successively as tutor, assistant professor of Greek and professor of Greek archaeology and epigraphy. Dr. Merriam did much to promote the study of classical archaeology in the United States. In 1887-88 he was director of the American School at Athens. He published 'The Pheaeans of Homer' (1888); 'The Greek and Roman Crab of the Odebe Crab in Central Park' (1883); 'The Sixth and Seventh Books of Herodotus' (1885); 'The
Law Code of Gortyna in Crete; (1886); 'Telegraphy among the Ancients' (in Papers of the Archaeological Institute of America; Classical Series III, Cambridge 1890).

MERRIAM, mér-í-am. Clinton Hart, American biologist and author: b. New York City, 5 Dec. 1855. He was graduated from Yale in 1877 and from the College of Physicians and Surgeons in New York in 1879, and practised medicine 1879-85. He was United States Bering Sea commissioner in 1891 and visited Alaska in the interest of fur seal investigations. He has held various commissions from the government in the field of biology and has made extensive trips in its interest in the far West. In 1910 he was placed in charge of the biological and ethnological investigations carried on under the fund established by Mrs. Harriman. He has written 'Birds of Connecticut' (1877); 'Mammals of the Adirondacks' (1882-84); 'Results of Biological Survey of San Francisco Mountain Range and Desert of Little Colorado in Arizona' (1890); 'Flora and Fauna of the Death Valley Expedition' (1893); 'Life Zones and Crop Zones of the United States' (1893); 'Insects of the South Pacific' (1896); 'Totemism in California' (1908); 'The Dawn of the World' (1910), and about 400 papers on zoological, botanical and ethnological subjects.

MERRIAM, Henry Clay, American soldier: b. Houlton, Me., 13 Nov. 1837; d. 1912. He was graduated from Colby University, and began the study of law; but in 1862 entered the Union army as captain in a Maine regiment. He was at the battle of Antietam in 1862, and organized the colored troops in 1863, being lieutenant-colonel of the Louisiana Native Guard (a negro regiment) when it went into the war; he led the assault on Fort Blakely 9 April 1865, and obtained a medal of honor from Congress for gallant conduct. In 1866 he was appointed major in the regular United States army, and rose to brigadier-general in 1897 and major-general of volunteers in the Spanish War, 1898. He served in many expeditions against the Indians, and protected American citizens in the valley of the Rio Grande in the region of the U.S. and Mexican border. In 1898 he was commander of the departments of the Columbia and California, and organized, equipped and forwarded the troops to the Philippines; and in 1899 was sent to the Philippine Islands in command of the troops from the United States. In January 1900 he was placed in command of the Department of the Colorado, and in 1901 was retired from active service. He is the inventor of the Merriam infantry pack.

MERRIAM, John Campbell, American educator and palaeontologist: b. Hopkins, Iowa, 20 Oct. 1869. In 1887 he was graduated at Lenox College, Iowa, and in 1893 received the degree of Ph.D. at the University of Munich. In 1894-99 he was instructor in paleontology and historical geology in 1905 assistant professor; in 1905-12 associate professor, and after 1912 professor of paleontology at the University of California. Professor Merriam is a Fellow of the American Association for the Advancement of Science, of the American Palaeontological Society, and other learned bodies. He is the author of numerous papers on fossil reptiles and fossil mammals of western North America, and on the general historical geology of the Pacific Coast region.

MERRIAM, William Rush, American financier: b. Wadsworth's Mills, N. Y., July 1849. He was graduated from Brown College, Wisconsin, in 1871 and entered the First National Bank of Saint Paul where he was cashier in 1873. In 1880 he was president of the Merchants' National Bank there and in 1882 became a member of the State legislature of Minnesota, and was speaker in 1883. He was elected governor of Minnesota in 1889 and was director of the United States census in 1898-1903.

MERRICK, Frederick, American educator: b. Wilbraham, Mass., 1810; d. 1894. He received his education at the Wilbraham Wesleyan Academy and at Wesleyan University. He was made principal of Amenia Seminary at Amenia, N. Y., and held the chair of natural science at Ohio University, Athens, Ohio, from 1838 to 1843. In the latter year he began his connection with Ohio Wesleyan University which continued until his death. For 13 years he was president of that institution. Merrick was a supporter of the Underground Railway and otherwise an active Abolitionist. He was ordained to the ministry of the Methodist Episcopal Church and took part in the General Conferences of 1860, 1864 and 1876. He endowed the Merrick lectureship at Ohio Wesleyan University. He published poems and contributions in religious journals and the volume, 'Formalism' (1865).

MERRICK, mer'i-ík, Robertson, English novelist: b. Belize Park, London, 21 Feb. 1864. He was educated at Brighton College, and among his novels, several of which have been reprinted in this country, are: 'Mr. Bazalgette's Agent'; 'The Man Who Was Good'; 'Cynthia: A Daughter of the Philistines'; 'Home Fights Out of the Window.' He is also the author of several plays.

MERRIFIELD, mér-yí-fild, Webster, American educator: b. Williamsville, Vt., 27 July 1854; d. 22 Jan. 1916. He was graduated from Yale in 1877 and was an instructor there 1882-83. From 1884 to 1891 he was professor of Greek in the University of North Dakota, professor of political economy, 1891-1903, and president of the institution since 1891.

MERRILL, Elmer Trueblood, American university professor: b. Millville, Mass., 1 Jan. 1860. In 1881 he was graduated at Wesleyan University and subsequently studied at Harvard. In January 1900 he was placed in command of the Department of the Colorado, and in 1901 was retired from active service. He is the inventor of the Merriam infantry pack.

MERRIAM, WILLIAM RUSSELL, American financier: b. Wadsworth's Mills, N. Y., July 1849. He was graduated from Brown College, Wisconsin, in 1871 and entered the First National Bank of Saint Paul where he was cashier in 1873. In 1880 he was president of the Merchants' National Bank there and in 1882 became a member of the State legislature of Minnesota and was speaker in 1883. He was elected governor of Minnesota in 1889 and was director of the United States census in 1898-1903.

MERRICK, Frederick, American educator: b. Wilbraham, Mass., 1810; d. 1894. He received his education at the Wilbraham Wesleyan Academy and at Wesleyan University. He was made principal of Amenia Seminary at Amenia, N. Y., and held the chair of natural science at Ohio University, Athens, Ohio, from 1838 to 1843. In the latter year he began his connection with Ohio Wesleyan University which continued until his death. For 13 years he was president of that institution. Merrick was a supporter of the Underground Railway and otherwise an active Abolitionist. He was ordained to the ministry of the Methodist Episcopal Church and took part in the General Conferences of 1860, 1864 and 1876. He endowed the Merrick lectureship at Ohio Wesleyan University. He published poems and contributions in religious journals and the volume, 'Formalism' (1865).

MERRICK, Robertson, English novelist: b. Belize Park, London, 21 Feb. 1864. He was educated at Brighton College, and among his novels, several of which have been reprinted in this country, are: 'Mr. Bazalgette's Agent'; 'The Man Who Was Good'; 'Cynthia: A Daughter of the Philistines'; 'Home Fights Out of the Window.' He is also the author of several plays.

MERRIFIELD, Webster, American educator: b. Williamsville, Vt., 27 July 1854; d. 22 Jan. 1916. He was graduated from Yale in 1877 and was an instructor there 1882-83. From 1884 to 1891 he was professor of Greek in the University of North Dakota, professor of political economy, 1891-1903, and president of the institution since 1891.

MERRILL, Elmer Trueblood, American university professor: b. Millville, Mass., 1 Jan. 1860. In 1881 he was graduated at Wesleyan University and subsequently studied at Harvard. In January 1900 he was placed in command of the Department of the Colorado, and in 1901 was retired from active service. He is the inventor of the Merriam infantry pack.

MERRIAM, John Campbell, American educator and palaeontologist: b. Hopkins, Iowa, 20 Oct. 1869. In 1887 he was graduated at Lenox College, Iowa, and in 1893 received the degree of Ph.D. at the University of Munich. In 1894-99 he was instructor in paleontology and historical geology in 1905 assistant professor; in 1905-12 associate professor, and after 1912 professor of paleontology at the University of California. Professor Merriam is a Fellow of the American Association for the Advancement of Science, of the American Palaeontological Society, and other learned bodies. He is the author of numerous papers on fossil reptiles and fossil mammals of western North America, and on the general historical geology of the Pacific Coast region.
MERRILL. MERRIMAC

MERRILL, Frederick James Hamilton, American geologist: b. New York, 30 April 1861. In 1885 he was graduated at the Columbia School of Mines, received the degree of D.Ph. there in 1890 and was assistant in the New York Geological Survey 1883-89. In 1890-93 Dr. Merrill was assistant State Geologist of New York. In 1890-94 he was assistant director, in 1894-1904 director of the New York State Museum. He had charge of the New York exhibits at the expositions, Chicago 1893, Boston 1897 and St. Louis 1904. Since 1890 he has been in private practice as mining geologist. He published 'Salt and Gypsum Industries in New York' (1893); 'Mineral Resources of New York' (1896); 'Road Materials and Road Building in New York' (1897); 'Natural History Museums of the United States and Canada' (1903).

MERRILL, mērl, George Edmands, American Baptist clergyman and educator: b. Charlestown, Mass., 19 Dec. 1846; d. Hamilton, N. Y., 11 June 1908. He was graduated from Harvard College and entered the Newton Theological Seminary in 1872. Entering the Baptist ministry, he was pastor at Springfield, Mass. (1872-77); at Salem, Mass. (1877-85); at Colorado Springs (1885-87); and at Newton, Mass. (1890-99). In 1899 he was called to the pastorate of Columbia University, Hamilton, N. Y., where his administration improved the standard and awakened interest in many new lines of college activity. He wrote 'Story of the Manuscripts' (1881); 'Crusaders and Captives' (1882); 'The Reasonable Christ' (1893); 'The Parchments of Faith' (1895).

MERRILL, George Perkins, American geologist: b. Auburn, Me., 31 May 1854. He was graduated at the University of Maine in 1879. He has been head curator of the department of geology in the United States National Museum since 1893, and professor of geology and mineralogy in George Washington University since 1893. He was special agent for the 12th census. He has published 'Stone for Building and Decoration' (1891-1903); 'Granites, rock-weathering and Soils' (1897-1907); 'Handbook of the Department of Geology United States National Museum' (1892); 'Non-Metallic Minerals' (1901-04-10); 'History of North American Geology' (1905); 'Catalogue of Meteorite Collection in United States National Museum' (1915), and many papers to scientific societies. Dr. Merrill is a member of the Geological Society of America, of the Washington Academy of Science and of other learned bodies.

MERRILL, Lewis, American soldier: b. New Berlin, Pa., 28 Oct. 1834; d. Philadelphia, 27 Feb. 1896. He was graduated from West Point in 1855, and at the outbreak of the Civil War was appointed colonel of a volunteer cavalry regiment and served with distinction through the war. He was active in warfare and affairs, and performed the notable service of breaking up the Kuklux Klan in 1868, which was recognized by Congress after some delay by promotion to the rank of lieutenant-colonel of cavalry. He retired from active service in 1891.

MERRILL, Selah, American Congregationalist clergyman and archeologist: b. Canton Centre, Conn., 2 May 1837; d. 1909. He was educated at Yale and at the New Haven Theological Seminary and was ordained to the ministry in 1864 when he entered the Federal army as chaplain. He held pastorates in Leete, N. Y., and in San Francisco, and was for a time professor of Hebrew at Andover Theological Seminary. In 1882-86, 1891-94 and since 1898 he served as United States consul at Jerusalem and made valuable archaeological researches and discoveries there. In 1898 he became consul at Georgetown, Gruzina. He wrote 'The Time of Christ' (1881); 'The Site of Calvary' (1885); etc.

MERRILL, Stephen Mason, American Methodist bishop: b. Jefferson County, Ohio, 8 Sept. 1825; d. Keyport, N. J., 12 Nov. 1905. He studied for the ministry and was ordained by the Ohio Conference in 1846, and in 1859 was editor of the 'Western Christian Advocate.' In 1872 he was appointed bishop. He published 'Christian Baptism'; 'Union of American Methodism'; 'Sanctification' (1901); 'Miracles' (1902).

MERRILL, William Emery, American military engineer: b. Fort Howard, Wis., 10 Oct. 1837; d. near Edgefield, Ill., 14 Dec. 1861. He was graduated from West Point in 1858 and for a year prior to the outbreak of the Civil War was assistant professor in engineering at West Point. He went to the front and served with distinction at Yorktown, Chippawa, Missionary Ridge and other famous battles and in 1864-65 had charge of the railroad which supplied the armies in Georgia and Tennessee and was brevetted colonel for his services. After the war he served as chief engineer on the staff of General Sherman and was engaged in western surveys and the improvement of rivers. He was in charge of the improvement of the Ohio River at the time of the death which occurred on a railroad train. He wrote 'Iron Truss Bridges for Railroads' (1870) and 'Improvement of Non-Tidal Rivers' (1881).

MERRILL, Wis., city, county-seat of Lincoln County; on the Wisconsin River, on the Chicago, Milwaukee, St. Paul Railroad; about 145 miles north of Madison. It was settled in 1875 and incorporated in 1878. It is in a part of the State where the chief industries are connected with lumbering. Merrill has manufacturing establishments for shingles, laths, planed lumber, sawed lumber, sash doors and blinds, clapboards, lumber for interior finish, flooring, etc. It has a high school, a daily newspaper, an opera house, a court-house which cost about $100,000, and the T. E. Scott Public Library. Pop. 8,689.

MERRIMAC, mērl-mak, a river of New Hampshire, which has its source at Franklin, where the Pemigewasset and Winnipaug rivers unite. The Winnipaug is the outlet for the lake of the same name; the Pemigewasset has its rise in the northern part of Grafton County, in the White Mountains. The Merrimac flows nearly due south into the State of Massachusetts when it turns, continuing its course east, then northeast to the Atlantic Ocean. The mouth of the river is a tidal estuary which is navigable for steamers of good size. At the entrance is a sand bar which is constantly changing, and which is a hindrance.
to navigation. The river is navigable for small steamers as far as Haverhill. The extensive water-power of the Merrimac has been the main cause of the development and prosperity of the entire region. Some of the largest cotton mills of the country were erected on its banks, and many woolen mills, carpet mills and other manufactories. Newburyport is at the mouth of the river. Other important places on its banks are Haverhill, Lawrence and Lowell, in Massachusetts; and Nashua, Manchester and Concord in New Hampshire. The length from the source of the Pemigewasset to the ocean is 183 miles; its drainage area 5,000 miles.

MERRIMAC, The, a frigate of the United States navy. See Monitor and Merrimac, The.

MERRIMAN, mēr'ı-man, Henry Seton. See Scott, Hugh Stowell.

MERRIMAN, Mansfield, American engineer and author: b. Southington, Conn., 1848. He graduated from the scientific department at Yale in 1871, was with the United States Corps of Engineers for two years, and in 1875 became instructor in civil engineering at the Sheffield Scientific School (Yale). In 1878 he resigned as professor of civil engineering at Lehigh University, which he occupied for 29 years. During a part of this period he was also called upon to assist the United States Coast and Geodetic Survey. Since 1903 he has devoted most of his time to compilation on important works, mainly in hydraulics. He has written many textbooks, widely used by the colleges. Among them are 'Method of Least Squares'; 'Mechanics of Materials'; 'A Text Book on Roofs and Bridges' (4 vols., Jacob co-editor); 'Treatise on Hydraulics'; 'Handbook for Surveyors'; 'Strength of Materials'; 'Precise Surveying'; 'Elements of Sanitary Engineering'; and 'Elements of Hydraulics.' Every one of these has passed through several editions. He was also chief editor of the 'American Engineers' Pocket Book,' and has contributed to numerous technical and scientific papers.

MERRITT, Ernest George, American physicist: b. Indianapolis, Ind., 28 April 1865. In 1881-82 he studied at Purdue University and in 1885 was graduated M.E. at Cornell. He made graduate studies at Cornell in 1887-88 and at the University of Berlin in 1893-94. In 1888-91 he was instructor in physics, in 1892-1903 assistant professor, and after 1903 professor at Cornell. From 1909 to 1914 he was dean of the Graduate School. Dr. Merritt is a contributor to scientific journals on investigations in physics.

MERRITT, mēr'lt, Wesley, American soldier: b. New York, 16 June 1836; d. Washington, D. C., 3 Dec. 1910. He was graduated from West Point in 1860 and served with honor through the Civil War and for bravery at Gettysburg he was brevetted major. His services at the battles of Yellow Tavern and Winchester gained for him the rank of brigadier-general and major-general. He was assigned chiefly to frontier duty from the close of the Civil War until 1882 when he was made superintendent of West Point and in 1887 placed on duty at Fort Leavenworth, Kan. He commanded the Department of the East, 1897-98 and in May 1898 was put in command of the United States troops in the Philippines and conducted the campaign to a successful termination. After the close of the Spanish-American War he was ordered to Paris in order to assist the work of the French commissioners. He was retired in June 1900.

MERRITT, William Hamilton, Canadian mining engineer: b. Saint Catherine's, Ontario, 1855. He received his education at Upper Canada College, the Royal Military School, and the Royal School of Mines, London. Returning to Canada he practised his profession in Toronto; was a member of the Canadian commission to the Paris Exposition of 1878 and subsequently was made lecturer in mining engineering in the Kingston School of Mining. He became a cornet in the governor-general's body-guard in 1884, took part in suppressing Riel's rebellion in 1885, in the Boer War in 1899-1902. Mr. Merritt was also chosen president of the Ontario Mining Institute. He contributed to the 'Proceedings' of the London Geological Society, the 'Proceedings' of the American Institute of Mining Engineers; the 'Proceedings' of the Canadian Institute and is author of 'Economic Minerals of Ontario' (1896) and 'Field Testing for Gold and Silver' (1900).

MERRY, William Walter, English Anglican clergyman and classical scholar: b. Worcestershire, 6 Sept. 1835. He was educated at Balliol College, Oxford, and has been rector of Lincoln College there from 1884. He is widely known for his editions of the classics published by the Clarendon Press, including the 'Odyssey' (Books I to XII, 66th thousand; XIII to XXIV, 16th thousand; and the plays of Aristophanes. He is the author of 'The Greek Dialects' (1875).

MERRY DEL VAL, Rafael, cardinal of the Roman Catholic Church: b. London, 10 Oct. 1865. His father, Don Marquis Merry del Val, was partly of Irish ancestry, being descended from the Irish family Merry established in Spain; and his mother, daughter of Don Pedro José de Zulueta, Count de Torré Diaz, although of Spanish origin, was English by education. At the time of Rafael's birth his father was secretary to the Spanish embassy, London, the boy's early studies being pursued in the English metropolis. Later he attended the Jesuit College of Saint Michael, Brussels, afterward taking a course at Ushaw, and was subsequently chosen private tutor to Alfonso XIII. When his father was appointed Spanish Ambassador to the Vatican young Rafael accompanied him to Rome and entered the Gregorian University where, in preparation for the priesthood, he studied philosophy and theology, receiving the degree of doctor of philosophy and theology conferred by this institution. At the age of 24 he was ordained a priest and, although intended for the diocese of Westminster, was retained in Rome and soon became secretary to Pope Leo XIII. Four years later he was appointed master of the robes and privy chamberlain to Leo XIII, taking up his residence in the Vatican. Despite Monsignor Merry del Val's youth his linguistic knowledge included a fine command of English, French, Spanish and Italian, and his cosmopolitan training qualified him admirably for the fulfillment of various important missions. In 1887 he accom-
MERRY ENGLAND — MERSHON

gained the papal envoy, Monsignor Scilla, to Queen Victoria’s jubilee and in 1896 went as papal delegate to Canada to investigate the question of separate Catholic schools in Mani- toba. He is known to his Holy See calling for the Alfari vos, Leo Xili’s famous letter to the Catholics of Canada. It was likewise in 1896 that Monsignor Merry del Val was made secretary to the commission appointed to determine the validity of Anglican orders. In 1899-1901 he was president of the Congregation of the Holy Office, and in 1900 he consecrated titular bishop of Nicaea and in 1902 made titular archbishop of Nicocia. The same year he was appointed papal envoy to the coronation of King Edward VII and his book on the ‘Truths of the Papal Claims’ was given to the public. In the interregnum following the death of Leo XIII, Cardinal Oreglia, dean of the College of Cardinals, named Archbishop Merry del Val secretary to the conclave of cardinals that elected Pope Pius X and the manner in which he appointed the young archbishop Papal Secretary of State and on 9 Nov, 1903, elevated him to the cardinalate. Cardinal Merry del Val is secretary of the Congregation of the Venerable Fabric of St. Peter’s Basilica and also a member of the Commission for the Codification of Canon Law. His term of office as Papal Secretary of State expired at the death of Pius X.

MERRY ENGLAND, a popular name for England. The word merry is used, not in the sense of gaiety, but according to its earlier meaning, that is, agreeable, or pleasant; as in the phrase, “merry month of May.”

MERRY MOUNT, a district near the present town of Quincy, Mass., which in the early colonial days of New England was occupied by a party of men belonging to the Church of England. They paid little respect to the rigid and austere habits of the Puritans whom they greatly offended by the laxity of their manners. An attack was made upon this settlement by the forces of the Plymouth colony in 1630. John Lothrop Motley, the historian, produced in 1849 a romance entitled ‘Merry Mount.’

MERRY WIVES OF WINDSOR, The, Shakespeare’s greatest prose play. It contains only about 15 per cent of verse lines, and in the spirit of its scenes is equally subdued, save for a flash of the old fire in the fairy poetry at the close. Dennis and Rowe report a story, current at the opening of the 18th century and inherently plausible, to the effect that this play was written within two weeks to the special order of Queen Elizabeth, who desired to see Falstaff in love. The wish is worthy of the Queen’s taste and the manner in which it was satisfied indicates that Shakespeare did not work spontaneously. In point of time the play belongs with the greatest comedies — with ‘Much Ado about Nothing,’ ‘Twelfth Night,’ and ‘As You Like It.’ It was licensed for publication in January 1602 and most likely composed shortly before, for it is hard to believe that the Falstaff of this play can have been created while recollection of the great Falstaff of ‘Henry IV’ (1597, 1598) was very fresh in the actor’s mind. The manner in which it was composed shows a radical difference between the two characters. In the ‘Merry Wives’ Falstaff loses most of his peculiar wit and all the graver, pathetic side of his char-

aceter. He loses his charm, not only for the spectator but for his companions. There is a sense of positive disaster in seeing the invincible lovable knight of ‘Henry IV’ and ‘Henry V’ transformed into his own creatures, Nym and Page (II, i), just as there is in bearing the fatal strain of the Godfriard episode ignominiously relating to Brook-Ford (in III, v) the woe of his composure. ‘I do begin to perceive that I am made an ass,’ he is forced to say in the final scene, and the Shakespeare we have felt as keenly as his readers the pain of reducing Falstaff to the level of Dogberry and Bottom. The play is brisk and entertaining, and is constructed with masterly technique, but it is the sort of character and with unlikely incidents and type-figures — Slenor, Sir Hugh, Dr. Caius, the Host, when compared with Mercutio, Sir Toby, or the old Falstaff, are like pygmies and giants. There is no reason to believe that the Merry Wives of Windsor was regarded with special favor by the Elizabethans. After Restoration it seems to have become one of the most popular of Shakespeare’s comedies, though Samuel Pepys registers emphatic dissatisfaction when he says, ‘I have seen Falstaff in love and thought he saw The Merry Wives of Windsor.’

MRS. THOMAS LANDER, in ‘The Amours of Sir John Falstaff,’ since that last of the romantic movement, it has been one of the least liked of Shakespeare’s comedies.

TUCKER BROOK.

MERSEN, Treaty of, effected 8 Aug. & at Mersen, Holland, between Charles the 8th of France and his half brother, John of Branden- borg, by which Lotharingia or Lorraine, kingdom of their nephew Lothair II (d. 880), was divided between the east and west Frankish realms — France and Germany. From this date the history of the two national divisions and of the European state system begins.

MERSEY, mer′zi, England, a river forming Stockport by the union of the rivers Goyt and Tame. It flows in a general south- easterly direction to Runcorn, where it expands into an estuary two to three miles broad, near the mouth of which, on the north side, is Liverpool with Birkenhead opposite, and below which joins the Irish Sea. Since 1866 a railway tunnel under the Mersey has afforded communication between Liverpool and Birkenhead. The entire length of the river, including the estuary, is 70 miles. Principal affluent, the Irwell, on which it is navigable. The Bollin and the Weaver are affluents from Cheshire. With the Mersey and Irwell is now closely connected by great Manchester ship canal (q.v.) which opens into it.

MERSHON, Ralph Davenport, Amer., electrical engineer and inventor; b. Zanesville, Ohio, 14 July 1868. In 1890 he was graduated at Ohio State University; from 1891 to 1901 he was connected with the Westinghouse Company at Pittsburgh and New York, and thereafter entered private practice as consulting engineer. He has done important work on both the transmission systems in Colorado, Montana, to Tokio, Japan, and in South Africa. He invented the six-phase rotary converter, a con-
pounded rotary converter, a system of lightning protection for electric apparatus and a compensating voltmeter. In 1912-13 he was president of the American Institute of Electrical Engineers and is a member or Fellow of several scientific societies. He is the author of numerous technical papers.

MERSINA, Asia Minor, town on the south-east coast of Asia Minor, five miles south by west of Adana. It is a principal seaport on the south coast. The climate is unhealthy in summer. The harbor is an open roadstead. An American mission is located here and there is also a consular agent of the United States. Pop. 15,000, half of whom are Christians, Athenians, Greek and Turks.

MERSON, Luc Oliver, French painter: b. Paris, 21 May 1846. He studied at the École des Beaux Arts and was a pupil of G. Chassevent and of Pils. His first picture exhibited in the Salon was 'Leucothoë and Anaxandros' (1867). In 1869 he carried off the Grand Prix de Rome, the highest ambition of art students, by his painting 'The Soldier of Marathon.' He produced the same year 'Apollo the Destroyer,' now in the Museum of Castres. In 1873 he painted 'The Martyrdom of Saint Edmund of England' (Museum of Strasbourg). Since then he has devoted his pencil to the portrayal of legendary and mythological scenes and incidents. His chief works in this class are 'The Vision, a Legend of the 14th Century' (1873); 'A Patriotic Scene' (1873); 'Saint Michael' (1873); 'Saint Francis and the Wolf of Agubbio' (1878); 'Saint Isidore' (a triptych) (1879); 'The Judgment of Paris witnessed by Eros' (1884); 'Mankind and Fortune' (1892); 'The Annunciation' (1903). He has also frescoed with the life of St. Louis in the Palais de Justice at Paris.

MERTHYR TYDFIL, mɛr'thɛr tɪd'vɪl, or TYDVIL, Wales, a market and manufacturing borough of Glamorganshire, 24 miles by rail northwest of Cardiff, on the northern end of Taff Vale. It is the third largest place in Wales, and with the suburbs is 27 square miles in area. From an unimportant village in 1780, Merthyr Tydfil has become a prosperous centre of steel and iron manufactures, owing to its situation near the valuable coal and mineral fields of South Wales. Bessemer steel was first rolled into rails here. Since the local iron became reduced, the pig is mainly imported from Spain. The town has undergone much modern improvement and is noted for its municipal enterprises, one of its investments being the purchase of the historic Cyfarthfa Castle, with a small lake and 62 acres of ground, and converting them into a public park and two sewage farms are maintained. Pop. about 83,946.

MERTON, Walter de, English bishop: d. about 27 Oct. 1277. He was graduated at Oxford University, of which he was appointed chancellor by Henry III in 1261, and three years later instituted the collegiate, or separate house system at the University, by establishing the college which is called after his name. Here the secular clergy were to be educated in philosophy, the liberal arts and theology. The system he thus introduced has been the secret of success both to Oxford and Cambridge, and was originated chiefly with the object of raising up secular schools which might check the power of the monasteries and eventually supplant them as centres of education. He was appointed bishop of Rochester in 1274.

MERTON COLLEGE, Oxford, England, was originally founded in 1264 at Malden, Surrey, by Walter de Merton (q.v.), and removed to Oxford in 1274, where its collegiate buildings are among the oldest of the university. In the city, the chapel especially being noted for its proportions and beauty. The foundation consists of a warden, 19 fellows, 18 postmasters or scholars, 34 exhibitors, four lecturers, two chaplains, and in 1912, 150 undergraduates. Among its famous alumni are Harvey, the demonstrator of the circulation of the blood. Anthony Wood, Sir Thomas Bodley and Sir Richard Steele.

MERU, mɛr'oo, in Hindu mythology, the sacred mountain at the earth's centre on whose summit resides Siva, the sustaining and unifying power of the universe. It is the abode of the celestial beings. It was believed that the planets revolved around it.

MERV, mɛrv (sometimes written Merv), Russia, an oasis in Central Asia, in the south-western part of Western Turkestan, and about 120 miles north of the frontier of Afghanistan, now traversed by the railroad from the Caspian to Samarkand. It has an area of 1,900 square miles, and is crossed by the 37th meridian and 62d parallel. One-fourth of this area is artificially irrigated. It is watered by the Murghab and produces wheat, cotton, sugar, silk, etc. In the midst of the oasis are the ruins of the ancient town of Merv, founded by Alexander the Great, and subsequently held by Syrians, Arabs, Mongols and Persians. A new town, New Merv, has grown up on the Murghab, where the Trans-Caspian Railway crosses the river, with a citadel; it has been made the capital and its population is about 15,000. The oasis generally is the principal seat of the Tekke Turcomans, who from this centre used to make predatory incursions into Persia and Afghanistan. In 1815 the oasis was subjugated by the Khan of Khiva, to whom it remained tributary for about 20 years. Subsequently Persia attempted to make good the claims which it had long made to this district, and in 1860 fitted out an expedition for the purpose, which, however, miscarried completely, as did another expedition in 1876. In 1881 General Skobelev led a Russian expedition against the Tekke Turcomans, captured their stronghold of Geok-Tepe, and received the submission of their principal leader. The district of Merv subsequently came under the power of Russia. Merv is of great strategical importance, and considerable interest was attached to it in connection with the advances made by Russia in the direction of India. Pop. 250,000.

MERWIN, Henry Childs, American lawyer: b. Pittsfield, Mass., 5 Aug. 1853. He was graduated from Harvard in 1874 and was for some years lecturer in law at the law school of Boston University. Has been employed by the Massachusetts legislature since 1900 to write and revise statutes. Beside editing several legal works he is the author of 'Patentability of Inventions' (1884); 'Road, Track and Stable',...
(1893); 'Life of Aaron Burr' (1899); 'Life of Thomas Jefferson' (1901); 'Life of Bret Harte' (1910).

**MERYCODUS**, or **COSORYX**, a small antlered antelope fossil in the Miocene formation of the western United States. It was about the size of a dorcas gazelle, but with shorter limbs and neck and belonged to the family Antilocapridae, now represented only by the pronghorn; but it bore relatively tall three-tined antlers, which were deciduous and precisely like those of deer. Minute lateral toe- rudiments hung high above all the hoofs, but these were relatively smaller than in deer; in the modern pronghorn no trace of these remains. It was probably a collateral ancestor of the antelopes. **Blastomeryx** is a closely related genus somewhat more primitive. A very complete skeleton, collected by W. D. Matthew, is exhibited in the American Museum of Natural History at New York.

**MÉRYON**, Charles, shär·e mä-ré-ôn, French etcher; b. Paris, 23 Nov. 1821; d. Charenton, 14 Feb. 1868. He entered the navy, after studying at Brest, but failing health, forced his resignation, and he settled in Paris, studying etching there. His chief works were picturesque spots in old Paris, many since destroyed. A series of 23 plates by him appeared 1850-54. His last years were spent in an insane asylum at Charenton. Consult Wedmore, 'Méryon and Méryon's Paris' (1879); Burty, 'L'Œuvre de Charles Méryon,' translated by Huish (1879); Bouvenne, 'Notes et Souvenirs sur Charles Méryon' (1883).

**MESA**, Arix., town in Maricopa County, on the Arizona Eastern Railroad, 20 miles south-east of Phoenix. It contains numerous Toltec remains, a government experimental farm and power plant, the Granite Reef Dam, a public library and fine school buildings. It has extensive agricultural, fruit-growing and stock-raising interests. The town grew from a Mormon colony established here in 1879. The municipality owns the water supply system, Pop. 1,690.

**MÉSA**, or **TABLE MOUNTAIN**, any flat topped hill which stands out prominently above the surrounding area. The flatness is usually due to a thin layer of hard rock capping the hill. Many of our most noted mesa areas are the result of lava flows that cap and protect softer layers beneath. Butte is sometimes used in a similar sense, though it is more often applied to steep-sided prominent hills that are not notably flat-topped.

**MESA VERDE NATIONAL PARK**. Colo., a reservation of 48,966 acres in Montezuma County, southwestern Colorado. Within its area, in canyons of the Mancos River, are the most remarkable of the many ruins of prehistoric cliff dwellings in the southwestern United States. The Mesa Verde (from the Spanish word mesa, so named from its vegetation) is a high table-land, dividing the Mancos and Montezuma valleys. This mesa is elevated above the valleys some 2,000 feet, and rises abruptly from their floors, with precipitous sides, like the wall of a cliff. The northern extremity of this great mesa terminates in Point Lookout, which juts out between the two valleys, a landmark for miles in all directions. The highest part of the Mesa Verde National Park, Point Notch, near the northern boundary, is 3,585 feet above sea-level, while Point Lookout has an elevation of 8,428 feet above sea-level. The northern edge of the mesa terminates in a precipitous bluff, averaging 200 feet in the floor of the Montezuma Valley. The gentle slope of the mesa is to the south, so that a person on the northern rim has a view in all directions. The surface of this table-land is broke by innumerable canyons, which start from the very edge of the mesa on the northern and western sides, and, growing deeper and more rugged as they descend, finally open out into the Mancos Canyon. These canyons have many great caverns in their side walls, with the overhanging rocks for roofs, and in these caverns were found the ruins of the cliff dwellers. The principal ruins are found in Navajo, Cliff, Soda, Long and Rock Canyons, though there are hundreds of lesser ruins in all the canyons in the park. Spruce Tree House is in Spruce Creek, a branch of Navajo; Cliff Palace is in Canyons; Balcony House is in Soda; Peabody House and Inaccessible are in Navajo; Ledge House is in Rock Canyon. A ruin in Long Canyon was entered by one of the rangers in 1914 for the first time since it was abandoned by its original tenants. Its position, having protected it from all vandalism, and it was found just as it had been left, no one knows how long ago. One sealed room contained a fine collection of jars and implements. It was reached by swinging a ladder over the cliff and anchoring it at the top, and down this swinging ladder the ranger went and anchored it at the bottom. Now tourists make the descent. These ruined houses, villages, are found in the recesses of the canyons and, protected from the weather, are remarkably well preserved. Some are small, with only a few rooms, while others are large and must have accommodated a larger population. The ruins found on the mesa, without the protection of the overhanging cliffs, have not withstand the ravages of time and are now but mounds of stone and earth.

While the ruins in the Mancos Canyon were explored as early as 1874, the most important escaped discovery until 1888, when R. Wethered and C. Mason of Mancos, in search of a herd one day in December, penetrated a path of tree wood to the edge of a deep-sides canyon on the opposite cliff, sheltered by a huge, massive vault of rock, there lay before their astonished eyes a whole town, with towers and walls rising out of a heap of ruins. They named the place 'Cliff Palace,' and the same day discovered, in another canyon, another large cliff dwelling to which they gave the name of Spruce Tree House, from a great spruce growing among the ruins. The word dwelling is misleading; for most of these buildings were villages, not towns. It is not a doubt that undoubtedly a town of importance, harboring at least 350 inhabitants.

The arrangement of houses in a cliff dwelling of the size of Cliff Palace, for example, is characteristic and intimately associated with the distribution of the social divisions of the inhabitants. The population was composed of a number of units, possibly clans, each of which had its own social organization more or less
1 SUN TEMPLE, MESA VERDE NATIONAL PARK, SOUTHWESTERN COLORADO
This ruin, in "The Land of the Cliff Dwellers," was excavated in 1915 by Dr. J. Walter Fewkes, of the Smithsonian Institution, Washington, D. C. It is 131 feet long. Dr. Fewkes is of the opinion that the structure was intended for religious and not domiciliary purposes.

2 BALCONY HOUSE, MESA VERDE NATIONAL PARK, SOUTHWESTERN COLORADO
This ruin is the third in size of the numerous prehistoric ruins on the Mesa, and one of the most interesting and most spectacularly situated. Two kivas, or underground ceremonial chambers, are shown in the foreground.
distinct from others, a condition that appears in the arrangement of rooms. The rooms occupied by the men practically were the living rooms, although generally neighboring rooms were distinguished from one another by their uses. Thus, each clan had its men's rooms, which was ceremonially called the "kiva." Here the men of the clan practically lived, engaged in their occupations. Each clan had also one or more rooms, which may be styled the living rooms, and other enclosures, for granaries or storage of corn. The corn was ground into meal in another room containing the meate set in a bin or stone box, and in some instances in fireplaces, although these were generally placed in the plazas or on the house tops. All these different rooms, taken together, constitute the houses that belonged to one clan.

The conviction that each kiva denotes a distinct social unit, as a clan or a family, is supported by a general similarity in the masonry of the kiva walls and that of adjacent houses ascribed to the same clan. From the number of these rooms it would appear that there were accommodations for at least 45 per cent of the people. The kivas were the rooms where the men spent most of the time devoted to ceremonies, councils and other gatherings. In the social conditions prevalent at Cliff Palace the religious fraternity was limited to the men of the clan.

Apparently there is no uniformity in the distribution of the kivas. As it was prescribed that these rooms should be subterranean, the greatest number were placed in front of the rectangular buildings, where it was easiest to excavate. This was the usual custom when these structures were built far back in the cave and enclosed by a double wall, the intervals between whose sections were filled with earth or rubble to raise it to the level of the kiva roof. In that way they were artificially made subterranean, as is the ritual required. Easily reached from Denver and Colorado Springs, Mancos on the Rio Grande Southern Railroad is the preferable starting point by stage or automobile to explore the mesa. Consult United States Department of Interior Bulletins "The Mesa Verde National Park" (Washington, D. C., 1915); Nordenskjold, B., "The Cliff Dwellers of the Mesa Verde" (Stockholm 1893).

MESABI RANGE. See IRON ORE—Iron Ore Districts.

MESCAL, a fiery liquor produced in Mexico from several species of Agave (q.v.). The most famous liquor, however, is made from the "hearts" of the species Agave tequilana. The city of Tequila, in the state of Jalisco, is the center of this particular industry. The Tequila Agave resembles in the appearance of its stiff lance-like leaves the sisal hemp plant, though it sends out its leaves from a great bulb-like cellular mass which forms the heart of the plant. This heart, when denuded from its leaves and detached from the root, is clef in two, and a dozen of these pieces make a fair load for a mule, for they must be transported from the fields where grown to the city, sometimes a journey of several miles. These hearts are roasted in pits, within the distillery enclosures, dug four or five feet deep and considerably wider. A hot fire is built of mesquite wood, and large stones distributed through the fuel. The "hearts" are then heaped over the burning mass until a huge mound is formed, which is covered first with grass and then with earth, and the mass left several days to cook. When the mound is opened the raw product is found to have changed to a dull brown in color, and the juices to have been converted into sugar. White hot and steaming, the mass is taken to another pit, stone paved, on the bottom of which revolves a heavy stone crusher, really an arrester operated by mule power. Here it is ground into pulp and the semi-liquid mass carried in deep trays on the heads of Indians to the vats where it remains to ferment. Then it goes to the rude stills, and is run off as mescal. The commercial mescal is a colorless liquor sometimes with a slight amber tint, though much of it is like alcohol. Some of the higher grades are given fancy names which serve as trademarks. It is far too strong a liquor to be drunk with impunity, though its fiery quality seems to suit the Mexican taste for hot things. Zolot is another liquor, made in the same way from the bulb-like heart of a species of Dasylium, which is said to be as strong as 95 per cent alcohol. This liquor should not be confounded with aguardiente, which is made from sugarcane. The Mexican name means burning water.

MESCALA. See MEXCALA.

MESCALEROS (Spanish, mescal, a native drink used in Mexico, Guatemala, and along the southern boundary of the United States), an Apache tribe so called because it was the most enterprising of mescal. Somewhat of a nomadic character, they covered territory, at times, between the Rio Grande and the Pecos in New Mexico and southward into Mexico. They gave the governments of the United States and Mexico trouble, from time to time, but not so much as their relatives in Arizona and northern Mexico. In 1873 a reservation of 475,000 acres was set apart for the use of the Mescaleros in Southern New Mexico. The tribe now numbers about 500.

MESDAG, mës'däg, Hendrik Willem, Dutch marine painter; b. Groningen, 23 Feb. 1831. He was a banker, following in his father's footsteps, until his 36th year, when he devoted himself to art, studied under Alma Tadema, who was a relative, and under Roeufs, and lived at The Hague, with a studio at Scheveningen. He takes a foremost rank among modern painters of the sea, and conveys the idea of water-masses and motions very felicitously. The report circulated in American newspapers of his death, 4 Aug. 1902, was false. Mesdag's pictures include "Fishing Boats at Scheveningen," "Strand of Scheveningen," "Morning on the Scheldt," "In Peril," and many other views of the North Sea. Consult Zilken, "H. W. Mesdag" (English version by Bell, 1896); and Marius, "Dutch Painting of the Nineteenth Century" (1908).

MESENTERY, a double fold of the peritoneum which attaches the small intestine to the spinal column, but in such a manner as to permit great freedom of motion. The corresponding support of the large intestine is the mesocolon, with the mesentry. The mesentry contains between its folds several blood-vessels, lacteals, lymphatics, nerves, and the ganglia called mesenteric glands, which are connected with the lymphatico-lacteal system.
It is about four inches wide, and extends nearly the whole length of the intestine. It is subject
to several diseases, the most frequent of which
is tubercular degeneration of some of its nu-
merous glands. For this and other diseases
of the mesentery, see PERITONITIS.

MESHA, king of Moab mentioned in
11 Kings iii. 2-27. This monarch threw off the
yoke of Israel, then ruled by Ahab, and the lat-
ter's sons, Ahaziah and Jehoram. Later Jeho-
ram, with the aid of the kings of Judah and
Edom, defeated Mesha and his hosts. Mesha
was defeated and besieged in Kir-hareseth, but
managed to hold out against his enemies al-
though his country was overrun. See MOABITE
STONE.

MESHED, měsh'ěd, or MESHED, měsh'-
ěd, Persia, capital of the province of Khor-
san, in an extensive valley 500 miles northeast
of Isphahan. It is surrounded by walls, and has
many ruinous houses, but its principal street is
spacious and broad, and is bordered by a water-course,
the banks of which are shaded by trees, passing
through it, while at its extremity are seen the
splendid cupola and gilded minarets of the
mosque containing the shrine of Iman Riza, the
son of Ali, the founder of the Shiiites. This
tomb has a gorgeous interior, a vast hall, like the
central nave of a cathedral, rising lofty
into a central dome ornamented with the rich-
est colors and a profusion of gilding. This
shrine attracts a vast number of pilgrims. Here
also is the mosque of Gohur Shah, considered
one of the most beautiful and splendid in Persia. The chief manufactures are velvets,
sword-blades and some silk and cotton goods.
A considerable number of the inhabitants are
employed in cutting the turquoises obtained in
the vicinity. The situation of Meshed on sev-
eral great caravan routes makes it an important
centre for the produce of surrounding coun-
tries. The customs receipts for the territory
approximated $250,000 annually up to 1914, but
fell off nearly one-half during the World War.
Pop. about 61,500.

MESHTROVITCH, Ivan, Yugoslav sculp-
tor: b. Otvice, Northern Dalmatia, 1883, the
son of a Croat. He was educated at the Vienna
Academy of Arts and first exhibited his work
in that city in 1902, and in 1911 his studies for
the Serbian National Temple at Kosovo were
shown in Rome. An artist of the highest type,
edowed with astonishing ability, he is regarded
in Europe — especially in England — as one of the
greatest sculptors that ever lived. In 1915
a representative committee brought him to Lon-
don and organized an exhibition of his works
at the Victoria and Albert Museum. Art, politi-
cal idealism, mythology and religious mysticism
are inseparably bound up in his creations. His
remarkable talent is expressed in the eclectic
style of objects of which he is master; it would
seem that all known styles converge in Meshtro-
voitch: Egyptian, Greek, Baroque, Byzantine,
Assyrian and the most violently realistic mod-
ernism. Consult 'Ivan Meštrović: A Mono-
graph' (London 1919), by Sir John Lavery,
Dr. Seton-Watson and others, with 68 photo-
graphic plates.

MESMER, Friedrich (or Franz) Anton,
frédrik ån'tôn měs'měr, German physician:
b. Itzmang, near Constance, Baden, 25 May
1733; d. Meersburg, Baden, 5 March 1815. He
was educated in medicine by Van Swieten.
De Haen of the University of Vienna, who
some study of astrology, came to believe in the
influence of the stars, and attributed this sus-
pended influence to magnetism. Having at first
believed in the cure of diseased bodies by the
use of magnets, he came wholly to discard
magnets and declared that an occult force, which
he called animal magnetism, pervading the
verse, resided in himself and afforded him
influence over others. In 1778 he went to Par-
and set the town astray. He had undoubtedly
an honest belief in the efficacy of his discourses
but he took advantage of popular interest to
thrash his methods with mystery. Finally the
government appointed a committee of medici-
and members of the Academy of Sciences, including Benjamin Franklin, to
investigate the matter; and the committee in
port, admitting many facts but attributing the
to physiological causes and not to any such
power as animal magnetism, so credited Mesmer that he went to London
later to Germany. The name mesmerism was
formerly applied to the entire class of pheno-
ena now known as hypnosis (q.v.). He now
claimed that there was a force, called the
body generally called 'magnetism', which
under the control of the human will, and when
the control of this force passes to the
hypnotism occurs. Among his writings are:
'Mémoires sur la Découverte du Magnétisme
Animal' (Paris 1784); 'Histoire de la Cura
métisme Animal' (1783); and the 'Mémoires
F. A. Mesmer sur ses Découvertes' (1784).
See ANIMAL MAGNETISM; HYPNOTISM.

MESMERISM. See HYPNOTISM.

MESNE (měn) PROCESS, in law, an
intermediate process which issues pend-
ent upon some collateral interlocutory mat-
terial and final process, or process of execu-
tion and then signifies all such processes as
arise between the beginning and end of the

THROUGH.

MESONERO ROMANOS, mě-sō-něr-o
rō-mä'nos, Ramon, Spanish writer: b. Mar-
1803; d. 1882. After a short time spent
in mercantile life he turned to journalism
and at some time spent on the Madrid Preci-
ier founded the Semanario Pintoresco Epi-
which he continued to edit and manage
1842. Mesonero was a great lover of his na-
which, in his youth, was still the
fashioned Spanish capital teeming with
native life, before it had begun to reflect
fashions, customs and manners of Paris.
ribs, with his fellow city-dweller
nowhere and on every occasion; and
this intimacy sprang interesting and
written sketches of popular types, manner-
customs. His comprehensive knowledge of
native city appears in 'Memorias de Madrid';
'Escenas Matritenses' (2 vols., 1836); 'Mi-
memorias de un sententón' (1880), and 'El
Antiguo Madrid.' Mesonero is one of the
masters of modern Spanish. His language
was ever graceful, tending to a slight differ-
but always preserving its purity and idiom.
comprehension and force. A collected edition of his works was published in Madrid in 1881 under the title "Poesias de Ramos de Romano". In 1903-05 two volumes more of his hitherto unpublished writings also appeared in Madrid. Consult for biographical sketch, Northup, G. T., 'Selections from Mesopon Romanos' (New York 1913).

**MESONYCHIDÆ, a family of Creodonts, prehistoric mammals, which were much more highly specialized than any other. They acquired a wolf-like form, with a very long slender tail, and legs and feet digitigrade gait indicating powers of speed beyond those of any other creodont. Their heads, however, were disproportionately large and bear-like.

The general structure, nevertheless, shows that they could not have been rapid and aggressive in their habits, and their teeth suggest that they lived principally on vegetable diet. Their development into byenalike creatures may be traced to nearly the close of the Eocene.

**MESONYX, a primitive carnivorous animal of the group Creodonta (q.v.), which must have resembled in external aspects, when alive, the modern Tasmanian wolf of Australia. Its remains are found fossil in the fresh-water formations of Eocene Age along the eastern base of the Rocky Mountains, and a complete skeleton is mounted in the museum of Princeton University, and a restoration is exhibited in the American Museum of Natural History in New York. (Mesonyx obtusidens) indicates an animal as large as a Saint Bernard dog, with its hindquarters drooped somewhat, like those of a hyena and a very long, slender tail. It is the type of a large family (Mesonychidae) of wolf-like beasts widely distributed in time. Guindon Woodward, 'Vertebrate Palaeontology' (London 1898); Osborn, 'Age of Mammals' (New York 1910).

**MESOPHYTE (Gr. 'mid-grower*), in botany and forestry, a term used of plants which grow naturally in soil of moderate moisture. Thus the term is contrasted on the one hand with xerophyte, 'dry-grower', and hydrophyte, 'wet-grower,' these latter terms being applied to plants requiring very little or very much moisture. Since soil of moderate moisture varies from moist to dry, whereas both the dryer and wetter soils are comparatively invariable in this respect, it naturally follows that Mesophytic plants show more adaptability to conditions of moisture than either hydrophytes or xerophytes. For the same reason, no doubt, the mesophytic flora, being comparatively stronger, is denser and marked by much wider variations of species, than the scanty and monotonous growth of poorer, because of wetter or dryer, soils.

**MESOPOTAMIA, from Greek mesos, middle, and potamos, river: a geographical term applied to the territory lying between the Euphrates and Tigris in Western Asia. The Arabs call those rivers El-Prat and Shatt respectively; the latter is also called Ed-Dijleb in its lower course. The boundaries of this region (which forms no single political division) are: Northward, it includes all (Turkish) territory south of Diarbekr, and running parallel with the Persian frontier down to the gulf. As regarded by geographers, it is bounded on the north by the Armenian Taurus, on the east by the Iranian frontier mountains, on the south by the Syrian steppe, and the Persian Gulf on the southeast. The Persian Gulf is divided into the three vilayets of Mossul, 35,130 square miles; Bagdad, 54,540 square miles; and Basra, 53,580 square miles; total, 143,250 square miles. The population of Mesopotamia is generally stated to be about 2,000,000, but competent observers consider 1,300,000 to be nearer the mark. The country to which the name properly applies as extending between the two rivers has a gradual fall of nearly 1,000 feet from the spurs of the Taurus range to an old coastline south of Hit, whence an almost unbroken plain stretches to the Persian Gulf. The natives give the name of El Jezir (the island) to the upper or northwestern portion, and that of Irak Arabî (the ancient Babylon) to the lower or southeastern section. This latter, indeed, is often excluded as being beyond the confines of Mesopotamia proper. Low ranges of hills break the great plain of Upper Mesopotamia; between them the Khabur and its tributaries flow to the Euphrates desolate region that was once thickly populated. The mountain district bordering the plain and stretching to the Persian frontier forms part of *Kurdistan,* a mere name that has no concrete geographical existence, being mostly comprised in the vilayet of Dihok and belonging mainly to Mesopotamia. Ethnically it includes the Kurdish and the Arab nomad tribes—respectively of Iranian and Semitic stock. Upper Mesopotamia is rich in grain, wine and pasture; the lower is fairly dry and unfruitful. Between the Khabur and the Euphrates lies the Biblical Aram-Naharaim, or Syria of the Two Waters, also called Padan-Aram, or Syria of the Plain. It is mentioned in the Old Testament in connection with Isaac and Jacob (Gen. 24 and 27). The Greek title was probably not in use till after Alexander the Great invaded the East. The soil consists of a sandy clay of excellent agricultural properties; only where water falls is incapable of cultivation. Its remarkable fertility is shown by the fact that it still remains unexhausted after having supported through many centuries the Assyrian, Babylonian and Persian empires. The number and vastness of the ruins that lie scattered over this region from Babylon to Nineveh still bear silent testimony to its former flourishing condition. Since the cuneiform inscriptions gathered from these ruins have yielded up their secret to the researches of modern science, we have learnt with certainty that the plains of Mesopotamia were the scenes of successive civilizations, revelled in splendor and antiquity only by those of ancient Egypt. To-day, in certain localities, may be found lions, leopards, wild asses, boars and gazelles.

Mesopotamia is essentially a land of origins; so far as we know it cradled the human race and nurtured it for centuries until a new era was introduced by the Flood incidents, which are recorded not only in the Hebrew Scriptures, but also in the cuneiform inscriptions. Its early history is one of constant struggles for supremacy between contending nations. Mesopotamia and its adjacent plains have been associated with some of the most important turning-points of human history; for millennia
these lands contained the capitals of great world-empires and have been closely connected with the growth of history. Even in the World War of 1914-18, Mesopotamia — by reason of the Bagdad Railway schemes — played a rôle the importance of which is as yet but inadequately recognized, for that railroad was the keystone in the German army's plans of invasion. The Mesopotamians sprang from the Chaldeans, the primitive inhabitants; from the Cushites, who in the reign of Nimrod built the cities of Edessa and Nisibis; and from the descendants of Shem, of the tribe of Thara. The Hebrew race took its rise from this land when Abraham came from Ur of the Chaldees and settled in Canaan. It was also in this plain of Shinar that the confusion of tongues occurred. Babylon was the mother of astronomy, and the 12 divisions on the dials of our clocks originated there, while the influence of Hammurabi's famous laws has penetrated down the ages into the legal codes of modern times through the intricate systems of Greek and Roman legists. Mesopotamia, founded by part of Nimrod's dominions, the founder of Calneh or Nippur. After an interval of more than 700 years (2000 B.C.) Cushan Rishathaim reigned in Mesopotamia, who extended his territory over the Euphrates. The Israelites, who possessed Palestine, were compelled to pay him tribute for the space of eight years. In the Golden Age of the Assyrian power (790 B.C.) Mesopotamia was entirely subjected to that empire, and suffered the fate of its subsequent conquerors. Trajan brought it under Roman dominion in 106 A.D., but the Persians did not permit the Romans to remain long in undisturbed possession, for it was a constant cause of war between the Roman and Persian empires, and at last the Persians in 363 A.D. When the Arabs in 631 established a new empire upon the ruins of the Sassanide kingdom, Mesopotamia was also obliged to submit to the storm. In 1040 it fell into the hands of the Seljuks. From that time it had many rulers in rapid succession. Genghis Khan made himself master of it in 1218, but in 1360 it fell into the hands of Tur Ali Bey. Timur conquered it 40 years later, and in 1514 it was incorporated in the Persian Empire under Ismael Sophi. In 1554, however, the Persians were compelled to surrender more than half of it to the Turks; and though they again recovered the lost portion in 1613, they were unable to withstand the attacks of Amurath IV, who united this in 1637, with many other provinces, to his empire. Despite its vicissitudes and the wars fought on its soil, the country remained rich and prosperous until the battle of Kadiis (635 A.D.) placed it at the mercy of the Arabs. Assyria and Babylonia were the wealthiest countries of antiquity, and Mesopotamia, though in the great Persian Empire. In olden times Babylonia was perfectly irrigated, but the wonderful system of canals fell into ruins under the Turks. As the nomads pressed forward the peasants were driven from their lands, the great irrigation works were neglected, and the Euphrates no longer controlled, spread out into wide fever-bearing marshes. The work of devastation commenced by the Arabs was completed by Tartars, Mongols and Turks, with the result that one of the most fertile regions in the world became practically a desert abandoned to nomads. The Arabs now form the majority of the population, though the original inhabitants are still represented by Kurds, Yezidis or "devil worshipers," Nestorians, Chaldeans or Roman Catholic Arameans and Jacobites in the north; and by Sallians in the south. There are about 50,000 of them in the few residences in Mesopotamia who guard with reverence the traditional tombs of Joshua near Bagdad, of the prophet Ezekiel near the banks of the Euphrates, and of Ezra the Scribe on the Tigris near Kurnah. Besides its wealth of biblical associations, Mesopotamia is a land of sacred memories to hundreds of millions of Mohammedans. Two gilded domes on the splendid mosque at Kazaim cover the tombs of eminent teachers; this and the mosque at Samarra are Shiah shrines. A mile away, on the left bank of the Tigris, is the stately Hanif mosque of the Sunnis at Muaththam, and the famous mosque of Abd ul Kadir is in Bagdad. The tomb of Mohammed's barber, Salman Pak, is near. Bagdad was originally the capital of the holy Mohammedan cities of Kerbela and Nejaf. Broke the banks of the Euphrates, to which thousands of embalmed corpses are brought by pilgrims every year from India and Persia for interment. Under the blighting misrule of the Turk Mesopotamia has become one of the most desolate countries on earth, swarming with vermin and insects. What little manufacture is carried on is used for home consumption. Sugar, cloth, coffee, iron, indigo and copper are imported, and chief exports are dates, wool, cereals, gum, rice and hides. The foreign trade is mainly with Great Britain, India and Persia. Passengers and merchandise are carried down the Tigris from Diarbek to Bagdad on rafts of inflated sheepskins. Sailing boats are used below Samarra, while from Bagdad to Basra on the gulf river steamers ply. Steamers can navigate the Euphrates as far up as Meskineh. The principal towns are Diarbek, Urfa (Edessa), Harran, Mostil and Bagdad. Basra, on the Shatt el-Arab (the confluence of the Tigris and Euphrates from Kurna) is the port of transshipment from river to ocean craft. Mesopotamia has the evil reputation of being the home of the bubonic plague, and British and American doctors have labored for many years to grapple with that disease and the deadly cholera.

Mesopotamia and the War. — It has already been mentioned that Mesopotamia was the keystone of the Pan-German scheme by reason of the Bagdad Railway. According to German authorities on the subject, there were three alternative plans to promote the expansion of Germany into a great world-emprise. In the early stages of the Pan-German movement, the vision of its advocates was fixed upon South America as the greatest German territory on which a Greater Germany might be built. Here, however, the Monroe Doctrine stood in the way. The British Empire, as the largest landholder in the world, then became the focus of the Pan-Germanists, and here, also, a formidable barrier stood in the path — the British navy. Two avenues being thus barred by obstacles which could only be removed by an overwhelmingly powerful fleet, a third plan presented itself, a plan which provided for
overland expansion where no Monroe Doctrine existed and no British navy could intervene. The scheme was to gain control of the Balkan peninsula by the elimination of Serbia, the only hostile barrier separating the Central Powers from a friendly power, Bulgaria. This accomplished, the road lay open to Constantinople, a junction which, in its turn, opened the door to Asia, via the Persian Gulf; to East Africa and Australia. The principal artery of communication lay in Mesopotamia—the Bagdad Railway. It was calculated that this project could be carried out in 3 years, coming into physical contact with either British territory or navy, and would place Germany in a position eventually to strike both at India and Egypt, a variation of Napoleon's plan of campaign for breaking the power of Britain. According to Prince Bllow, former German chancellor, this undertaking "threw open to German influence and German enterprise a field of activity between the Mediterranean Sea and the Persian Gulf, on the rivers Euphrates and Tigris, and along their banks. Mesopotamia and the province anywhere, it is in Mesopotamia (Imperial Germany, p. 116). These words were no exaggeration, for Sir William Willcocks, an English engineer who had surveyed the country and planned a gigantic system of canals and waterways, said in 1903, that "of all the regions of the earth, no region is more favored by nature for the production of cereals than the lands on the Tigris. This authority stated that the irrigable area of Mesopotamia was from two to three times as large as that of Egypt, which leads to the presumption that the country could support some 30,000,000 people. Persia and Turkey being decrepit and moribund states, the Pan-Germanists saw in Mesopotamia a field for exploitation which would make it for Germany what Egypt was to Great Britain or Morocco to France. German professed had painted the possibilities of this region to enthusiastic audiences in glowing colors, and had not omitted to point out that a German foothold on the Persian Gulf would imperil the position of Great Britain in India and Egypt. Now the most important route of the British Empire is the sea-route from England to India and Australia, and the Persian Gulf as a strategical British position has been pointed out by Admiral Mahan, on account of the Red Sea being merely a continuation of the Suez Canal, both of which could be dominated by a hostile power holding the Gulf. The British, however, have not awakened to the importance of the Gulf only in recent years, for already in the days of Queen Elizabeth it was visited by English vessels; before ever the Turkish flag appeared on the shores of Arabia the English flag was known and respected in the Persian Gulf. The East India Company planted a depot at Bandar Abbas in its early days and for nearly two centuries fought with Dutch and Portuguese rivals. The Anglo-Indian navy first surveyed the gulf and provided for its lighting to guide navigation. For 50 years the British hunted the pirates in the gulf and destroyed their strongholds. Altogether, for 300 years the British have been the guardians of the gulf, by protecting British subjects engaged in trade or shipping, by fighting the plague and introducing the elements of sanitation among the natives on the coastline. All that Great Britain took in return was a spot on an island for a telegraph station; but she allowed no compromise on one point—that no power should be permitted to seize territory and no other flag should dominate those waters. The future of India and of the empire was bound up with British prestige in the Persian Gulf. These considerations explain the suspicion and mistrust of Great Britain regarding the absorption of Mesopotamia by Germany—an avowedly hostile power. In 1899 a German company obtained a concession from the Sultan to build a railroad from Konieh—the terminal of the Anatolian Railway—to Bagdad and Basra on the Persian Gulf, and from that year dates the German penetration of Mesopotamia. On realizing the political objects underlying the scheme, Great Britain protested and a diplomatic conflict began which was still in progress when the war broke out. During 1913-14 a strange medley of diplomatic negotiations were being held on the question of Mesopotamia and the Persian Gulf. England, France, Russia, Germany and Turkey were involved, with the result that Germany obtained the acquiescence of the powers to be the sole concessionnaire of the railroad, thus England forced Germany and Turkey to fix the terminal well inland at Basra. The lighting, marking and policing of the gulf by England was confirmed by Turkey. Meanwhile, Russian diplomacy had succeeded in creating intangible spheres of influence in Turkish territory by which the German railroad through Mesopotamia was hemmed in on either side, while Great Britain held the key of the exit. As compensation for being restricted at that exit, Germany received a concession to build a line from the Bagdad Railway to Alexandretta on the Mediterranean. At a later date Great Britain was apparently willing to grant an extension of the German sphere, for Prince Lichnowsky (d. v.) records in his famous Memorandum that "the greatest concession Sir Edward Grey made to me personally was the continuation of the line to Basra. We had not insisted on this terminus in order to establish connection with Alexandretta. Hitherto Bagdad had been the terminus of the line. The shipping on the Shattel-Arab was to be in the hands of the international commission. We also obtained a share in the harbor works at Basra and even acquired shipping rights on the Tigris, hitherto the monopoly of the firm of Lynch." He goes on to say that "by this treaty the whole of Mesopotamia became our zone of interest. . . . This treaty, of course, was neither signed nor published owing to the outbreak of the war, otherwise the ex-ambassador remarks, an agreement would have been reached with England which would have finally ended all doubt of the possibility of an Anglo-German co-operation. See War, European: Turkish Campaign.

MESOZOIC ERA, in geology, the middle period of life in geologic time, also called the Secondary Period. Paleozoic precedes and Cenozoic follows this era, these two terms referring respectively to "older" and "newer," or "earlier" and "later," forms of prehistoric life. The subdivisions of the Mesozoic are the Triassic, Jurassic and Cretaceous periods (q.v.).

The Life of the Mesozoic.—The life history of the era can be best understood, by first referring to the life of the Paleozoic (q.v.). That era was closed under conditions (aridity, glaciation and mountain making) unfavorable to plant and animal life, and as a result many which genera failed to live from Paleozoic on into Mesozoic. The long-hinged brachiopods, so characteristic of the earlier era, became extinct early in the latter. A few of the more primitive types persisted, but brachiopods became relatively unimportant. The old straight cephalopods actually became extinct with the passing of the Paleozoic. The nautiloid type lived on through, even to the present time, but the era was characterized particularly by the dominance of a type called the ammonites, which appeared in late Paleozoic and died out at the close of the Cretaceous. They evolved rapidly and are valuable time markers. The Mesozoic has often been called the age of reptiles. This group of vertebrates, which appeared toward the close of the Paleozoic, in primitive form, developed rapidly into a number of highly specialized types. The dinosaurs (terrible reptiles) developed along several lines. The carnivorous group walked on two legs, the two front limbs being very short. This was the reptile that made the famous three-toed tracks of the Connecticut Valley. Some of these dinosaurs got to be as long as 40 feet. Herbivorous types also developed, great awkward beasts, some of them 80 feet long, 16 feet high and weighing probably 30 tons or more. This type was the largest land animals that ever lived. Late in the era peculiar armored dinosaurs, also armed with great horns on their heads and spikes on their tails. The ichthyosaurs (fish reptiles) took to the sea and developed fins, much after the manner of modern fish. The pterosaurs (wing reptiles) developed the power of flight, some of them having a wing spread of 20 feet. These unusual reptiles all died off suddenly at the close of the Cretaceous, and in the following era reptiles took on a modern aspect. Peculiar birds with teeth, the first known representatives of the feathered world, are found fossil in Jurassic and Cretaceous rocks. A few primitive mammals may have survived in pockets of Lower Cretaceous, but the group did not develop fast until after the close of this era. Among the common groups of flowering plants do appear until Cretaceous times.

Paleogeography of the Mesozoic in United States: In the middle of the Cretaceous period, practically all of the United States east of Mississippi was land. During Cretaceous time the sea encroached on the coastal plain but did not reach the eastern interior region. The history of the west was more complex. During Triassic a considerable part of the Pacific coast region was under water but most of the interior was land. Similar conditions prevailed during early Jurassic, but late in the period a great arm of the sea encroached from the Arctic, reaching as far south as northern California. The great differences in fossils to indicate that this bay was not connected with the Pacific directly. This arm of water withdrew before the end of the period and was marked in California and Oregon by folding and intrusion of igneous rocks, making the mountain ranges known as Sierra Nevada and Cascades. In the west Upper Cretaceous was marked by a great land sea, over the site of the Great Plains. Rocky Mountains, reaching from the Gulf of Mexico to the Arctic Ocean. Toward the end of the period this sea retreated, leaving swamps in which coal was formed. The sea was brought to a close by a great period of folding known as the Laramide Revolutions which uplifted the Rocky Mountains, in the process of which the Colorado Plateau was formed.

MESQUITA, mäs'kē-tā, Salvador b. Rio de Janeiro, 1569, Rome, in the early 18th century. He was born in Brazil, where he entered holy orders and was well known for his Latin scholarship, "Sacramentum Ephesenum" (1688), a sacred book. His poetry was also noted and established his poetic fame among contemporaries. His tragedies, profane and religious, "Demetrius," "Pereus" and "Prasias" were all appearing at Rome between 1690 and 1708, and had a great influence on the drama.

MESQUITE, a tree or shrub (Prosopis glandulosa and P. juliflora) of the legume family Mimosaceae. Several species of mesquite very common in the southwestern United States from Texas to California, extending south through Mexico and tropical America. In the United States they usually shrub, although a few present south large trees. The branches are armed with spine, the leaves compound of numerous leaflets, the flowers small and greenish, in spikes, and the fruit of long and hiscent pods. In the arid southwest the quide is often the only source of food which is not obtained from the branches from the very large roots. The pods are eaten by cattle, and sometimes by people, for the sweet pulp and seeds. The screw-pod mesquite or tornillo is Prosopis pubescens, another northwestern plant, whose pods are coiled in a spiral, resembling a screw.

MESS, in the army and navy, and particularly the latter, a company of officers, or a ship, who eat, drink and associate together; in military language, a sort of "mess house"
ordinary, established and regulated by the rules of the service, for all the officers in a regiment, and supported by their joint subscriptions, supplied by a small allowance. Similar institutions are extended to the non-commissioned officers of a regiment. The enlisted men mess by companies as a rule, but often it is desirable to cut the company into squads for mess purposes. The post commander supervises a small board to take care of uniform mess arrangements. In active service the officers are apt to mess with their own troops, but in camps they have their separate mess. In the navy it is usually convenient to have a captain's mess, another for the warrant officers, another for the junior officers, and another for the warrant officers, etc. The men's mess for the sailors or marines is styled the "general mess," but this is usually divided into sections, as a matter of convenience. It has become common to employ ammunition passers as mess attendants.

MESSAGER, André Charles, French composer: b. Montluçon, 30 Dec. 1853. He received his musical education at École Niedermeyer, Paris, and subsequently studied under Saint-Saëns in the city. He was appointed organist at Saint-Sulpice in 1874. A symphony of his won the gold medal of the Société des Compositeurs in 1876. In 1880 Messager became music director at Sainte Marie-des-Batignolles. Three years later he completed the comic opera by Bernicat, "François des bois," and in 1883 produced his own operetta, "La Fauvette du temple" and "La Bérarême." The following year saw the production of his ballet, "Les deux pigeons," at the Opéra. Messager's reputation was most strongly under the operatic "La Basoche," produced at the Opéra Comique in 1890 and in English in London in 1891. It was followed by the operas "Madame Chrysanthème" (1893); "Mirtette" (1894); "Les petites Michus" (1897) and "Véronique" (1898); "Les dragons de l'île pératricie" (1905); "Fortinou" (1907); "Béatrice" (1914). Messager became conductor at the Opéra Comique in 1888; was one of the directors of the Covent Garden Opera in 1901-07, and was conductor at the Paris Grand Opéra after 1907. From 1907 to 1914 he was also joint director with Brousson of the Grand Opéra and after 1908 was conductor of the Concerts du Conservatoire.

MESSALA (mé-sä'lä) CORVINUS, Marcus Valerius, Roman soldier, orator, and writer: b. about 65 B.C.; d. about 2 B.C. He received a part of his education in Athens, returned to Rome before the second triumvirate and joined the Senatorial party. He fought with Brutus and Cassius at Philippi, 42 B.C., and afterward attached himself successively to Antony and Octavius, served at the battle of Actium, 31 B.C., and the same year was chosen consul. He subdued Aquitania, of which he was made proconsul and was honored with a triumph. For a time he was a prefect of Rome and held the office of aedile. Messala was the favorite of Horace and other distinguished men of the age, a zealous patron of literature and art, notably of the poet Tibullus, and one of the most eminent of Roman orators.

MESSALINA, mēs-sə-līn'na, Valeria, Roman empress. She married Claudius (later em-

peror) in 38 A.D.; bore him a daughter, Octavia, and a son, Britannicus; proved herself vicious, licentious and vulgar by her many open amours; and in her husband's absence formally married Gaius Silius, whom she attempted to make emperor. Claudius refused or delayed to punish her, and Narcissus, the emperor's favorite, had her put to death. (whether with Claudius' knowledge or not is not known) in 48 A.D. Her reputation was tarnished by the story of Stahr's "Agrippina, die Mutter Nero's" (1880).

MESSENE, mé-sēn'ē, the capital of Messenia in Peloponnesus, founded by Epaminondas (369 B.C.) after his victory of Leuctra over the Lacedaemonians, and situated at the foot of the hill of Ithome, the fortress of which formed the acropolis of the new capital. The latter was surrounded by massive stone walls, flanked with towers, of which there are still considerable remains at the modern village of Mavromati. The Greek Archaeological Society, in 1895, excavated a colonnade and other parts of the ancient agora. Messene with its acropolis was next to Corinna, the strongest city of Peloponnesus. It was supplied with water from a mountain called Clypsyas, the spring of which still exists.

MESSENA, mē-sēn'ē, in Greece a monarchy in the western part of Messenia (Peloponnesus), bounded on the north by Elis and Achaea and Arcadia, on the east by Arcadia and Laconia, on the south and west by the Ionian Sea. The greater part of the surface is a fertile plain, but there are mountainous lands in the east and northeast. Kalamata, the capital, is in the southeast on the Gulf of Koron (Messenian Gulf). When Messenia was a state of ancient Greece its chief cities were Methone and Pylos (Navarino). Later Messene (Mavromati) was the capital, and the strong mountain fortress was Ithome. A ridge of Mount Taygetus separated Messenia from Sparta. Messenia is celebrated for the long struggle of the inhabitants with the Lacedaemonians in defense of their liberty. In the first Messenian War (743-723 B.C.) the Lacedaemonians, with the Athenians, invaded Messenia. For 20 years the Messenians defended themselves valiantly under their king Aristodemus, who in consequence of an answer of the Delphic oracle which promised them the victory on condition of the sacrifice of a virgin of the royal family, offered his own daughter as the victim. Her lover, to save her life, declared her to be pregnant by himself; and Aristodemus, to prove her innocence, stabbed her with his own hand, and caused her to be opened and sacrificed. The Messenians, though for some time successful, were finally obliged to submit by the loss of Ithome. About 40 years after they again rose, and thus commenced the second Messenian War (685 B.C.), which ended in their entire submission. A part of the Messenians emigrated to Sicily, and there founded Messana (see MESSINA) on the site of the ancient Zancle (668 B.C.). Those who remained were reduced to the state of helots. After 200 years of servitude they again took up arms. This third Messenian War lasted 10 years (465-455 B.C.), and resulted in the expulsion of the Messenians from the Peloponnesus. Epaminondas restored them, gathering together the exiles from the various lands
in which they were scattered. Within the space of 85 days they completed and fortified Messene (369 B.C.), and maintained their independence till the country was conquered by the Romans. The Messenians remained true to their customs, manners and language through all changes of fortune.

MESSIAH. See MESSIAH.

MESSIAH, The, is a term which is, in John i, 41, and, in John iv, 25, but without the article, applied to Jesus of Nazareth, as the appointed king of the Kingdom of God. The Greek word which is the translation of the Aramaic term meaning Messiah, namely, מֶשֶׁה, in English Christ, is used of Jesus in this same sense throughout the New Testament. The word Messiah itself is a modified transcription of the Greek word Μεσσίας. The extract transcription would be Messias, as the word appears in the Authorized Version of both the passages cited above, and the form Messiah is due to the influence of the form of the original Aramaic and Hebrew word. For the word which appears in Greek as Μεσσίας was, in Aramaic and Hebrew, מֶשֶׁה (Messi'ah). All the other forms of the term Messiah, as well as the Greek equivalent, μεσσία, and the English Christ, mean Anointed One, and refer to Jesus, when applied to him, as God's Anointed King.

In the Old Testament, מְשֶׁה (Messi'ah) (English Messiah) is used, in a few cases, without the article, and as an adjective, of priests who were appointed to their office (Lev. iv, 5 and 16, vi, 22). But, in the definite sense of the Anointed One, or the Messiah of Jehovah (the Lord's Anointed), it is used, with a very few possible exceptions, only of kings. Thus, in 1 Sam. ii, 35, it is the name of the king of Israel in general. In 1 Sam. xii, 3 and 5, xxiv, 6 and 10, it is used of Saul; and, in 2 Sam. xiv, 21, xxiii, 1, it is applied to David. In Lam. iv, 20, it denotes Zedekiah, King of Judah; and, in Isa. xiv, 1, it is applied to Cyrus, King of Persia. Two possible exceptions to its use to denote kings may be found in Psa. cv, 15 (quoted in 1 Chron. xvi, 22) and Hab. iii, 13, where it seems to be used to mean the nation of Israel as the priestly people of Jehovah, although, even in these cases, its use may refer only to the king. In Daniel ix, 25 and 26, it is very difficult to decide the true meaning of this word, because of the great uncertainty in relation to the correct interpretation of these verses. According to the various interpretations which have been given to them this word would mean a high priest, a royal ruler, or that great king of the kingdom of God known to us as Jesus of Nazareth. It is not certain, however, that both times it is used in these verses it has the same meaning. In Psalm ii, 2, the best and most probable interpretation would make the term denote the great coming king known to us as Jesus the Christ. This is the only passage in the Old Testament in which this term can be taken with any reasonable degree of probability to refer to our Saviour.

In the non-canonical, literature, the first clear application of the term Messiah to the great coming king of Israel is found in the Psalter of Solomon, dating from about 63 B.C. In this poetical collection we have a full and clear description of this king and his work under this title. There are, indeed, in the Sibylline Oracles and the Book of Enoch, expressions and terms which must be supposed to refer to the coming and expected king of Israel, but the name Messiah is not used in these writings.

While the pre-Christian use of the term Messiah to denote the divinely appointed and eternal king of the Kingdom of God is thus limited, the Old Testament abounds in statements and teachings relating to this king, and that form of the Kingdom of God in which he is to be ruler and sovereign. In some of the passages relating to this final form of the Kingdom of God it is said that Jehovah himself will be the king, as he was, in reality, in all the history of the kingdom of Israel. Consult as examples of passages of this kind, Isa. ii, 2-4, Isa. xxxviii, 22, Ezek. xx, 33, Ezek. xxxiv, 15, Zeph. iii, 15, Zech. xiv, 16. In other passages, in harmony with the idea that, while Jehovah was always the real king of Israel, he was represented in the government by a vice-regent king, his anointed on the throne of David at Jerusalem, it is declared that a great and eternal coming king, who is in some of the passages Messiah, as well as David, will reign as king in the final form of the Kingdom of God. Among the passages of this kind may be cited Psa. cx, Isa. ix, 6 and 7, Jer. xxxiii, 5-8, Jer. xxx, 8 and 9, Ezek. xxxiv, 23 and 24, Ezek. xx, 4, 24, Hos. i, 4, Mic. v, 2-5, Zech. ix, 9. Just what will be the relation in person and in nature, between Jehovah and this Davidic king, is not made clear, or even asserted, in the Old Testament.

Independently, therefore, of the use of the term Messiah, there was a natural and sufficient basis in the Old Testament for the widely-spread belief in regard to the coming of a future Davidic king called the Messiah, which appears to have existed in the time of Jesus. In this belief Jesus himself shared, and this Messiah, or Christ, he both verbally and formally claimed that he himself was. A virtual claim of this kind is found in Matt. xvi, 13-20, and in the parallel passages, Mark viii, 27-30, and Luke ix, 18-21, and also in the act done by Jesus, of which he has said, Matt. x, 38, l-11, and the parallel passages, Mark xi, 1-10, and Luke xix, 29-40. A formal claim of Jesus to be the Messiah is found in John iv, 25 and 26.

The rejection of the claims of Jesus by the Jewish nation, and the continuation in that nation of the belief in a coming Messiah, were the occasion of the appearance in Jewish history of several who claimed to be the Messiah after the time of Jesus. Of all these the one who was most generally received as the Messiah by the nation, and who accomplished the most for his people, was Simon bar Cochba (or bar Kozeba), who flourished 130-35 A.D., in the reign of the Emperor Hadrian. For two years and a half, bar Cochba reigned as king, and, at the head of an army of 200,000, the might of Rome. But, in the end, he and his nation were both crushed beneath the power of Rome.

The Jews of the present day are not all of the same opinion in regard to the Messianic hope. The conservative, or Orthodox, Jews are still looking for the coming of the Messiah, the
great king of the line of David. With the liberal, or Reformed, Jews, so far as the term Messiah is used at all, it is made to stand for a personification of a system of ideas and doctrines, and the coming of the Messiah will be the deliverance from the narrow and exclusionary ideas of the Christian religion.

MESSIAH, The (Der Messias). Klostock’s Messias is German Pietism’s most important contribution to literature and modern Germany’s most pretentious epic poem, consisting of 19,458 dactylic hexameters as compared with the 12,310 of Homer’s Odyssey. When the first three cantos appeared in 1748 in the Bremer Beiträge (Bremen Contributions) it took the public a year to get accustomed to the novelty of its form and content, after which its success was unprecedented, its readers awaiting with impatience the next two cantos, which appeared in 1750, and the next five, which appeared in 1755. On these 10 the fame of the work must rest; for the following cantos, five in 1768 and five in 1773, were probably as disappointing then as tiresome now.

The theme is the redemption of mankind, and the poem starts with Christ’s entry into Jerusalem on Palm Sunday, the most exalted subject at hand for the young Jena student of theology, who at the time was an adherent of Pietism, becoming of importance to Milton through the writings of Bodmer. On going to Leipzig in 1747 Klostock recast the prose beginnings into hexameters, thus breaking with the traditional Alexandrines and losing a storm of criticism on his head from the school of Gottsched, while that of Bodmer applauded. It has been said that the work of no German poet before Richard Wagner before Richard Wagner before Richard Wagner has been so pronouncedly admired. Goethe’s Autobiography tells us that his father banished the book from the house because of its blank verse. However, Klostock broke the sway of the French in epic verse as Lessing did later in the drama, demonstrating the necessity of the German language in English. He learned a great deal from Milton, but his nature was essentially lyrical, contemplative, mystic, and he often smoothes the epic possibilities of his subject in a flood of fervent, more or less seraphic, religious ecstasy, which exhausts the reader. Instead of strong contrasts, going from darkness to light, from misery to bliss, he attempts to portray a mental state of continuous, dazzling brilliancy. Instead of an alternation of clashes there is a contemplative passivity, from which result endless repetitions and long drawn out speeches; so to speak, a massive elaboration of the text of Handel’s oratorio, which was but seven years older. Certain descriptions, however, are very successful, such as those of hell, the council of the devils, their punishment through transformation, the trip through the universe made by angels and devils, and especially the vision of the last judgment. Klostock’s taking over of the Miltonic cosmogony gave him the opportunity of portraying a great struggle between the powers of light and darkness for the soul of Christ and therefore of man, but instead his angels paralyze their adversaries with a look, which method of warfare is not epic, though perhaps pietistic.

His forte is to excite feeling and to lend expression to the inexpressible even when his characters become speechless. No German poet before him had so mastered the capacities of the language, whether in choice of words or in rhythmic cadence. In a sense he became the creator of modern poetry, dictating his own flood of epic-imitations on various biblical subjects attested his contemporary influence, and all the younger poets of his day learned from him, but the 19th century admired him from an ever increasing distance. CARL E. EGGER, Assistant Professor German, University of Michigan.

MESSINA, mēs-ē-nā, Sicily, town and seaport, capital of the province and on the strait of the same name. Messina is walled, flanked by bastions and defended by a citadel on the south and several forts both on the east and west. The harbor is one of the best in the Mediterranean and so much resembles a sickle that the town took its original Greek name from that implement, called zanclo. The main entrance is a broad quay called the Marina, adorned with statues and fountains and forming a favorite promenade. The streets of the old town are narrow and dirty, but the modern town, built
since the earthquake of 1783, is generally composed of houses of two stories and has spacious streets, well paved with blocks of lava. Among the public edifices are included nearly 50 churches, many of them of great beauty and adorned with fine sculptures and paintings. The cathedral is a Gothic structure, with a somewhat heavy exterior, but supported within by vast pillars of granite, supposed to have belonged to a temple of Neptune. The viceroy's palace, the archiepiscopal palace, the senate house, grand seminary, college, large and well-equipped hospitals, extensive convents, and theatres, lazaretto and arsenals are some of the other buildings worthy of notice. The manufactures consist chiefly of silk goods. The trade, both transit and general, is extensive. The principal exports are silks, olive oil, lueded and other seeds, oranges, lemons and other fruits; corn, wine and spirits; salted fish, licorice, lemon-juice, shumac, essences, rags, brimstone, etc. The tunny and other fisheries are carried on to a considerable extent. A destructive earthquake in the locality 26 Dec. 1908 destroying about half of the buildings and causing the loss of more than 7,700 lives, probably more than half of them residents of Messina. The principal shock was at 5:21 A.M., and the tidal wave that followed, 10 feet in height, swept all before it on the low shore. Notwithstanding this frightful casualty, the city so far recovered that in 1910 the exports were $11,000,000 and the imports about $5,000,000. Messina has a government university, founded in 1549, which had 692 students in 1901. It has faculties of law, medicine, science, and classics. It has also a naval seminary and a number of elementary schools. Messina, under the name of Zancle, is said to have been founded 1004 A.C.; the Messenians obtained possession 668 A.C.; it became a free city of Rome 241 A.C.; the Saracens captured it in 831; Richard I of England with his crusaders spent six months there in 1194, sacking the town on leaving; from 1282 to 1713 the Spaniards ruled, though the French held it briefly 1676-78; in 1783 an earthquake caused great destruction of life; in 1854, 15,000 died of the cholera; in 1860 the city came under Italian rule, and was peaceful and prosperous until the 1908 tragedy. The population before the earthquake was 150,000, but in 1911 was reduced to 126,557.

MESSINA, Strait of (Italian, Faro di Messina; Latin, Fretum Siculum), a channel which separates Sicily from Italy and connects the Tyrrenian and the Ionian Sea. It has a length of about 20 miles, and gradually widens toward the south, attains, on the parallel of 38°, a width of 11 miles; but in the north, where it is narrowest, does not exceed two miles. The depth is great, in some parts over 4,000 feet, and a strong current continually running with the tide makes the navigation somewhat difficult; but by no means so formidable as was feared by the ancients, to whom the rock of Scylla, and the whirlpool of Charybdis, on the opposite side, but at some distance to the south, seemed so dangerous that it was generally believed to be impossible to avoid the one without being dashed upon the other.

MESSMATES, Animal. See COMMENSALISM.
the Hungarian forces in the north, but on 4 January his army was routed at Kaschu. In April 1849 after the declaration of independence he again took command of the Hungarian forces, but after the defeats at Szőreg and Gadány he fled to Turkey. He subsequently lived in England, France, the island of Jersey, and in 1853 came to the United States.

META, ma’tä, a river of South America, which has its rise on the eastern slope of the Andes Mountains near Bogotá in Colombia. It is formed by the junction of two small mountain streams, which unite about 40 miles southeast of Bogotá; then flows east-northeast into the Orinoco; a course of about 650 miles.

METABETCHOUAN, mét‘chê-cho-an’, Canada, a river of Quebec flowing into Lake Saint John from the south. It is a broad stream, 90 miles long, and navigable for considerable distance. The celebrated Falls of Metabetchouan over 230 feet high are near its mouth.

METABOLISM (Greek metałôh a change), the whole series of physico-chemical processes connected with the manufacture of protoplasm and with nutrition and growth. Under the term is included all those changes by which various energy transformations are made possible in the human body. It has been divided into constructive metabolism (anabolism), and destructive metabolism (katabolism). The former comprises the processes by which the substances taken as food are converted into protoplasm, while katabolism is the means by which the protoplasm is broken down into simpler products, such as the excretory or waste matters. Metabolism thus comprises the elementary vital phenomena of plant and animal life. These are the occurrences associated with changes of substance, of form and of energy. All organisms undergo continual changes of their protoplasm, etc., alterations of their form and transformations of the energy which they get from the environment. The human body is essentially an energy transformer. Thus as regards food, since all living matter is continually undergoing decomposition, it must take in substances that contain all the chemical elements of which it is constructed, but the food differs with every form of cell. Plants live chiefly on inorganic substances and animals on organic, that is, material already prepared; no animal being able to live on simple inorganic compounds. Among animals there is a remarkable adaptation to a single kind of food. For example the larva of the fur-moth lives exclusively upon the hairs of fur, which consist of pure keratin; this substance, which is closely allied to proted, is therefore capable of furnishing all the elements necessary for the formation of the protoplasm of this caterpillar. Dogs when worked hard have been found to be able to live on pure proted food. On the other hand, according to Verworn, it is impossible for an animal to live solely on carbohydrates or fats, or even on the two together, since there is no nitrogen in these substances.

Vital motion or metabolism is a complex sharply characterizing living organisms, and the taking in of food and the excretion of waste products give to the organism the material with which to regenerate itself and to grow. Metabolism is increased by heat, the consumption of oxygen being increased in cold-blooded animals, but warm-blooded animals undergo a decrease under heat. Thus man in winter has a much more active metabolism than in summer, since he consumes more food at low temperatures.

It is claimed by Verworn that every species of animal possesses a specific metabolism, and that under certain conditions products of metabolism may stimulate an animal to increased growth, while under other circumstances they may retard growth. Thus the histolytic urease in moderate amounts exerts a favorable influence on the size of larvae of seaurchins. Illustrations are afforded by experiments in raising snails and water-fleas (Daphnia) in small volumes of water; besides the diminished volume, the water fouled by their excretions may not only dwarf but gradually kill them, or produce changes of form. Metabolism is more active in the young than in the adult. Between 9 and 14 a boy requires as much food as a full-grown man, and during the next five years more than he needs. The same is not true of girls who increase the amount of metabolism up to the 11th year.

Consult Verworn, General Physiology (New York 1899); Vernon, Variation in Animals and Plants (New York 1903); Starling, "Human Physiology" (Philadelphia 1915); Bayliss, Principles of General Physiology (New York 1915).

METACENTRE, in hydrostatics, the point of intersection of a vertical line passing through the centre of gravity of a floating body as a ship in equilibrium, and a vertical line through the centre of gravity of the fluid displaced, if the body be turned through a small angle, so that the axis takes a position inclined to the vertical. If the metacentre is above the centre of gravity, the position of the body is stable; if below it, it is unstable. In shipbuilding a vessel must be so designed that its metacentre (its changing centre of buoyancy) is not likely to oscillate so as to permit capsizing.

METACHROMOSIS, the change of color brought about in the surface of certain animals, either voluntarily or involuntarily, to make them conform to their surroundings. It is exhibited in many of the lower animals as a protective device, especially in cuttlefishes, caterpillars, various amphibians, especially frogs and certain lizards, notably the chameleons. The dark pigment to which the brown or gray colors of metachroic caterpillars are due is deposited in the cells of the outer skin, while the green coloring matter is found in the underlying fat; and, as Carpenter says, experiments have shown that the presence or absence of both kinds of pigment is determined by the surrounding objects through the quality of the light reflected from them, the suppression of the superficial dark pigment allowing the deeper green to show through the skin, and thus give its hue to the caterpillar. It has been shown that the formation of the dark pigment is hindered by the action of certain yellow rays which are absorbed by dark objects, but reflected from green leaves and shoots. The process of change in squids, frogs, etc., through nervous and muscular waves, called chromatophores, is somewhat different, and is explained in the article CHAMELEON.
METACINNABARITE—METAL WORKING MACHINERY

The power possessed by these animals of adapting their color to their surroundings must be of the greatest value to a frigate and a frigate enemy. Consult Beddard, ‘Animal Coloration’ (1892).

METACINNABARITE, a native sulphid of mercury, occurring amorphously, when it is black or dark gray, or in tetrahedral crystals. To its black color it owes its early popular name, Ethiop’s mineral. Metacinnabarite is found in California.

METAGENESIS, or HETEROGONY, a term proposed by Owen for a form of parthenogenesis. It is that form of alternation of generations (q.v.) of which one generation reproduces only asexually, by division or budding, the other exclusively by laying eggs. A good example is the mode of reproduction of hydromedusa in which the hydra-like stage gives rise to medusa, the latter laying eggs. Another case is that of the aphides, whose asexual individuals produce multitudes of young by budding, the next generation consisting of males and females, the latter laying fertilized eggs. An individual of the first generation is called the nurse; one of the second generation the sexual animal.

Another term for this phase of reproduction is heterogony (or heterogenesis), which Hertwig defines as “regressive alternation of generations.” He mentions another form of heterogony where two generations with different forms and structure alternate. For example, a hemaphroditic thread-worm (Ascans nigrovenerosa) lives in the lungs of frogs; it produces a form (Rhabdonema nigrovenerosum) which lives in mud, and which lays eggs giving rise to the ascaris of the frog.

METAHEWETTITE, a dark red mineral consisting of hydrous calcium vanadinite occurring in microscopic crystals with uraninite and carnottie at several localities in Utah. Probable composition CaO.3V₂O₇.9H₂O; a source of vanadinite.

METAL WORK, any work done in metals, but especially handwork practised as a decorative art, in which the materials are metal and the designs are executed in repoussé or relief. The metal is ornamented by carving or by expert hammering as of thin sheet metal. The term includes jewelry (q.v.) and goldsmith’s work; hence its materials are often the precious metals and its end personal adornment. But it is often applied to larger work and especially to metal decoration in architecture, apparently a later development in the arts than was the jeweler’s trade, which flourished in classical antiquity, and everywhere seems to have quickly followed the most primary knowledge of metallurgy in industrial evolution. The Middle Ages were the great period of metal work, notably in connection with Gothic art. Even the more valuable metals were lavishly used in this epoch, as before in the Byzantine period, and since in the architecture of the Greek Church, above all in Russia. One of the foremost instances of Italian metal work is to be found in the altars of Saint James at Pistoia and of the baptistery of Saint John in Florence. Each of these was the work of a line of great artists, whose elaborate work upon them covered more than a century. Cellini (q.v.) was the greatest metal worker of the 16th century. Even more important than the work in silver and gold are the great bronze doors in the Florence baptistery, one by Ghiberti and another by Pisano, each the product of a score of years of labor, and both dated from the 15th century. wrought iron was to begin to be used in the 14th century, between the 13th and the 18th centuries in the church gates, grilles and screens in ecclesiastical and in German locks and hinges of great beauty, it came to its most perfect form. The sepulchral brasses of German, French and English churches should also be mentioned.

METAL WORKING MACHINERY, a term including practically all machines by which metals are converted into shapes required; modern structural work and the industrial trades. They may be conveniently arranged under the following named classes: Lathes or drills; punchers; shears; machinery; grinders; riveters; drop hammer bending rolls; rolling machines; press planers; saws and special machines.

Lathes are turning machines used to turn cylindrical surfaces by rotating a blank metal against a fixed cutting tool. They are also used for spinning sheet metal into form. The principal parts are the head stock holding the driving cone and revolving spindle; the stock supporting the back centre, and capstan of being clamped at any point on the face of the bed or frame, and the rest carrying the tool head. The bar of metal worked is fastened to the head and tail stock and rotated or turned by belts from shafts or by electric motors, while the rest carries the cutting tool is moved parallel with the axis of the bar from the surface of which a shaving is removed. By suitable attachment the lathe may be used for tooling flat surface sawing or grooving and cutting gear wheels. These machines are made in a great number of sizes, of which the principal forms are designated as follows: 1) The hand driven by hand power, usually by a drill bit, but sometimes by an assistant at the crank, is without self-acting feeding devices for the lathe. A lathe driven by a hand gear small and light, worked by the operator and adaptable to work as delicate as that of the watchmaker and jeweler. 2) The self acting lathe, in which the cutting tool is moved in a carriage which is moved by mechanism means, causing it to traverse automatically as the object being turned. These lathes are adapted for screw cutting and are often designated (4) The chucking or face lathe, for turning cylinders several feet in diameter and up to a foot in length, such as engine cylinders and automobile cylinders and jackets of large size. The turret lathe belongs to chucking class, the face of the chuck is horizontal, the revolving spindle being vertical. (5) The boring lathe used for working on internal cylindrical surfaces, where the stock is small and the work is to be bored to a work bench. An automatic lathe is one of the larger types fitted with mechanism by which it stops itself when the work is set to do has been completed. Any lathe may belong to the single geared or back gear.
1. Vertical Spindle Milling Machine
2. Automatic Gear Cutting Machine
3. Automatic Screw Machine
4. Surface Grinding Machine
type. In the latter a set of gear wheels operates a back shaft, by which the speed of the work may be greatly reduced. Overhead shafting on the lathe standards or on the ceiling provides means for giving a revolving motion to the tools at work, thus affording a combined motion of great variety and intricacy for involved work.

actuated by a pulley, and a table upon which chucks or holding devices are arranged. Gear-wheel attachments to the cone pulley provide for changes of speed or greater driving power at the cutters. The advantages gained by their use are as follows: The rotary cutters insures a continuous cutting operation, with a constantly changing cutting edge; the outlines of the work and the form of the cutting edges are exactly similar; once adjusted, all work is turned out uniform in size and shape, and any unlimited variety of shapes may be obtained by simply varying the form of the cutters, while the only special operating skill required to maintain the form of the cutters and set the work.

The modern milling machines have been brought to a high degree of perfection and produce work in a truly wonderful variety. The milling cutters are worked singly or in gangs of many forms on the same shaft. The tables are provided with longitudinal feed and cross feed, and the tools with vertical feed as well. Some of the numerous operations performed are planing of plain and curved surfaces, grooving, slotting, dove-tailing, cam cutting, ratchet wheel and gear cutting — spur, spiral and helical, as well as bevel and worm gearing, sawing, slitting, making of taps and reamers, etc. The automatic milling machines reproduce with great accuracy the form of any pattern inserted as a control, practically without attention.

Grinders.—The recent development of grinding machines has placed them in the front rank of metal working machinery as the finishers. They take work rough finished from the lathe and the milling machines and bring it to the finest degree of perfection. Not only do they finish the work of the other machines, but they also grind to exquisite form the tools with which the other machines do their work. In the automatic section of the work is ground accurately to size regardless of the wear of the wheels during the process, beginning the grinding with a coarse feed and throwing in the fine feed automatically as the piece approaches its true size. The machine once set, piece after piece is automatically machined to pattern size without attention except the removal of the finished work and the placing of another rough piece. A great deal of work formerly turned to extreme accuracy on lathes is now finished direct from the forging on the supersensitive automatic grinder and with a very considerable saving of time. See Grinding.

Riveters.—Riveting machines are made in two forms, stationary and portable; the former used in heavy work are operated by pressure generated by steam or hydraulic power, while in the portable form the moving die is actuated by steam or compressed air, with hammer-like blows. They are employed to drive and head hot rivets in boiler work, bridge building and other structural work with results far superior to hand work in rapidity. The usual form of the stationary type is a U-shaped frame or yoke. The ends of the arms are provided with dies projecting inwardly, one being fixed while the other has a reciprocating motion. The rivet being placed in the hole is compressed endwise between the dies, so that pressure forces the metal of the rivet into the ir-
regular edge of the hole, clamps the plates together and forms the rivet head.

Drop Hammers.—Heavy drop hammers are used for forging and also for welding, and are operated by hydraulic or steam power. They consist of an anvil upon a solid base of steel blocks laid over oak timbers to give elasticity to the machine. Above the anvil vertical housings capped by steel arches support the hammering ram and the platforms upon which the piston cylinder and other actuating machinery is placed. By the use of swages, fullers and flatters, hot metal is hammered into forms, often by the use of a progressive series of dies. The largest hammer of this kind was erected in 1891 at Bethlehem (Pa.) Steel Works. Its general dimensions and weight are as follows: Height, 90 feet; width, 42 feet; weight of anvil and foundation, 1,800 tons; weight of housings, steam chest, pressure cylinders and piston, about 1,000 tons. Ram 19 feet long, 10 feet wide and 4 feet thick.

Presses.—By the use of presses sheet or plate metal is converted into utensils of any desired form. They are usually operated by hydraulic power; are provided with dies between which the metal is pressed into the required form, and are capable of being constructed to exert an unlimited amount of pressure. Forging presses are made in all sizes adapted for uses ranging from the pressing of watch-cases to the forging of steamship shafts and of armor plates weighing up to 1,400 pounds. Forgings thus made are superior to hammered forgings. They are designed for working metals either hot or cold.

Planers.—Planing machines are used to obtain flat surfaces on metal. There are two types; those in which the motion of the table relative to the cutting tool is rectilinear and those in which that motion is rotary. In general construction a planer consists of a traversing table on which the work is fastened; a bed to receive the table and guide it in a right line; a cross slide to support the slide rest carrying the tool; standards bolted to the bed and supporting the cross slide, and the mechanical devices for feeding and regulating purposes. The power supplied from shafting by being formed by gear-wheel attachments into the reciprocating motion of the table, causing it to slide back and forth between the vertical guides, thus bringing the work against the cutting tool which shaves off successively, side by side, narrow thin strips of metal until a perfectly flat surface is produced. Planers are built in various sizes, the larger machines being equipped with tables 7 to 8 feet in width and 2 feet long.

Saws.—In metal working, saws belong to the class commonly termed finishing machines. For cutting plates and bars into shorter lengths they are in extensive use, affording a great economy of time. They are built in a great many sizes and forms, both stationary and portable, equipped with single cutters or cutters arranged in gangs. For cutting off large bars such as steel beams, rails and similar shapes, saws with single cutters are generally used, the object being to cut off the carriage and move into contact with the edge of the circular cutter. Some machines used for lighter work are so arranged that the circular saws are moved...
METALLIC CURRENCY — METALLURGY

The extent to which they made use of metallurgical processes. In fact, a prominent metallurgist of the 19th century when delivering an introductory address to students of metallurgy was accustomed to charge them that "in proportion to the success with which the metallurgical art is practised in this country, will the interests of the whole population directly or indirectly in no insconsiderable degree be promoted."

As an industry, it requires a wide knowledge of the sciences, embracing chemistry, physics and mineralogy, as well as the practical application of knowledge in mechanical and electrical engineering. As some of the oldest historical works make reference to metallurgical processes, the actual practice of the art must go much farther back into prehistoric ages. It had its inception at the time when men, ever advancing, replaced their stone implements by others of greater usefulness made from metals. Their methods of extracting and refining were in many respects comparable with those used to-day except in the introduction of mechanical methods. For the early development of chemistry was very closely allied with metallurgy. Many of the older treatises on theories of chemistry are attempts to explain metallurgical reactions. Prominent among these men was the separation of lead from the precious metals, gold and silver, by its combination with oxygen, a process practised and much speculated upon by the ancients. Gold was probably the first metal known as it occurs naturally in the metallic state, is bright, heavy and easily worked. Iron, copper, silver, tin and lead were other metals known to prehistoric men. Quicksilver is mentioned in the times of the Greeks and Romans. In the 15th and 16th centuries we hear of antimony, bismuth and zinc, with arsenic added at the close of the 17th century. Nickel, cobalt, manganese and platinum came in the 18th century, the remainder belonging to the 19th and 20th.

There are four great periods in the annals of metallurgy. The first extended from prehistoric times to the 1st century. In the year 77 Pliny, the Elder, in his work, "Naturalis Historia," collected all existing knowledge concerning metals to his day. The second period ending with the 15th century had as its chronicler Agricola. In "De Re Metallica" next came a period of comparative stagnation with relatively few important advances until the 19th century ushered in the fourth, our present period, one filled with development.

Properties of Metals. — All metals are distinguished by numerous characteristic properties which fit them for their various industrial applications. A brief outline of these follows:

Density. — All common metals except aluminum are relatively heavy, specific gravities ranging from 6 to 22 times that of water at ordinary temperature.

Metallurgy, the extraction of metals from their ores and so refining and fashioning them as to fit them for use in the metal industries, is the most ancient of arts. The annals of history show that the degree of civilization attained by a race was directly proportional to
solidification. Structure.—This is revealed in fractures examined by the eye and in polished cross sections examined under the powerful eye of the microscope. Unmistakable evidence of the thermal and mechanical treatment which the metal has undergone is furnished the expert by such examination. Such a study often serves to distinguish one metal from another, and to determine under what conditions it has been worked, and at what temperatures. Wire is produced with the same coefficient of expansion as glass for use in electric light bulbs. Before the metallurgist can use this alloy we used the rare metal platinum for this purpose. Alloy steels of unheard-of strength and durability are produced for use in automobiles and airplanes.

Innumerable articles of common and special use show that most metallic objects are also possessing special properties to meet specific needs. Frequently the change of a few tenths of a per cent of the amount of a constituent present in an alloy will cause the most startling changes in the properties of the resultant metal. Of all the innumerable operations of metallurgy there is hardly one which does not require the application of heat for its success or survival. Heat is usually supplied by the combustion of a fuel and must be applied in many different ways and under various conditions to suit the metallurgical process to be carried through. To carry through the metallurgical requirements we must know the characteristics of the available fuels in order to determine which are to be used and the methods of using them to produce desired results.

Fuels.—Although fuels are complex chemical combinations, the main heat-producing elements of all are carbon and hydrogen. When a fuel is once kindled the combustion will continue as long as the heat evolved is sufficient to keep the temperature above the ignition point. Essential conditions for perfect combustion are: first, sufficient air brought into intimate contact with the fuel; second, sufficient time in which it may act; third, temperature suitable for combustion must be maintained throughout. From these considerations it is evident that less excess air need be used when gaseous than solid fuels to get an intimate mixture. Mechanical methods of producing mixtures are frequently employed. The form of solid fuel affects combustion, porous fuels taking more air, making fuels causing imperfect combustion, etc. With perfect combustion, the products are carbon dioxide and water. The atmosphere in the furnace resulting from the products of combustion may be either neutral or oxidizing. Oxidizing is undesirable, which results from perfect combustion is very difficult to maintain. Under ordinary conditions we either supply an excess of air which results in an oxidizing atmosphere, or we do not furnish enough air for perfect combustion and this results in a fuel ragging process.

There are long and short flame fuels depending upon the amount of combustible gases evolved and the facilities existing for mixing air and gas. All these are important considerations in the use of fuel and design of combustion chambers. Fuels are rated by their calorific values. There are three classes: solid, liquid, and gaseous. The solid are classified as natural (wood, peat, lignite, coal) and prepared (charcoal, coke, bessemer, etc.). The liquid fuels are petroleum, as petroleum; and asphalt, as distilled oils, tar, etc. The gaseous fuels may be divided as natural gas, or artificial (manufactured gas, oil, water, coal, blast furnace producer gas, etc.). Each of these different classes of fuels presents its own problems.
METALLURGY

combustion and its characteristics must be known and considered in designing the furnace in which it burns. A furnace which burns coal, oil, or gas is not the same as a blast-furnace. Work the compressive strength of the fuel must be considered as that determines the weight of charge it can support.

Apparatus.—Having determined the conditions and methods by which the heat is to be generated and applied to the metallurgical process, we must consider the requirements of a containing vessel which will stand the often-times intense heats employed, have a certain amount of strength and at the same time exert beneficial, not harmful, chemical effects on the charge. The materials to which we turn to play this part in our sequence of processes are known as refractories. An ideal refractory not only should be a poor heat and electrical conductor, but must also resist the action of the high temperature causing it to melt away, resist the effects of sudden temperature changes, have mechanical strength and resist chemical changes. As no single material having all these qualities exists, metallurgical furnaces must be constructed in parts, i.e., a refractory inner lining of the heating section, a protective outer shell, and an outer wall for strength and protection. The principal constituents of refractory materials are aluminum silicates or clays, silica, alumina, lime, magnesia, chromite. These materials, though relatively insoluble in themselves at the temperatures of metallurgical processes, must in order to be in shape to be used as furnace walls, be mixed with other ingredients which increase their mechanical strength at the expense of refractoriness. The common forms in which refractories are used, are as follows: Fireclay, composed of hydro-silicate of alumina combined with fragments of other materials. It is plastic when wet, becomes brick-like when burned at red heat. It is used as clay for binder and in making fire-bricks. Basaltic, a magnesium calcium silicate, is much used in brick form but is usually, after calcining and crushing to small size, mixed with dehydrated tar and rammed in to make a furnace bottom. Chromite, a compound principally of the oxides of chromium and iron, is used in the brick form and as a cement. Carbon bricks also find a use where a reducing atmosphere is required.

Refractories are classed chemically, as acid, basic or neutral; and by this arrangement, silica is the principal acid refractory. Bauxite, lime magnesite and dolomite are basic, while fireclays, clays, and basic materials in contact with each other readily slag and melt away. They cannot be used in contact with each other but may be used in the same furnace with a separating layer of neutral material.

Furnaces.—Metallurgical furnaces are divided into two broad classes: first, those in which the heat comes directly from the combustion of fuel; second, those in which electrical energy supplies the heat. Under class one fall the hearth furnaces, as the smith's forge, and the shaft furnace, as the blast furnace and the cupola. In these the fuel and charge to be heated are in direct contact. Then there are the reverberatory furnaces for roasting and smelting, where combustion takes place in a separate chamber and the charge is heated by the flame, also the closed vessel type of furnace, as crucible, retort, muffle, etc., where the charge is inside sealed off from the source of heat which plays on the outside. Under this class also, come those furnaces which merely contain, using no outside fuel, the heat coming from the charge itself, as the roasting kiln, bessemer converter, etc. The electrical furnaces are classed as: direct resistance, the charge itself being a part of the electrical circuit or resistor; indirect resistance, where the charge is surrounded by an electrically heated resistor; direct arc furnaces, the charge forming one or both poles of an arc; indirect arc, the charge being in a space heated by an arc; arc resistance, where the charge is one pole of an arc and also a part of the electrical circuit.

Ores.—The metals occur in nature either as pure native metal or in combination with other materials in an ore. Ore is defined as a metal bearing substance from which a metal, alloy or metallic compound can be extracted at a profit. It usually consists of, one or more economic minerals and a waste product or gangue. Ores are named according to their leading useful metal and are classified by the gangue as siliceous, calcareous, ferruginous; or broadly speaking, as acid and basic fluxing ores. Another classification refers to treatment, as smelting or milling ores. The metals occur in nature as native metals, gold, silver, copper, mercury; as oxides, iron, tin; as sulphides, and under this class come selenium, tellurides, arsenides, antimonides; as halide, silver, mercury; salts of acids, carbonates, silicates, etc. The largest number of commonly worked ores are in the oxide and sulphide classes.

Methods of Treatment.—It is here, by the treatment of the ores that we can divide metallurgical methods into two broad classes: wet metallurgy and dry metallurgy. The wet method of treating an ore involves a leaching by a chemical solvent, followed by a means of separation of the required metal from solution. The dry method involves smelting and subsequent purifying methods by means of high temperatures. Considering dry metallurgy, the ore as it is dug out of the ground is seldom in a condition fit for smelting. Some ores may only require to be crushed to a satisfactory size, as the oxide ore of iron, haematite; others must be heated to drive off moisture and volatile matter, called calcining; others must be roasted; still others are weathered. Calcination, or the process of roasting, removes the most volatile matter and the temperature is usually carried out in heaps, stals or kilns. Calcining in heaps consists of building up a pile of alternate layers of wood or coal and ore to the height of five or six feet, then igniting at the bottom and letting it burn itself out. This process is usually carried out in yards where protection from the winds
METALLURGY

which will cause uneven burning, is afforded.
The stall is the first improvement on the heap
and consists of a four-walled enclosure, three
permanent and the fourth built in after charg-
ing. A hole must be dug for an oven, the
ignited heat set free is sufficient to keep the
process going. The process must be con-
tinuous and the losses of heat be kept at a
minimum. This process is suitable only in ores
which are rich in sulphur. A very large num-
ber of ores require a reduction in the smelting.
Roasting consists of heating the ore in contact
with oxygen, chlorine, carbon, water vapor or sulphur, to a temperature below fusion
or at most to incipient fusion with the purpose
of driving off a volatile component. Roast
may be oxidizing, reducing, chloridizing or
sulphating, according to the ore and the product
desired. The most common form of roast is
the oxidizing roast of sulphide ores to eliminate
the metallic sulfides. In some cases, lime, where
a metallic oxide of the metal for smelting.
This is called dead or sweet roasting and re-
quires prolonged heating and much stirring.
Otherwise, the sulphide is converted partially
into oxide and partially into sulphates with some
remaining remaining sulphide. The process is
used as a preliminary to a wet metallurgical
process whereby a chloride is produced which
is amenable to solvents. Roasting may be car-
ried out in heaps, stalls, shaft furnaces or re-
verbratory furnaces.

The smelting of which the calcination,
roasting, crushing, etc., are preliminary prepara-
tions processes, consists in separating the metal
and gangue by their difference in specific
gravities after fusion. A necessary adjunct of
the smelting operation is a flux which renders
the naturally insufisible gangue readily fusible
by the formation of a slag with it which is
easily separated from the heavy metal. The
fluxes are earthy materials and may be acid or basic, depending on the character of the ore
used. Acid gangue in the ore requires basic
flux and vice versa. Lime, a basic flux, is
usually used in the carbonate form or limestone.
Clorophs, calcium chloride, is used only in small
amounts to increase the fluidity of the slag.
Base, strong basic, also reacts as a desulphurizing agent. Siliceous or acid fluxes are sand,
quartz, etc. Smelting is usually either oxidizing or reducing. The reducing smelting in treating oxide ores has for a reduc-
ing agent carbon monoxide formed from coke
which is a part of the furnace charge. Oxidiz-
ing smelting is practised mainly with the pur-
pose of refining a crude metal as many metallic
impurities can be removed in this way. Other
metallurgical processes will not be considered,
where advantage is taken of the difference of melting
points of easily fusible compounds from insuf-
sible ones, when the combination is heated to the
lower melting point the more easily fusible
runs out leaving the highly insufisible gangue;
distillation and sublimation, where the metal is
driven off as a vapor, then condensed as a
liquid or solid; scorification, or the roasting of
an alloy with the object of removing the more
oxidizable metal as a slag. This process is
usually really only for iron and lead. Other processes are cupellation, similar to scorification where the oxidizing
is carried out on a hearth or cupel which is of
a material to absorb the fused oxide.

Wet metallurgy in general involves the
separation of a metal in the form of a soluble
salt from the insoluble gangue by means of
solvent followed by the recovery of the de-
solved substance, by evaporation or precipita-
tion. After the material is separated in the
ore, usually gold or silver, is treated with mer-
cury which dissolves the metal, and on subse-
quent heating the mercury distilled off, leaves
the metal. The ores need to be in a finely
divided state and in such form as to be readily
amenable to solvents which frequently by means
of preliminary treatment, as roasting, weathering,
etc. The solvents in common use are water
aqueous solutions of gases; acids; bases, etc.
Solutions. These solvents are used diluted or
are warmed. Ores for leaching are classed as
sands and slimes, the sands being coarse enough
to permit the leeching by percolation. The
slimes are so fine as to prohibit this method
and require an agitation of slime with solvent.
This glos solution leaves the slime to coagulate,
then separated by filtration or decantation.
The solution is then concentrated by evaporation and the salt crystallized out. In dealing with precipitates they are usually
dried in muffle, or reverbratory furnaces. In
modern clay and iron smelting, the solution
of the slimes is by the flotation process of separa-
tion. The slime or pulp is fed into the bottom of a
tank and agitated with oil and compressed air.
Under this treatment the metal particles float
on the surface while the gangue particles sink.

Metals produced by the above methods are
rather impure. For final refinement of a metal
and its production in the purest possible form
for electrolysis is resorted to. Reduced to its
simplest form electrolysis consists of a solution
of a salt of the metal to be purified in which the
electrodes are dipped, one being of the impure
metal and the other of the pure. When the
electric current is passed through this bath
the electrode of impure metal is dissolved and
chemically pure metal is deposited on the
other electrode. After the metal is produced
by some of the above processes it is usually
made into some alloy by fusion with other
metals and elements, then cast from the molten
state into the desired shape, which must be forged by hammering, rolling, pressing, etc., into the desired form. The
hot working operations are frequently followed
by cold rolling as strips, sheets, spinning or press ing for shapes, cold drawing for wire. All
these operations require careful and frequent
heating and cooling. The metal must be
reheated to remove strains and make it soft.
In the case of steel produced by alloying car-
bon and iron it may be used for tools which re-
quire hardening and Tempering by heating to a
definite temperature, quenching in water or oil
and then reheating to some lower temperature.

All of these processes fall under the met-
allurgist's care as surely as the original ex-
traction and refining. See ALUMINUM; COPPER;
DISCOVERY AND DEVELOPMENT; COP-
PERS AND BRASS INDUSTRY; ELECTROCHEMICAL INDU-
STRIES; IRON AND STEEL INDUSTRY and articles
on the other metals.

METALS

The elements which compose all natural objects are divided by chemists into two classes, metals and non-metals. Formerly the classification was based on physical properties, and the metals were then defined as those elements which were opaque, had a metallic lustre and were good conductors of heat and electricity; now the division is made on chemical properties, upon the foundational principle that the hydroxides of metals are bases, while the hydroxides of non-metals are acids. However, no sharp line can be drawn between the metals and non-metals, since a few of the elements will classify as either. Some metals have a high specific gravity, but lithium, sodium, potassium, etc., float on water, and in general the metals of highest specific gravity are least active chemically. Of the 83 recognized elements, 64 are regarded as metals.

Class I. Two sub-classes: (1) Lithium, sodium, potassium, rubidium and caesium; (2) copper, silver and gold.

Class II. Two sub-classes: (1) Calcium, strontium, barium and radium; (2) glucinium (or beryllium), magnesium, zinc, cadmium and mercury.

Class III. Three sub-classes: (1) Aluminium, gallium, indium and thallium; (2) cerium, lanthanum, neodymium, praseodymium, samarium, europium and gadolinium; (3) terbium, dysprosium, holmium, yttrium, erbium, thulium, ytterbium, scandium, luteum and cubelium.

Class IV. Two sub-classes: (1) Titanium, zirconium and thorium; (2) germanium, tin and lead.

Class V. Two sub-classes: (1) Vanadium, niobium (or columbium) and tantalum; (2) arsenic, antimony and bismuth.

Class VI. Chromium, molybdenum, tungsten and uranium.

Class VII. Manganese.

Class VIII. Three sub-classes: (1) Iron, nickel, cobalt, (2) rhodium, ruthenium and palladium; (3) osmium, iridium and platinum.

A mass of any metal is considered to be composed of atoms arranged in molecules, and any change in the arrangement of the molecule means a change in physical characteristics. Thus crystalline structure may be obliterated by rolling or hammering a metal and by the same means the specific gravity may be increased, since the molecules are forced nearer together.

All metals with the exception of bismuth are lighter when molten than when cold. Bismuth, like water, reaches its greatest density just before solidifying. The relative specific gravities of some common metals in the solid and in the liquid state are shown by the following table, compiled by Sir Roberts-Austen.

The fracture of a metal is not a distinguishing property but an evidential feature which gives much information about the manner in which it cooled, the presence of impurities, etc., and is of great practical value. Thus foundry iron is in many instances still graded and sold by its fracture, and in smelting copper and refining lead the decisive points in the processes are determined by the fracture of test samples. Slow cooling, as with chemical solutions, tends toward the formation of large crystals, giving a coarse fracture, while a sudden cooling may prevent the formation of crystals and thus give a fracture of fine texture. Crystalline structure, which determines fracture, may be affected by repeated shocks or vibrations. In this way the wrought-iron chains on railroad cars to prevent accident in case of a coupler breaking may by the jolting of ordinary service become so crystalline as to break when they are needed. Very low temperatures, as shown by the experiments of Dewar, also affect in a marked manner the crystalline structure of some metals. Any metal is fusible; though arsenic sublimes at 356° F., it may be fused under the pressure of its own vapor. When heated, metals show a red and finally a clear white color. The temperatures corresponding to these colors are approximately: incipient red, 975° F.; dark red, 1200°; incipient cherry red, 1400°; clear red, 1830°; white, 2370°; dazzling white, 2730°.

The color of a metal depends on its selective absorption of light waves of different wave lengths. Unless the light penetrates the metal, it is all reflected and the metal looks white. The selection of light rays may be from several parts of the spectrum; this is the case with copper which has a reddish hue. Anything which increases the absorption deepens the color. This can be done by reflecting a ray of light many times from two or more surfaces made of a given metal. Silver, golds and golds make the same result by finely grooving a metal surface. Owing to this absorption of light by a metal the color of the light reflected differs from that transmitted. Thus gold can be made so thin that some light will get through. This light is bluish green, while in reflected light, gold appears yellow. Silver is white by reflected light, while the transmitted light through silver foil is blue.

Malleability is the property that permits a metal to be hammered or rolled into sheets. Ductility which permits it to be drawn into wire. Both are dependent on the tenacity of the metal, the latter more than the former. The relative malleability and ductility of the principal metals is as follows:

Note: Not yet (1917) determined. The interpolation point indicates that the figure quoted is approximate.

The mobility of the molecules of a metal is increased by temperature. Thus a coiled nickel wire may be made absolutely straight by suspending a weight on one end and heating the wire to white heat by the flame from an alcohol lamp or Bunsen burner. Zinc at its melting point is brittle, but at a temperature of 150° it is quite malleable.

Metals can occlude gases. Thus a given volume of palladium cooled from red heat in hydrogen absorbs 900 times its volume of that gas. Hydrogen passes through red hot iron or platinum, and nascent hydrogen, assisted by atmospheric pressure will pass through a thin plate of cold iron as shown by Deville. A liquid metal can penetrate a solid; A bar of as rubbed with mercury absorbs enough in a very short time to become brittle. A solid metal may penetrate another when both are cold. This can be shown with plates of gold and lead rolled together and allowed to stand.

For further information about the metals, see special article titled "The Metals," as in: AlUMINUM; ANTIMONY; I od; Lead; Silver, etc. Consult Friend, J. N. (editor). 'Textbook of Inorganic Chemistry' (9 vol. London 1914-17).

Richard Feher, Editorial Staff of The Americans.

METAMERISM, in chemistry, that variety of isomerism in which chemical compounds have identical percentages of composition and also like molecular weight. When two or more chemical compounds have the same empirical formula, but consist of different radicals united by an element (or a radical) that is common to them all, the compounds are said to be *metameric.* The property itself is called *metamerism.* The common element that unites the radicals is usually oxygen or nitrogen. Good examples of metamerism are afforded by the compound ethanes and ethers. Dipropyl ether, ethyl-methyl ether, and ethyl-buty! ether, for example, all have the empirical formula C₄H₈O, but dipropyl ether contains two propyl radicals (C₃H₇), ethyl-methyl ether contains one radical of methyl (C₂H₅), and one of any (C₃H₇), and ethyl-buty! ether contains one radical of eth! (C₃H₇) and one of butyl (C₄H₉); the two radicals being connected, in each case, by an oxygen atom. The structural formulae of these respective compounds are therefore as follows:

**Dipropyl ether.** Methyl-ethyl ether.

\[ \text{C}_3\text{H}_7 > \text{O} \]

**Ethyl-buty! ether.**

\[ \text{C}_4\text{H}_{10} \]

\[ \text{C}_2\text{H}_5 > \text{O} \]

\[ \text{C}_3\text{H}_7 \]

\[ \text{C}_4\text{H}_{10} > \text{O} \]

\[ \text{C}_4\text{H}_{10} \]

The following amines, which all have the empirical formula C₄H₉N, illustrate metamerism in which nitrogen is the connecting element:

**Propylamine Methylethylamine Trimethylamine**

\[ \text{C}_4\text{H}_{10} \]

\[ \text{CH}_3 \]

\[ \text{CH}_3 \]

\[ \text{CH}_3 \]

\[ \text{CH}_3 \]

**Metamorphic Rocks**

**Metamorphic geology,** that branch of geology that deals with the causes and results of metamorphism (q.v.).
have undergone sufficient heat and pressure to be altered into a different kind of rock. In this way limestone becomes marble, sandstone is changed to quartzite, and shale passes over into slate or schist. Metamorphic rocks are usually the result of processes of heat and pressure where the rocks have undergone much folding and compression. See MARBLE; QUARTZITE; METAMORPHISM, and the section on Metamorphic Rocks in the article on Rocks.

METAMORPHISM. When rocks of either igneous or sedimentary origin undergo sufficient heat and pressure so that they largely develop new minerals, and become other types of rocks, they are said to be metamorphosed, and the process is called metamorphism. Such changes may be brought about in many ways. One of the most familiar is the process of weathering (q.v.) by which the minerals of a granite, for example, undergo alteration, the quartz remaining behind as quartz, the feldspar altering chiefly to clay, and the soluble lime, magnesia, potash and soda going to sea, the first two forms of feldspar, the latter to produce the salt of ocean water. Thus the complete weathering of a granite and the sorting of the products finally results in the formation of shale, sandstone and limestone. This phase of metamorphism is called kata metamorphism. It is produced by the atmospheric agencies and results in simpler mineral compounds and rocks.

If on the other hand, a sedimentary rock be subjected to intense heat or pressure, or both, the minerals present recombine to form new minerals, usually more complex, which are better suited to conditions of heat and pressure. This phase of metamorphism is usually called anamorphism. In general usage, the term metamorphism is commonly restricted to what is here termed anamorphism, that is, to those changes due to heat and pressure. The term metamorphic rocks (q.v.) is wholly restricted to rocks which have undergone changes of anamorphic nature. Thus, for example, a shale which has resulted from the weathering of a granite, though it has undergone metamorphism in the broadest sense, is not considered a metamorphic rock.

The heat and pressure which cause metamorphism may be produced by compression and folding, or by heat alone. In the latter case it is said to be dynamic or regional metamorphism; or they may be due to the intrusion of large masses of highly heated igneous rock (magma), in which case there is said to be contact metamorphism.

Regional metamorphism results largely from pressure, heat is only incidental. The most common minerals to result are those which are flat like mica (q.v.), or elongated like hornblende (q.v.). These naturally develop in parallel arrangement with their smallest dimension opposed to the pressure, that is their larger dimension is at right angles to the compression. This seems to be the easiest way in which such minerals can develop. As a result of this arrangement, such rocks split more easily in certain directions, just as wood splits parallel to the grain. This is called cleavage, and is best manifested in slates (q.v.) and schists (q.v.).

Contact metamorphism, on the other hand, is due largely to heat; pressure plays a less important part. The changes at a contact may be of several types. The rocks may be simply baked or they may be actually fused. The minerals present may recombine to form new minerals. There may be much new mineral matter actually added from the igneous mass, as in the case of contact ore deposits, where ore minerals make up a large part of the contact rock. Or the heat of the igneous mass may drive off substances already present, especially water and carbon dioxide. At most contacts these processes have probably all played a part. The intensity of the metamorphism and the width of the altered zone depends on several factors, such as the size and temperature of the igneous body, the amount of the water or steam present, and the resistance of the enclosing wall rock. A quartzite (q.v.) wall rock may be little changed, while a limestone (q.v.), because of its greater solubility, may be profoundly altered. An abundance of steam aids in producing a marked effect, since it readily works its way out through pores in the rock, carrying with much mineral matter. As gas is produced largely by steam or hot water it is termed hydrothermal metamorphism. Changes produced by ordinary circulating waters are sometimes termed hydrometamorphism. See CLEAVAGE; GEOLOGY; METAMORPHIC ROCKS; ORE DEPOSITS. Consult Van Hise, C. R., 'A Treatise on Metamorphism,' (U. S. Geological Survey, Mon., XLVII, Washington 1904); Leith, C. K., and Mead, W. J., 'Metamorphic Geology' (New York 1915); Leith, C. K., Rock Cleavage (U. S. Geological Survey, Bul. 239 Washington 1905); Grubenmann, U., 'Die Crystallinen Schiefer.'

METAMORPHOSES. Ovid's 'Metamorphoses,' or 'Transformations,' were published in the year 8 a.d., when the poet was 50 years old. They were finished just before the issue of the imperial order which consigned Ovid to banishment at Tomi on the Black Sea for the remaining eight years of his life. In consternation at the punishment which had overtaken him, he elsewhere tells us that he consigned to the flames his own copy of the poem. But other copies were already in the hands of his friends; it is to these that we are indebted for the preservation of the work.

The poem consists of 15 books in hexameter verse descriptive of the various transformations through which various men and women were conceived to have gone. In the conception of the Greeks almost every river, rock, spring, tree and mountain had attached to it the legend of some such wonderful metamorphosis. Thus the poplar trees are the weeping sisters of Phæthon; the laurel is Daphne; a spring is Arethusa; etc. The source of this multitude of transformations found in ancient legends is doubtless to be sought in the ancient conception of inanimate objects as animate. Each rock and tree and hill with the Greeks and Romans was a personal being endowed with a spirit. Thus the poplar trees and the fountain and the laurel were regarded as animate to start with; they had not merely become so by receiving the souls of certain men and women. To the vivid imagination of the Greek the waving form of rustling tree or shrub, the moving mass of bubbling or falling water suggested life and individuality; and the problem was to account for the present form. The inanimate objects represented as the result
of transformations had, accordingly, been conceived as animate from the outset, and the stories of their transformations are merely later inventions devised to account for their primitive conception as personal beings.

Some 250 of the stories belonging to the body of Greek and Roman legend and mythology receive treatment in Ovid's work, which thus becomes a fairly complete treatise on the classic myths. Among the most important of these are the stories of Deucalion and Pyrrha, Daphne, Phaëthon, Cadmus, Semele, Echo, Narcissus, Penelope, Pyramus and Thisbe, Ino, Perseus and Andromeda, Niobe, Procris and Philomela, Medea, Thesues, Scylla, Daedalus, Philemon and Baucis, Hercules, Orpheus, Adonis, Theseus.

Relatively little space is devoted to the actual metamorphosis in Ovid's poem. The transformation is simply the culmination of a story, generally one of some length. Thus after detailing with great fullness the adventures of the ill-fated Phaëthon with the horses of Helius, Ovid passes on to his brief recital of the transformation of Phaëthon's mourning sisters into poplar trees. So with the other stories; the transformation holds an inconspicuous place, being simply the feature common to all. The different narratives are woven together ingeniously. There is no break. Each is connected with the preceding and following by some natural link, so that we have one continuous narration from the transformation of the stones of Deucalion and Pyrrha into men to the transformation of Julius Cesar into the comet which appeared after his death. By the poet's fiction, therefore, the treatment is made to assume the illusion of chronological sequence. In the last books Ovid approaches the legends of the Trojan cycle and of early Roman history, gradually bringing the reader to the events of his own day.

With great artistic skill the poet varies the manner of presentation. The larger part of the stories are his own narration, but monotony is avoided by resort to other devices. Thus a number of legends are put in the mouth of Orpheus. Others are recounted by the three daughters of Minyas to while away the time as they sit at their spinning.

The 'Metamorphoses' is Ovid's masterpiece and has long enjoyed high favor. The poet's own faith in his work is indicated by the concluding verses of the final book, in which he gives free expression to his confidence in the immortality which he feels it has won for him: "Of the stars his name shall soar; as far as the Roman dominion reaches his work shall be read, and it shall live for all eternity." The most recent translation is by F. J. Miller in the Loeb Library.

CHARLES E. BENNETT.

METAMORPHOSIS IN ANIMALS, the changes which in many animals take place between the time of birth and maturity. The causes are most probably changes of habitat, of seasons, of food and the acceleration in growth resulting from the approach of sexual maturity. Familiar examples are the change of the caterpillar into the butterfly, of the tadpole into the toad or frog.

In the frog and toad, metamorphosis is complete and thoroughgoing. The embryo on hatching from the egg has a large head and body, but no tail; in a few days its tail grows and it becomes a tadpole, when it first looks like a fish but without fins or limbs. With the growth of the tail, the external gills appear, and the mouth is formed, while the intestine becomes very long and closely coiled. The mouth is armed with horny, comb-like plates, on which great numbers of microscopic teeth which are shed continuously. In changing from the tadpole to the toad or frog, the body, including the skull and rest of the skeleton, and the viscera are made over anew; the external gills disappear, the front legs bud out and the adult form is attained. While most amphibians pass through such a metamorphosis, in a few forms, owing to the absence of water or other changes in the environment, development is directly from embryo to adult. Metamorphosis may be retarded by cold and shortened by hunger, and in the amphibians as in insects the changes are greatest in modern and specialized forms, as frogs and toads.

The metamorphosis of the butterfly is the most complete of those already mentioned. The life of the insects is divided into four stages, that of the egg, larva, pupa and imago or adult. During the larval and pupal periods the insect is, so to speak, a different animal from the adult. The caterpillar is armed with big jaws and can eat voraciously; in shape and structure it differs widely from the winged adult. The pupa or chrysalis is also different from the larva, and also from the imago; it takes no food and rests almost motionless. On the other hand, the butterfly has no jaws, while its maxillae form a long coiled-up tongue, beautifully adapted for probing the corollas of flowers. Though these changes appear to be sudden, the internal alterations of cells and tissue which lead to them are gradual. Pupation is usually three to five days before the adult can be recognized. At first the caterpillar becomes restless and stops eating. If a spinner it spins a cocoon, or if it enters the earth to undergo its transformation into a chrysalis, or, if a larval butterfly, it attaches itself to some fixed object, as a tree or fence. Profound changes now take place in the mouth-parts as well as the nervous, muscular and other systems of internal organs.

But the changes are most marked in the fishes and their allies. At one end of the maggot stage, the internal organs are destroyed, breaking up and forming a creamy mass, and the appendages and wings arise from massed internal masses of cells called 'imaginal buds' which are present in the maggot. The body is thus entirely made over anew. But while the process of destruction of the larval organs and appendages goes on, there is also a constructive process, during which the organs of the adult state are being built up. It is thus evident that the sharp division of the life-history of the insect into larval, pupal and adult stages closely applies to the external surface of the body. The internal processes of development, on the other hand, form a continuous series of transformations between which is no sharp line of demarcation. Yet as a whole the form of the
lava, pupa and imago are kept distinct in adaptation to their separate environments and habits.

**Hypermetamorphosis.**—This name is applied to the changes undergone by certain beetles (Meloe, Styla, etc.), in which there are more than the usual number of larval and resting or pupal stages. Thus, in the common oil-beetle (Meloe) and in the blister-beetles (Epicauta), the larva hatches as a minute, active, triangular creature which is a parasite in bees' nests, feeding on their eggs; it passes into a larval stage when it is a grub-like larva; active, the body being thick, cylindrical, soft and fleshy; this passes into a motionless semi-pupa, and thus after molting assumes a footless larval form; it then transforms into a true pupa like other beetles. There are thus four distinct larval stages, besides the pupa and beetle. Now these stages correspond to the habits and food of the young beetle, and these supernumerary stages and marked changes of form are evidently due to changes of environment. No metamorphosis is incomplete, the young differing mainly from the adult in not having wings. Also the most primitive arthropod animals, such as the horse-foot crab (q.v.), the spiders and mite-raptodes, pass through no metamorphosis.

**No Distinct Metamorphosis in the Primitive Insects.**—The wingless insects (Synthia, Hystricina, etc.) do not pass through a growth-like stage. It appears, as first suggested by Fritz Muller, that the habit of metamorphosing is an acquired one. Thus in the more primitive winged insects, such as the cockroach, grasshopper, bug, etc., metamorphosis is incomplete, the young differing mainly from the adult in not having wings. Also the most primitive arthropod animals, such as the horse-foot crab (q.v.), the spiders and mite-raptodes, pass through no metamorphosis.

**Metamorphosis in the Lower Animals.**—The more specialized ccelenterates (Medusa), the echinoderms, mollusks and crustaceans, as well as many worms, undergo remarkable changes of form. (See Larva.) The larva of the marine anemids is a top-shaped ciliated creature (trophicere) entirely different from its parent. The marine mollusks pass through a larval condition (religere). But the young of the sea-urchin, star-fish and holothurians differ remarkably from their parents in being bilaterally symmetrical. They hatch as swimming and not swimming: they serve as fodderings from which the body of the adult is developed. The shrimps, etc., are hatched in a nauplius or six-legged form, and crabs in a zoa form.

**Metaphor,** a figure of speech expressed in a single leading word; a simile—for example, "The man is a lion." a metaphor; "The man is as bold as a lion." is a simile.

Metaphor is an ideal characterization or illustration which may be affirmed by one mind and denied by another, or affirmed and denied by the same person at different times; it is a kind of comparison in which the speaker or writer rejects the circumlocution of the simile and attains his end immediately by establishing the identity of his illustration with the thing spoken of. It is thus of necessity, when well conceived and expressed, graphic and striking in the highest degree, and has been a favorite figure with poets and orators and makers of proverbs in all ages. Even in ordinary language the meanings of words are in great part metaphors; as when we speak of an "acute" intellect or a bold orator: all such words are in metaphor, and the language may be called metaphorical.

**METAPHOSRIC ACID.** See Phosphoric Acid.

**METAPHYSICAL DETERMINISM.** See Determinism.

**METAPHYSICS** (from Gr. Meta physika, "after physics," alluding to the position of Aristotle's treatise on metaphysics in his works). Metaphysics and epistemology (q.v.) are the twin sciences; it is the branch of philosophy of the nature and of our knowledge thereof. Metaphysics seeks for the criteria of being, epistemology for those of truth. As the truth is generally conceded to possess some peculiarly intimate relation to reality which is not found in the case of error, and as our sole avenues of access to reality are those of experience, be it sensory, rational, emotional or volitional, the boundary line between epistemological and metaphysical opinions is of the most obscure and wavering nature, so that a separate study of them is exceedingly unprofitable. We shall accordingly shift our standpoint continually from that of one science to that of the other.

Metaphysics is not a subject which one can study or refuse to study as will, whether it is explicit or not, there is always some criterion of truth, of reality, that permeates our barest common sense. This may be metaphysically inadequate, but must be metaphysical. When I draw a distinction between a dream and an experience of waking life, between a truth and a lie, between a fact and an error, I am drawing a metaphysical distinction. When a physicist reduces the table before him to a vast aggregate of electric charges, or asserts the basic identity of time and space, or interprets light as a transverse electromagnetic vibration, he is nothing if not metaphysical, for he is drawing a distinction between the appearance of things and their underlying reality. Even those who claim to be agnostics or sceptics in the professor's chair, are tainted with metaphysics in their daily life, for the only agnosticism, the only scepticism which can free itself from all blemish of metaphysics is an agnosticism, a scepticism so complete that it does not even tentatively maintain any criterion of reality or unreality, of truth or falsity.

We have accordingly three stages of metaphysics to discuss: (1) the metaphysics of common sense; (2) the metaphysics of the natural scientist; (3) the metaphysics of the technically trained philosopher.

(1) **The Metaphysics of Common Sense.**—The average philosophical layman, be he educated or not, believes that the wall he sees in front of him, the cane that he holds, the song that he hears are real, with an immediate and undeniable reality. He is indifferent to the wall, the cane, even the song would be the same without anybody to experience them. He is also confident that he exists, and that his existence is utterly independent of any experience he may have. Now, this view that there and I am in here, and that seeing is something which needs no analysis (for so the layman believes), works remarkably well; providing I only see things that are so. It is, however, clear that in my dreams and other illusions I frequently see things that in some
manner are not so. If seeing is an immediate relation between me and my object, what is my object when I dream of something which, in every common-sense interpretation of the words, does not exist?

This is obviously the highest common factor of metaphysics and epistemology, for it unifies the fundamental questions of the two sciences, the nature of truth and that of reality. What is more, it is in essence the one cardinal problem of both sciences, the great problem of error. The problem of error may be approached from two different angles, according as there are supposed to be real entities which form the objects of erroneous experience, or no such entities at all. In the latter case, experience must be interpreted as not essentially a subject-object relation. As we shall see, practically all the earlier modern philosophers held that erroneous experiences have objects. The second alternative is indicated in Spinoza and appears in the philosophies of Kant and Hegel.

(2) The Metaphysics of Natural Science.

Of course, science as such can have no genuine metaphysics. For science is one — unless we adopt the pragmatist attitude — and cannot be changed into a falsehood merely by looking at it through the spectacles of a particular discipline. Nevertheless, there is a certain conventional metaphysics which may be read between the lines of the majority of scientific textbooks, the habitat of which is the laboratory and the specimen-box. Though this may be traced to the Greeks, it owes its incarnation in its present avatar to Descartes and Locke. Both these writers, who are conventionally called dualists, since they believe in the essential distinction of mind and matter, are really rather what one might name tennarists, inasmuch as they posit between the self and its objects a third class of entities, the ideas, by the mediation of which the mind of self is aware of the outer world. Dreams differ from true waking experiences in that the ideas they contain have no realities corresponding to them. Modern science has turned the real universe into a world of material particles, or of electric charges, without any intrinsic color or sound, and has relegated these latter qualities to the realm of ideas. The physical correlates of these ideas are, of course, particles or charges in motion. By the mediation of the nervous system these particles or charges and their movements are supposed to produce certain alterations in the brain — Descartes considered that they were in the pineal body, while the advance of modern science has placed them in the cerebral cortex — which have as invariable concomitants certain ideas or ideational processes. It is these that form the sole direct object of human inspection.

This theory is perfectly successful in explaining error, but remarkably inadequate in accounting for anything of the nature that it is, which is not a mere accidental blundering belief. The situation is quite analogous to that of a man gazing at the cover of a book and trying to know what is inside. This knot or rib in the cloth may be an exposition of this or that theory, but if the book is permanently locked up, and is opaque, we can never know this. We consequently find that at the very beginning additions and modifications were made in the theory. These, however, belong to

(3) The Metaphysics of the Technical Philosopher. — Modern philosophical tradition may be said to commence with Descartes. Accordingly, he is the first man with whom the metaphysical issues of the present day receive the division and treatment with which we are familiar. We have divided the world into separate realms, apparently of mind and matter, but really of soul, matter and idea. Nevertheless, he saw the difficulties of the problem of error and tried to give it a more adequate solution than that pertaining to the conventional philosophy of natural science. At the founder of modern mathematics he tried to introduce mathematical criteria of truth into metaphysics, and so he starts with the proposition, 'I think, therefore, I am,' the denial of which he regards as self-contradictory in the same sense in which "2 has a rational square root" is self-contradictory. Having thus obtained the existence of the self, he goes on to demonstrate that God exists: If I have an idea of a most perfect Being, and this idea can only come from the truth it essentially is the one, unless we adopt the pragmatist attitude and cannot be changed into a falsehood merely by looking at it through the spectacles of a particular discipline. Nevertheless, there is a certain conventional metaphysics which may be read between the lines of the majority of scientific textbooks, the habitat of which is the laboratory and the specimen-box. Though this may be traced to the Greeks, it owes its incarnation in its present avatar to Descartes and Locke. Both these writers, who are conventionally called dualists, since they believe in the essential distinction of mind and matter, are really rather what one might name tennarists, inasmuch as they posit between the self and its objects a third class of entities, the ideas, by the mediation of which the mind of self is aware of the outer world. Dreams differ from true waking experiences in that the ideas they contain have no realities corresponding to them. Modern science has turned the real universe into a world of material particles, or of electric charges, without any intrinsic color or sound, and has relegated these latter qualities to the realm of ideas. The physical correlates of these ideas are, of course, particles or charges in motion. By the mediation of the nervous system these particles or charges and their movements are supposed to produce certain alterations in the brain — Descartes considered that they were in the pineal body, while the advance of modern science has placed them in the cerebral cortex — which have as invariable concomitants certain ideas or ideational processes. It is these that form the sole direct object of human inspection.

This theory is perfectly successful in explaining error, but remarkably inadequate in accounting for anything of the nature that it is, which is not a mere accidental blundering belief. The situation is quite analogous to that of a man gazing at the cover of a book and trying to know what is inside. This knot or rib in the cloth may be an exposition of this or that theory, but if the book is permanently locked up, and is opaque, we can never know this. This knot or rib in the cloth may be an exposition of this or that theory, but if the book is permanently locked up, and is opaque, we can never know this. We consequently find that at the very beginning additions and modifications were made in the theory. These, however, belong to

The author concludes by emphasizing the importance of Descartes' philosophy in shaping modern thought. His followers, without exception, laid far more emphasis on this phase of his philosophy than he himself. In the systems of Gualthez and Malebranche, God becomes the agent causing every change in mind and matter, whereas in Leibniz there shall be a corresponding change in the other. From this Occasionalism it is but a step to the monism of Spinoza, for whom mind and matter are but two among an infinite number of aspects of the one reality, God. From another standpoint, the entire world is the content of intellecution, without the mediation of the Cartesian and Lockean "ideas." Spinoza retains the logical, mathematical, intellectualist standards of truth and knowledge which were set up by Descartes, but he has also a mystical, emotionalistic view of the nature of reality, in that he believes that this is most truly perceived through the Intellectual Love of God.

The Deus ex machina survives in the view of the next great continental philosopher, Leibniz, instead of the two substances, mind and matter, of the Cartesian tradition, he supposes an infinity of substances, the monads, all participating to some extent of a mental nature. In place of calling upon God's continual intervention to stop the phenomena in accordance with the facts, Leibnitz supposes that at the Creation the Lord foreordained that all these many experiences should keep time, just as two perfect clocks, wound up and set together, will agree.
on all subsequent occasions until they run down. It is the problem of error as it appears in the philosophy of Leibnitz almost in its Cartesian form.

Leibnitz regarded the monads as possessing ideas of various grades of clearness and distinctness, and believed that matter was made up of those with the least ideas. Because he considered matter to be of the nature of mind, Leibnitz is called an idealist, and is classed together with Berkeley, whom we shall next consider. By observing the vast distance that separates the system of these monads, it will be possible to see how little content inheres in this term, which, with its contradictory realism, has been singled out by a certain American philosophical school as the index of a grand dichotomy of all philosophical systems.

Berkeley belongs to the British empiricist tradition. His immediate philosophical ancestor is Locke. Unlike Locke, however, Berkeley saw that no object not directly given can furnish a test of empirical reality, nor an aid in its production, because it was also the traditional consist of selves and their ideas or sense-data. This does not mean that he rejected natural science, but that he insisted that all its propositions were capable of expression in terms of ideas. Such ideas are not immediately given to any person he considered to reside in the mind of God, one of whose functions it becomes, to put it crudely, to watch things when nobody is looking and to see that they do not vanish away. However, it will be noticed that an idea in the mind of God which is not experienced by us is as inert, remote and useless from an explanatory point of view as a bit of matter. Furthermore, the self apart from its ideas does not appear to play any great part in knowledge. Given an experience, nothing more seems to be added by the adjunction of the self. For these reasons, the next successor to the British tradition, David Hume, rejected both the Berkeleyan matter — thinking God and the soul as a specific entity, and interpreted the world purely and simply as an aggregate of sense-data.

We thus see the contrast between the natural-scientific and the Humanian view of the universe; for the naive scientist, a bit of experience is a really an aggregate, bit whereas for Hume an atom in motion would have to be interpreted in terms of bits of experience. Unfortunately, Hume possessed neither the scientific knowledge nor the logical mechanism to carry out this process in any but the crudest and most schematic way, and his philosophy of space, time and causality is in detail as bare and inadequate and unsatisfactory as any yet devised. Recently, however, Bertrand Russell, who is essentially a Humanian in spirit, though he adopts the independent nature of the soul as at any rate a plausible hypothesis, has developed a treatment of these subjects, and of many other allied ones, which is at once scientific and at bottom after the manner of Hume. Matter, for instance, is treated (Hume would have it) by saying "(the sum) of its appearances; an atom or electron becomes a class of sense-data or a relation between them, or something of this general nature. The scientific analysis in terms of atoms and electrons is recognized as valid, but as based on a deeper analysis into the experiences out of which atoms and electrons are artefacts.

This recrudescence of British empiricism, however valid its opinions and valuable its results may be, is off the main stream of philosophical development during the latter part of the 18th century and the entire 19th. This main stream has its source in Kant, who, to continue the metaphor, marks the junction of the currents of British and of Continental thought. What is most distinctive in the thought of Kant is his definite and final occupation of the standpoint, it will be true ground for the determination of the problems of metaphysics. Now in so doing, Kant is making thought the measure of reality, and this seems to be only repeating the judgment of Spinoza. But there is a great difference. Kant declines to accept Spinoza's doctrine of thought and reality. The real is more than the content of thought. In fact Kant returns to the ancient intuition of thought as formal, and the real as in some sense its correspondent. This is also the tradition that Hume belonged to, from which Hume departed, as we have seen, with a result that is often called scepticism. Now the history of Kant's thought shows that, while he clung to the belief in the mere formal character of thought, his thought was also strongly in the direction of scepticism. Moreover it was on account of his failure to completely achieve what he calls his Copernican revolution, and which was in fact a reaction toward a constitutive doctrine of thought, that he was never able, during the whole of his critical period, to reach a satisfactory conception of the relation of thought to reality. Had Kant completely achieved the mental revolution he proposed, the result would have been, that in epistemology he would have asserted the doctrine of Spinoza, the identity of the real with the content of thought. The knowable world would thus have been identical with the real world and Kant would have escaped the dualism between knowledge and reality into which he actually fell. Kant also denies the universality of thought; at least in the ontological sense. The thought that functions epistemologically is my human relative thought which can only pronounce judgments that are subjectively valid for me; that is, that its content is valid for my subjective cognition. It gives me a world, in other words, in which I can work out the practical issues of my life, but it does not give me the world of real things in themselves with respect to which my attitude must be one of renunciation. As a metaphysic critical idealism simply carries its program out in the field of ontology. The presumption of the identity of what is thought with the real cannot be carried out objectively. Kant's metaphysics is therefore necessarily non-critical. To complete itself ontologically, it is true, but the ideals it reaches have no other than subjective value. Their hypothetical content can never be identified with the real, and the Kantian is per force obliged to represent the whole ontological region as an indeterminate X and to look for
the satisfaction of his wants to extra-metaphysical forces. These he finds in the domain of emotions.

In Hegel we have also an example of a thinker who approaches metaphysics along the epistemological way. But Hegel is a much more thoroughgoing thinker than Kant. He starts no doubt with the Kantian traditions in mind and his first great task, the development of his logic, is formal. But Hegel is not a formal thinker, in the sense that he divorces content and form. Thought is formal. This Hegel is not afraid to confess, but it is also ontological. At the same time there are no outlying realities, like the Kantian things in themselves. How is this? Are we to have the spectacle of a lapse into Spinoza? Our apprehensions are ungrounded, for Hegel asserts calmly that the form creates the content. Hegel asserts the identity of thought and reality in the sense that the real is, and is only, what the thought thinks it to be. It is the real by virtue of the thought thinking it to be. This sounds like a dangerous kind of subjectivity, till it is learnt that by thought Hegel means, not your thought or yours, as simply my or your intellectual function, but the thought that is universal and that thinks the universal. So much for Hegel's epistemology. In Hegel's system epistemology and metaphysics are simply two aspects of the same thing. In epistemology we have the system logically conceived; that is in view of the process which the finite thought of the individual must pass through in order to apprehend it; whereas in the metaphysics we have the system presented in its unity as a self-completing whole. Epistemologically the dialectic is the movement by which results are achieved; metaphysically it is the Divine Spirit of the system as a whole. Error is accounted for precisely by the disparity between individual and universal thought.

One of the most remarkable aspects of the metaphysics of the past century is the strong voluntaristic or emotionalist trend which is to be observed among writers of the most different philosophical ancestry. Schopenhauer, though he was a follower of the Kantian tradition, interpreted the course of events as the manifestation of a world-will, which performs the functions of the Kantian thing-in-itself. This will manifests itself in man as will in the ordinary sense, while in matter it is seen as force. A view which displays an analogous voluntaristic or rather activist trend, though in every other respect most unlike that of Schopenhauer, is pragmatism, the chief exponent of which was the American philosopher William James. This view states that the truth of a theory or the reality of a system is not merely determined but constituted by what is in some sense the ease with which it can be applied and the value of the results of this application. A similar position is that of Henri Bergson, who maintains that the analysis of science yields us only half-truths, while the real nature of the world is shown to us by intuition, which exhibits it to us as the working of a certain vital impulse.

There is no metaphysics at the present time which can lay claim to a general acceptance. The 19th century domination of all philosophy by the memories of Hegel and Kant is passing away, and the tendency of worshiping these great men as philosophical demigods is widely extinct. Their followers, numerous though they are, must dispute their realm with the modern critical adherents of the British tradition, armed with modern logic, mathematics and science, and with the pragmatistic-Bergsonian tendency.

Before closing this article, let there be word of caution to the reader against the facile metaphysical criticism which depends on labels. We have already seen that the line of cleavage between idealism, or the view that things are either thoughts or their thinker, and realism, which affirms the existence of other entities, does not itself mark one of the great philosophical dichotomies; Berkeley, the first typical British idealist, and Leibnitz, the idealist of the Continent, both, fell into the epistemological difficulties which are generally accepted as characteristic of realism, in that the problem of the relation between the known and the known remains in what is essential the Lockean or Cartesian stage. The distinction between spiritualism, which is almost a synonym of idealism, and that which regards matter as constituted of psychical elements, materialism, which analyzes mind in terms of matter, is similarly not a touchstone to the nature of the views which it denies. The only really satisfactory method of metaphysical criticism is by the critical analysis of each philosophical system according to its own concepts. See *Epistemology; Philosophy: History of*; and the articles on the individual philosophers mentioned.

**METASOMATISM.** According to the United States Geological Survey, *metasomatism* may be defined as the process by which through chemical interchange, a mineral or aggregate of minerals undergoes partial or
complete change in chemical constitution. In more simply stated, metasomatic ore bodies are formed when the ore substance replaces the rock particle by particle, instead of filling already existing cavities. Replacement is frequently used as a synonym for metasomatism, and ore bodies so formed are usually called replacement bodies. Replacement, unfortunately, by some writers, to indicate cavity filling, and these authors use the term metasomatic replacement in the same sense in which others use the term metasomatism. According to the most careful usage metasomatism and replacement are synonyms, and apply to ore bodies replacing the wall rock particle by particle. "Metasomatic replacement" is then pleonastic.

METASTASIO, Pietro, pé-á-tró má-tás-tá'-zé-ō (properly PIETRO TRAFASSI), Italian poet; b. Rome, 13 Jan. 1698; d. Vienna, 12 April 1782. His poetical talents were early displayed in improvisations, and often he drew about him a crowd to listen to some versified narrative. The jurist Gravina, who thus accidentally became acquainted with his talents, took him under his protection, called him (by an Italianized translation of his name into Greek) METASTASIO, paid great attention to his education, and on dying in 1717 left him an estate of $20,000. On 15 April 1718 he was received into the Arcadian Academy with the name of Artino Corasio, and in 1720 entered at Naples the office of the attorney Castagna, who disowned literary work, and kept him severely to the law. He wrote anonymously 'Gli Orti Esperidi' (1722), but the authorship was soon revealed, and Metastasio left the lawyer's office, studied further, and wrote a series of musical dramas, or melodramas in the true sense, which were set by leading composers and given with great success. In 1730 he settled in Vienna as court poet, and there in 1730-40 wrote his best works, 'Demetrio,' 'Issipile,' 'Demofonte,' 'La Clemenza di Tito,' 'Attilio Regolo.' In the consideration of Metastasio's rank as a poet, his work must be viewed not absolutely, but with regard to its original environment, as done in collaboration with a composer, and rendered by great artists. He wrote, too, for the predominant partly vocal, partly instrumental, partly opera, partly opera, and with this his poetry fell into comparative neglect. His writings have been praised so much that it is inexcusable to call him a poet, and the few editions of his works are that of 1780-20 (Paris), Consult Massa, 'Pietro Metastasio' (1822); also Lee, 'Studies of the 18th Century in Italy' (new ed., 1908).

METASTASIS (1) in medicine, a change in the seat of a disease, attributed to the translation of morbid matter to a part different from that which it had previously occupied, or to the displacement of the irritation. Mumps is a disease peculiarly liable to induce metastasis. In adult males the inflammation of the parotid gland is most frequent, and in adult females to the breasts or ovaries, in the latter case ovaritis. Mastoiditis often results in similar shifting of the inflammation by the travel of blood clots, and the inflammation may reappear in any of a dozen places. (2) In botany, a change produced upon a substance designed for the nutriment of a plant, to make its assimilation more easy. Thus, when the starch formed in the leaf of a potato has to be transferred to the tubers as a depot of nutriment material, it is first changed into a soluble substance—glucose. See Metabolism.

METATE, the stone implement on which grain and other substances, more especially corn, were ground before the discovery of America and are still ground throughout the territory of the United States occupied by the Pueblo Indians, and in Mexico, Central America and much of South America, more especially the west coast. See Mortar.

METAURUS, mé-tá-rús, or METAURO, má-tow-ró, Italy, a river in the Marches, which flows northeast past Saint Angelo in Vado, and falls into the Adriatic, southeast of Fano; total course, about 50 miles. It is noted for the victory gained by the Romans under the consul Claudius Nero and Livius Salinator near its banks over the Carthaginians under Hadsrulph 207 B.C.

METAVOLTINE. A sulphur-yellow mineral occurring in aggregates of hexagonal scales at Madeni Zakh, Persia. Dichoic. Hardness, 2.5; specific gravity, 2.53; composition: Sulphuric acid, 46.90; sesquioxide of iron, 21.20; protoxide of iron, 29.2; potash, 9.87; soda, 4.65; water, 14.58. Much of the mineral called misy belongs to this species.

METAYER, mé-á-yer, Fr. mä-tä-yä (L. Latin, medietarius), a name given in France to the cultivator of a métairie or farm who reserves for himself one portion of the produce as the price of his labor and gives the proprietor the other, which represents the rent of the land after deducting what is necessary to keep up the stock. The greater part of the centre and south of France, and almost the whole of Italy, is cultivated by metayers, who are in general upright, economical and industrious. This system of farming on shares, usually half and half, has been tried to some extent in the southern United States, but has never been popular either with farmer or tenant. The system is intended to let the farm run down, because of uncertainty that he will have it in following years. The system also seems to work against the introduction of improved machinery. See Agriculture in the United States.

METAZOA, one of the two great sections into which Huxley divides the animal kingdom, the other being the Protozoa. The Metazoa embrace all animals composed of more than a single cell, that is all that develop through eggs or ovum. The Porifera or sponges are the lowest of the Metazoa. See Anatomy, Comparative; Protozoa.

METCALF, William, American steel manufacturer; b. Pittsburgh, Pa., 1838; d. 1909. In 1858 he was graduated at the Rensselaer Polytechnic Institute, Troy, N. Y., and from 1860 to 1865 supervised the manufacture of Rodman and Dahlgren guns at Fort Pitt, Pittsburgh. In 1858 he entered the steel manufacturing field, and in 1898 organized the Ithaburgh Steel Company, of which he was president for 11 years. It is said that Metcalf made the first crucible steel in America. He was president of the
American Institute of Mining Engineers in 1891 and of the American Society of Civil Engineers in 1893. He published 'Steel—A Manual for Steel-Users' (1896).

METCALFE, Samuel L., American physicist and scientist; b. near Winchester, Va., 1798; d. 1856. In 1823 he was graduated in the medical department of Transylvania University; established a medical practice at New Albany, Ind., and visited England in 1831. Upon his return to his native country he made a geological tour in Tennessee, North Carolina and Virginia. Later he settled in New York where he took up scientific work. He published 'Narratives of Indian Warfare in the West' (1821); 'A New Theory of Terrestrial Magnetism' (1841); 'Manual of Chemical, Critical and Vital Agencies in the Phenomena of Nature' (2 vols., 1843; 2d ed., 1859).

METCHNIKOFF, Elie, Russian bacteriologist; b. Kharkoff, Little Russia, 15 May 1845; d. Paris, France, 15 July 1916. Following his education at Kharkoff, Metchnikoff studied at Giessen and Munich, and in 1870 he was appointed professor of zoology at Odessa. He held this post until 1882, when he resigned to devote himself to private researches into the anatomy of invertebrates. It was while working at last on the forms of life such as sponges that he first made the observations which constituted the basis of all his subsequent work. In 1888 he had attracted the notice of Louis Pasteur, the founder of the famous Pasteur Institute for the treatment of rabies, in Paris, and he was invited to become one of Pasteur's associates. In 1895 he succeeded as the director of the institute, a post which he held to the time of his death. In his study of longevity, Metchnikoff came to the belief that it should not be concentrated for persons to live to the age of 150 years. He found every indication that the human mechanism was calculated to last far longer than it actually does. His researches showed among other things that animals which had no large industries lived to an advanced age, particularly birds, which preserve their youthful agility and spryness to the end of their long span. In the case of human beings he found that even among those whose sufferings are not too great there were few who wanted to be put out of their agony by death. They all wanted to live. If the normal specific longevity were attained by human beings he believed that old and not degenerate individuals would detect the instinct for life and acquire an instinct for death and that as they had fulfilled the normal cycle of life, they would accept death with the same relieved acquiescence as they now accept sleep. On his seventieth birthday, in 1915, Professor Metchnikoff received a present of a golden book, forming a unique record of the latest scientific researches, signed by men of science of the day. Although there was much controversy in the scientific world regarding his original ideas, he was fully recognized as one of the most eminent bacteriologists. In 1908 the Nobel prize for medical research was divided between the late Dr. Paul Ehrlich, of Berlin, and Professor Metchnikoff. The $20,000 which fell to his reception he devoted entirely to the furtherance of his scientific researches. Personally he was not well off, and throughout his long life sacrificed all but the plainest living necessities to the cause of science. He was the author of a number of books including 'Lectures on the Comparative Pathology of Inflammation' (London 1893); 'Immunity and Infective Diseases' (New York 1912); 'La mort sur le nature humaine; essai de philosophie optimiste' (1903). English translations of lectures are 'The New Hygiene' (Oxford 1907); 'The Nature of Man' (New York 1912). He edited, with Sjæruppe and others, 'Medicaments microbiens, etc.' (1909). Cense, 'Annales de l’Institut Pasteur' (Paris), ii; Slosson, E. E., 'Major Prophets of ToTo (Boston 1914).

METELLA, Cæcilia, daughter of Metellus Creticus. Her tomb is the best known of a many that once lined the Appian Way for some miles beyond the walls of Rome, because the law which forbade burial within the city limits.

METELLI, mét-lē’l, a Roman family of gens Cæcilia. QUINTUS CÆCILIUS METELLUS MACEDONICUS defeated the Etruscans. This Metellus, the Macedonius, received a triumph 146 B.C. QUINTUS CÆCILIUS METELLUS NUMIDICUS rendered himself illustrious by his successes against Jugurtha, Numidian king. He took, in this expedition the celebrated Marcus Cæcilius Metellus received the surname of Pius on account of the love which he displayed for his father when he besought the people to recall him from banishment in 99 B.C. In 83 B.C. he was tribune in the consulship. QUINTUS CÆCILIUS METELLUS CREDIUS conquered Crete, and conducted it to a Roman province in 67 B.C. QUINTIUS CÆCILIUS METELLUS PIUS SCIPIO adopted son of Metellus Pius, in 52 B.C. was colleague in the consulship with Pompey, who had married his daughter Cornelia. He exerted himself to the utmost to destroy the power of Caesar and strengthen that of his son-in-law. He commanded the centre of Pompey's army at the battle of Pharsalia, and after the terrible Abut (48 B.C.), which was fought by him at Thapsus 46 B.C. He died by his own hand.

METEMPSYCHOSIS. This ancient theory has at times been confounded with reincarnation. While both imply that man lives again but the propositions present radical difference. See REINCARNATION; TRANSMIGRATION.

METEORIC WATER. See GEOLOGICAL WATER.

METEORITES, also called Asteroid Meteorites and Meteoric Stones, are bodies that enter the earth's atmosphere from without and are being intensely heated by impact with the earth's surface or ground. If the fall occurs at night, the meteorite is seen as a ball of fire passing through the heavens and frequently leaving a brilliant train of material behind it; usually sparks and fragments are thrown off from the head. Sometimes this bursts in pieces with a great explosion and finally settles on the ground. In hundreds, or even thousands, of pieces. If it is too far away from the observer, its passage through the air may be heard as a continuous
roaring sound accompanied by frequent detonations of great volume; if a meal, louder and more distinctly heard, is both seen and heard, the distance from the observer to the meteorite at the time may be very accurately determined by the consideration that sound travels but 1,040 feet a second while the transmission of light is practically instantaneous. The observer is thus fortunate enough to witness a meteoric fall should therefore take means to estimate the number of seconds which elapse between when the explosion is seen and when the sound reaches him. This is usually done by beginning to count, or to repeat the letters of the alphabet, or some piece of doggerel at the first instant and breaking off at the second. By a repetition immediately afterward, which is timed by a watch, a quite accurate approximation will be obtained. If in addition the apparent position of the meteor among the stars is noticed at the beginning and end of its appearance or (if the phenomenon is witnessed in the daytime) if the approximate bearing and elevation above the ground are noted at the two instants, the time being also stated, at least approximately, the observer will have secured a record which will be of real scientific value.

Meteorites are of two classes—the stony meteorites and the iron meteorites. The former are about 10 times more numerous than the latter. In the iron meteorites iron usually forms more than 90 per cent of the entire mass, but it is almost invariably alloyed with nickel. In the stony meteorites mineral combinations occur which are peculiar to these bodies, and serve as one of the ear marks by which they may be recognized when they were not seen at the time of their fall.

Other distinguishing marks of meteorites are found in their physical appearance and structure. They are covered with a blackish crust formed by surface melting during their passage through the air. This crust consists mainly of oxide of iron, and is magnetic. Pits and hollows are formed in the surface of a meteorite by the fusing of the less refractory minerals and these are a characteristic feature.

When a portion of the surface of an iron meteorite is polished and then etched with acid peculiar markings, called from the name of their discoverer, are visible, as a result of the etching. These are among the most trustworthy criteria of the meteoritic origin of suspected masses of native iron.

About one-third of the chemical elements known, in the laboratory, have been found in meteorites. But no new element has ever yet been discovered in them. The following elements occur, in greatly varying quantity, sometimes a mere trace being present:

Iron Carbon Oxygen
Nickel Sulphur Hydrogen
Cobalt Phosphorus Nitrogen
Copper Silicon Chlorine
Magnesium Titanium Chromium
Arsenic Calcium Lithium
Manganese Helium

As the true nature of shooting stars was not understood until after the investigation that followed the great shower of 1833, so the true nature of meteorites was recognized only after a remarkable fall of those bodies which occurred in the neighborhood of L'Aigle on 26 April 1803. Nine years before, in 1794, Chladni, a German physicist, had formulated the theory that meteorites before encountering the earth traveled in independent orbits in space, but his conclusions were not generally accepted until the occurrence at L'Aigle had focused the attention of men of science. On that occasion between 2,000 and 3,000 meteoric stones were scattered over an area about 80 miles long by three miles wide. The French astronomer, J. B. Biot, visited L'Aigle, carefully examined the fallen stones and collected and discussed the evidence of eye witnesses. Thereafter the idea that meteors and meteorites were simply atmospheric phenomena was abandoned, and the fact of their extra-terrestrial origin was generally recognized. It is now perfectly certain that meteorites cannot have originated in volcanic eruptions on the earth or on the moon, as some have supposed, but that they came from remote parts of our solar system, or, more probably, from beyond its borders, or even from the region of the stars. That this is so is definitely proved from the velocities (many times observed), with which the stones fell on the earth. It is found that before the collision they must have been falling toward the sun along such elongated paths as that upon reaching the earth's orbit their velocity of motion was very approximately 20 miles a second. This is the velocity which a body would acquire in falling to this distance from the sun in an infinitely great distance away, and leaves no room for doubt that each of these bodies was pursuing its own independent orbit about the sun before it suffered collision with the earth.

Many records of the fall of meteorites have been found in ancient annals, and in modern times, with so many observers continually watching the sky, the number of meteorites seen in flight is annually quite large, although the actual falls observed are always comparatively rare. The number entering the earth's atmosphere in a year has been estimated all the way from 70 up to 3,000 or 4,000. In 1879, on 10 May, there was a shower of meteoric stones over Iowa, the largest mass weighing more than 400 pounds. The last considerable fall in this country was recorded on 19 July 1912, when a remarkable detonating meteorite fell near Holbrook, Ariz. In this case the explosion so completely shattered the meteorite that the largest fragment found weighed but 14 pounds. Upward of 14,000 separate stones were gathered, their total weight being 481 pounds.

Perhaps the most famous meteorite of antiquity was the so-called stone of Egos-Potamos, which fell in Thrace in 466 B.C., and which was described as equaling two millstones in size. Plutarch speaks of it in his life of Lysander. In the Middle Ages the Stone of Euisiasheim was very celebrated and bore the object of superstitious reverence. It fell at Euisiasheim in Alsace on 7 Nov. 1492, when the Emperor Maximilian was at that place. Fragments of this body were taken to Paris and London, but the principal mass, weighing more than 200 pounds, was suspended in the choir of the church of Euisiasheim.

Almost every large meteorological museum contains specimens of meteoric stones and meteoric irons. There are some remarkable examples in the National Museum at Washington and the British Museum. An iron mass, supposed to be of meteoric iron, discovered at Cañon Diablo, Arizona, proved,
METEORITIC HYPOTHESIS — METEOROLOGY

on examination a few years ago, to contain minute black crystals resembling the diamond, and a meteorite which fell in Russia contained similar black crystals of carbon. It is yet a disputed question whether the huge masses of iron, weighing many tons, which were brought from Greenland to Stockholm by Baron Nordenskjold, are really of meteoric origin. The same question attaches to a fragment of a nebula transported from Greenland to New York. Other masses of this kind exist in various parts of the world. There is no record of their having fallen from the sky. A complete catalogue of all the region of North America, together with a description of their falls, an analysis and a detailed description of the structure in each of them, and also a very complete bibliography was published in 1915 by O. C. Farrington. This work forms volume XIII of the "Memoirs of the National Academy of Sciences" (Washington).

METEORITIC HYPOTHESIS, the theory of cosmogony professed by Sir Norman Lockyer, to the effect that all astronomical systems, including the nebulae themselves, and in particular those containing solar bodies, are formed and satellites result, not from the condensation of a nebula, but from the interferences and collisions of meteors more or less fortuitously grouped in space and with more or less fortuitous velocities. The structure of Saturn's rings and the behavior of the outermost planets seem to be susceptible of a better explanation on this theory than on the nebular hypothesis (q.v.), but certain difficulties have been met in connection with a peculiar line in the spectrum of a nebula, which according to the meteoritic hypothesis are formed from the substance of meteors, contain an element, nebulium, found nowhere else in the universe.

METEOROLOGICAL SOCIETY. The Royal, a scientific body with headquarters in London. Its organization dates from the year 1660, and in 1866 it was incorporated. All theories and facts pertaining to meteorology are sought for in its records, the development of that science in all departments being the object of the association. Besides fellows, the Society consists of honorary members, this distinction being bestowed upon distinguished persons of other than English nationality. The Society publishes the Meteorological Record and the Quarterly Journal.

METEOROLOGY, meteoron + logos, literally the science of the things in the air. Meteorology has come to mean that part of natural philosophy that treats of the physics of the air and the mechanics of its motions. It includes climate (q.v.) and weather. The distinction in the meaning of the two terms is apparent when it is stated that one may well speak of the weather of to-day, or last month, or some past year, but not of the climate of a day, a month or a year, which is determined by finding the averages and the extremes of all the weather conditions for a long series of years of the temperature, precipitation, humidity, sunshine, cloudiness and wind velocity and direction.

Theoretical Meteorology aims to trace out the workings of definite laws to explain the various atmospheric phenomena, and properly may include a study of variations in solar radiation, as affecting the earth's temperature, or as the primary causation of terrestrial storm. Meteorology proper, the science of meteorology to the art of weather forecasting, which, so far, has not passed beyond the rudimentary stage, and in various ways to utilize knowledge of the physics of the for the commercial industries.

History. The true meteorological science was not applicable to man's knowledge of the atmosphere, the weather, the time Virgil, Cicero and Aristotle wrote of the weather. As late as the time of the founding of the first of the 13 original colonies, Jamestown, Va., in 1607, practically nothing was known of the properties of the atmosphere, and methods for the measuring of its phenomena. The development of the thermometer and Torricelli's invention of the barometer in made study and investigation possible.

American scientists may well be proud of the services rendered by their countrymen to humanity in adding to our knowledge of the atmosphere. The act of the great Franklin, drawing down the lightning of the clouds and identifying it with the electricity of the laboratory, is the first important step in the approach to meteorological science. In 1747, while making observations at Philadelphia of a lunar eclipse, in co-operation with his brother at Boston, he learned that storms moving from the west, as all storms of the middle latitude do, first begin with easterly winds, and that an approach a place of observation become western; he came near discovering the cyclonic system of storms. Following the winter of 1772, famous in history for the phenomenal severity of its cold, and its long duration, Franklin, in a letter to a correspondent in Europe, called attention to the violent eruption of Mount Hecla the preceding year, and suggested that the dust therefrom may have been carried into the high strata of the atmosphere and spread around the earth by the winds. His idea was that this dust would screen off some of the sun's rays and add to the cold of winter. As in many other things, he had a prophetic vision for there no longer is doubt that violent volcanic eruptions thrown into the upper air bring quiescent particles which, though moving easterly currents in the middle latitudes and westerly currents in the tropics, are so distributed around the earth as not only to affect the colors of the sky for two or three years after, but to modify the weather. Deplorable the earth in this year of 1919 still is feeling the cooling effects of the explosion of Katmai, in the Alaskan Peninsula, in 1912, augmented by volcanic explosions in Japan in 1913.

The author of the Declaration of Independence, Thomas Jefferson, took daily observation of the weather. He even carried his barometer to Philadelphia and twice recorded the temperature of Independence Hall on July 1776. He owned one of the oldest barometers then in the colonies. In co-operation with James Madison (after bishop, but living at Williamsburg, some 200 miles east of Monticello), he determined that changes in the barometer first began several hours earlier at the westernmost station. The British ransacked his home and broke his barometer. It is said
that he berated them more for the destruction of his cherished instrument of the weather than he did for their burning of the National Capitol. As early as 1735 Hadley, an Englishman, had published an article explanatory of the trade winds, and Dalton, another Englishman, in 1793, made the first attempt to explain the phenomena of the atmosphere through the principles of philosophy. It was then believed that storms were straight-line gales. It remained for Redfield, an American, in 1831 to publish an epoch-making essay, in which storms were depicted as circular gales moving in concentric curves nor along radical lines into the interior of the storm, but spirally inward. Tracy proved that Redfield was right, for he showed that the rotation of the earth must deflect all air currents to the right of the initial direction in the northern hemisphere, whether in storm-whirls or out of them. From 1840 to 1860 the other Americans who added most to our knowledge of meteorology were Maury, Coffin, Henry, Lapham and Loomis. Mathew Fontaine Maury, of the United States navy, was the pioneer in marine meteorology. He mapped the oceans and determined the direction and force of winds and water currents. In 1855 he published his "Physical Geography of the Sea and its Meteorology." See Weather Bureau.

Source of the Atmosphere.—The larger planets of the solar system are believed by many scientists to have hot atmospheres still in violent agitation. According to the La Placion hypothesis of the origin of the earth, millions of years ago it also had a similar atmosphere. Much of the hot vapors which largely composed the earth's atmosphere during the early period of its existence, have been absorbed by its rocks or filtered away into space. The residual is saturated with our present atmosphere. The moon shows no refraction or diffusion of light, such as would occur with an atmospheric envelope. It is dead. It died young because it is too small to have sufficient attraction of gravitation to long retain a life-sustaining atmosphere; or in fact, any atmosphere, the darting molecules of which have high velocities, and are captured by larger celestial bodies.

Before the sun can have an atmosphere suitable for life an incomprehensible period will have elapsed, its light will have gone out, its heat will have ceased to reach the earth and the other planets in appreciable quantities, the earth will have been dead millions of years, and the sun itself will only receive heat and light from the feeble rays of the stars which, unlike itself, have no atmosphere. Even though it had a suitable atmosphere, it must remain dead, for there is no external source whence it can receive appreciable heat.

Those who follow the Planetaryesimal hypothesis are required to believe that the earth's atmosphere has never been hot and has grown denser rather than rarer, with the growth in size of the earth.

How Atmospheres are Lost.—Gases that cannot be held by the moon may be held by the earth and those that can escape from the earth may be held by the larger planets. An understanding of how gases are lost through the kinetic energy of molecules requires that a careful account be taken of the relations that exist between the attraction of gravitation of planets, their temperatures, and the weight of the molecules of the different gases that compose their atmospheres. The speed of the molecules depends on its temperature and its mass, being less at low temperatures and greater at high temperatures, and light molecules moving more swiftly than heavy ones. A gas is composed of molecules that dart about at velocities which, in connection with numerous collisions (seven or eight millions for each molecule near the earth in 1 second of a second) and the energy of each molecule, may allow a certain proportion of them at any one time, to reach velocities so great that, if they pass into the outer layers of the air, where collisions are rare, they may escape from the attraction of the planet and pass away never to return. According to the kinetic theory it would appear that the earth's gravitation and the temperature of its outer air are such as to retain without appreciable loss argon, carbon dioxide, oxygen, nitrogen, vapor of water, and ammonia, but that helium and hydrogen, because of their lesser specific gravity, escape from the top of the atmosphere about as fast as they are supplied from hot springs and other sources at the bottom.

Proportion of Gases Allied—Samples of air taken at various elevations up to nine miles show the atmosphere to be a homogeneous mixture, with the proportions the same at all elevations; but this is what one would expect from the mixing of the air by the ascending and descending whirls of cyclonic storms. Storms operate only in the lower air, and all ascending and descending currents practically cease below the 10-mile level. Above this altitude it reasonably may be assumed that the heavier gases steadily lose in proportion to the lighter ones until at about the 50 miles nothing but hydrogen and helium remain.

Atmospheric Air.—The earth is surrounded by four important atmospheres—nitrogen, oxygen, vapor of water and carbon dioxide—and others of lesser importance, each carrying itself, in accordance with Dalton's law, practically as it would do if the others were not present, except that its rate of diffusion is retarded by their presence. This composition is atmospheric air—usually called air. Both by volume and by mass oxygen and nitrogen are the principal atmospheres. They, like the others, are in mechanical mixture and not in chemical combination. Because of their relatively greater importance separate articles are devoted to nitrogen and oxygen (q.v.). But it should not be thought that because they are the other constituent gases are relatively small, they are not vitally important in carrying on of the functions that nature seems to have assigned to the air.

As well as germs, dust and cloud particles, air, over land, contains sulphates in minute quantities, and over the sea and near the sea-
shore salt left from the evaporated spray can always be detected.

**Carbon Dioxide.**—In cities the amount of carbon dioxide is considerably greater than in the country, frequently rising to 0.07 per cent by volume, and even to 0.10 per cent when there is but little wind to scatter what accumulates near the ground. In crowded theatres Angus Smith found as much as 0.72 per cent and in mines 2.5 per cent. The latter amount would soon be destructive to animal life. This gas is 1.50 times as dense as an equal volume of air. Its density causes it to collect in mines, sewers, cellars and other low and confined places, unless there is forced ventilation. The sweep of the American cold wave, with its heavy air moving at a high velocity, is highly beneficial. It searches into cracks, crevices and into enclosures that are not hermetically sealed and expels the foul air. All nature feels the revivifying effects of rain and high wind; one washes out the carbonic-acid gas (carbon dioxide) from the air, with the dust and other particles in suspension; the other enters our habitations and drives out the poisonous atmospheric accumulations. It cannot be too strongly impressed upon the reader's mind that oxygen, the life-sustaining principle of the air, decreases, and carbon dioxide, a poison, increases in air that is breathed, or in air in which candles, oil-lamps or gas are burning; and that all places of habitation, especially those that are used for sleeping-rooms, should have a continuous supply of fresh air.

**Water Vapor** is another of the four important atmospheres. It may vary in amount from a fraction of 1 per cent for the arid regions to 5 per cent of the weight of the air for the warm humid regions. It is a little over one-half as dense as atmospheric air. When the air has taken up all the water vapor that it can contain at a given temperature it is said to be saturated. Saturation seldom occurs in free air, except inside of a dense fog or cloud, or within the thin stratum of air that by contact with a cold surface has had its temperature lowered to the point of condensation. Even during heavy downpours of rain, the air near the earth's surface is usually capable of evaporating some of the rain that is falling through it. In fact light precipitation may be entirely taken up by the lower air and never reach the earth. The dew point is the temperature of saturation. The relative humidity is expressed in percentages of the amount necessary to saturate. At a temperature of 32° F., air resting over a moist surface may continue to increase the amount of its vapor of water content until it contains 21.1 grains per cubic foot, which amount is sufficient to exert a pressure in all directions equal to the downward pressure of 0.18 inch of mercury; it will then be saturated and its relative humidity be 100 per cent. The point to which attention is especially directed is that the pressure of 0.18 inch indicates the maximum pressure of water vapor at 32° temperature, and any further evaporation must be accompanied by an equal amount of precipitation. Now, if this air be suddenly raised to 51° (its capacity per cubic foot will be increased to twice what it was at 32°, the 21.1 grains will only be equal to one-half the number necessary to saturate and the relative humidity be expressed by 50 per cent instead of 100 per cent.

**The absolute humidity** is expressed in grains per cubic foot, or by the pressure in inches of mercury. The hygrometer measures the amount of water vapor.

**Ozone** has powerful bleaching and disinfecting properties. By reason of the weak condition of the molecular structure it is a much more active oxidizing agent than oxygen, and this fact in part accounts for the amount observed in the air near the ground and for the almost total absence of ozone for the air over large cities, where decaying organic matter exists at all times in comparatively large quantities, the ozone rapidly entering into chemical union with whatever is in the process of decay. Ozone in the minute quantities found in nature is healthful, but the quantity is not large that will cause the death of an animal confined in the air containing it. It may be that the invigorating effects of the crisp air of a frosty morning, and of the air of the cold waves of winter, are due in part at least, to the ozone and electricity in the air; and may not the healthfulness of certain air be due to the increase with elevation of the ounce of ozone or the absence of ozone and the ozone due to the lesser quantity of ozone and the ozone due to the lesser quantity of the ozone and the ozone due to the lesser quantity? Sea air also is rich in ozone and efficient in dust and noxious germs. The maximum daily amount greets the early riser; ozone is present in greatest quantity between 4 and 9 A.M., and in winter the amount is greater than in summer.

**Dust in the Air.**—Dust rains into the atmosphere from outer space, and meteorites that are consumed through the heat generated by striking into our air contribute to the supply. Other sources are volcanoes, combustion, salts in the spray of the ocean and small particles of matter lifted up by the winds.

A recent research by Humphrey shows that each of the important volcanic eruptions since 1750 have effected a cooling of the earth's temperatures through the action of dust shot into the upper air and wafted about the earth. It is shown that the ratio subsisting between the size of the dust motes and the wavelength of solar and terrestrial radiations reflects back into space more of incoming than is intercepted out-going heat from the earth. Each important eruption has affected the temperature of the earth and color of the sky for a considerable period of time.
that the sun; with an absolute temperature over 20 times as high as the absolute temperature of the earth, controls the surface temperature of our planet and its atmosphere.

Sun's Heat Variable.—The number of gram-calories received per minute on a square centimeter of normal surface outside the earth's atmosphere is called the solar constant. In Abbot's refined measurements at Mount Whitney he obtained values of the solar constant varying from 1.93 to 2.14, the mean for the first two years being 2.02.

Unequal Heating of Land and Water.—The thermal effect of a given mass of heat falling upon various forms of matter differs with the substance; this is notably apparent when the matter is land, water or air. The same amount of heat will raise the temperature of a water surface only about one-fourth as much as it will raise the temperature of a land surface. Water rejects by reflection a considerable amount of the solar radiation that reaches it, while land reflects but a small part, and of that which falls upon the top layer of water much is expended in the process of evaporation and does not impart warmth to the water. Solar radiation also penetrates water to a considerable depth and is quite uniformly absorbed by the whole stratum penetrated. These conditions give to large water surfaces and the air immediately over them a much lower temperature during the day and a much higher temperature during the night, and also lower temperatures during summer, and higher temperatures during winter, than occur over a land surface of the same latitude and approximate elevation.

Ocean Temperatures.—Because of the displacement of oceanic isotherms by ocean currents it is impossible to name a definite temperature as prevailing over oceans at all places on a given parallel of latitude. But in a general way it may be stated that at the equator there is a surface temperature of 82° to 84° F., which changes less than a degree between day and night, and not over 5° between winter and summer; at a depth of 400 fathoms the temperature is 44° and unchangeable, and below 1,000 fathoms it is but little above the freezing point of fresh water—namely, 34° to 36°. At latitude 70° north the temperature has but little diurnal variation, and ranges from 35° in winter to 45° for summer; at a depth of 400 fathoms it remains steady at 32°. From this level there is a gradual decrease to a depth of 1,000 fathoms, where a constant temperature of 28° exists, and below this to the bottom there is no change.

Vertical Decrease of Temperature.—From the Paris records the mean fall in temperature per 1,000 feet up to a height of 20,000 feet is 2.4 in winter, 2.8 in spring, 2.6 in summer, 2.5 in autumn and 2.6 for the year. From the Berlin records it is 3.1 winter and spring and 3.0 in summer and autumn. It should be noted that the decrease is greater at Berlin, which is farther from the influence of the ocean than is Paris. In the interior of the United States it is still greater.

Isothermal Layer.—During the past 15 years the atmosphere has been explored to altitudes of from 15 to 30 kilometers by the sending up of sounding balloons equipped with suitable instruments. We find that there are two distinct strata in our atmosphere that inter-
mingle but slightly: a lower turbulent one, in which all of the ascending and the descending whirls that constitute storms and cold waves operate, and a second in which the temperature decreases rapidly with elevation; and an upper or outer one, in which there is such small change of temperature with elevation, so far as observations have reached, that it is called the isothermal layer. The lower stratum is about 12 kilometers or 7.5 miles thick, the upper one extends to limits unknown. The average temperature for summer at the top of the storm stratum is 52° C., and 8 kilometers higher in the isothermal stratum, 51°. In winter the temperatures at these two places are 58° and 57° C. Note that the temperature slightly increases with elevation in the region above storms; although we feel justified in assuming that farther out the temperature must lose with altitude until at the outer limits of the atmosphere it approaches absolute zero. The greatest altitudes reached showed about one-half the difference in the temperature between winter and summer that is found at the earth's surface.

**Diurnal Range of Temperature.** — The average difference between the temperatures of day and those of night diminishes with ascent in the free air until at only a few thousand feet from the surface of the earth (3,000 to 5,000) there is no difference between the heat of midday and that of midnight. The diurnal range of temperature is greatest at the equator and diminishes irregularly with latitude, being greater over land than over water on the same parallel.

**Annual Range of Temperature.** — The annual range of temperature increases with latitude for the interior of continents and least for islands and near the oceans. It decreases with gain in elevation in free air, being about 7° C. at 18 kilometers about the earth.

**Frosts._** As previously explained, a given quantity of heat being absorbed by different substances of unequal specific heats will produce a different temperature in each; the lower the specific heat of a substance the higher will be its temperature; and besides different substances have different coefficients of absorption and reflection. Therefore, under the same insolation rocks, clay, vegetation and other substances come to temperatures that differ by many degrees. The air next to earth largely partakes of the temperature of the surface, and in consequence when the sky is clear so that incoming and outgoing radiations may progress freely and the air is little disturbed by wind, wide variations in the temperature of a thin stratum of lower air may occur over adjacent plots of ground of precisely the same elevation, but different covering, and frost form. Difference in elevation may also cause marked differences in minimum air temperatures where the surface covering is uniform and frosts of varying degrees of intensity occur. During clear, cool nights with light winds, frosts will occur in bogs or on low, damp ground, while in the surrounding uplands the temperature may be 10° to 20° higher.

**Atmospheric Pressure.** — The attraction of gravity of the gases of the atmosphere causes them to exert a pressure on the surface of the earth. The average pressure at sea-level is about 14.7 pounds per square inch. If we re-

move the air from the inside of a vessel by means of the air pump or otherwise, then the external pressure becomes at once apparent. This pressure is in all directions, upward as well as downward, and is measured by the mercurial barometer. See **Barometer**.

To get the true pressure of the air it is necessary to apply corrections for temperature (32° F. is the standard), gravity, which varies with latitude, and instrumental error; and when these corrections are added to the barometer readings from several stations to be compared it is required to reduce them to what they would be if the stations all had a common level. Usually they are reduced to sea-level by adding to each the inches of mercury equivalent in weight to the column of air between the barometer cistern and sea-level. This is the pressure usually entered on weather charts.

**Isobars.** — In order to present graphically the distribution of atmospheric pressure on the earth's surface it is customary to draw lines through points having the same sea-level pressure. These lines are called isobars.

**Barometric Gradient.** — The distance between isobars shows the steepness of the barometric gradient. The unit of horizontal distance usually employed is the distance of 1° on a meridian. Thus, if the difference in pressure between two points is one inch and the distance between them is equal to the length of 10° on a meridian the barometric gradient is 0.1 of an inch.

**Distribution of Pressure.** — The average of all the pressures of the year show belts of high pressure at about latitude 35° north and south, and a belt of low pressure at the equator, all of which move north and south appreciably with the annual march of the sun.

W. J. Humphreys computes the vertical temperature gradient to be as follows:

There is a close relation between temperature and pressure. If one takes the average pressures for all the warm months and those of all the cold months it will be found that the continents have low pressures in summer and high pressures in winter, and that the intensity of the low and of the highs will bear a definite relation to the size of the continent area and its distance from the equator. These conditions are reversed on the oceans, the low occurring in winter and the highs in summer. The heat of summer raises the land to a higher temperature than it does the water. The air expands, rises and overflows to the ocean, leaving a deficient pressure on the continent and an excess on the seas. In winter the land loses heat much more rapidly by radiation.
Cyclones.—The cyclone, or low pressure, is a system of spirally inflowing winds which ascend in the region of the centre, cool by expansion with gain in altitude and usually cause precipitation in the form of rain or snow. At or below the heights of the wispy cirrus clouds the air flows outward, and at some more or less remote place moves downward in the form of an anti-cyclone. Storms move eastward in the middle latitudes and westward in the tropics, and rotate counter-clockwise in the northern hemisphere and in the opposite direction in the southern hemisphere. While the velocity of gyration may be anywhere from zero to 100 miles per hour, depending upon the steepness of the barometric gradient toward the centre, the velocity of translation of the whole whirling mass usually varies from 20 miles per hour in summer to 40 miles in winter.

Anti-cyclone.—In the anti-cyclone all the movements of the cyclone are reversed except the direction of translation. The air flows downward near the centre and spirally outward along the surface of the earth. It usually is accompanied by clear, cool and settled weather, and this notwithstanding the fact that the air heats by compression as it descends, which apparent inconsistency will be explained in the paragraph on Cold Waves.

Origin of Storms.—Any flowing together of the air between two anti-cyclones must produce a cyclone, and it has been shown that the unequal heating effects of land and water surfaces may be sufficient to initiate cyclonic and anti-cyclonic action.

A hypothesis to account for the beginning of storms that is attracting the attention of meteorologists, assumes that the earth, at times, passes through shafts of extra solar heat, which expand the air at the equator more than they do at higher latitudes, causing the atmosphere at the equator to bulge up until masses at high levels gravitate toward the poles. These masses cool by expansion and by radiation, gain in specific gravity and sink to the earth in the middle latitudes or the north part of the temperate zone. As they come down they rotate in an anti-cycloonic manner and constitute cold waves. Each descending mass forces the ascent of cyclonic whirls or storms on either side. The storms thus formed may move eastward for great distances and over land and oceans before being disintegrated. According to theory these extra heat shafts from the sun may persist for months and return to affect our weather with each 25-day rotation of the luminary. An allowance of 18 days is made for the air to perform the overhead circulation from the equator after each heat impulse before the cold wave appears on our western border. According to this hypothesis these cold masses should settle over land in winter and over oceans in summer, which agrees with observed fact.

Abbot's researches have shown much of the varied character of solar radiation. With a continuation of his work and of that of Kimball, of the Weather Bureau, whose investigations were begun and continued for many years under the direction of the author, the time may come when the general character of seasons may be foretold.

Temperatures of Cyclones and Anti-cyclones.—According to Ferrel and other early
students temperature is supposed to be arranged systematically about the centres of cyclones and anti-cyclones. We now know that such is not the case, that the cyclone as a whole is not a warm area, nor is the anti-cyclone a cold area, but that the rising temperature occurs on the western side of the high area and on the eastern side of the low area, and that the falling tempera- 

ture is on the western side of the low area and on the eastern side of the high area.

Hurricanes.—The hurricane of the West Indies is the same as the typhoon of the Philippines and the China coast. The ordinary 

cycnostic storm that crosses the United States is about 1,000 miles in diameter. The hurricane is a cyclone usually of only about 100 to 300 

miles in diameter, but with a gyrostatic velocity far in excess of the storms of the temperate latitudes. It occurs in the tropics, moves west- 
ward and northeasterly at the rate of only 7 to 12 

miles per hour, while the air inside of the storm may be whirling at the rate of over 100 

miles. At latitude 26° its path recurves in the form of a parabola, and the storm passes to the northeast. They occur mainly in the four months July to October.

Tornadoes.—The tornado also is cyclonic in its movements, but instead of being 1,000 miles in diameter like the continental cyclone, or 100 miles like the tropical hurricane, it usually has a diameter of gyration of only about 100 to 300 yards, and its speed of rotation is so terrific that no instruments have ever held together long enough to measure its velocity, which must equal or exceed that of a rifle bullet, as the writer has seen wheat straws that were shot by the wind of a tornado one-half inch into the tough body of an oak tree, and a two by four pine scantling driven through five-eighths of an inch of solid iron. As a rule they occur in the spring of the year, in the southeast quadrant of a cyclone, when the temperature and humidity are high. Their direction nearly always is toward the northeast. They occur with the greatest frequency in the States bordering on the Mississippi River.

Thunderstorms.—The thunder storm turns about a horizontal axis instead of a vertical one, as in the case of the tornado. On land thunderstorms occur most frequently at specified hours of the day or night, such as 3 to 5 in the afternoon or 9 to 10 in the evening, and sometimes even at 2 or 3 in the morning, but no such periods are observed over the ocean. They occur at any hour of the day or night with equal frequency. In regard to the electrical phenomena of the atmosphere it is not safe to hazard definite statements, but possibly auroras are due to earth-captured solar electrons, while the lightning of a thunder- 

storm owes its origin, chiefly at least, to the 

electrical separation produced by the action of wind on raindrops.

Cold Waves.—The area and intensity of cold waves depends upon the size of the con- 

tinents and their latitudes. The interiors of North America and of Siberia experience more severe cold than occurs at either pole. Departures from the normal tempera- 

ture of a time and place are due to the dynamic heating and cooling of the air through its upward and downward motions below the six or seven-mile level. Air heats by com-
pression at the rate of about 1° for each 700 feet of descent in the anti-cyclone, but heating induces clearness through the evapora-

tion of clouds and allows a rapid loss of heat by radiation. And then the temperature of the air before it starts on its downward journey is so low that no ice remains, and that the falling tempera-

ture is on the western side of the low area and on the eastern side of the high area.

Warm Waves.—In summer there are periods of stagnation in the drift of the air 

and the lows. At such times if a high stagnantly rests over the south Atlantic Ocean be- 

tween Bermuda and the coast of the United States and a low over the northern Rocky Mountain region, there will result what is popularly known as a warm wave, for there will slowly and steadily flow from the high to the low, where the pressure is greater, toward the northwest, where the pressure is less, and receiving constant accretions of heat from the hot, radiating surface of the earth, finally become abnormally heated. This superheated condition continues until the high over the ocean dies out or drifts away. Consult Bus-

rel, William, ‘Treatise on the Winds’ (New 

York 1893); Flammarion, ‘Thunder and Lightning’ (Boston 1906); Hann, ‘Lehrbuch der Meteorologie’ (3d ed., New York 1912); Moore, ‘Descriptive Meteorology’ (New York 1912); Moore, ‘Practical Exercises in Elementary Meteorology’ (Boston 1899).

Willis Luther Moore

Professor of Meteorology, George Washington University.

METEOROLOGY. Marine, differs from that of land areas chiefly from the fact that the rays of the sun penetrate more deeply into the ocean substance than into the land and that diffusion of this heat through the water is not of the same uniformity. An example of this is seen in the climate of the British Isles, Ireland particularly, where the prevalent west winds coming from the great ocean area temper the climate to a remarkable degree. It is a fact notable in connection that in the approach of winter the northern hemisphere, when the frost line of the land areas has reached as far south as parallel of 38° N., on the ocean areas it is at 65° N. Ocean storms are generally more severe than land storms, but exhibit a close approximation to theoretical form and progress can be much more accurately forecast. Consult McCadie, A. G., ‘Principles of Geography’ (Chicago 1917); Moore, Sir J., ‘Meteorology Practical and Applied’ (London 1910).

METH. See MEAD.
METHANE—METHODIST CHURCHES OF THE WORLD

METHANE, CH₄, also known in the impure state as Marsh Gas, or Firedamp, is found in large quantities in the gases evolved from petroleum seeps, oil springs and mud volcanoes. It is present in stagnant pools (hence the name marsh gas) and in certain localities where organic matter is allowed to decay in a limited supply of air. The firedamp of coal mines is methane mixed with a small percentage of carbon dioxide, nitrogen and oxygen. Enormous quantities of methane are present in the burning gases that constitute the “Holy Fire” at Baku in the neighborhood of the Caspian Sea. Methane is formed in the fermentation of compounds like cellulose, milk sugar or calcium butyrate, in the thermal decomposition of alcohol, ethene, ethylene or acetylene and in the dry distillation of vegetable matter. Illuminating gas, produced by the destructive distillation of coal, may contain as much as 40 per cent of methane by volume.

The compound may be prepared in a fairly pure state, (1) by treating commercial aluminum carbide with water; (2) by the interaction of hydrogen and an oxide of carbon at 250° C., in the presence of finely-divided catalysts like cobalt, nickel or iron; (3) by heating a mixture of fused sodium acetate and dry soda-lime; (4) by the interaction of carbon bisulphide, metallic copper and hydrogen sulphide at an elevated temperature; (5) by maintaining charcoal from sugar in a stream of pure, dry hydrogen at 1.150° C. Chemically pure methane has been prepared by the reduction of methyl iodide. In this process the iodine is mixed with equal volumes of alcohol and treated with the zinc-copper couple.

Methane is a colorless inodorous gas with a density = 0.559 (air = 1). It burns with a faintly luminous flame and with the evolution of much heat. Mixed with air or oxygen in certain proportions and then ignited it explodes violently. It forms methane with 9.5 volumes of air an extremely explosive mixture.

On account of its low boiling point methane was for a long time known as one of the permanent gases. It was liquefied by Calliet in 1774, and it is colorless, boils at -164° C. and solidifies at -185.5° C. when the pressure is diminished to 80 millimeters.

Methane is a saturated compound and is extremely stable. Reagents like fuming nitric acid, strong sulphuric acid or phosphoric anhydride have practically no action upon it even at elevated temperatures. In the presence of chlorine, bromine or fluorine, methane undergoes a chemical change by substitution, i.e., by the replacement of one or more hydrogen atoms by the equivalent atoms of the halogen. Long contact with chlorine, for example, even in diffused daylight and at ordinary temperatures, will convert methane into CH₂Cl (methyl chloride), CH₂Cl₂ (methylene chloride), CH₂Cl₃ (chloroform) and CH₄Cl (carbon tetrachloride), a molecule of hydrochloric acid being evolved with the introduction of each atom of halogen. At temperatures not lower than 1.300° C. methane has been completely decomposed into carbon and hydrogen. With a mixture of nitrogen and hydrogen in the electric arc it has been successfully converted into hydrocyanic acid. Patents have also been taken for the oxidation of methane (under the catalytic action of tan bark) into formic acid, methyl alcohol and formaldehyde. See Gases in Mines and Coal.

METHODIST CONCERN. See Methodist Churches of the World.

METHODIST CHURCH (SOUTH). See Methodist Churches of the World.

METHODIST CHURCH UNION. The Methodist Episcopal Church was divided in 1844 by the subject of slavery. This led to the formation of the Methodist Episcopal Church, South. Beginning with a conference at Cape May, in 1876, several attempts have been made looking toward union. The General Conference of the Methodist Episcopal Church, South, appointed a commission in 1914. The next General Conference of the Methodist Episcopal Church which met at Saratoga, N. Y., in 1916, also appointed a commission. The commissions have held several meetings together but have not yet arrived at conclusions. The bond between the two denominations is very close. They have already united in some of their mission work, especially in education and publication. Many leaders of the Methodist Protestant Church look forward to the time when their body will also be included in the union. The combined membership would be in excess of 6,000,000. In the meantime the three largest groups of colored Methodists including the African Methodist Episcopal Church, the African Methodist Episcopal Zion Church, and the Colored Methodist Episcopal Church, have taken the preliminary steps leading toward union in 1924. They hope that the negro members of the Methodist Episcopal Church will unite with them. The total combined membership of the four groups would be more than 3,000,000.

METHODIST CHURCHES OF THE WORLD. A group of 25 organized bodies which represent an evangelical type of the Christian religion, and which, rising under the Wesleys in England, in the 18th century, has spread to all countries and has become one of the great Christian Communions.

History of English Methodism.—The rise of Methodism was on this wise. John and Charles Wesley, clergymen of the Church of England, as their father was before them, formed, 1729, at Oxford University, with others, a club for the promotion of personal religion. Being very earnest young men, they proceeded to draw a series of rules of conduct, which were somewhat strict for the times, and observed so carefully that they were called in derision, “Methodists,” and their little company was termed the “Holy Club.” They prayed much, read devotional books and visited the sick and unfortunate. The age was one of laxness in religious observance and of indulgence in gambling, drinking and other vices and immoralities, which invaded church circles. This tended to deepen the earnestness and enthusiasm of the young reformers and a revival was the natural outcome, the sweep and influence of which no one of the period could have imagined. Three men of remarkable power were at the head of the movement, John Wesley (born in 1703), preacher, leader, organizer, author, indefatigable worker; Charles Wesley.
Methodist Churches of the World

(born in 1707), pupil orator, unequalled hymn writer; George Whitefield (born in 1714), evangelist, whose fiery zeal and persuasive eloquence won tens of thousands on both sides of the ocean. All of them were pre-eminent as the religious experiment passed through several stages, the last of which was in 1734, when at a Moravian meeting in London, he felt his heart strangely warmed. The next year he began to organize converts into societies, which was the actual epoch of Methodism. Opposition in the Church of England, which closed its churches to him, compelled him to resort to open-air preaching which multiplied his hearers and made the movement a people's movement. The preaching was clear, direct, simple, setting forth the doctrine of a free, full, present salvation from sin by faith, and presenting the religion of the heart rather than of the head. The Wesleys never severed their relation with the Church of England, nor abandoned its doctrinal and ecclesiastical systems. Methodism in England was a movement within the Church, to which the societies looked for the sacraments until after the death of the founder.

The Methodist system was a gradual development out of the conditions which formed Wesley to take steps contrary to his High Church ideas. Consociated places being shut to Methodist meetings, he had to build chapels and hold services in schools, private houses and barns, and in the open air; ministers being too few to do the work, he called to his aid laymen; societies increased so rapidly that it was necessary to plan for their care, hence the annual conference; changes in appointments being necessary, the itinerancy was developed to regulate them. Other distinctive features of Methodism, the class meeting for testimony and prayer; bookrooms for the publishing and sale of a growing body of denominational literature, and the conference study for the training of preachers not college bred, were likewise in answer to the demand of a rapidly expanding propaganda.

British Methodism did not, after the death of John Wesley, escape the fate of division. Indeed, radical doctrinal differences developed between him and Whitefield, and a separation took place, the latter being a pronounced Calvinist and the former a strong Arminian. One cause or another brought a number of separations, with 9 or 10 different branches. By the process of union several of these have disappeared and there are now five distinct bodies, not including the Welsh Calvinistic Methodist Church which affiliates with the Presbyterian churches.

1. Wesleyan Methodist Church.—John Wesley dominated in absolute fashion the organization he had created, until the success of the American Revolution compelled recognition of the independence of the societies in the United States and in England, as long as he lived. He held both property and patronage, but in anticipation of his death (1791), he prepared a Deed of Declaration which constituted 100 of his members, selected by himself, to hold the Church property and provide for the annual appointment of the preachers. Thus was distributed the large powers which he had held in his own hands and which he was apparently unwilling to entrust to any individual as his successor.

The first Wesleyan Methodist Conference was held in 1744, when Wesley counseled his preachers and a few clergymen who tendered his work, and rules were adopted for the benefit of the societies and the preachers. Later separate conferences were held in Ireland, which Wesley had first visited in 1747, and in America, in 1775, with whom he had been sent in 1769. In 1770 there were upwards of 29,000 members and probationers in the British societies, and at the time of Wesley's death 71,568. This success had not been obtained without a great deal of hard labor, in which Wesley himself was the chief, continually preaching, preaching at all hours of the day and night, and enduring besides the natural discomforts of his journeys and exposures of quay, abuse and even mob and individual violence.

After his death the Conference was at first on the question of the administration of the sacraments. At its session in 1792, it prohibited them, removing the prohibition in 1793 and subsequently providing for them, and later shifting the ordinance of ministers. In the Nineteenth Century, Higher Church Bodies were formed and other denominational enterprises instituted. There are two colleges, Wesley, at Sheffield, and Queen's, at Taunton, a theological college in four places. Lay members were admitted to the Conference in 1855. Beside the annual Conference in England there are conferences in Ireland, France and West Africa. The Church has in Great Britain (1917) nearly 492,000 members and probationers, and in other conferences and its foreign missions, 361,956; in all, 853,985. Methodism was intensely missionary in its spirit, by which has been carried to the ends of the earth. Wesley's first missionaries were sent to the African colonies and next to the West Indies. In Missions in Africa and Ceylon were begun 1811 and 1813, respectively. Now the missions of the Methodist bodies of Great Britain, Ireland, and Australasia are in all the countries some of the earlier and most notable successes being in Fiji and other South Sea islands, for which savagery was banished long ago, and the various missions reported to the Ecumenical Methodist Conference in 1911 a total of $2,540,000 in income for foreign missions which are in the countries of the East Asia, Africa, South America and the West Indies.

2. Primitive Methodist Church.—The body of this body in 1810 was due to the cooperation by the Wesleyan Conference of meetings which Lorenzo Dow, an American preacher, had introduced in England, and its exclusion of Hugh Bourne as a candidate for promoting them. The Primitive Church was the largest of the branches which have separated from the original body, having 197,205,217 members. It gives a large place to the men in its government. Hartley College, Newcastle, belongs to it.

3. United Methodist Church.—The result of a union of the Methodist New Connexion formed in 1796 by Alexander Kilham, who was excluded from the Conference for a determined opposition to what he called the despotism...
METHODIST CHURCHES OF THE WORLD

the Conference; the Bible Christians, formed in 1810 by William O'Bryan (who had been excluded as a layman) to give more power and opportunity to laymen; and the United Methodist Free Churches, which was itself an organization into which had been merged (1837) several bodies known as "Protestant Methodists," "Wesleyan Methodist Association," "Wesleyan Reformers" and others, all arising out of disciplinary processes by the original body. The Church resulting from the union of 1907 numbered... 4. Wesleyan Reform Union.—A small body of 8,770 members, continuing the organization which refused to enter the union of 1851. 5. Independent Methodist Churches.—There are 146 of these churches, which are congregational, or independent, with 391 ministers and 9,298 members. These four bodies have in all 405,949 members. Adding the 853,398 Wesleyan Methodists gathering in 259,307 meetings for the British group, with 6,263 ministers and 16,955 churches. The British group, together with the Australasian, constitutes the Eastern Section of the Ecumenical Methodist Conference, the Western Section being composed of the churches and the Methodist Church of Japan, which was organized of mission churches of the Methodist Episcopal Church, the Methodist Church of Canada and the Methodist Episcopal Church, South. The Conference meets decennially and is represented in the intervals by an Ecumenical Commission. Methodist in Australasia.—British Methodism was early planted in the Australasian colonies, the first church in that continent having been formed in 1816. Most of the British branches came in process of time to be represented there, but a union movement which began in 1896 in New Zealand and spread to Australia resulted in a merging of all branches in 1902, save the Primitive Methodists of New Zealand, who maintained a separate existence. There are two bodies: 1. Australian Methodist Church, a body of 149,878 members, with 985 itinerant ministers (1917). It has a General Conference, and missions among the Aborigines and the pagan South Sea Islanders and in India. It is also active in education. 2. New Zealand Methodist Church.—This body has 24,730 members, with 196 ministers. It maintains missionary zeal and promotes education. Methodist in America.—The largest group of Methodist churches is that of the United States, consisting of 16 bodies, to which must be added two bodies for Canada and one for Japan, all constituting the Western Section of the Ecumenical Methodist Conference—19 bodies in all, with 8,622,395 members. 1. Methodist Episcopal Church.—Immigrants from Ireland and England brought Methodism to the American colonies. The first to land, so far as records go, were the Methodists, who had settled in Ireland, and who came thence to America to engage in linen-weaving. The head of the group was Philip Embury, a local preacher, and their class-leader. They arrived at New York in August 1760, probably held meetings occasionally, but formed no society, so far as the record shows, until 1766 when Embury began to preach regularly and formed what was known as the "first Methodist society in America." Two years later the "first Methodist church in America" was built and opened. The third building occupies the original site, and John Street Methodist Church, New York City, is the oldest Methodist society in America. About the same time, as the historical statement of the Methodist Discipline has it, Robert Strawbridge, a local preacher from Ireland began to preach and form societies at Sams' Creek and vicinity, on Long Island, Md. A log chapel was built soon after. Some claim that the Maryland beginning was prior to that of New York. The matter is in controversy. In response to urgent letters from New York, Wesley sent over (1769) two preachers, Pilmoor and Boardman, to help the "brethren in America." These were followed by others, including a young Methodist preacher from England, Francis Asbury, who arrived in Philadelphia in 1771. All the other men sent by Wesley returned to England after the outbreak of the Revolutionary War; but Asbury threw in his lot with the Americans and remained to spread Methodism from Georgia to Canada and to the regions beyond the Alleghenies. He organized a book of discipline for their regulation, and administered it with fidelity and firmness. The founder of American Methodism had qualities as a leader and organizer as great, in some respects, as those of Wesley himself, to whom he yielded nothing in zeal, devotion and capacity for work. No man of his time knew the cities, towns and frontier settlements better than Asbury, who held a firm grip of preachers and societies through the formative period, from the time of his arrival in 1771 to the day of his death, 21 March 1816. When he came, 316 Methodists were reported for the American continent; when he died, the number had reached 214,235, surpassing by several thousand the strength of the mother Church in England. New York, Philadelphia and Baltimore were the early centres of the new denomination; but the greater work was done in the country districts, which, covered with a system of circuits, brought groups of small societies under the care of preachers and multiplied the power of the humble itinerants. An important conference was held in Philadelphia in 1773, with 10 preachers, all Europeans, all of the lay order, present. It acknowledged the authority of Wesley and his conference, accepted the doctrine and discipline of British Methodism, forbidding, in loyalty to Wesley, the administration of the sacraments, for which Methodists must look to the Episcopal churches. Opportunities for this were few, and Asbury's iron hand could not always enforce obedience to this rule. Unordained preachers, selected from among converts who had "gifts and graces," served the societies for the next 10 years, there being none others, and none with power to ordain. After the new nation was recognized, the Church was organized in 1816. A conference of the preachers in Baltimore late in December 1784, a letter was presented from Wesley saying that as the colonies were now independent, both in civil and ecclesiastical matters, he deemed it necessary that the Methodist societies, long deprived of the ordinances, should have them and should have their own
form of government. Having failed to secure ordination for any one from the bishop of London and having for some years been convinced of the necessity of having bishops of the same order, and therefore have the same right to ordain, he had appointed Thomas Coke and Francis Asbury to be joint superintendents in North America. Upon Coke, already a presbyter of the Church of England, he had laid hands in a ceremony of ordination or consecration. The General Conference proceeded to organize the Methodist Episcopal Church, with doctrinal standards, including 25 articles of religion, adopted from the 39 articles of the Church of England, and a discipline. It elected Coke and Asbury as superintendents, or bishops, defining their powers and duties, and Coke ordained Asbury deacon, elder and bishop. This action of the Conference had the effect of settling the controversies which had distracted the societies over the administration of the sacraments, and it provided for ordained men, at a time when such were few and far between, even in the older denominations.

From this time on the Church grew in numbers; annual conferences were created, the itinerancy firmly established, a publishing house set up for denominational literature, schools opened, provision made for training ministers in a course of conference study, and the institutions of an aggressive denomination, including a Church press, home and foreign missions, Church extension, a fund for superannuated ministers, etc., gradually developed.

The peculiar features of the Methodism of Wesley were also those of the Methodism of Asbury: itinerant preachers, whose appointments were changed every year or oftener, then every three years; local preachers; local churches; itinerants whose ranks the itinerants were recruited; class-leaders for 12 or more members, for prayer, testimony and advice; probation for six months for new converts; Gospel preaching of a fervent type designed to convict of sin and bring repentance and faith in Christ for salvation and sanctification; a ministry of two orders, deacon and elder, and circuits connecting several societies under one preacher. American Methodism differed from English Methodism in its conference system—quarterly, for the societies, held by the presiding elder; district, for all the societies under the care of the presiding elder; annual, for the itinerants, and general, for legislation and administration and judicial decision; bishops for the whole church, not diocesan, but itinerant. The General Conference, characteristic of all branches, meets once in four years. Lay delegates were admitted in 1872. They equal in number the ministerial delegates.

Its missionary enterprise has been wide and extensive. It had from 1819 to 1905 one society for home and foreign missions. Since the latter date, it has had a Board of Foreign and a Board of Home missions and Church Extension. The home operations include all classes of population, English and foreign-speaking, also Indian and Negro. For the work the expended in 1917, including the Woman's Home Society, was more than $2,400,000. The Foreign Board, together with the Woman's Foreign Society, expended in 1917 $3,716,000. The foreign work, is in Europe—Russia, Finland, Scandinavia, Germany (two annual conferences), Austria-Hungary, Bulgaria, Switzerland, France and Italy—aggregating 74,488 communicants; in Mexico and South America, 18,422 communicants; in India, Burma, Malay and the Malay Peninsula, 270,046 communicants; in Japan, China and Korea, 82,424; and in Africa, 20,332.

The grand total of Foreign mission communicants is 475,212. The growth of the Church in the United States was almost without parallel. At Asbury's death in 1816 it had 214,235 members; at the end of 1916, 100 years later, it had had, including missions on all continents, save Australia, 4,128,004, notwithstanding losses by repeated division, with 20,503 itinerant ministers, 13,239 local preachers and 30,738 churches, with 4,579,029 in its Sunday schools, and 596,628 in its Epworth Leagues, not including junior members. The estimated value of its church and parsonage property was upward of $250,000,000. Its universities, colleges, seminaries, academies, etc., are numerous, strong, well-endowed and prosperous. Its hospitals, homes for aged and children have come into existence in the last half-century, and are found throughout its boundaries. It is a polyglot Church, having services in German, French, Bohemian, Italian, Spanish, Portuguese, Greek, Hebrew, Norwegian, Danish and other European tongues and also in various Indian dialects.

Division has disturbed the Methodist Episcopal Church almost from the first; O'Kelly led out a small company of dissentients in 1793; several organizations were formed before 1830 by withdrawing colored members; a large number were alienated in 1830 as the result of controversy over what was characterized as autocratic rule; later the slavery question became a dividing issue; resulting in a separation in 1841-43, and in 1844-45 in the largest division of all, taking away nearly half of the members reported at that time. Some of the divisions have disappeared, but of those remaining all but one, the Primitive, grew out of differences in government, administration and discipline.

2. Methodist Episcopal Church, South.—The existence of slavery in the South after it had ceased in the rest of the States, the struggle to expand it to the border States, and the enforcement of the Fugitive Slave Law sharply accentuated and divided American opinion, and inevitably drew the Churches into the controversy. Anti-slavery sentiment became vigorous and outspoken in the North and roused strenuous opposition in the South. The Methodist Church tried to repress abolition agitation in its ranks, on the one side, and to avoid complicity with the institution, on the other. When Bishop Andrew became a slave holder, through inheritance by his wife, the opposing opinions forced a solution upon the conference in 1844. The sentiment of the Northern delegates supported a resolution advising Bishop Andrew to "desist from the exercise of office" so long as he continued to hold slaves. The other bishops united in suggesting that the matter be postponed to the conference of 1848, and that meantime, the work of the bishops be so arranged that Bishop Andrew be given oversight in that section of the country where his services would not meet with objection. But this and other compromises were put aside, under the
fear that otherwise the Church would be broken up in portions in the North, and the resolution was adopted by a vote of 110 to 68. The next day the General Conference refused to say that the action was simply advisory. Thereupon Southern delegates, who had refused to allow Bishop Amory to enter a protest, and a special committee was appointed to see what could be done. This committee reported a plan of separation which was adopted by a large majority. In the event of the formation of a separate body in the South, the plan provided for the equitable division of the book concern accounts, stock, funds, etc., if the annual conferences should agree to the necessary change in the constitution; those in the South did so agree, but the Northern conferences refused. The General Conference of 1848 declared the “plan” null and void; but meantime the Southern conferences had organized the Methodist Episcopal Church, South.

The new body had in 1846 upward of 455,000 members, including 125,000 negroes. It suffered much during the Civil War, which was fought on territory occupied by it, its losses in members, white, being 112,000 in the period 1860-66; but by 1869 these had more than been made good. Small separations (see Congregational Methodist Union) in 1871, 1892, 1894, and 1896, have added more. The growth has been continuous and large, reaching 100 per cent in the 30 years ending with 1917, when there were 2,172,628 members, 7,530 itinerant ministers, 1,745,233 scholars in Sunday school, 131,129 in the two national institutions. Its membership, 17,376 churches, valued at $63,824,000. It has prosperous home and foreign missions, a full equipment of educational institutions and benevolent organizations. Since Vanderbilt University ceased to be accepted as an institution of the Church, two universities have been established, Emory, at Atlanta and Southwestern, at Dallas, Texas. There are also numerous colleges and other institutions for both sexes. The Methodist Episcopal Church, South, existed in 1861 with 5,000 members but has grown since then, with home and foreign missions which are under one administration. Its foreign missions are in Mexico, Cuba, South America, China, Japan, Korea and Africa.

In doctrine, discipline and government the Church, South, does not differ, except in a few particulars, from the body from which it separated. It gives its bishops a qualified veto over legislation they may deem unconstitutional, there is a limited lay representation in the annual conference, and probation for membership is not required. Appointment of ministers without same charges is subject to limitation to a term of years, a restriction which the Northern body removed in 1896. A joint commission of 25 from each Church is endeavoring to agree (1918) upon a plan for a reunion of the two Churches, which promises ultimate success. The feeling in the Southern General Conference (Atlanta Ga., May 1918) resulted in a nearly unanimous vote to continue the commission but there was nothing in the action to remove the deadlock on the question between the two Churches. The reunited Church would have nearly five and a half million members, with more than 28,000 ministers and 48,000 churches. The plan also provides for a merging of colored bodies in a sectional conference, with representation in the General Conference, which is to unite all the sectional or regional conferences.

3. Methodist Protestant Church.—This body was created by a general convention held in November 1830, in Baltimore, of Methodist reformers, most of whom had withdrawn from the Methodist Episcopal Church. They had advocated reduction of the power of bishops; the election of presiding elders, instead of appointment by the bishops; the admission of laymen to all conferences, and various other reforms by the leaders, including Nicholas Snethen and Asa Shinn. The new body began its existence with 83 ministers and about 5,000 members, and grew for a time quite rapidly. It admitted laymen to the general and annual conferences, and substituted presidents, elected annually, for bishops, and arranged for the appointment of pastors by a stationing committee. The anti-slavery agitation resulted in a division in a division of this Church (1858) and the creation by the Northern conferences of the Methodist Church. As a close of the war the two Churches were reunited under the original title, which the Southern branch had retained. At the reunion in 1877 there were 116,542 members. The gains in the last 25 years have not been very large. There were in 1915 about 200,000 members, with 1,410 itinerant ministers, including women, and 2,400 churches. There are publishing houses at Baltimore and Pittsburgh, missionary and other denominational societies and educational institutions. It has educational institutions in Japan, India and China, on which upward of $59,000 was expended in 1917.

4. Wesleyan Methodist Church.—Methodist ministers and members, mostly in the State of New York, who demanded the abolition of slavery and were opposed to secret societies, organized this body in 1843. It refused to admit to membership persons connected with slavery or secret societies, and rejected the episcopacy. Within two years after its organization it had 15,000 on the roll but has grown little since, having in 1916 about 20,000, with 600 ministers and about as many churches. It has a publishing house at Syracuse, N. Y.

5. Free Methodist Church.—This body was organized in 1860 by a convention of ministers and laymen, some of whom had been expelled from the Genesee conference of the Methodist Episcopal Church as the result of agitation on subjects of doctrine and practice. Free Methodists insist on non-conformity to the world, plain and simple living, oppose costly churches and emphasize the doctrine of sanctification. They have bishops, elected every four years. Their publishing house is in Chicago. The Church had in 1917 nearly 35,000 members, with 1,250 itinerant ministers and 1,175 churches. It has missions, home and foreign, and educational institutions. It raises nearly $125,000 a year for its foreign missions in China, India, Japan, Africa, the West Indies and Panama.

6. Primitive Methodist Church, the result of migration from England and Canada, and not of any division on this side of the sea. It has two annual conferences and 8,600 members.

7. Congregational Methodist Church, the outcome (1872) of withdrawals from the Methodist Episcopal Church, South, on account of ob-
METHODIST CHURCHES OF THE WORLD

jections to its system of government. A small body known as the New Congregational Methodist Church separated in 1851 from the original body. There was also a colored Congregational body, which has disappeared. The two which remain have together about 18,000 members, mostly in the South. Independent Methodist churches have dwindled to the point of insignificance.

Colored Methodist Churches.—Methodism with its fervent appeals and experiences attracted negroes from the first, both North and South. "Black Harry" accompanied Bishop Asbury on some of his journeys, and often spoke with mingled power to his own people. Asbury's attitude toward slavery was one of opposition, and he had little or no caste prejudice. Accordingly many negroes became members of the Methodist Episcopal Church, particularly in the cities of New York, Philadelphia and Baltimore. The services of white ministers was not always obtainable or satisfactory, and as early as 1787 some colored people in Philadelphia withdrew and Bishop White, Protestant Episcopal, ordained one of their number to serve them. Bishop Asbury likewise ordained, 1799, Richard Allen, a colored man, and gave him his freedom. Including 341,000 colored members in the Methodist Episcopal Church in 1917, and the various distinct colored branches, there are in all about 1,800,000 negro Methodists. The United States census of negroes in 1910 considerably reduces this number, but the Churches say the government figures are too low.

8. African Methodist Episcopal Church, organized in Philadelphia, 1816, with Richard Allen, ex-slave, as its first bishop. In doctrines, discipline and government it does not differ materially from the Methodist Episcopal Church, from which it sprang. It has been very prosperous, and under the leadership of Bishop Daniel A. Payne, who graduated from the Reformed Theological Seminary of Gettysburg College, it has made great progress. It has four universities, including Wilberforce University, in Ohio. It began foreign missions early in its history in Africa, the West Indies and elsewhere. It has 16 bishops, 5,000 ministers and 600,000 members. The United States census figures for 1916 are 552,265.

9. African Methodist Episcopal Zion Church, organized in New York City as a society for separate worship in 1796, formally as a denomination in 1820. It was the result of a desire of colored members to conduct their own worship. They built a church called Zion and occupied it in 1800. For some years white ministers served it as pastors. Then they secured colored ministers. James Varick was their first bishop. Since 1880 their bishops have been elected for life instead of for four years. It has nine bishops and a full list of denominational boards for its missions and benevolences, and several colleges. It carries on foreign missions in Africa, the West Indies and Guiana. Its publishing house is in Charlotte, N.C. The number of its members, 1915, was 569,000, with upward of 3,500 itinerant ministers and 3,200 churches. The United States census of 1916 cuts down the membership to less than 250,000.

10. Colored Methodist Episcopal Church, organized in 1870, under the auspices of the Methodist Episcopal Church, South, of ministers and members connected with the latter body, which reported nearly 208,000 colored members in 1860. Seven years later it had 54,000, the rest having gone into the various colored churches or into the Methodist Episcopal Church, which created the Freedmen's Aid Society after the war. The Colored Methodist Episcopal Church has grown rapidly, reporting in 1900 about 205,000 members, in 1917 it had 251,560 members, with 3,400 ante labor, ministers and 3,285 churches. It has colleges and benevolent societies, eight bishops and a publishing house at Jackson, Tenn.

There are minor American Methodist Episcopal Churches, beginning in Wilmington, Del., in 1813; (b) African Union Methodist Protestant, dating from 1832; (c) Zion Union Apostolic, organized in 1868; (d) Reformed Methodist Union Episcopal Church, with which these bodies have together some 35,000 members.

Methodist Church of Canada.—Methodism reached Canada both from the British Isles and the United States. The first preacher to hold services there was Laurence Coghlan, one of Wesley's preachers, who had brought the Methodist Church to Newfoundland in 1765. Methodists from John Street Church, New York, arrived in 1783, at Dr. Coke ordained in Baltimore, Md., two years later for Nova Scotia. In 1791 the New York conference sent preachers to Nova Scotia and New Brunswick. Bishop Asbury himself visited Canada in 1811. Out of these beginnings came several branches in Canada, the Methodist Episcopal, the British Wesleyan, the Primitive, the Bible Christian and others. All in name became an independent body in 1869 and united, excepting a remnant, with the Wesleyan Church in 1883. In 1874 the Methodist Church of Canada was formed by a union of several bodies, which was made complete 1903 by the merging with it of other bodies. With the exception of a small colored organization and of a few churches belonging to Methodist Churches of the United States, the Methodist Church of Canada is the one Methodist body north of the border. It has an itinerant force of 2,989 ministers and 3,782 churches. Negotiations have long been pending for the union of this Church with the Presbyterian and Congregational churches. It has been approved by the respective Churches, but has been postponed until the end of the war. The Methodist Church of Canada conducts missionary operations through one society, aided by the Woman's organization. Its foreign missions are in Japan and China, on which it expended in 1917 $850,000.

1. British Methodist Episcopal Church, a small body of colored members in Canada, one bishop, one annual conference and members.

2. Methodist Church of Japan, an independent Church organized in 1907 of missionaries and members of the missions of the Methodist Church of Canada and of the Episcopal Churches of the United States. It has a bishop, several annual conferences.
METHODIST EPISCOPAL CHURCH—METHUSELAH

METHODIST EPISCOPAL CHURCH, Board of Education of, a body organized by a committee of the General Conference of 1864 to consider the disposition of moneys raised as educational funds.

METHODIST EPISCOPAL CHURCH, The. See Methodist Churches of the World.

METHODIST EPISCOPAL CHURCH SOUTH. See Methodist Churches of the World.

METHODIST NEW CONNECTION. See New Connection Methodists.

METHODIUS, mé-thô'di-ús. See Cyril-Lus and Methodius.

METHUEN, mé-thu'en, Paul Sanford, BARON, English general: b. Corsham Court, Wiltsire, 1 Sept. 1845. He is descended from Sir Paul Methuen who effected the treaty, named after him, between England and Portugal in 1703. He studied at Exeter and joined the Scots Guards in 1864; saw special service on the Gold Coast in 1873; received a medal for bravery in the Ashanti campaign in 1874; became attached in Berlin (1877), assistant quartermaster-general Home District (1881) and quartermaster-general Egyptian War (1882); won a C. M. G. in Bechuanaland (1885); was in command of the Home District from 1892 to 1897; and commanded one of Buller's divisions in the unsuccessful attack at the beginning of the South African War to relieve Kimberley. At Magersfontein he was terribly beaten. With Lord Roberts he marched on Pretoria in May 1901. In March 1902 he was captured between Vryburg and Lichtenburg, but immediately released. His ill success in South Africa was attributed to the difficult circumstances, and he was placed over the Eastern Command after the Boer War. In 1907 he was commander-in-chief in South Africa and in 1909 governor of Natal. He received the Grand Cross V.O. in 1910 and was created field-marshal in 1911.

METHUEN, Mass., town, in Essex County, on the Spicket River and on the Boston and Maine Railroad, about two miles north of Lawrence. It was settled in 1641 but was a part of Haverhill until 1725 when it became the town of Methuen. The government is administered, as in the early days, by town meetings. It has a number of manufacturing establishments, chief of which are cotton and woolen factories, bell foundry, organ factory, knitting mills, hat factory, worsted goods and yarn factories and basket factories. It has good schools and the Nevins Memorial Library. Pop. about 14,000.

METHUEN TREATY, a commercial treaty between Great Britain and Portugal, signed in 1703 and annulled in 1835, having to do with the tariff on wines and wool. It was negotiated by Sir Paul Methuen, the British Ambassador to Portugal.

METHUSELAH, mé-thu'sel-ā ('a man with a dart?'), Hebrew patriarch. The name appears in old manuscripts also as Mathusafa
METHYL ALCOHOL — METHYLATED SPIRIT

and Mathusale. It has been variously translated as "Man of God," "Man of the Javelin," "Man of Sin," "Man of Selah." Because Selah was a title of the psalmist, these other derivations are possible. He is remarkable as the oldest man mentioned in the Bible, his age being stated in Genesis v, 27 as 969 years. According to Hebrew chronology and to that of the Samaritan version (which, however, reduces his age to 720 years), he died in the year of the Flood; but the Septuagint calculation makes him die six years earlier. Few will be found who believe that a man ever attained such an age. The most rational conclusion is that the original writer had in mind a period different from the year of 365 days. Consult Langdon, S., in 'Proceedings of Biblical Archaeology' (London 1914).

METHYL ALCOHOL. See ALCOHOL and METHYL.

METHYL AND ITS DERIVATIVES, in chemistry; this name is given to the hypothetical radical CH₃, assumed to exist in methylic alcohol and in very many other carbon compounds. Methylic forms the first of the series of alcohol radicals, the general formula of which is C₄H₄n₊₁, and gives rise to an almost innumerable list of compounds. In the year 1848 Frankland and Kolbe, by the action of potassium on ethyl cyanide, obtained a gas the composition of which agreed with the formula CH₄; now such a body may be regarded either as (1) ethyl hydride CH₂H₂, or (2) as two atoms of methyl linked together to form one molecule.

CH₄

CH₃

For a considerable time the new substance was supposed to be free methyl, that is—

CH₃

CH₂

and to be isomeric, but not identical with ethyl hydride C₂H₄.

According to the generally received views concerning atomicity (see CHEMISTRY) such a body must not exist in the free state; it was therefore in keeping with chemical theory to believe that in the moment of its liberation the atoms of this substance should combine together in pairs to form the stable molecule—

CH₃

CH₂

A few years later Frankland succeeded in preparing the same body by the action of zinc on ethyl iodide, Zn + 2C₂H₅I = ZnI₂ + 2C₂H₅. Frankland compared the action of chlorine on this supposed C₂H₄ with the action of the same gas on the so-called ethyl hydride (C₂H₂H), and concluded that the two bodies were not identical. Schorlemmer has, however, studied this action of chlorine more carefully, and he finds that the resultant substances are the same in each case. The reactions which take place between equal volumes of chlorine and of the gas C₂H₄ may be thus formulated:

1. C₂H₄ + Cl₂ = C₂H₄Cl₂ + HCl.
2. C₂H₄Cl₂ + Cl₂ = C₂H₅Cl + HCl.

The first reaction is the principal one; small quantities of the body C₂H₄Cl₂ (dichloro-ethane) are, however, always formed. The identity of the two substances formerly known as ethylene and vinyl chloride has been proved, so that we now know of only one body having the formula C₂H₄; to this substance the name of ethylene is given; it forms the second hydrocarbon in the marsh-gas, or C₂H₂-series. From these considerations it is evident that the radical methyl is known by the combination with other bodies. By the action of chlorine on certain methyl compounds the body CH₃Cl is obtained, from which again the bodies CH₃CH₂Cl, CH₃CHCl₂, and CCl₄ may be produced. The oxide of methyl (CH₃)₂O, or methyl ether, is produced by the action of sulphuric acid upon wood spirit; this ether may take as typical of a large series, in which one of the groups CH₂ is replaced by another radical (either alcoholic or acid). The hydroxyl derivative of methyl, or methylic alcohol, CH₃OH is prepared in many ways. The most generally employed method consists in rectifying the product obtained by the dry distillation of wood (hence its common name — wood alcohol or wood naphtha); but in order to obtain perfectly pure methylic alcohol it has been found necessary to prepare a methylic ether, generally methoxylic ether, decompose this by distillation with water, and dehydrate the alcohol so obtained by means of quicklime. Methylic alcohol is a colorless mobile liquid, having a specific gravity of 0.725 at 25° C.; its boiling point lies between 140° and 140° F. It mixes with water in all proportions with the evolution of heat. It burns with a clear blue flame. It is a ready solvent for fats, resins, camphor and fatty oils. The presence of a certain amount of methylic alcohol in ordinary or ethylic alcohol does not affect the use of the latter substance in many chemical operations. Such a mixture is known in commerce under the name of methylated spirit. Methylic alcohol yields by oxidation formaldehyde (CH₂O), thus CH₃OH + O₂ = CO₂ + H₂O.

Another important series of methyl derivatives consists of substances known as methyamines; these are strongly basic and are generally regarded as ammonia in which one or two hydrogen atoms are replaced by one, two or three atoms of CH₃, thus giving rise to two other groups—dimethylamines and the trimethylamines. The we know of the substances NH₂CH₃, NH₂(CH₃)₂, and N(CH₃)₃. Further, we know of such bodies as ammonium iodide and chloride, so we are acquainted with the corresponding methyl-ammonium salts N(CH₃)₄Cl etc. Methylene is a colorless gas with a sweet odor resembling ammonia. It is highly inflammable, and burns with a yellow flame. In group CH₃ may also be introduced into part of the natural alkaloids (see ALKALOIDS) evoking rise to methyl derivatives of these base. Another extensive series of derivatives are the methylenes, of large importance in the manufacture of dyestuffs.

METHYLATED SPIRIT, alcohol or spirit of wine containing 10 per cent of wood naphtha, which contains a large proportion of methylic alcohol (see METHYL). It is now used in the arts as a solvent, for preserving specimens, in the manufacture of varnishes; for burning in spirit and other lamps.
METHYLENE—METRIC SYSTEM

METHYLENE, Bichloride of, an organic compound of great value as an anesthetic. It is a liquid divided and subdivided the same like that of chloroform, and is pleasant to inhale.

METHYLENE BLUE, an aniline dye a bluish crystalline powder having a bronze-like lustre. It is used in medicine, and in malaria is given as a substitute for quinine. See Dyes.

METIS, më'tës, in ancient mythology, the first wife of Jupiter, whom he was said to have devoured, after which Minerva (q.v.) was formed within his head.

METLAHKATLA, mët-lâ-kâ'tlã, or METLAHKATLALAH, the native name of the oldest and most successful mission among the Indians of British Columbia, founded in 1857, by William Duncan, an English missionary, who developed a model community from a tribe of the lowest cannibals. A government school was opened there in 1913. Consult Archbender, K. J., 'Apostle of Alaska' (New York 1909).

METONIC CYCLE, a period of 19 solar years, after which the new and full moon fall on the same days of the year as they did 19 years before. This cycle was the discovery of Meton, a celebrated Athenian mathematician, 432 B.C. The Metonic cycle contained 6,940 days, which exceeds the true length of 19 solar years by 5½ hours nearly. On the other hand, it exceeds the length of 235 lunations, or synodic revolutions of the moon, by 7½ hours only. In the ecclesiastical calendar the number of the year in the cycle is called the golden number (q.v.). The cycle is supposed to commence with the year in which the new moon falls on the 1st of January.

METRE, mët're, the unit of length in France,—39.37079 English inches, roughly one yard 3 1/3 inches. The metre was intended to be the ten-millionth part of the quadrant of a meridian of the earth. The centimeter, the one-hundredth part of a metre or nearly 4/10ths of an inch, possesses more advantages in physics as a unit of length; it is also found very convenient for many purposes for which the English yard is employed. See METRIC SYSTEM; WEIGHTS AND MEASURES.

In music, the equalization of time in the division of a composition. The measure (q.v.) is the smallest element in metre; two measures make a section, two sections make a phrase and two phrases make a period. See Music.

In poetry, that measure of verse that determines the rhythm. It is commonly divided into feet and lines; a series of feet is a colon. See POETRY.

METRIC SYSTEM, The. In the latter half of the 17th century, the French astronomer, Jean Picard (1671), and the Dutch physicist, Christian Huygens (1673), proposed as a standard unit of length that of a seconds pendulum at sea-level on the 45th degree of latitude. This is only about six millimeters shorter than the meter now in use. Some years earlier, Sir Christopher Wren had advocated that a half-seconds' pendulum should be chosen as such a unit; this would have approximated one-half the length commonly given to the ancient cubit. In 1670, the French mathematician, Abbé Gabriel Mouton, had suggested as a length unit one minute of the earth's circumference, what is now in use as a geographical mile, and he had divided and subdivided the inch accordingly. A good Latin terminology for the various divisions and multiples. However, more than a century was to elapse before, under the inspiring influence of the spirit of innovation born of the French Revolution and its precursor, the American War of Independence, a new scientific and logical system of weights and measures was created, one which has already replaced the old and illogical systems in a great part of the world and is probably destined to become, before many years shall have passed, the universal system. In view of the opposition to any change in this direction still shown by many to-day in England and the United States, it is a strange coincidence that in the very year (1790) when the first steps leading to the establishment of the metric system were taken in France, a new system of weights and measures was offered by John Miller, to the British House of Commons, and also by Thomas Jefferson, the Secretary of State, to the House of Representatives of the United States. Jefferson's report formulated a decimal division of the various units. A still closer approximation to the metric system was present in that proposed by the inventor, James Watt, who selected as the unit of mass a definite volume of water, and provided for a simple interrelation of the units of length, area, volume and mass; he communicated this to Talleyrand.

As has been stated, it was in 1790 that the project for a new system of weights and measures was taken up by the French National Assembly. In March of that year, Talleyrand published a proposition to this effect, which he and Prieur des Vernois submitted to the Assembly. That body after referring the project to the Committee on Agriculture for preliminary consideration took it up on 8 May 1790 and on 22 August; a decree, sanctioned by Louis XVI, provided for the establishment of a new system, invited other nations to participate in the project and entrusted to the Académie des Sciences the task of determining on the unit to be employed as a standard. Some representatives from Spain, Italy, Denmark, the Netherlands and Switzerland took part in the discussion of the plan. The Académie des Sciences, in accord with the provisions of the decree, appointed a committee composed of the scientists Borda, Lagrange, Lavoisier, Tillet and Condorcet, and on 27 Oct. 1790, this committee submitted its report to the Assembly. To secure additional data, a second committee was appointed, in which Laplace and Monge were substituted for Lavoisier and Tillet. This second committee, in its report of 19 March 1791, recommended the adoption of the one ten-millionth part of the quadrant of the earth's meridian as the standard unit of length. The Assembly accepted this suggestion, and on 26 March 1791 appointed five commissions, each charged with some department of the arduous task. It was decided to make, as an exact basis of calculation, a measurement of the degrees on the meridian of Paris. The composition and attributions of the commissions were as follows:

- Cassini, Méchain, Legendre: to measure the difference of latitude between Dunkirk and Barcelona, and to compute the triangles.
2. Monge and Meusnier; to compute the bases.

3. Borda and Coulomb; for the observation of the pendulum.

4. Lavoisier and Gay-Lussac; for researches as to the weight of distilled water.

5. Tillet, Brisson and Vandermonde; for comparison of ancient measures.

On 1 Aug. 1793, the Convention passed a decree, on the proposition of Arboisat, to the effect that the use of the new system should be declared obligatory at the end of the year. In this decree the nomenclature of the system was determined. Unavoidable delays in the measurement of the arc necessitated some successive modifications, and it was not until the 11th Ventôse, An III (1 March 1795) that an approximately definite report was sent in, to be followed by the decree of 18th Germinal, An III (7 April 1795), which finally established the different parts of the metric system. Lavoisier and Gay-Lussac assisted by Le Fèvre-Curieau, and Fabbri in determining the exact weight of a definite volume of water.

The decree of 7 April ordered the continuation of the operations for the exact determination of the units, and to this end provided for 12 commissions to be named by the Committee of Public Instruction. The members chosen were: Berthollet, Borda, Brisson, Coulomb, Delambre, Huity, Lagrange, Laplace, Ménard, Monge, Prony and Vandermonde. On 16 July 1795, Borda and Brisson presented their report of the verification of the meter, but the measurement of the meridian arc, begun by Delambre and Méchain, 25 June 1792, could only be terminated in 1799. It is interesting to learn that, some years later, the work was continued in the Balsatt Islands by Biot and Arago.

As a first step in the legislative enforcement of the system, a decree of 23 Sept. 1795 (1st Vendémiaire, An IV) had provided that its use should be obligatory in the commune of Paris. The department, in the "Constitution de l'An IV (1795-96)" its principle was formally recognized. On 16 Oct. 1798 (25th Vendémiaire, An VII), there assembled in Paris a body composed of the delegates of 10 independent nations, designated to establish finally the fundamental units. The French, as is natural, were supported by the Swinden, of the Batavian Republic, who gave the conclusions arrived at, and determined the length of the meter as 443.296/1000 lines of the old "Toise de Pêrou," the latter being approximately equivalent to 6.3944 English feet. This report was adopted by the Convention 22 June 1799 (4th Messidor, An VII), and the prototypes in platinum of the meter and kilogram were presented by the Institute. They were immediately deposited in the Palais des Archives of Paris, copies being placed in the Conservatoire des Arts et Métiers, and in the Observatory of Paris, while iron meters were consigned to several foreign countries, including the United States.

It is well worthy of note, in view of the eventual adoption of the metric system that at first its progress was slow. For quite a time the people continued to cling to the older measures, and this led, under the First Empire to the promulgation of a ministerial edict, dated 28 March 1812, authorizing the employment of "transitory measures;" among which were the use of a toise (fathom) of 2 meter (the actual length of the old toise was 196 meters), of an arpent (ell) of 1.20 meters, of a buir (bushel) of 12.5 liters, and it was not until the monarch of Louis Philippe was absolutely final and decisive action was taken in the matter. The Marquis de Laplace presented to the Chamber a report, upon which was based the law of 4 July 1837, according the terms of which all weights except those established by the laws of 18 Germinal, An III and of 19th Frimaire, An VIII (7 April 1795 and 10 Dec. 1799) should be prohibited after 1 Jan. 1840. Belgium, Holland and Greece were the first countries to adopt the metric system, and before the close of the 19th century, it had become the standard with 40 nations, and had attained worldwide use in science.

Nearly a score of years before the passage of the law just mentioned, the movement for the adoption of the system in the United States had already found able advocates of the most notable being John Quincy Adams, who in a report made to the Senate, on 22 Feb. 1821, proposed that an international conference should be held to study the metric system and to provide for co-operation with France tending toward its universal adoption. In the same year two metric standards, one of platinum, were sent to the United States by Albert Gallatin (1761-1849), the first Minister to France. They were both authenticated by a certificate from the great physiciain Arago, stating of the kilogram that it differed less than 1 milligram from the original "kilogramme des Archives." In form it is a cylinder with flat bases, the edges slightly rounded. Height and diameter are nearly equal, and approximate 39.5 millimeters each. The only distinguishing mark is a faint lathe tool mark of a pen within a circle. The square mahogany box in which it was placed bore the following: engraved on a silver plate attached to the box; "Kilogramme comparé pour son Poids a l'He- lon Protyle des Archives de France, et véri- par M. Arago. Fortin fecit." Despite the assertion that its variation from the standard was but 1 milligram, it was found, when compared in 1872, with a "kilogramme des Archives," to be 4.25 milligrams light, and this finding was confirmed in 1884, when it was taken to the International Bureau of Weights and Measures at Sèvres, and compared with auxiliary kilograms known to have the same values as the kilogram of the Archives. The final determination gave the error as 4.8 milligrams. The intrinsic worth of this priceless kilogram to-day, with the metal quoted at $3 per ounce Troy, would be $3,375, while at the time it was made the value would hardly have exceeded $300.

Older than the Arago kilogram is the commitee meter, as it has been called, which was given to Mr. F. R. Hassler, later superintendant of the Coast Survey, by J. F. Traut, a deputy from the Hérmicque. It was brought by Mr. Hassler to the United States in 1805, and was a short time later donated to him the Philosophical Society of Philadelphia. Not long afterward, when Mr. Hassler...
up the Coast Survey work, the society placed this standard at his disposal, and until 1890 it served in a quadrant of the earth's meridians. Almost a half century elapsed after the proposal of a metric conference by John Quincy Adams before this project was realized. On 1 Sept. 1869, a decree of Napoleon III summoned an international conference to provide for the production of new and absolutely exact metric standards of mass and length. Fifteen nations responded to this invitation, and the delegates assembled in Paris, 8 Aug. 1870. In spite of the fearful disasters of the French armies and the consequent rapid invasion of French territory by the Germans, five meetings were held before the conference was forced to disband. The following were the 15 countries accepting the invitation of the French government to send representatives to this first Paris conference of August 1870: Austria, Ecuador, France, Great Britain, Greece, Italy, Norway, Peru, Portugal, Russia, Spain, Switzerland, Turkey, United States, and Colombia.

The project was not abandoned, however, and a second conference was called two years later, under the Third Republic, and representatives of 30 nations assembled in Paris on 24 Sept. 1872, remaining in session until 12 October of that year. Their deliberations resulted in the adoption of 40 resolutions bearing on the construction of the new standards; of these 21 especially applied to the meter and 12 to the kilogram, the remainder referring to various details of the plan to be pursued, and to the precautions to be taken for the preservation of the standards when produced, as well as for the maintenance of their invariability. A most important point was the exact determination of the alloy to be employed, and the eventual decision was that it should be one of 90 per cent platinum and 10 per cent iridium, a tolerance of 0.01 per cent in excess or deficiency being permitted. This alloy possessed at once a high degree of hardness and of resistance to chemical action, and also was susceptible of receiving an exceedingly fine finish. A main share in the task of ensuring the production of a thoroughly satisfactory amalgamation of the metals was entrusted to the chemist, Henri Sainte-Claire Deville. The first ingot made had a weight of 238 kilograms and is commonly known as the "alloy of 1874," from the year in which it was produced. This alloy, however, did not meet with the approval of the commission, although several standards were made out of it to test its qualities. It was now determined to have recourse to the skill and experience of the great London firm of platinum refiners, Messrs. Johnson, Matthey and Company, and as a result of patient effort they were finally able to offer a casting which was found by the chemists of the International Commission, and by those of the French section, to exceed the requirements; from it were made 31 prototype meters and 40 kilogram weights. The meters were sent, early in 1887, to the International Bureau to be compared with the "mètre des Archives" and also with one another. By 1889 this task had been accomplished, and on 26 September of that year the work of the International Committee was continued by the resolution of a general conference assembled at Paris. The meter and the kilogram found to be in closest agreement with the meter and kilogram of the Archives were denominated the "International Meter," and the "International Kilogram," and were deposited in the International Bureau of Weights and Measures, in a vault provided with three separate locks, the keys to which are in the possession, respectively, of the Custodian of the Archives of France, the president of the International Committee and the director of the International Bureau. The vault must not be opened oftener than once in a year, and in the presence of the three officers to whom the keys have been confided. To each of the contributing countries were given two of each of the new standards, which were all accompanied by attested certificates of comparison, two hard glass thermometers, each of which had a table of corrections in terms referring to the hydrogen scale, and a piece of the alloy cut from the end of the bar and destined to be used in testing the coefficient of expansion; each kilogram had a rock-crystal box and other requisites for its safe conveyance. The meters allotted to the United States, Nos. 21 and 27, bore corrections of +2.5 microns and —1.6 microns, respectively; the probable error of the determinations being estimated, as a result of 784 individual comparisons, at less than 0.2 microns. The two kilograms assigned were numbered 4 and 20, and had corrections in weight of —0.075 and 0.039 milligrams, and in volume of 46.418 and 46.402 milliliters, respectively. Here from 1,002 individual weighings, the error of the determinations is less than 0.002 milligrams. Meter No. 27 and Kilogram No. 20 were carefully packed and brought to this country under seal by George Davidson of the Coast and Geodetic Survey. On 2 Jan. 1890, President Harrison received them at the Executive Mansion. The seals were broken in his presence, and he gave a certificate to the effect that they had been received in good condition, and that he was fully persuaded they were the standards to which the report referred. The kilogram and meter were received July 1890, and were deposited in the Office of Weights and Measures where the meter and kilogram recognized by the President as national standards had already been placed. By a decision made by the superintendent of weights and measures, on 5 April 1893, and approved by the Secretary of the Treasury, the international meter and kilogram were made the fundamental standards of length and mass in the United States, this applying to the customary weights and measures as well as to those based on the metric units. The standards passed under the control of the Bureau of Standards on its establishment 1 July 1901, pursuant to the provisions of the act of 3 March 1901.

The International Prototype Meter is an irido-platinum bar, 102 centimeters in length. Three lines are engraved near each end of the bar; they are from six to eight microns wide, and about one-half millimeter apart, and the meter is defined as the distance between the middle line of each group, when the temperature of the bar is at 0° C. The lines used to define
the meter and its subdivisions were traced at the Conservatoire des Arts et Métiers in Paris. Within the preliminary work for the production of the new standards was in progress, in March 1875, another international conference was called by the French government, in which France, the United States and 15 other nations out of the 19 represented signed a convention on 31 May 1875, providing for the establishment and support of a permanent International Bureau of Weights and Measures, the management and control of which should be in the hands of an international committee having 14 members, each from a different country. As a site for this bureau, the French government assigned a piece of ground at Sèvres, in the Park of Saint Cloud, declaring it to be neutral territory. It was agreed that the expenses of the bureau were to be borne by contributions paid by the contracting governments, the amount being proportionate both to the population of the country and the extent to which the metric system was used there.

The routine work of the bureau is performed under the supervision of a body termed the International Committee of Weights and Measures. This in turn is subject to the control of a general conference to which all the contracting governments send delegates, and which is to meet at least once every six years. This conference is charged will all questions regarding the measures to be taken to spread the use of the metric system in the countries which have not yet adopted it, and it is also called upon to pass definitely upon any new fundamental determinations that may be proposed.

The Advantages of the Metric System and its Proposed Adoption by the United States and Great Britain.—The initial difficulty and expense incident to a substitution of the metric system for that now in use in the United States and Great Britain have been much exaggerated by many writers on the subject. There would be no necessity for a wholesale replacing of the machinery appliances now in use; all that would be needed in the great majority of cases would be to re-mark them in accordance with the metric scale, and to adjust their operations in accord with metric requirements. It has been truly said that the only machines that would altogether lose their usefulness would be those for making the old measures. It need never be necessary to change the present lathes, drills, shapers, etc., since there would be no necessity for the manufactured objects to have a particular metric size; all that would be needed would be to have them marked and listed in the metric designations of their actual size. It should be borne in mind, in this connection, that at present the sizes of parts are seldom exact unit sizes, since they are not made to conform to an arithmetical rule but to the exigencies of their practical mechanical use.

The metric system finds an earnest advocate in Hon. William C. Redfield, Secretary of the Department of Commerce. In an address at the Fifty-first Annual Meeting of the Chambers of Commerce of the United States, in Washington, on 2 Feb. 1917, he said of our present system of weights and measures that it "stands as a bar across that path to foreign trade which it is necessary that we should tread." In another

address, made before the Philadelphia Chamber of Commerce, 10 Jan. 1917, he noted that it required four pages of an official publication to describe the various kinds of bushels that exist in America, and that the Philadelphia mint buys all its supplies and common metals by one kind of weights and measures, its precious metals by another, and does all its laboratory work by a third. He cited for the establishment and support of a permanent International Bureau of Weights and Measures, the management and control of which should be in the hands of an international committee having 14 members, each from a different country. As a site for this bureau, the French government assigned a piece of ground at Sèvres, in the Park of Saint Cloud, declaring it to be neutral territory. It was agreed that the expenses of the bureau were to be borne by contributions paid by the contracting governments, the amount being proportionate both to the population of the country and the extent to which the metric system was used there.

The routine work of the bureau is performed under the supervision of a body termed the International Committee of Weights and Measures. This in turn subject to the control of a general conference to which all the contracting governments send delegates, and which is to meet at least once every six years. This conference is charged will all questions regarding the measures to be taken to spread the use of the metric system in the countries which have not yet adopted it, and it is also called upon to pass definitely upon any new fundamental determinations that may be proposed.

As one of the great merits of the system, we have the following emphatic opinion from the late Lord Kelvin (William Thompson, 1824-1907): "I believe I am not overstating the truth when I say that half the world that is in direct touch with our markets—by clerks and draughtsmen in engineers' and surveyors' offices—I am sure at least one-half of it—is work entailed upon them by the inconvenience of the present farrago of weights and measures. The introduction of the French Metric System will produce a great simplification in the business offices of all kinds—engineering, commercial, and retail shops."

The Rt. Hon. Arthur J. Balfour, replying in 1895 to a deputation advocating the introduction of the system in England, used the following words: "Upon the evidence before me I think there can be no doubt whatever that the judgment of the whole civilized world, not excluding countries which still adhere to the antiquated systems under which we suffer, has long decided that the metric system is the only rational system known."

As a step in the direction of the metric system, the decimalization of the coinage has found some favor in England recently, the present florin (a two-shilling piece) being proposed as a new monetary unit since it is exactly one-tenth of a pound sterling. The British farthing is one ninety-sixth of a florin, an exceedingly trifling reduction of its value would make of it a "cent" representing the one-hundredth part of the florin, and worth only a very small fraction less than one-half of the United States or Canadian cent. Another idea has been to add ten-pence to the value of the pound, which would then contain 250 pence or 1,000 farthings of unchanged value. A new florin, as the tenth of this new pound, would contain 100 farthings. It is interesting to note that the proposition to decimalize the British coinage by making the florin, the tenth part of a pound sterling or sovereign, a money of account, and sub-dividing it into hundredths, has for several years been essentially introduced in Peru, where
the gold *libra*, coined as an exact equivalent of the British pound sterling, is divided into 10 *shillings*, the sol thus being worth 2 cents. The price of $0.48665, or the same as the British florin. The sol is in turn divided into 100 *centavos* worth 0.48665 cent of our money.

Probably no profession would benefit to a greater extent by the introduction of the metric system than would that of mining-engineering. This is eminently an international science, and to maintain a place in the first rank of his profession the mining engineer must keep himself constantly informed as to the latest methods and improvements introduced in foreign lands. Wherever the metric system is employed, all the data on this profession are expressed in metric weights and measures. When, however, the United States engineer wishes to use these data in connection with his own work, or to compare them with those recorded in foreign native systems and machinery, he is forced to make a number of very tedious calculations before he can arrive at any exact comparisons. An approximate idea he may indeed quickly gain, but in any event, all mere approximations are practically useless.

The metric system has for some time been in exclusive use in the medical department of the United States army, and with the entry of the United States into the war against the Central empires, it was used in the manufacture of certain sizes of guns, notably in those forming to the famous French "75's," the 75-millimeter guns that have proved their superiority to the other field artillery of similar size and also of the 105 millimeter and the 155 millimeter guns. The General Chief of Staff wrote in January 1918, that it was followed in the preparation of operation orders and in map construction for the troops in France, as well as for firing data for artillery and machine guns to be used there. The artillery and machine gun material intended for service abroad was modified to conform with metric measurements.

Another step in the adoption of the system in the United States has recently been taken in the gem-dealers' industry. This concerns the adoption, in precious stone commerce, of an international metric carat of 200 milligrams, to take the place of the various and discrepant national carat-weights that have for so long been sources of serious annoyance, inconvenience and loss of time for gem-dealers. In a paper read in Chicago before the International Congress of Weights and Measures, held in connection with the World's Columbia Exposition of 1893, the writer suggested dividing the carat into 100 parts, and constituting a standard international carat of 200 milligrams, that is, 5 carats, or 20 pearl grains, to a French gram. This represented a depreciation in weight of only about 2½ per cent from the carat-weights most in use. Great credit for having definitely initiated this much-needed reform is unquestionably due to M. C. E. Guillaum, Director of the Bureau International des Poids et Mesures at Sèvres, who energetically and successfully advocated the reform in 1896 before the Commission des Instruments et Travaux, in Paris.*

Simplicity of the Metric System.—There is only one system of weights and measures in the world by means of which, if a voyager were wrecked on a desert island with only one measure, and that so small that it could be put in a lady's thimble, he could reconstruct all the measures for distance, for weight and for capacity, could map out the island, weigh up to tons and know the capacity of any receptacles he might construct. This system is the metric system, and that measure is the cubic centimeter, made hollow, and graduated on the edge in millimeters.

Having this, he could mark a stick up to a meter, dividing it into decimeters, centimeters and millimeters. This meter multiplied a thousand times would give him the kilometer—the standard measure of distance. It would also enable him to determine how many square meters the island measured, and hence how many ares (100 square meters) and hectares (10,000 square metres) it covered in area. Or, he could fill the cubic centimeter with water, which would weigh one gram, and multiplying this by a thousand would give him a kilogram, the standard measure of weight. The cubic centimeter would hold one liter of water and 1,000 milliliters would give him the liter, the standard measure of capacity.

The meter for the unit of length, the liter for the unit of capacity and the gram for the unit of mass or weight is the sum and substance of the metric system. The three units (meter, liter, gram) with the following divisions and multiples are winning their way into general use because they are best suited for practical purposes.

The prefixes from the Latin, milli; centi; deci; representing respectively a thousandth, a hundredth and a tenth, and those from the Greek, deka, hecto and kilo representing respectively 10, 100 and 1,000 may be used with any of the metric units. Investigation and experience in the United States and in metric countries, however, indicate the desirability of holding to the metric weights and measures given in the foregoing table, as these are considered sufficient and best for professional work, the industries and trade. Ten meters, for instance, is a width more readily understood than one dekameter.

The metric weights and measures were all based on the unit of length. The liter, the unit of capacity, is almost exactly equivalent to a cubic measure 10 centimeters on each edge or 1,000 cubic centimeters (cm³ or cc). As greater accuracy could be obtained by basing the unit of capacity upon the unit of mass, the definition was written as follows: "A liter is a unit of capacity equivalent to the volume occupied by the mass of one kilogram of pure water at its maximum density at a temperature of 4° C (39.2° F) and under the standard atmospheric pressure of 760 mm." One milliliter, equivalent to 1.000027 cubic centimeters of water, weighs one gram. Technically, however, the gram is one thousandth of the kilogram, which is the standard for mass or weight.

## Table of the Metric System and Equivalents

</table>

### Capacity

1 cubic inch = 16.38706 milliliters
1 U.S. fluid drachm = 0.5966 milliliters
1 U.S. fluid ounce = 29.5735 milliliters
1 U.S. dry quart = 0.9463 liter
1 British dry quart = 1.0141 liters
1 U.S. gallon = 3.7854 liters
1 British fluid drachm = 3.5515 milliliters
1 British fluid ounce = 28.4133 milliliters
1 British liquid quart = 1.1365 liters
1 British imperial gallon = 4.5460 liters

### Mass or Weight

1 grain = 0.0648 grams
1 pennyweight = 1.555 grams
1 apothecaries' scruple = 1.2960 grams
1 apothecaries' drachm = 3.8879 grams
1avoirdupois ounce = 28.3495 grams
1 troy ounce = 31.1035 grams
1 avoirdupois pound = 453.5924 grams
1 troy pound = 373.2400 kilograms
1 long ton = 1.0160 metric tons
1 short ton = 0.90719 metric ton

The equivalents given in this article are based upon the following fundamental equivalences:

- 1 United States inch = 1 meter
- 39.370079 inches = 1 meter
- 2.540062 United States centimeters = 1 meter

A quantity can usually be expressed as a whole number if the proper metric weight or measurement is used. Even when a fraction is needed to express the metric equivalent of another weight or measure, one or two figures to the right of the decimal point generally give sufficient accuracy. Equivalents such as those in the tables here given are intended to be used only to the required degree of accuracy. For example, four inches is equal to about 10 centimeters; if greater accuracy is desired 10.2 centimeters or 102 millimeters may be taken.

### Metropolitan City, Ill., city, countyseat of Massac County, on the Ohio River, here spanned by a fine modern bridge, and on the Illinois Central and the Chicago, Burlington and Quincy railroads, about 150 miles southwest of East of Springfield. It is in a healthful location built on a high bluff, with an incline towards the river. The site was selected in 1700 French, when Fort Massac was erected. Permanent settlement was made until 1843, when it was incorporated in 1843. The city has mills, basket and box factories, flour mills, jute mills, furniture and furniture factories, municipal electric light and water plant. The city is the trade centre for nearly all of Massac County and is an active shipping point along the river. The form of government is aldermanic. There are grade schools, the R. W. McCartney Public Library, the Odd Fellows Temple, a sanatorium, hall, courthouse, music-hall, several churches and recreation parks.

METROPOLITAN, the Greek name of an archbishop, whose see is that of Metropolis, the chief place of a province. The metropolitan is above the bishop, but below the patriarch. The title of patriarch, however, is in use only by Eastern churches. In Russia the metropolitan is at the head of the hierarchy. In the Catholic Church an archbishop may bear this title even though he does not have a metropolitan as a see, thus the archbishop of Westminster is styled metropolitan.

### Metropolitan Museum of Art

See Art, Metropolitan Museum of Art.
11 June 1859. He was educated at Strasbourg; when only 17 represented the Westphalian province at the Congress of Vienna in 1794; and assured himself a place in diplomacy by marrying the granddaughter of the Austrian chancellor, Kaunitz, in 1795. This marriage not only gave him entry to the best society, but brought wealth, and as at the Congress of Rastatt he represented the Westphalian college, where he served his apprenticeship in politics. In 1801 he was sent to Dresden by Austria; two years later to Berlin; there a part of his mission was to cultivate the friendship of the French Ambassador. He did this so well that that official induced Napoleon to suggest to Austria that Metternich would be a most acceptable representative at the Tuileries; and so in 1806 he was sent to Paris, where he ingratiated himself with Caroline Murat, sister to Napoleon, and with Talleyrand. On the outbreak of the war between France and Austria, Metternich was put to much personal inconvenience by Napoleon, who forcibly detained him for three years. Thereafter he entered eagerly into the anti-Napoleonic league established in the formation of the Quadruple Alliance; and as Germany proved successful, took no part in the national sentiment which arose, but directed himself solely to the aggravandizement of Austria, hence doing his best to preserve the French boundaries as they had been and to render Austria the only gainer among the powers by the reapportionment of Europe. He is credited with having planned and brought about the marriage of Napoleon and Marie Louise. In the years that followed he carried things his own way in Austria, planned the Holy Alliance and was extremely reactionary in his internal and foreign policies. In the difficult times of Napoleon's supremacy and his fall Metternich guided Austria's policies with a masterly hand. As a diplomatist he was the equal of any of his time. In 1814 he visited England and formed the quadruple alliance. He was the master spirit at the Congress of Vienna and for 15 years thereafter was the leading statesman of Europe. The Revolution of 1830 in France showed the ill-success of his program; and the rising of 1848 and the insurrection in Vienna itself made it necessary for the Emperor Ferdinand to dismiss his reign. He kept some power even then, his counsel being frequently sought. Consult Gross Hoffinger, 'Fürst Metternich und das österreichische Staatsystem' (1846); Mazade, 'Un chancelier d'ancien régime: le régime diplomatique de M. de Metternich' (1889); Malleson, 'Life of Prince Metternich' (1888); Demelitso, 'Metternich und seine äußere Politik' (1898); Sandeman J. A. C., 'Metternich, Life and Career' (New York 1911).

METZ, mēć, Germany, an important fortified city and episcopal see of Alsace-Lorraine, on the Moselle, which here divides into several arms, 79 miles northwest of Strasbourg. It is the third city of Alsace-Lorraine and has four representatives in the First Chamber of the Prussian Diet. The major part of the town stands on a hill and is enclosed by a strong wall, outside of which there is a series of strong detached forts of excessive strength. Metz is also the centre or seat of control of the group of forts which includes Diedenhofen and Bitsch. In 1912 the garrison numbered 23,000. The cathedral is a late Gothic structure, surmounted by a spire of open work 397 feet high. There are imposing public buildings. The manufactures consist of woolens, cottons, hosiery, hats, muslin, glue, leather, etc. Several battles were fought in the neighborhood and under its walls between the Germans and French in August 1870. The Germans subsequently invested the town, and, being reduced to a state of famine, on 28 October it capitulated with 180,000 officers and men under the command of Marshal Bazaine. The near-by cemetery of Chamiere holds the remains of over 7,000 French soldiers who perished here. It was included in the cession of territory to Germany at the Peace of 1871. Metz was anciently known as Divodurum, and later the Romans restituted it Mediornatica, of which Metz is a contraction. The Romans built military roads through the territory, and a fine aqueduct, of which traces remain. Attila sacked the town in the 5th century. After the retirement of the Huns, the Franks obtained control and made it the capital of Austrasia. In 870 it was included in East Francia, and developed its prosperity, increased, and in the 13th century, as a free imperial city, it attained the zenith of its prosperity. It was taken by the French in 1553. This ownership was later confirmed by the Peace of Westphalia in 1648. Thereafter it remained until 1870, with the rest of Alsace-Lorraine, a peaceable French territory. For its history in 1870-71, see France-German War. Marshal Pétain entered the city at the head of the Tenth Army on 19 Nov. 1918 amid great rejoicing. After 47 years of German domination Metz was reunited to France. Pop. 68,596.

MEUDON, mé-dōn, France, a town southwest of Paris, near the Seine, on the railway to Versailles, six miles to the west. It had formerly a fine château, built by Louis XIV, surrounded by the Forêt de Meudon, still a favorite holiday resort of the Parisians. This château was fitted up in 1812 by Napoleon I for Marie Louise, and it was a residence of the Napoleons under the Second Empire, but was ruined during the siege of Paris in 1870. An astronomical observatory has since been established in the remains of the castle. The Duchies of Galliera established here a home for the aged and for orphans, at a cost of $2,800,000. Meudon has glass-works, bleach-fields, extensive government munition works and other industrial establishments. Rabelais was for a short time curé of Meudon. Pop. of commune about 12,292.

MEULEN, me-lēn, Adam Frans van der, Flemish painter: b. Brussels, 1 Jan. 1632; d. Paris, 15 Oct. 1690. He studied under Snayers; removed to Paris; and there became court painter to Louis XIV, for whom he painted many battle scenes.

MEUNIER, mē-ne-ē, Constantin, Belgian artist: b. Brussels, 1831; d. there, 4 April 1905. He is known as a historical and genre painter as well as a sculptor of considerable power, thorough his naturalistic spirit and the revolting; and it would seem as if his studies in Madrid had brought him under the influence of Ribera and his sanguiinary school. He has produced some vivid pictures of life in the colliery district amid whose unhappy surround-
ings he has made his home. His 'Martyrdom of Saint Stephen' in the Ghent Museum is quite in the spirit of Ribera and shocks the mind by its brutal literalness. 'The Peasants' Rebellion' is an example of his energy and force as a realist in modern life. His statue 'The Lost Son' is in the Berlin National Gallery.

MEUNIER, Etienne Stanilas, French geologist: b. Paris, 1843. A student of the Paris faculty of sciences, he attained his doctor's degree in 1869 and was laureate of the Academy of Sciences in 1878. In 1892 he was appointed professor of geology at the National Museum of Natural History. He was made a knight of the Legion of Honor, and has been vice-president of the Geological Society of France. His chief publications are 'Le ciel géologique' (1871); 'Géologie des environs de Paris' (1875; rev. ed. 1912); 'Geologie récente d'Europe' (1889); 'La géologie comparable' (1895); 'Nos terrains: géologie populaire' (1896); 'La géologie générale' (1903); 'La géologie expérimentale' (1904); 'Les convulsions de l'écorce terrestre' (1910).

MEURICE, Francois Paul, frán-swá pël mé-rës, French dramatist: b. Paris, 1820; d. there, 11 Dec. 1905. He was educated at the Collège Charlemagne and entered upon a literary career. He worked for a time in collaboration with Dumas, with whom he made a translation of Hamlet, and was entrusted by Victor Hugo, his brother-in-law, with the publication of his complete works. He published 'Benvenuto Cellini' (1852); 'Fanfan la Tulipe' (1858); 'Cado' (1868); 'Césara' (1869), etc.

MEURSIES, mér-seez, Johannes Van Meurs, Dutch scholar and historian: b. Lovsduinen, 1579; d. 1639. Besides 'Glossarium Graeco- Barbarum' (1614) and 'Athenae Batavae' (1625) for his edition of Greek authors he wrote numerous introductory essays which J. F. Gronovius reprinted in 'Thesaurus Antiquitatum Graecarum.' His complete works were edited by Lami (12 vols, Florence 1741-63).

MEUSE, méz, or môz, river which rises in France in the south of the department Haute-Marne, and with a northward trend crosses the northwestern corner of the department Vosges where between Bazeilles and Noncourt it has a subterranean course of three and a half miles. It traverses the departments Meuse and Ardennes, and on reaching Sedan enters Belgium. At Namur where it receives on the left its largest tributary, the Sambre, almost doubling its volume, it changes its course to northeast, and passes Liége, where it is augmented by the Ourthe; it separates Dutch from Belgian Limburg, passing Maastricht and Roermond, at the latter of which it receives the Roer. In the northern part of Dutch Limburg its course is changed to northwest, and subsequently it becomes west. The whole of its after-course is through the Netherlands, in which it forms for some distance the boundary between North Brabant and Gelderland. It finally joins the left bank of the Waal, one of the arms of the Rhine, and gives its name to the accumulated flood of these streams, which, proceeding west through Holland proper, is divided near Dordrecht into two great rivers, the one of which bends round to the north and reaches Rotterdam; the other branch continues west; shortly after the branches again unite and discharge themselves into the North Sea. The direct length of the Meuse is 230 miles; and its length includes windings is 580 miles. It is navigable for about 460 miles. A section of the Meuse river is selected by the French government before as the location for a chain of protective fortifications, which became known as the Meuse line. The forts extend for 31 miles from Verdun to being disposed along the eastern banks of the river. The names of the forts are Verdun, Saint Mihiel, Gericourt, Troyon, Longuyon, Saint Aignant, Gironville, Jous sous les Croix, Tours. There was also constructed a series of forts from Fagny to Neufchâteau; this region saw some of the heaviest fighting of the Great War. See WAR, EUROPEAN.

MEXICALÁ, mäs-käˈla, or MECICALÁ, mäs-kälˈä, a river of Mexico, in the northern part, which has its rise in the mountains southeast of the City of Mexico, and flows generally west for 450 miles to the Pacific. It is called the Atayoc in the first part of its course, and the boundary line between the states of Michoacán and Guerrero, it is called Rio de las Balsas. The port of Zacateula is at its mouth. It is a swift-flowing stream, and has a number of low cascades and rapids.

MEXICA, Tex., city in Limestone Co. on the Houston and Texas Central and Trinity and Brazos Valley railroads, 40 miles northeast of Waco. Natural gas and oil are produced nearby and cotton and corn are extensively cultivated. The city has a bromptory, cotton mills and oil mills, city hall, road repair shops, and a public library. The commission form of government is in operation. Pop. 2,690.

MEXICAN ARCHAEOLOGY. See MEXICO—ARCHAEOLOGY.

MEXICAN HAIRLESS DOG. A hairless-like dog, of uncertain origin, with hair except a tuft on the crown of the head, another on the tail and a few scattered on the body; the skin is greasy, tough and dry. Clavijero describes a large hairless dog found among the Mexicans by the Spanish conquerors, whose puppies were esteemed for edible delicacy; and others are recorded as having occurred in ancient Peru and on the West Indian islands.

MEXICAN JUMPING BEAN. See JUMPING BEANS.

MEXICAN LITERATURE. See MEXICO—LITERATURE.

MEXICAN NUN, The, name given to: JUANA INEZ DE LA CARRA, MEXICAN POET: b. Miguel de Nepantla, near Mexico, 12 Nov. 1851; d. Mexico, 17 April 1895. She was not known in Mexico for her learning, but in the conven of San Jerónimo, after some years abandoned her studies wholly devoted to the convent, and saved her church and aid of charity. Her death occurred during a severe epidemic. Among her works are 'Poésias Sagrados y Profanas'; 'El Nido Alégorico', and the comedy 'Los Empeños Una Casa.'

MEXICAN ONYX, a stained and banded
variety of Calcite. It is not true onyx. See Calcite; Onyx.

MEXICAN SUBREGION, a faunal district of the Neotropical region embracing the low hot coast region of Mexico. See Zoogeography.

MEXICAN TEA, See Goosefoot.

MEXICAN WAR, The. The annexation of Texas in 1845 laid the foundation for the war with Mexico. Although Texas had been for many years practically free, and had been recognized by the United States, England, France and other countries, yet Mexico still refused to acknowledge its independence. When therefore the United States proposed to admit Texas into the Union, Mexico gave warning that the annexation would be equivalent to a declaration of war, and on 6 March 1845 protested, and soon afterward withdrew her Minister and severed diplomatic relations. Her acts, however, scarcely justified her threats, as at that time at least little or no preparation was made for war. It has, therefore, been claimed that had the American government used a conciliatory policy peace might have been preserved, and friendly relations re-established.

At the moment, however, the Mexican people and authorities were in a rather belligerent attitude, due in part to pride, and in part to an expectation that the United States would soon be involved in a war with Great Britain over the Oregon boundary, in which case Mexico would have a powerful ally to aid her. Did President Polk at this point seek to strengthen this hope in the minds of the Mexicans, intending at the proper moment to make a compromise and peace with England, as was done, and thus leave Mexico at the mercy of the United States? Perhaps history can never answer the question, but events at least seemed to march in harmony with the thought. For Mexico soon found herself in the dilemma that she must either sell California to the United States, receiving in return a goodly sum of money to support her pride, or engage in a war to sustain her honor and territorial integrity. Mexico bravely, but perhaps not wisely, chose the latter alternative, not fully realizing the inequality of the contestants, nor the depth of the humiliation to which she would be subjected. Designing nothing that would bring to the United States California without war; but its acquisition was to be the principal measure of his administration. Hence if war was the only means to secure it, war it must be; at least enough to get possession of the desired territory. 

Causes of the War.—The immediate occasion, however, of the war was the dispute in regard to the western boundary of Texas. Proclaiming her independence in 1836 Texas asserted that her western boundary was the Rio Grande to its source, hence due north to the 42d degree of north latitude. The following year the United States recognized her independence, and in December 1845, by a joint resolution, admitted her into the Union as a State, the boundary dispute was to be settled by the United States. President Polk accepted the boundary line claimed by Texas, and 13 Jan. 1846 ordered Gen. Zachary Taylor to march to the eastern bank of the Rio Grande as the western boundary of the United States. Mexico insisted that the Nueces River — 100 miles eastward — was the true western boundary of Texas, and therefore that General Taylor was now on Mexican soil. On 18 April 1846, the first blood was shed in a conflict between a band of Mexican troops that had crossed to the eastern side of the Rio Grande and a company of American soldiers. The news of this action was immediately communicated by General Taylor to President Polk, who sent his now noted message to Congress, asserting that war was begun by the act of Mexico on American soil. Congress accepted, after a stormy debate in the Senate, the President's statement, and war was recognized as existing.

Other causes than the two already noted were also at work, and helped to make a decision in regard to the justness of the war still more difficult. Mexico for many years had been in a chronic state of revolution. The natural result followed. American citizens in Mexico sustained property losses and doubtless were frequently unjustly arrested and even imprisoned. Claims arising from these had been in part settled under a convention of 1840; but many of them were still pending. Some were just; more, either unjust or extravagant in amount. President Polk united these unsettled claims with the boundary question, and demanded that Mexico receive an envoy extraordinary with power to settle both — on its face an eminently fair proposition. On the other hand, Mexico professed to be ready to receive an ambassador to settle the boundary dispute, but declined to receive Mr. Sliedell as our minister when commissioned to settle all disputes, insisting that the two questions were distinct in kind and origin and should not be united. President Polk in his message asserted that this action of Mexico was in violation of her promise to receive a minister, and hence justified his administration in its measures, and forced him to take possession of the disputed territory.

The need of more slave territory was perhaps another factor in causing the war. At least many from the South took an aggressive position on all questions in dispute between the two countries and thus made a peaceable settlement more difficult. Both the economic and the political reasons for more territory began to be felt by 1840 — the one to have new soil over which to spread the land-exhausting system of slavery; and the other to have new territory out of which to carve new slave States that the equilibrium between slave and free States might be maintained. Some other factor tending to arouse the war and aggressive spirit may be noted. The cry of "manifest destiny" played a part. Many, especially in the West, felt that the Pacific Ocean was the natural western boundary of the United States. They also demanded the "Golden Gate" that commerce might be opened up with the Orient. The two great parties — the Whigs and the Democrats — divided quite sharply on the question; in fact so completely that the war became almost a party, instead of a national, issue. The Democrats, as a rule, supported the administration and its claim that the war was just. The Whigs, on the contrary, asserted that it was a most unholy and unrighteous war, and characterized it as Polk's war. Lincoln, entering Congress in 1847, became a severe critic of the
policy pursued, while Tom Corwin of Ohio went so far as to use this language: "If I were Mexican, I would tell you. Have not room in your own country to bury your dead men? If you come into mine we will greet you with bloody hands, and welcome you to hospitable graves." President Polk summarized his reasons for recommending that Congress recognize war as existing as follows: "The grievous wrongs perpetrated by Mexico upon our citizens throughout a long period of years remain unredressed; and solemn treaties have been disregarded.... Our commerce with Mexico has been almost annihilated." He then adds: "As war exists, and... exists by the act of Mexico herself, we are called upon, by every consideration of duty and patriotism, to vindicate, with decision the honor, the rights, and the interests of our country."

The Campaigns. — The war with Mexico was accepted as a fact by Congress 13 May 1846. There were four principal fields of action: (1) in Texas, where Capt. John C. Frémont and Admiral Stockton were in command; (2) in California, where Capt. John C. Frémont and Admiral Stockton were in command; (3) in New Mexico, with Gen. Stephen W. Kearney leading the American forces; and (4) from Vera Cruz to the City of Mexico, under the command of Gen. Winfield Scott, the commander-in-chief of the American armies. Everywhere success attended the American arms. Perhaps it was the first war in history, lasting two years, in which no defeat was sustained by one party, and no victory won by the other.

General Taylor defeated the Mexican troops at Palo Alto 8 May; at Resaca de la Palma the following day and captured Matamoras on the 18th. He remained near that city for some weeks to recruit his army and prepare to advance into the interior. On 24 September he entered Monterey, after a siege of four days, and a gallant resistance by the Mexicans. Taylor's most famous victory, however, was won on 23 Feb. 1847, at Buena Vista. General Scott gave orders, which unfortunately fell into the hands of Santa Anna, the Mexican general, for General Taylor to send some nine regiments to aid Scott in his proposed attack on Vera Cruz. Santa Anna immediately marched his whole command against Taylor, expecting to crush him in this weakened condition. It was 20,000 men against about 5,000. But the skill of Taylor, the persistence of his army, the organization and equipment of the American troops, won a great victory. Taylor became the hero of the hour, and Buena Vista made him an irresistible Presidential candidate.

Frémont's course in California has been a subject of keen controversy. As leader of an exploring expedition he was already in northern California, and early in 1846 was recalled to the Sacramento Valley. California was the goal of the political policy of Polk's administration. The means to secure its acquisition was by acquiring territory by purchase or by filling the territory with American settlers who in course of time might bring it into the Union as Texas had already been annexed; or it might be effected by securing the goodwill of the native Californians who were already jealous of Mexican rule. The latter policy seems to have been the one adopted by the administration. The American consul at Monterey, Mr. Larned, was developing this policy with a good prospect of success, it is claimed, when Frémont appeared on the scene. He seems to have developed a fourth policy, namely, the establishment of an independent government under the control of the American settlers in the Sacramento Valley. This movement resulted in the "Bear Flag Republic", a virtual civil war between the native Californians and the American settlers. At the moment the Mexican War began and the "Bear Flag" was replaced by the "Stars and Stripes" it has been claimed by some California historians that Frémont's course, had not the Mexican War come at the moment it did, might have lost California to the United States. The native Californians, alienated as they were by course, might have put themselves under an English protectorate in revenge for the treatment accorded them. Be this as it may, by the end of the year all California was conquered and held. Along the Baja Grande, under the command of Gen. Zachary Taylor; (2) in California, where Capt. John C. Frémont and Admiral Stockton were in command; (3) in New Mexico, with Gen. Stephen W. Kearney leading the American forces; and (4) from Vera Cruz to the City of Mexico, under the command of Gen. Winfield Scott, the commander-in-chief of the American armies. Everywhere success attended the American arms. Perhaps it was the first war in history, lasting two years, in which no defeat was sustained by one party, and no victory won by the other.

Scott had been chafing in Washington during the summer and fall of 1846 while Taylor was winning his brilliant victories. He asked to go to the front to assume chief command, but the administration retained him at the capital under the plea of needing his advice. As it happened this Democratic war was offered by Whig generals. Scott had already been a Whig candidate for President. The chance was now made that Scott was kept from command for fear that success might make him a more formidable candidate in 1848. Finally, when he was sent to the front in January 1847, the army was raised that the purpose was to fill the lustre of Taylor's victories, or at least to divide the popular support between the two generals in such a way as to destroy the political prospects of both.

General Scott invested Vera Cruz in March 1847, and by the 27th had captured the fortress which had been thought to be almost impregnable, and was ready to enter the city. On 3 April he started into the interior, and on the 18th captured Cerro Gordo; the 19th, Planes, and the 20th Portezuela. On 15 May he entered the important city of Puebla. Remaining there for some weeks he again advanced, in August toward the capital, and on the 10th cast a sight of the city of the Montezuma. Important victories were won at Contreras and at Churubusco. He captured Molina del Rey 8 September, and five days later the victory of Chapultepec gave him the city of Mexico itself which he entered on the following day with an army of only 5,000 men. The war was practically over, but the victory was so complete that it began to be a question whether there was any government left with sufficient power to negotiate a treaty of peace. An agitation began with friends both at home and abroad, looking to the annexation of the whole of Mexi-
Calhoun on the one hand, Webster and a majority of the Whigs on the other, joined hands to defeat this plan. President Polk was finally forced to make the ultimate decision. N. P. Trist was sent in March 1847 to Mexico to make a treaty of peace. Failing he was ordered in the fall to return to Washington; but despite his instructions, he remained in Mexico, and on 2 Feb. 1848 concluded a treaty of peace in harmony with his original instructions. The administration was in a quandary. To ratify meant to condone the disobedience of Trist. To reject would not only prolongation of the war, but time to perfect the intrigue for the assassination of "All Mexico." President Polk, after some hesitation, decided to send the treaty to the Senate for its consideration. Received 23 February, it was ratified, after some amendments, 10 March, by a vote of 38 to 14. On 30 May, ratifications were exchanged and the war was at an end.

The Mexicans had fought bravely, even stubbornly and at times skilfully, yet in every contest, in every battle the odds were greatly in their favor, without a single victory. In part superior leadership and training won for the soldiers of the northern republic; in part their cooler and more persistent character; but in the main it was not bravery, nor generalship, nor even character that won. It was science, science and education applied in the equipment of the armies, the guns of the soldiers, the cannon on the ramparts and the powder in the arsenals which made the one so much more effective than the other that the most daring bravery was no counterpoise.

The Treaty of Peace.—The treaty of Guadalupe Hidalgo gave to the administration of President Polk the territory that his diary informs us he intended to acquire, California and New Mexico. Mexico in return for the loss of its fairest northern provinces was paid $15,000,000, and released from all claims of all kinds held by citizens of the United States against her, estimated at $3,250,000, which the United States assumed. Boundary lines were drawn, and provision made in regard to other questions at issue between the two countries.

Results.—Usually successfully waged wars redound to the credit of the party in power. In the Mexican war, the democratic party, the author and supporter of the war, was defeated by the Whig party, the party of opposition and criticism, in the Presidential election of 1848. The Whigs made use of the popularity of a successful general to defeat the party that had made his glory possible. Evidently the American people were ready to accept the fruits of the war, but also ready to punish the party they believed had wrought in a wrong manner. A large number of young officers, destined to renown in later years proved their worth in this war. U. S. Grant and Wm. T. Sherman, R. E. Lee, "Stonewall" Jackson and Jefferson Davis, in the great Civil War, foreshadowed, in this Mexican struggle, the greatness that was to be theirs in the "days that tried men's souls" from 1861 to 1865. It is a tribute of 522,589 square miles of territory—an empire four times as large as Great Britain, was the most important immediate as well as remote result. It was important in the issues that its acquisition precipitated. Should it be slave or free territory? Who should determine its institutions? Out of this question grew the larger one, who had the right to control the institutions of the territory in general? To settle the first question David Wilmot of Pennsylvania, proposed the celebrated "Wilmot Proviso" (q.v.) which would exclude slavery forever from all territory acquired from Mexico. Four long years of intense and bitter debate followed. This question and a series of others were settled temporarily, in the Compromise of 1850. The second question was answered by the phrase "Non-intervention," which meant, or soon came to mean, one thing to Douglas and the Northern Democrats, and another to Davis and the South. Three main theories were evolved or defended to answer the third query. (1) That Congress had the right to control the institutions of the Territories and could make them slave or free at its will. (2) The Dickinson-Cass-Douglas doctrine of Popular or in "Squatter" sovereignty:—the doctrine that the people of a territory themselves, while yet in a territorial status, determined their own institutions. (3) The radical Southern view that slaves were property, and, as property might be taken into any Territory, the common public domain of the States, with no constitutional power anywhere to hinder or prevent. It was important secondly in its industrial and political effect on the nation. The United States now had an outlook on the Pacific Ocean comparable to that on the Atlantic. China, Japan and the Orient were brought within the circle of its influence. Conditions favorable to further expansion were prepared. In addition to the great effect on commerce thus prefigured, that on wealth and industry was not less. The gold, silver, copper and other mineral wealth of the Mountain region was turned into the pockets of the American people. This vast addition of territory and wealth tended also to emphasize national pride and ambition; to arouse a still more intense belief in the "destiny" of the people to develop a more optimistic tone, and perhaps also to produce a more materialistic spirit.

MEXICO (Sp. México, officially República Mexicana and Estados Unidos Mexicanos), the southernmost country of North America and a federal republic, situated between 14° 30' 42" and 32° 42' north latitude, and between 86° 46' 8" and 117° 7' 31" longitude west of the meridian of Greenwich. Its name is closely aligned with the group of tribes who called themselves Mexico or Azteca. The name is derived from the tribal war-god, Mexico, also called Huiztilopochtli. The Spaniards gave the name Mexico to all the countries in which they found the Aztecs supreme at the time of the Conquest. Mexico is one of the most interesting of the countries of the Western Hemisphere, because of its distinctive civilization and social customs, many of which have persisted to our own day. It is also of importance because of its great natural resources, which now bid fair to be utilized for the benefit of her children instead of the predatory foreigner. These topics, together with the geography, art, architecture, literary history, commercial life and political history, are here treated under the following heads:

1. Area, Boundaries, etc. 9. Army and Navy.
3. Agriculture and Stock-Raising. 11. Religion.

1. AREA, BOUNDARIES, ETC. Mexico's total area is 767,326 square miles, and its boundaries are the United States on the north, Guatemala and Belize on the southeast, the Pacific Ocean on the southwest, and the Gulf of Mexico and the Caribbean Sea on the east. Its coast line on the east is 1,772 miles in length and on the west or Pacific side, 4,548 miles. The northern or United States boundary was fixed by treaty 2 Feb. 1848 and 8 Dec. 1853, and extends from the mouth of the Rio Grande, on the Gulf of Mexico, follows that river a distance of 1,136 miles, beyond El Paso, Texas; thence to a point on the Pacific Ocean, one marine league due south of the southernmost point on the Bay of San Diego. The total length of the northern boundary line is 1,833 miles. The Guatemalan boundary line was fixed by treaty 27 Sept. 1883 and 1 April 1895; and the Belize line by treaty signed 8 July 1893 and ratified 19 April 1897. The length of the southern boundary of Mexico is 642 miles.

By the treaty of Guadalupe-Hidalgo, ratified 2 Feb. 1848, and the Gadsden treaty of 3 Dec. 1853, Mexico ceded to the United States 930,590 square miles of her territory, or 163,800 more than half. The first-named treaty involved 362,487 square miles of domain, now part and parcel of the United States, as follows: Texas, 265,780 square miles; California, 15,808; Colorado (in part), 27,639; Kansas, 7,766; New Mexico, 65,201; and Oklahoma, 5,240. Under the terms of the second or Gadsden treaty the United States acquired 522,508 square miles, which are now held as follows: Arizona, 52,381; California, 157,801; Colorado (in part), 29,500; Nevada, 112,690; New Mexico, 42,000; Utah, 84,476; Wyoming (in part), 14,320. By virtue of the same treaty a later addition was ceded, consisting of 31,535 square miles to Arizona and 14,000 to New Mexico.

2. Political Divisions and Population. Mexico is divided politically into 27 states, three territories and a federal district. These and their areas and populations, capitals and population are as follows:

*Territories
Population.—The official statement of the Mexican government that the population of the country in 1867 was 14,634,004 in 1894, to 10,791,685 in 1896, to 13,607,259 in 1900 and to 15,063,207 in 1910, does not necessarily mean that the population had increased at the rate this increase in the census enumeration would seem to indicate, rather than the Gradual pacification of the country under the Diaz administration, the extension far and wide throughout the land of the administrative arms of the government, and a certain decrease in illiteracy had made the work of the census more effective. A prominent official connected with the census department in Mexico City expressed it as his opinion, in the presence of the writer, in 1910, that the actual population of Mexico was at that date nearer 20,000,000 than 15,000,000. Fundamentally the population of Mexico is Indian and mestizo (a mixture of Indian and European). (See MEXICO—ETHNOLOGY.) The official census of 1910 showed about 20 per cent white population; but it must be remembered that a large proportion of each Mexican citizen contains a certain amount of Indian blood in their veins; in fact there are very few of the older families that have not come under this influence. All children born of Mexican parents, whether in Mexico or in a foreign land, are, in the eyes of the law, Mexican citizens; and foreigners may become Mexican citizens by naturalization by making application to the department of foreign relations, provided they have resided five years in the country.

Topography.—The coast line of coast the peninsula of Lower California leads with 1,864 miles, Yucatan following with 615, Sonora 524, Sinaloa 317, Vera Cruz and Guerrero 286 each, Oaxaca 255, Tamaulipas 249, Campeche 224, Chiapas 137, Tabasco 119, Colima 99 and Michoacan 81. The greatest length of the republic is from northwest to southeast, 1,942 miles; and the greatest width, east and west, is from the mouth of the Rio Grande to the United States' western boundary, 1,833 miles; and the narrowest is from the mouth of the Columbia River, Alsea, Oregon, to San Francisco del Mar, on the Pacific, 134 miles. Mexico, California and Tehuantepes are the principal gulfs on the Mexican coast, the first being the largest in the world. In the commercial development of this continent they have performed and still perform a most important part. Mexico's great mass is the lofty Rocky Mountain plateau, which fills it almost from ocean to ocean, leaving but a narrow strip of coast. Entering from Guatemala (where a spur comes from the mountains of Lake Atitlán to San Francisco del Mar, on the Pacific, 134 miles wide at Oaxaca, with a steep descent and slender coast on the Pacific, but a more gradual one by the Pacific Coast, and the Gulf of Mexico towards Vera Cruz). This 'Coastal Plain' stretches northward to the vast plateau of Anahuac, 4,000 to 8,000 feet high, where the oceanic relations are reversed, the Atlantic side being precipitous and the Pacific terraced. There is no defined boundary between the Andes or Northern Rockies. The so-called cordilleras are merely the outer escarpments of the plateau, though often far above its mean level. loftiest of these is the Sierra Madre

of the Pacific, traceable at a mean elevation of over 10,000 feet from Oaxaca to the United States. It skirts the western coast within from 60 to 70 miles of the entrance of the Gulf of California. Thence onward a far wider coast land has silted up. Along the Gulf of Mexico are the correspondent cordilleras of Tamaulipas and Nuevo Leon, 6,000 feet in mean elevation. The southern coastal plain contains its height of 7,000 to 8,000 feet with great persistency to within 40 miles or less of the Atlantic. Through Lower California is a similar ridge some 3,000 feet high. The plateau is not a level surface. Railroad elevation north from the capital varies by 4,500 feet, declining northward; while the centre is intersected by short secondary ridges and valleys, mostly with the north-northwest trend. Most important of these is the Anahuac cedilla, surrounding the valleys of Mexico and Puebla; its culminating point is the Nevado de Toluca ("snow peak"), 15,163 feet. But across this, and generally contended with it, is a newer transverse ridge from ocean to ocean, traced by five active or recent volcanoes, Tepetla, Tacana, and several extinct cones, among which are Popocatépetl, 17,882 feet, and Ixtaccihuatl, 17,338 feet, in the centre, southeast of Mexico City, and Orizaba, eastward bordering Vera Cruz state, 18,696 feet. On the Pacific side is Colima (volcano), 12,860 feet; and the line runs out to the Revillagigedo volcanic islands. The sierras of Guerrero, Oaxaca and Chiapas are nearly parallel to this. The other high mountain peaks of the republic are the Malinche, between the states of Mexico and Puebla, 14,643 feet; the Cofbre de Perote, Vera Cruz, 14,042; Ajusco, in the southern part of the Valley of Mexico, 13,075; Tancitaro, 12,661, and Petamban, 12,300, in Michoacan; Derrumbaduras, 11,801, Ocelazin, 11,480, and Peñal, 10,744, in Puebla; Campanetepec, 11,139, Oaxaca; Lantinos, 11,021, Guanajuato; Tzirate, 11,022, Michoacán; Zumate, 10,994, and Nava- jas, 10,289, Hidalgo; and Laurel, 10,138, Aguascalientes. The mountains of Mexico are exceptionally picturesque and interesting, affording innumerable views and stimuli to the painter and naturalist.

Rivers.—Mexico possesses comparatively few rivers, and of these few are large and deep enough to be of commercial importance. Many of those marked on the map of the republic are either wholly or practically dry a part of each year. This is especially true of the northern half of the country. The most important rivers are the Rio Grande (Bravo del Norte), which forms the northern boundary line of the republic for 1,097 miles; the Rio Bravo, which rises in the mountains of the state of Mexico and empties into the Gulf of Mexico at Tampico, after a course of 300 miles; the Papaloapan, the source of which is in the mountains of Oaxaca and which crosses the state of Vera Cruz, emptying into the Gulf of Mexico at Alvarado, a river which also has its source in the state of Oaxaca, and crosses the state of Vera Cruz, emptying into the gulf at Coatzacoalcos, its length being 180 miles; the Grijalva, which rises in Guatemala and crosses Chiapas and Tabasco, to the Gulf of Mexico, 327 miles away from its source; the Usu- macinta, which also has its source in Guatemala, crossing the Mexican state of Tabasco
and emptying into the gulf a short distance south of Frontera, its length being 450 miles. Official reports state this to be the most navigable river in Mexico.

The Tuxpan River, which has its source in the state of Hidalgo, crosses Puebla and Vera Cruz and empties into the gulf at Tuxpan. It is navigable for small boats. The Lerma, 457 miles in length, which rises in the mountains of Tenango, in the state of Mexico, crosses Jalisco and Tepic and empties into the Pacific at San Blas. The Balsas, 428 miles long, the source of which is in Puebla and which crosses Mexico, Morelos, Guerrero and Michoacán, empties into the Pacific at Catemaco, in the latter state. The Yaqui, 391 miles long, which rises in the Tarahumari Mountains, in the state of Sonora, empties into the Gulf of California a short distance below Guaymas. The Fuerte, 335 miles long, which rises in the state of Chihuahua, crosses the state of Sinaloa and empties into the Gulf of California. Other rivers are the San Pedro, 298 miles; Nazas, 279; Ures, 200; and Sinaloa, 260.

Lakes and Lagoons.—The principal lakes of which are large, are Chapala, in Jalisco, a beautiful body of water some 51 miles long and 18 miles wide, the shores of which have become a favorite summer resort for wealthy residents of Mexico City, Guadalajara and other parts of the republic; Pátzcuaro (in Michoacán), around which there clusters a wealth of historic, artistic and poetic interest; Cuitzeo, in the same state; Chalco, Xochimilco and Texcoco, in the Federal District and state of Mexico; Tecpanucapan, in Chiapas; Tequesquitengo, Coateloaco and Hueyapan, in the state of Puebla; Tlacotalpan, in Vera Cruz; Caiel and Carpiniero, in Tamaulipas; Encantado, in Tabasco; Bacalar, in Yucatán; and Urría, in Guanajuato. The principal lagoons are the Terminos, in Jalisco and Michoacán; Tamaulpa, in Vera Cruz; Madre de Tamaulipas; Mezcafilltan, in Tepic; Coyután, in Colima; Tepant and Coyuaya, in Guerrero; Superior and Inferior in Oaxaca; Parais, Coyote and Agua Verde, in Coahuila; Guzmán, Javo, Patos and Santa María in Chihuahua; Xaltoca, in the state of Mexico; Mextitlán and Apan, in Hidalgo, and Santa Ana, in Tabasco. There are numerous other smaller lakes and lagoons in the republic, which are of much local importance, but which do not appear on the ordinary maps.

Valleys.—The principal valleys of the republic are those of Toluca, Mexico, Cuernavaca, Puebla, Oaxaca, San Francisco and Orizaba, all of which are extremely rich in soil and most favorably situated as to climate and other conditions affecting their products, which include very nearly every article grown in other parts of the American continent.

Climate.—The chief natural glory of Mexico is its climate, which, though not as invigorating as that of some places in the United States, is the most delightful in the world. In few localities is there ever intense cold or intolerable heat. It is seldom that death results from freezing, and sunstroke is practically unknown. In the tierra caliente and litoral lowlands, the temperature varies from 77° to 82° Fahrenheit in the shade, while on the central plateau, which includes the capital city, it is much cooler in summer and warmer in winter than in the United States. In Mexico City the maximum summer temperature in the shade is 85°, and winter temperature 72°; in Guadalajara, 83° and 75°; in Oaxaca, 94° and 83°; in Jalapa, 89° and 87°; in Querétaro, 90° and 80°; in Guanajuato, 91° and 82°; in Pachuca, 80° and 77°; in Saltillo, 89° and 76°; in Mérida, 103° and 92°; in Maratán and 91° and 83°. The average night temperature in Mexico City from June to October is about 55°. The warmest months of the year in that city are April and May, the last two months preceding the beginning of the rainy season, which extends from June to November. In the region near the gulf and the Pacific Ocean, the rains are much heavier and more frequent, and begin earlier and end later. The average rainfall on the coasts is 44 inches and on the table-lands 24 inches. In Mexico there are but two seasons—the rainy, or summer, and the dry or winter. The temperatures of the spring and autumn months differ very slightly, and the seasons merge into each other quite imperceptibly. The nights are always cool, except in the hot country, where they are seldom uncomfortable. The warm and Pacific breezes compensating for the heat of the day. There are no radical or sudden changes of temperature; no prolonged term of heat or cold or storm; and on the table-lands all seasons are so nearly alike that most persons wear the same clothing of the same weight all the year. Except in the northern states, artificial heat is seldom provided, either in homes or places of business, even in mid-winter.

In few other countries is to be found such diversity of climate as in Mexico, whose coast extends across 18 parallels of latitude and where the altitudes of the towns and cities range all the way from 26 feet above the sea at Vera Cruz, to 8,760 at Toluca, each place or step in the ascent illustrating in its fruits, foliage and flowers the influence of every climatic phase and condition. The white peaks of Orizaba, Popocatepetl and Ixtaccihuatl look down upon a broad panorama of indescribable beauty to be seen only in this land of perpetual spring. The summer rains on the upper plateau increase and the spring increase the number and beauty of the flowers and the fruits develop, sweeten the atmosphere, and drive away disease. The sun’s rays, being always perpendicular, in the middle of the day are very intense. In the shade, however, it is never uncomfortable.

Flora and Fauna.—The physical conformation of Mexico is most favorable to the development of a wonderfully rich and varied economic flora. In the hot lands or coast region from the sea-level to an altitude of 1,200 or 2,000 feet, coconuts, cacao, vanilla, peppers, nutmegs, ginger, cloves and other spices and all the fruits of tropical countries are successfully and profitably grown; while sugar cane, coffee, rice, cotton, tobacco, hemp, oranges, lemons, limes, avocados, apples, peaches, papayas, pears, plums, figs, cherries, grapes, zapotes, pineapples, marmayes, pomegranates, yams, sweet potatoes, Irish potatoes—most of the edible roots, and in fact almost all the varieties of the hot country—are grown in the south, where they are found and successfully cultivated at altitudes up to and including the valley of Mexico, 7,500 feet above the sea. Wheat, corn
and most of the grains of commerce produce crops in some of the states, twice or three times a year, notably in Vera Cruz, Tabasco, Chiapas, Oaxaca, Guerrero, Michoacán, Jalisco, Mexico, fifty-two species of cereals and vegetables, 87 of fruits, 100 of odoriferous flowers, 56 of building woods, 21 of cabinet woods, 8 of gums, 3 of resins, 12 of woods of medicinal, 12 of woods of dye, and a high degree of perfection in Mexico. Flowers of almost innumerable varieties, from the gorgeous orchid of quaint and curious form and wonderful combination of colors, to the modest daisy, violet and tuberose, grow wild, in extravagant profusion, all the year round, the range of altitudes meeting the requirements of all the members of the floral kingdom. The flower markets of Mexico City, which are chiefly supplied from the chinampas (gardens in the bed of the half-dried lakes of the neighborhood), are among the objects of interest most enjoyed by the visiting tourist, and they testify to the beauty and brilliancy of the Mexican flora. This country has been deservedly named "the land of flowers," for everywhere and at all seasons there are flowers of every size and color. In the forests of the republic, especially in the tropical lands, are found many varieties of trees the timber of which possesses great value for building or cabinet purposes. Pine of several varieties, balsam, lignum vitae, Spanish cedar, mahogany, oak, rosewood, mesquite, olive, palm, alond, fir, sesame, cedar, camphor, india rubber, copal, cacao, 12 species of dye woods and numerous varieties of oil-bearing trees are among the varied products of the country, the arboreal vegetation of which embraces 114 different species of woods. Included in the fauna of Mexico are the American lion (puma), jaguar, ocelot, wildcat, wolf, coyote, bear, wild boar, sloth, monkey, hare, rabbit, squirrel, armadillo, deer, beaver, otter, mole, marten, leopard, turtle, which are principally found in the sparsely settled mountains and in the forests of the tierra caliente. None of these are much hunted, the inhabitants of the country having little or no taste for this kind of sport. In the tropics there are many varieties of rich plumaged birds, and song birds are found in all altitudes. Parrots and parakeets abound in the coast regions and are highly prized for their talking qualities and brilliant colors of green, yellow and red. Among the many species of song birds are the zenonla or mocking bird, the clarin and the nightingale. The birds of prey include the eagle, hawk, turkey buzzard and owl. The cotorra, talking loro, humming bird, sparrow, blackbird, twitter dove, woodpecker, swallow, magpie, heron, falcon, kite and great numbers of others, which inhabit the forests or fields where there is abundance of insect and other food for their sustenance, are found in Mexico. In all localities where there are fresh-water lakes, lagoons, ponds or rivers there are great numbers of wild ducks and geese, and in the forests the wild turkey abounds. Wild bees are numerous, and the Indians derive quite an income from securing their honey and marketing it in the cities and towns. Of domestic or barnyard fowl, the number and variety are very extensive, and their consumption is enormous. The waters of the Mexican gulfs, lakes and rivers are well stocked with many varieties of fish of excellent quality, the most prized being the red snapper. The markets of Vera Cruz, Tampico and other coast cities daily display a tempting supply of sharks, rays, porpoises, whales, Atlantic salmon, tarpons, and large quantities are shipped to inland points by railway, in refrigerator cars. In the immediate vicinity of Tampico many tarpon of large size are caught. Of reptiles there are many varieties, both venomous and harmless, especially in the southern forests. In the first named class are included boa, coals and rattlesnakes. There are many varieties of scorpions, tarantulas and lizards, some of the latter being so large as to be utilized by the natives as an article of food. To the latter class belongs the iguana which often measures over five feet in length.

2. MINERALS AND MINERAL PRODUCTION. For three centuries Mexico was the greatest of silver producing countries; from the single camp of Guanajuato came almost all of the silver mined during that period; and for one straight century the same camp gave to the world two-fifths of its silver. Yet today, after almost 400 years of exploitation, Guanajuato has still unexhausted underground wealth. Yet Guanajuato is but one of many great Mexican mining camps, known to the world for centuries. Whether the natives of Mexico prior to the Conquest formally worked gold, silver and copper mines is an open question, but that they did exploit the placer deposits of the rivers of the country there is no doubt. placer gold in quills passed as currency in Mexico at the time of the discovery and for years afterward. Gold, silver and copper ornaments, idols and other figures and often elaborately worked, existed in vast quantities at the time of the fall of the capital of the Aztecs. Since then, throughout four centuries, examples of the metal work of the natives of Mexico and Central America have frequently come to light; and still to-day explorers find these eloquent witnesses of the culture of the Indian empires of America in the graves of their nobles and princes and the ruins of their great cities.

Spanish Colonial Period.—With the fall of the capital of the Aztecs in 1521 there began a period of wonderful mining activity throughout the vast extent of the empire of the Mon- ezumas. From the time of their landing on the shores of Mexico near the side of modern Vera Cruz in 1519, until the conquest of the city of Tenochtitlán two years later, Cortés and his followers were inspired by a dream of great wealth to be amassed from the treasure of the emperor of the Aztecs. This dream was made more vivid by the presents of gold with which the unfortunate Indian ruler sought to bribe his unwelcome guests to leave the country. After the fall of the city the Spanish adventurers awoke to find their dream of sudden wealth unrealized in so far as the capital of the Aztecs was concerned. But they lived in an age when strange fantasy colored the lives of men. If the much-desired El Dorado was not in Mexico City, then it was somewhere else; and the hunt for the golden treasure was continued. Thousands of buscones (prospectors) radiated in all directions from the capital in search of the hidden treasure. In this hunt mines of fabulous richness were discovered and towns sprung up
like mushrooms in the almost inaccessible fastnesses of the mountains. By 1537, when the first official report of the vice-regal government was made, the mining industry had become firmly established in many parts of the colony and was already paying important contributions into the treasury of the Spanish court. From the establishment, in 1535, of a settled government under the direct representative of the Crown, this mining activity increased with great rapidity and continued to extend itself farther and farther from the capital, the centre of colonial life in New Spain; and the dream of finding El Dorado was never altogether dissipated during the 300 years of Spanish rule in New Spain. While the glitter of gold was always before the eyes of every buscon the soft, white gleam of silver brought unimagined wealth to thousands who often squandered their newly-acquired fortunes in the search for the alluring wealth yellow and exalting. How great was this treasure of silver wealth that Spain extracted from the rugged sierras of Mexico may be gleaned from a study of the report of the government mint. From 1537, when the newly-established royal mint issued its first statement of mining activity, to 1621, when Spain withdrew from the colony, the recorded silver production of the mines of Mexico amounted to $2,082,260,657. During the same period the gold output was only $68,785,411, or less than one-thirtieth of the silver returns. Large as these returns are, it must be remembered that probably not more than half the ore mined was ever reported to the government because of the excessively heavy taxes exacted by the Crown, which claimed as its right the royal one-fifth and frequently, under one pretext or another, succeeded in extorting more from the mine owners. Quicksilver and powder, the most important aids of the miner in Spanish colonial days, were royal monopolies and consequently were sold in Mexico at from three to five times their market values. These and certain local, city and port exactions mulcted the miner of at least another fifth of the output of his mines. Transportation of ore from remote interior points, over almost impassable mountain trails, occupied from weeks to months in transit between the mines and the capital or the nearest port. Provisions and mining supplies had to be brought to the camp in the same slow and costly manner. All these extraordinary expenses made it possible for the miner to work only the richest ore and forced him to leave untouched veins which, in modern times, have become sensational ore-producers. It forced him also to sort out the richest of his rich ores and to leave the poorer on the dump heap. These dump heaps, worked over by modern mining methods, have produced millions to foreign investors.

During the Spanish colonial period Mexico was literally the silver treasure-house of the world; and most of this wealth went to Spain; and it all, whether it went to the Crown or to Spanish adventurers and capitalists, contributed to make Spain the richest country in the world, thus shaping her destiny and making of her people a nation of adventurers seeking fortune in the vast colonial possessions covering the greater part of two continents, and disdaining the industries, trade and commerce. With her vast wealth Spain purchased from the rising industrial countries of those days, the Netherlands and England, what she required at home; and the mines of the colonies paid for it all. As a result, Spain was disrupted and the industries languished where wealth came so easily; and she taught the colonies to view life from her own point of view. Mining and the manipulation of vast estates became almost the only occupation of a gentleman for four centuries, from 1535 to 1935. Each mining centre in Mexico and the other Spanish American colonies, buscones were sent out constantly in increasing numbers to look for new mines. Men pawned their all to go on the same quest. Every decade witnessed its rush from one promising mining district to another. Taxco, Guerrero, was opened as a mining camp in 1522, the year after the fall of Mexico City; and from there numerous mining expeditions were sent forth to seek for new centres of wealth, until the far-distant state of Chihuahua in 1544. The discovery of Parral, Santa Bárbara and other rich mines caused a rush of miners from the centre and south of the country toward the north and west. In 1546 Zacatecas became the scene of the most sensational mining excitement, which began to shift it another two years, to Guanajuato. In the same year the Bolaños mines of Jalisco began to attract attention and other centres of rich mineral deposits were discovered in Zacatecas. The following year Hidalgo came into note through the sensational discoveries of ore at Real del Monte. All these mining districts were still producing ore with no signs of exhaustion and most of them are admittedly but partially exploited. In 1552 Durango was invaded and three years later, the discovery of bonanza ore in the Sombrerete mines brought the state of Zacatecas into the galaxy of shining silver states. In 1574 Charcas, San Luis Potosi, opened silver mines destined to make the state famous. About the close of the 16th century, the chief mining interests of Mexico centred about Mapimi, Durango, which promised to become a great gold and silver producer. Scores of other more or less important mines were opened in the following years, among them Guadalupe, San Luis Potosi, 1622; Basipilas, Chihuahua, 1632; Candelario, Chihuahua, 1638; Santa Eulalia, Chihuahua, 1700; El Caballo and other mines in the same state, 1738; the famous Magdalena district, Sonora, 1754; Talapujahua, Michoacán, 1740; a new Real de Monte district, 1759; the Victoria, Guanajuato, 1760; Catorce, San Luis Potosi, 1773 and La Purisima in the same state, 1780. All the districts mentioned were wonderful producers. The Mapimi mines, in Spanish times, produced huge amounts of silver and gold. The Batopilas mines have made the state of Chihuahua famous and the best mining operators of the 18th century El Caballo claimed to be the richest mining district in the world. In 55 years the recorded output was over $83,000,000. The
Mexico—Minerals and Mineral Production (2)

Parral district, famous in Spanish colonial days for its wonderful richness, has, in modern times, under English, American, German and other foreign operators, justly ranked as one of the most extensive and generally mineralized districts in Mexico. The Real del Monte, which also produced wealth in Spanish hands, its output in one year being $15,000,000, has since, under English capitalists, extended its field of operation and thus claims itself known wherever silver is bought and sold. But the greatest single silver mine in the world is the Valencian, which paid to the government from 1766 to 1826 taxes on $326,000,000. It probably produced over $5,000,000 a year for 60 consecutive years. Vast sums of English and American capital invested in this district have done much to develop it along modern lines and to make it known. In the one year 1713 it is recorded as producing $4,000,000, and so much for the next forty years that it made all its owners immensely wealthy. The Talpajahuata mine in eight years yielded $8,000,000. The 17th century was one of development for Spanish miners in Mexico and the next 100 years for the American governments. This did a great deal of harm to mining interests, created confusion and laid the door wide open for grafting. So in 1883 the Federal government was forced to assume charge of the direction and operation of all mines. Toward the close of this latter century the recorded yearly output of the mines of Mexico was $27,000,000.

The Revolutionary Period.—This, beginning in 1810 and continuing till 1821, disrupted all the affairs of the colony. Mining suffered so severely that it did not recover completely for nearly half a century after the Spaniards had left the country. In 1821 the output of the mines of Mexico had dropped to less than $3,000,000 a year.

From Iturbide to Diaz.—Mexico, under the administration of the emperor Iturbide, through the national congress in 1823, favored the development of the mining interests of the country. It abolished most of the exactions imposed upon miners during the 300 years of Spanish rule, and passed mining laws allowing foreigners to enter the mining business in Mexico. Notwithstanding the unsettled state of the country, the inducements offered to foreign capitalists and the English money poured into the country for investment in mining enterprises. This was the beginning of that great English influence which remained paramount in Mexican mining affairs until the beginning of the Diaz régime in 1876. During this period the records of the mints show silver $797,055,080; gold $47,327,383 and copper $5,227,855. Since then copper has become one of the largest and most important products of the republic. After the departure of the Spaniards from the country the capital in Mexico was possessed of sufficient capital and knowledge to work the mines abandoned during the revolution, many of which had reached depths requiring powerful pumping and other machinery and exploitation on an extensive scale to make the business pay. The English were quick to see the opportunity thus presented; and many companies were formed to acquire and work these old mines and to exploit new ones. In six years (1872-78) six powerful English companies, with a combination capital of 3,000,000 pounds sterling, entered the Mexican field. Among these companies were: The United Mexican Mines Association, owning mines in many states of Mexico; the Anglo-Mexican Company, which also acquired many mines; and the Real del Monte Company. These English companies did what the Spaniards had never done; transported powerful modern pumping and other machinery and operate upon insurmountable sierras and made it possible to work the rich ore below the water level of vice-regal days. They thus practically created new mines. Among these British investors are included most of the famous mines of those days; Valencian, Mellado, Villalpando, La Luz, Charcas, Catorce, Fresnillo, San ldelefonso, San Dimas, San Francisco, Guanacevi, Parral, Santa Elena, Batopilas, Real del Monte, Santa Gertrudis, Blanco, El Oro, Temascaltepec, Bolaños, Tezehuitlán (famous copper district), Taxco and Real del Castillo.

From Diaz to Madero.—From 1857 to 1883 the control of the Mexican mining laws was in the hands of the officials of the state governments. This did a great deal of harm to mining interests, created confusion and laid the door wide open for grafting. So in 1883 the Federal government was forced to assume charge of the direction and operation of all mines. At the same time a commission was appointed to consider the mining situation and to reform the mining laws, which it did in such a liberal spirit that mining again took a fresh and vigorous start. Porfirio Diaz began his administration in 1876 with a broad view of the necessities of his country. He extended the hand of welcome to capitalists of all nations who might help him to realize his dream of a greater and more prosperous Mexico. When Diaz returned to power in 1884 after Gonzalez' four years of office, he continued vigorously the policy of encouraging the mining interests of the country, which during his first term of the presidency (1876-80) had reached the value of $103,000,000 gold and silver, with the additional potential energy of hundreds of new mining claims registered, properties opened up and many abandoned mines put into operation once more. About this time American, German and French capitalists appeared upon the scene and began to compete vigorously with the English investors for a share in the Mexican mining business. By 1884 this competition had already become strong, and from then on it grew in intensity until, in 1913, when the revolution practically halted mining throughout the republic, it had assumed large proportions. Of the newcomers the Americans were the most aggressive. In 1884 Edwin Ludlow, representing American capitalists, began boring for coal in Mexico; and five years later the great coal deposits of Coahuila, at Sahiba and other points, came into full operation. In the 10 years following 1895 over 6,000,000 tons of coal were mined in Mexico, and by 1910 the output had reached 1,500,000 a year. The discovery and exploitation of coal in the republic gave great impetus to mining and other industries. Between 1885 and 1910 Lower California, Michoacán, Coahuila, Sonora and Puebla became great copper-producing states and as such attracted large sums of foreign capital; and the production of copper rose from 11,620 tons in 1895 to 55,000 tons in 1905. Owing to the slump in the price of this metal, this increase was not kept up during the next five years. Copper and petroleum and its products
were, however, the only mining interests that continued active throughout the revolution, the output of the former being valued, in 1912, at $38,500,000. Mexico ranks easily in second place among the great copper-producing countries of the world. In 1906 official returns showed in the republic 35,087 copper mines and mines containing copper values. After eight years of exploitation of antimony Mexico had more than become the world’s greatest producer of this metal, with vast deposits still untouched. Two years later her production of antimony had reached almost $2,000,000 per annum. At the beginning of the first Diaz administration capitalists began to pay attention to the gold deposits of the country, with the result that, between that date and 1909, considerably over $1,000,000,000 gold was mined. Even in 1912, notwithstanding the revolution, the gold mined was valued at over $50,000,000, while the fiscal year 1908-09 had produced $62,700,000.

In 1894 the introduction of the cyanide process began to replace the old patio process, thus giving an added impetus to the mining of low-grade ores and this helped the mining business. During the next few years the few capitalists began the utilization of water-power for the production of electrical power and electrical plants appeared in different parts of the republic. Of these the most extensive and important is that of Necaxa which supplies the power to light the City of Mexico and to run the tramways and many of the factories of the Federal District. It also furnishes 30,000 horse power to El Oro and electrical energy to other neighboring mining centres, including Pachuca. Mexico, on account of its mountainous nature, possesses a real wealth of water-power, which must soon be brought into use to develop her vast mineral riches, a very considerable part of which, owing to adverse natural conditions, still remains untouched. The most noteworthy development of the mineral wealth of the republic of recent years is to be found in the vast petroleum fields stretching down the Gulf Coast from Matamoros to Campeche, and probably farther, for the southern end seems to connect with the oil fields of Colombia. So great are these fields and so vast their wealth that Mexico must soon become the first oil-producing country of the world. Although oil was known to exist in Mexico for many years, it was not until 1901 that the Mexican Petroleum Company, a California corporation, began prospecting for oil in the neighborhood of Eban, near Tampico. About the same time W. Pearson and Son came into the field, with unlimited English capital. Then followed a rapid development of the oil fields near Tampico and on the Isthuem of Tehuantepac, Tuxpan, Minatitlán, the Papanata district and other points in the neighborhood. By 1907 the production of oil in the republic had reached 1,000,000 barrels a year and by 1913, 16,746,000. Two years later the output was 35,000,000 of which about 75 per cent was exported and in 1918 it was over 60,000,000. The returns in the near future promise almost double that of 1915 owing to the great well which the Mexican Petroleum Company opened in December 1915, which is said to exceed in flow the whole oil output of the State of California. According to the report of the Mexican Secretary of Industry, Commerce and Labor (1918), there are over 600,000 kilometers of oil lands in the republic. These extend along the Gulf Coast, the coast of Lower California and the Pacific coast; of these only 15,000 have been exploited. See bibliography under article MANUFACTURES.

3. AGRICULTURE AND STOCK RAISING. In normal times the chief agrarian product of Mexico is Indian corn, valued at from $80,000,000 to $100,000,000 a year, yet, owing to the unsatisfactory methods of cultivation still in use, it often happens that corn is not grown in the country for its own needs in which case the government is forced to throw off the duty and, in extreme cases, import corn itself in large quantities and sell it to the masses at cost. The next valuable product of Mexico is henequen, which is valued annually at over $40,000,000. As a greater part of this product is exported, constitutes the chief wealth of Yucatán, which has grown to be, for its size and population, the richest state in the republic, though it was once the poorest. Although Mexico has never been looked upon as a wheat-producing country, nor as a large importer of wheat, it is beginning to realize that its capacities in this direction are practically unlimited and an annual output of wheat valued at over $20,000,000 is not uncommon, while this figure is sometimes exceeded. One of the products of Mexico which has come of national importance within very recent years is rubber (including guayule), the output of which was over $33,000,000 in 1911, with vast extents of young rubber plantations ready coming into bearing. The following statistics of the growth of this industry are entered.

In the fiscal year ending 30 June 1911 the exports of henequen were valued at over $50,000,000; the cattle exports were $4,438,000. We did not include vast numbers which left Mexico without the knowledge of the government from those parts of the country under the control of rebel factions. Some of these were Guatemala, but the greater part to the United States. In the same year the value of the exports of corn reached nearly $10,000,000 from territory controlled by the then existing government. In normal times the value of the exports of sugar cane (sugar, alcohol, raw or lasses and cane) is second only to corn, reaching, as it does, usually over $800,000 a year. This is a branch of the native industries which is capable of great expansion since Mexico possesses vast bodies of land capable of the cultivation of sugar cane. The years of the revolution showed a very considerable increase in the exports of coffee, cacao, tropical fruits, guayule, henequen, dyewoods, cabinet and building woods, tobacco and vanilla. Owing to the fact that the sugar cane was the state of Morelos the sugar cane output increased to less than 1,000,000 pesos and the industry became practically paralyzed, from the condition it has not yet recovered, principally because the production of the sugar cane is...
its products calls for the investment of heavy capital and the employment of skilled labor in certain localities.

A brief reference to the chief features of the agricultural industry of the country will prove instructive and interesting.

Sugar.—The greater part of the cane is grown at altitudes above 2,000 feet, but the best results are obtained in the lower country, where it matures sooner and where it may be cut twice annually without necessitating replanting more than once in upward of 10 years. In the Cuernavaca Valley, state of Morelos, the first sugar-batches were cut by negro slaves bought at Vera Cruz, at from $300 to $400 each. But the experiment proved unsatisfactory and free labor was soon substituted. Now the plantations are worked chiefly by Mexican labor and the mills are supplied with modern machinery.

Tobacco.—This industry is also developing great possibilities. The climatic and soil conditions, especially in the tropics, are very favorable to the best results, and whereas in Cuba the soil, after 400 years of constant use, has become comparatively unproductive, in Mexico no artificial stimulant is needed until the flavor and aroma of the tobacco are conceded to be equal to those of the Cuban product. The chief tobacco states are Vera Cruz, Oaxaca, Hidalgo, Tabasco and Chiapas. Much of the Mexican tobacco is bought up two or more years in advance of production and resold as fine Cuban tobacco.

India Rubber.—While there has been much unsatisfactory experimentation with the rubber tree, the failures have generally been chargeable to lack of knowledge or experience or to the introduction of illegitimate speculation at the expense of practical results. There now exist in southern Mexico a number of large and very successful rubber plantations, which have already proved that cultivated rubber can be made a paying proposition. These are chiefly in Vera Cruz, Chiapas, Campeche and Oaxaca.

Agave or Maguey.—This plant, from which is extracted the drink known as pulque, which, with tequila, holds perhaps the most important feature of the agricultural interest of the central plateau. Although pulque contains only about 7 per cent of alcohol, it is intoxicating when drunk in large quantities. It possesses important medicinal qualities, is a tonic and very nutritious. From 350 to 700 agaves or magueyes to an acre are planted. They mature in eight years and give sap for a period of about five months, producing from 125 to 150 gallons of pulque each. The plants cost about $2 each by the time they have matured, and give a return of from $7 to $10 each. The pulque is secured by making a cavity in the centre of the plant, from the top, large enough to hold a few quarts, which are drawn out by rude syphons once a day. The leaves of the plants sometimes grow to be 12 feet long and weigh from 25 pounds to 100 pounds each.

Banana.—This fruit is successfully grown everywhere in Mexico between sea level and an altitude of 5,000 feet. It is easily cultivated and very profitable. Frequently a return of $1,000 is realized from an outlay of $300 in a single season. A plantation of 1,000 plants, costing $500, will, under favorable conditions, earn this amount, even though the methods used be faulty, the care exercised insufficient and the variety poor. A favorable feature of this growing is the fact that the ground occupied by the plants may also be utilized at the same time for the cultivation of coffee or other profitable products. Few other tropical fruits develop and become profitable as quickly as does the banana. Especially desirable are some of the smaller varieties, although they may not be as much sought after as the larger and more pretentious ones. Their flavor possesses qualities not found in any other known variety.

Orange.—The oranges of Mexico are rapidly and surely winning favor in the markets of the North. Their true worth has only recently come to be understood and appreciated by consumers. Although the orange finds favorable conditions in all the tropical and sub-tropical states, the best results thus far have been attained on the shores of Lake Chapala, in the state of Jalisco and in Vera Cruz, Michoacán, Sonora, Morelos, Durango, Nuevo León, Oaxaca and Puebla. The leading producers in 1914 were Jalisco, Yucatán, Michoacán, Morelos, Durango, Nuevo León, Oaxaca, Puebla, Sinaloa, Hidalgo and Vera Cruz. Although the oranges of La Barea, in the state of Jalisco, are considered the best in the republic, they have already found competitors in the products of Michoacán, Vera Cruz, Morelos and other localities equally favored by nature. The best results in orange growing are secured at elevations below 2,500 feet. The trees begin bearing when three or four years old and increase until the 12th or 15th year. Frost rarely occurs in any of the orange-growing regions of Mexico.

Lemon.—It is doubtful if any product indigenous to the soil of Mexico has been as sadly neglected as the lemon. So largely has it been relegated toward the lower end of the list of tropical fruits, in favor of the lime, that it can with difficulty be obtained in the markets, and when found is generally unsatisfactory in quality. And this, notwithstanding the existing very favorable conditions of soil and climate and the increasing demand in the world's markets. A very considerable area of the lemon crop of Mexico consists of wild fruit which, in many sections and especially on the Pacific Coast, is large and of excellent quality. It grows in the forests and jungles of the semi-tropical lands, at about the same altitude as the orange.

Lime.—This successful rival of the lemon, in Mexico, is grown chiefly in the states of Guanajuato, Puebla, Michoacán, Mexico, Jalisco, Oaxaca, Guerrero and San Luis Potosí. The lime of Mexico is of first-class quality, but like the lemon and the orange, can be greatly improved by the adoption of proper methods of cultivation and the exercise of reasonable care.

Pineapple.—In the production of this fruit Mexico excels and is constantly improving her output. The towns of Córdoba and Amatlán, in the state of Vera Cruz, have long been noted for the size and quality of the pineapples grown in the regions round about these. The fruit is also successfully raised in the states of Puebla, Hidalgo, Tabasco, Chiapas, Oaxaca, Morelos, Guerrero, Michoacán, Colima, Jalisco and Nayarit. It thrives best at elevations of 2,000 to 3,000 feet. It was cultivated before the Con-
quest. Its leaves have for centuries been utilized to a greater or less extent in the manufacture of cords, hemp by coarse methods, of rope, twine, thread, mats, bagging, hammocks, paper and cloth of various colors. The value of pineapple grown in 1913 is given as $642,382, the chief producers named in the official reports being the states of Nayarit (then territory of Tacubaya), Hidalgo, Veracruz, Oaxaca, Chiapas, Tabasco and Yucatán; chicle, or chewing gum, of which over $4,540,000 worth has been exported to the United States in a single year; the mango, one variety of which (the Manilla) seems to combine about all the more delicate and delicious flavors of the choice fruits of the world. Being very perishable, it cannot be transported a great distance without suffering serious depreciation in value. The apple, peach and pear are all grown in various parts of the republic, but none has yet been brought up to anything like the standard of excellence reached in the United States, notwithstanding that almost all the natural conditions are exceptionally favorable to their cultivation.

Stock-raising.—The plains of northern Mexico and the valleys of the southern portion offer most favorable opportunity for profitably engaging in the livestock business. The climatic and other conditions are very favorable, the grasses are most nutritious. The transportation rates and facilities are such that cattle can be raised in Mexico and shipped to the markets of the United States at a good profit. An idea of the increase of this industry in Mexico may be gained from the reports by the government of the number of cattle exported annually. These show a regular and very considerable increase in normal times. The para grass of the southern Mexican states is always greener and a great deal more nutritious than that of the northern plains. Durango, Chihuahua, Sonora, Sinaloa, Coahuila, Tamaulipas, Vera Cruz and Michoacan constitute an admirable field for the carrying on of the cattle industry. As far back as 1883, there "roamed over an area of 300,000 square miles in the northern part of the country," according to a well-known writer, "1,500,000 cattle, 2,500,000 goats, 1,000,000 sheep, 1,000,000 horses and 500,000 mules, and there were 20,574 cattle ranches in the republic, valued at $515,000,000." Between the cities of Jalapa and Vera Cruz, and between Vera Cruz and Cordoba, great numbers of cattle were to be seen from passing railway trains, their sleek and well-rounded sides testifying to the excellence of the indigenous grasses before the revolution came to partially destroy an industry that promised to become very much greater in the near future.

The future of agriculture in Mexico is now apparently brighter than it has ever before been. The government has attempted to settle questions which have long been calling for solution; and among these none is of more importance than those of Hidalgo and Tabasco, the death of the commercial law of the republic calls for the subdivision of the large estates of the country and for the creation out of the Indian and mestizo population of a gradually increasing agricultural class which shall grow into a great middle class in the not distant future. See bibliography under article MANUFACTURES.

4. COMMERCE. The efforts of the various governments of Mexico since 1876 have been steadily directed toward the encouragement and extension of the commerce and industries of the country, with the result that the present state of the nation is one of steady growth.

This has been done in the face of many and great difficulties. At the beginning of the Diaz regime Mexico was overburdened with debt, torn and wasted by revolution and party disaffections. The means of transportation were lacking; and ports, harbors and regular coast and ocean routes, both passenger and traffic, in the modern sense of the term, were non-existent. Therefore steady and profitable international relations had not yet been established. Mexico also lacked the educational knowledge and experience necessary for the building up of these. The third of a century spanning the beginning and the end of the Diaz regime witnessed a complete change in the commercial conditions existing in the republic. During this period harbors were constructed to accommodate great ocean-going vessels; international relations were extended and broadened; and the industrial, educational and commercial life of the nation quickened into notable activity. But the revolution of 1910 and the fratricidal strife that accompanied it set back the progress of the republic. Mexican commerce is peculiarly dependent upon the industrial and agricultural life of the nation because this alone makes possible the production of a vast number of foreign products. The disruption of the national life through the revolution vastly decreased the purchasing power of the Mexican people, and this, in its turn, very deeply affected its commercial activity. The almost complete destruction of the cattle business helped to still further intensify this arrested development. Along the old lines of its national life the income of the government declined in sympathy with the anarchical conditions existing throughout the country, to such an alarming extent that the most primary needs of the nation would have been lacking were it not for the fact that a new and important factor made itself felt strongly in the national life and largely supplied the lack in the national income by filling in the gaps caused by the lack of commercial activity throughout the nation. This was the rise to sudden importance of the mineral oil industry during the war years of 1914-18. But the storm and stress period through which the country passed from 1910 to 1919 is significantly reflected in the almost total lack of industrial and commercial statistics relative to the activities of the national life since the fiscal year 1912-13, when the last official census
was issued. This latter census represents the more or less normal life of the nation, which has been gradually returning to its pre-revolutionary condition throughout the whole extent of its territory.

From 1897 to 1904 the exports of merchandise from Mexico to the United States increased from $4,346,334 to $43,633,275; and the imports from the United States increased from $5,946,839 to $45,844,720. In the fiscal year 1912–13 the imports from all countries were valued at $60,827,910; of which $29,466,000 consisted of animal substances; $31,285,000 of vegetable substances; $46,711,978 of mineral substances; $21,281,571 of dry goods; $120,074,880 of chemical and pharmaceutical products; $6,744,083 of spirituous liquors and other beverages; $5,120,770 of paper and its applications; $23,383,611 of machinery and its parts; $4,600,890 of vehicles; $5,388,344 of arms and explosives, and $9,604,897 of miscellaneous articles. In the same year the exports totaled $300,405,000, the principal articles being: silver in various forms, $39,591,000; silver in ingots, $91,293,000; copper, $56,522,000; vegetable products, $85,693,000; animal products, $29,838,000; manufactured products, $3,549,000; miscellaneous, $2,917,410. Increase over the previous year, $2,410,000. Of the total imports $97,287,000 were from the United States; $25,220,000 from Germany; $25,900,000 from Great Britain; $18,338,000 from France; and $10,530,000 from Spain. The henequen exports, in the same period, were $30,134,000; uncured hides, $11,170,000; vanilla, $3,015,000; beans, $1,160,000; cattle, $7,552,000; leaf tobacco, $1,003,000; chicle (chewing gum), $4,342,000; fresh fruits, $1,019,000; zacate, $1,900,000; woods, $3,356,000; sugar, $860,562; Panama hats, $357,423; miscellaneous, $2,471,000. Of the total exports, $22,551,000 were to the United States; $31,147,000 to Great Britain; $16,438,000 to Germany; $7,151,000 to France; $2,182,000 to Spain. In the previous fiscal year the importations were $182,866,000, and the exportations $289,989,000. In the fiscal year 1894–95 the imports were only $66,200,000, and the exports $95,000,000, a remarkable record of progress in the brief period of 18 years.

The following table of exports and imports serves to show the progress of Mexican commerce during a very active decade of its history:

In order to show the relative importance of the Mexican custom houses, both maritime and frontier, the following statement of collections of import duties for the fiscal year 1912–13 is given: Vera Cruz, $81,793,000; Tampico, $45,832,000; Laredo, $18,866,000; Juarez, $3,356,000; Frutera, $11,248,000; Ciudad Porfirio Díaz, $4,387,000; Nogales, $1,857,000; Mazatlán, $2,514,000; La Morita, $6,057; Frontera, $1,486,000; Agua Prieta, $1,208,000; Soconusco, $16,061; Guaymas, $2,239,000; Acapulco, $611,342; Isla del Carmen, $264,317; Ensenada, $383,662; Mexico, $628,783; Chetumal, $480,602; La Paz, $206,722; Tuxpan, $743,322; San Blas, $151,602; Salina Cruz, $624,570; Tijuana, $212,847; Topolobampo, $147,310; La Ascension, $52,730; Camargo, $53,540; Mier, $9,707; Puerto Angel, $10,827; Manzanillo, $1,486,000; Matamoros, $1,680,000.

In the upbuilding of the foreign trade of Mexico, the construction of railways made possible the phenomenal results that have been achieved since 1898. The entire foreign trade of the country, practically, has been created since 1876, most of it since 1880. Before competition in the transportation of freight was provided, the rate from Vera Cruz to Mexico City, 264 miles, ranged around $68 per ton, going as high as $330 during the French intervention. Formerly almost all the first-class furniture imported by Mexico came from France, but now much of it is supplied by the United States and some of it is made at home. Most of the importations of agricultural machinery and implements are from the United States. The same is true of food stuffs, lumber, machinery for irrigation works, supplies for mining and for steam and electric power, unmanufactured leather, vehicles, boots and shoes, canned goods, patent medicines, livestock, cotton, manufactures of steel and iron, sewing machines and typewriters. From Spain and France come most of the wines and cognac. In normal times Germany and Belgium had, previous to the European War, a monopoly of the hardware trade, England and France of the dry goods trade, and France of the trade in notions, jewelry and fancy goods. Among the leading articles exported by Mexico are coffee, two-thirds of which goes to the United States and the balance to England, Germany and France; vanilla, sugar, tropical fruits, beans, livestock, precious metals, henequen, leaf tobacco, hides, rubber and talc.

Mexico has a "commodity code" which dates back to 1882 and which, among other things, provides that foreigners shall be free to engage in commerce, subject to the same conditions and requirements that apply to citizens; that all documents referring to matters of concern shall be recorded in a public register; that all business correspondence shall be preserved; that notice by circular or through the press shall be given of the character of any business about to be established and of any modifications or other changes subsequently made; that at least three account books,—a general day book, a book of inventories and balances and a ledger,—shall be kept in the Spanish language; that all brokers must be Mexicans by birth or naturalization, have a mercantile education and possess a diploma from the Minister of Fomento or other proper officer; that an unlawful agreement or contract involves no cause of action at law; that mercantile companies may consist either of a partnership under a collective name or with special partners, or may be an anonymous (stock) company, a society with special partners or a co-operative society; that all contracts for the formation of companies must be in writing and very full and explicit that no acts of companies cannot take effect until two months after publication of particulars, except
on payment of all debts; that foreign companies must register in Mexico and publish an annual balance sheet; that there may be temporary or "profit-sharing" mercantile associations, the first being without a firm name and making partners jointly liable to third persons; and the last named implying an association under which one or more persons may become interested in operations which one or more may undertake in their own names, but which involve only one legal entity and no responsibility on the part of a partner not joining in a contract with a third party; that the principal of any manufacturing or commercial business shall be responsible for the acts of his managers or employees; that no institution of credit can be established except by authorization of the Minister of Finance and the approval of Congress; that every merchant ceasing to make his payments, whose liabilities are more than 25 per cent in excess of his assets, who has made formal assignment of his goods, or who has absented himself without leaving any person in charge of his business who can pay his debts as they become due, shall be considered a bankrupt.

Foreign commerce for year ending 30 June 1914 (estimate of exports) $176,000,000; (estimate of imports) $150,000,000; total $226,000,000. For the year ending 30 June 1915, the estimate of the value of Mexico's exports was $150,000,000; imports $61,000,000; total foreign commerce $211,000,000. Imports from the United States in the year last mentioned (estimate of value) $34,200,000, and exports to the United States $115,000,000. The imports into the United States from Mexico in 1916 totaled $105,000,000 and the exports to that country reached $53,000,000 in the same year. In the nine months ending with March 1917, imports from Mexico were $80,692,000 and exports $47,501,000. In May 1917 the Mexican government prohibited the exportation of food stuffs and food animals to the United States because of the depleted stocks and herds in the country owing to the revolution. See bibliography under article Manufactures.

5. MANUFACTURES. Mexico is a manufacturing country in the very primitive sense of the word; for literally the greater part of her manufactured products are made either wholly by hand, by individual tradesmen each working on his own account, or in small shops where the machinery used is employed simply to aid the cunning of the hand. The field for manufactures of all kinds is most promising, since it offers raw material in great abundance, efficient, intelligent labor and a very considerable home market, with a still larger one in Central and South America.

Manual training has been introduced into the schools of Mexico and several arts and trades colleges are turning out skilled mechanics in all lines of industrial work. Wages are low, much lower even than in Europe, and the native workman in the factories already established throughout the country gives his employer little or no trouble.

Cotton.—In 1912, the last normal year since the outbreak of the revolutionary war that overthrew the autocratic Díaz régime, there were 148 cotton mills in the republic. Of these the one in Puebla, Mexico City and Oaxaca is near the capital, one at Coyoyacan and factories 32,000 workmen were employed to operate 62,000 spindles and 27,000 looms. The cotton goods produced were valued at over $50,000,000; and included sheetings, ticking, lining, drills, Shirtings, percales, quilts, napkins, table-cloths, woollen-cotton goods, knitted garments and fleece-lined underwear. The Mexican cotton factory, Huelva, employed, in the same year, about 2,000 hands and is capitalized at $6,000,000; the Compañía Industrial de Orizaba owns four cotton mills, has 4,000 looms and 10 printing machines in commission, is capitalized at $15,000,000 and employs 6,000 mill-hands. The San Antonio Abad, with an invested capital of $3,500,000, also operates four mills, three in the state of Mexico and one in Mexico City. El Porvenir y Anexas, at Villa Santiago, Nuevo León, is capitalized at $2,000,000, and the Veracruzana, of Santa Rosa, in the state of Vera Cruz, near Orizaba, at $3,500,000.

Woolen Goods.—There are a number of woolen factories in Mexico; but they are of less importance than the cotton mills, for the reason that the great mass of the lower classes wear cotton garments, thus creating a strong and constant demand for the latter goods. There are woolen mills in Durango, Aguascalientes, Guanajuato, Hidalgo and Puebla; but the most important establishment is in Tlalnepantla, in the state of Mexico and not far from the federal capital. The woolens made in the republic include suitsings, kerseymeres, carpets, blankets, rugs and knit goods. The city of Saltillo, in Coahuila, is noted for its handsome serapes (native blankets), for which there is a constantly increasing demand. These serapes, which are made on primitive Indian looms are exceedingly well woven, of fine texture, brilliant colors and pleasing designs. The San Idefonso factory at Tlalnepantla, with a capital of one and one-half million dollars, is one of the most successful manufacturing enterprises in Mexico and its goods are to be found on sale throughout the republic.

Silk.—Few countries have the natural advantages for raising and manufacturing silk possessed by Mexico. Throughout the greater part of the republic both white and black mulberries grow luxuriantly and require practically no care in their cultivation. So even is the climate in most parts of the country that silk worms can be grown out of doors practically all the year round; and they require but a small part of the care they must necessarily receive in Italy. Labor in Mexico is cheap and the masses of the people, once accustomed to cocoon raising and the cultivation of the mulberry tree, might be expected to thrive at the business as their ancestors did in all the industries, before Europeans came to disturb the current of their national life. The Indian is industrious when he works on his own account.

In Mexico City there is one important silk factory, which is engaged in manufacturing rebosos, the light shawls which the Mexican women of all classes wear almost universally, everywhere outside the larger cities. This factory received strong encouragement from the Mexican government which has, for some years, been anxious to establish the silk industry on a firm basis and to introduce the industry near the capital, one at Coyoyacan and
the other at Churubusco, began in 1907 the planting of 6,000,000 mulberry trees, from which it was proposed to send out free propagation slips to all parts of the country wherever people could be induced to plant trees and to go into the business of silk raising.

Textiles and Fibres.—There is perhaps no important product of the hat factories of the country that shows so much variety in forms of manufacture than that of fibre-plant products. Rope, cordage, thread, packing, carpets, rugs and practically every form into which linen, hemp, jute, ixtli, henequen and other native fibre plants and textiles are made, are manufactured in Mexico. Among the most important textile and fibre goods factories in the republic are La Aurora of Cuautitlán, near Mexico City, which has an invested capital of $1,300,000 and turns out bags and packing of all kinds; La Industrial Manufacurera Company, capitalized at $4,000,000 and operating six factories; the Linera de Mexico Company, capital $600,000; Santa Gertrudis Company, near Orizaba, capital $1,000,000, hands employed in normal times from 200 to 400, all hands, and the republic, wherever the numerous fibre-plants grow, which is almost everywhere, on highlands and lowlands alike, the natives carry on the manufacture of rope, cord, string, thread and other woven articles. It is almost exclusively because of its export to the United States, that the production of fibre-plant products is of such importance to the Mexican economy, as they are consumed by the descendants of the Aztec ancestors who made them before the Conquest. These products of the country can be found from the Rio Grande to Guatemala. Ixtli (agave rigide), a rather coarse century plant, furnishes a considerable part of the raw material for this industry. The maguey (agave Americana), from which the native pulque is extracted, also supplies raw material for the coarser kinds of rope, cordage and sacking. Even mats and rugs are made from it. In addition to the large and very general consumption of these goods, the exports to foreign countries amounted, in 1912, to $3,792,678.

Among the other fine fibre plants of Mexico are zapupe and pita, both of which furnish long, silken, strong commercial fibers, which are not exported because the home consumption demands more than the output. The best known, commercially, of all the fibres of Mexico is henequen grown in Yucatán and the neighboring states of Campeche and Chiapas, which is not produced in any other part of the republic. From the finer fibre of this plant there are manufactured in Mexico many varieties of woven fabric that resemble silk in appearance and softness of texture. In fact the best of the Mexican henequen is said to be equal in quality to the best of the American henequen. From the fibre, which is sometimes several inches long, are made many fine articles of cloth used by the women for their dresses and mantas and are used extensively throughout the country for the making of binding twine for reapers. Though no country in the world is richer than Mexico in excellent fibre plants, yet she imports large quantities of linens, hempen fabrics, yarns, laces, handkerchiefs, trimmings, carpets, rugs, curtains, quilts and almost every kind of goods manufactured from the various fibre products, all of which could be made at home from native-grown products at a great saving to the nation. Characteristic products are the henequen sombreros and the so-called Mexican Panama and other straw and reed hats. Most of the latter are made by individuals in their homes. The natives display much taste in this work, which is another of the numerous industries of the country handed down from father to son for hundreds of years. La Abeja (The Bee), in the Federal District, near the capital, with an investment of $500,000, is the most important producer of the hat factories of the country. Mexico, Guadalajara, Puebla, Vera Cruz and Oaxaca are from one to a score or more smaller hat factories, each of which has its own wholesale and retail store. In addition to these there are little shops that do a purely local business.

Beer, Wines and Liquors.—There is a large consumption of distilled and fermented liquors in Mexico, a very considerable percentage of which is made in the country. Within the past 10 years beer has come into favor, in the cities and larger towns, and it may be found on sale even in the smaller interior towns and villages, though there the consumption is slight. Its use is confined to the middle and upper classes almost exclusively because of the price beyond the use of the laboring class. There are large and well-equipped breweries in Mexico City, Oaxaca, Monterrey, Puebla, Vera Cruz, Orizaba, San Luis Potosi and Tampico, while the small installments of lesser importance exist in several of the smaller cities. In the capital there are several distilleries where whisky, brandies, cognacs and cordials of various kinds are made. In the Parras district of Coahuila and in some other parts of Mexico excellent mezcals are produced, and wherever sugar is grown, which is pretty general in the low, hot lands of the coast country, aguardiente (native rum) and excellent alcohol are manufactured. Many of the sugar plantations possess the most modern plants for making these products. Much of the Mexican aguardiente is shipped to Europe where it is turned into cognac. Tequila, a strong alcoholic liquor somewhat like Holland gin, is manufactured extensively in Mexico, but most of the output is consumed at home, for its use is general throughout the country. Like pulque, tequila is manufactured from the century plant. The use of pulque is more extensive than that of either tequila or aguardiente; but it is confined to the upland plateau and the country at a higher elevation than in the towns or more, because there grows the maguey from which it is manufactured. On the uplands it has been, for many years, the greatest of the industries of the country, after mining, millions of acres being devoted to the growing of the maguey. Another distilled product called mescal is made from another and smaller species of the agave; and it is extensively used in the region where this latter plant thrives.

Soap, Candles and Chemical Products.—A great part of the raw materials used in these industries is still imported though the republic is capable of producing most of them. The Laguna Soap Company, capital $5,000,000, formed by the amalgamation of two large cottonseed-oil companies, produces daily in normal times and conditions, 400 tons of cottonseed oil, 7,500,000 pounds of soap and 2,000 metric tons of glycerine, together with a variety of edible cottonseed-oil products. It employs from 300 to 1,000 men. The Union Soap Factory of Torreón, capital $2,000,000, engaged principally in the manufacture of soap
and glycerine. The company also has a large refining plant near Torreón. There are a number of smaller soap and candle factories scattered throughout the republic. Chemicals, paints, varnishes and acids are also manufactured in or near numerous cities and towns. A few years ago all the petroleum and petroleum products used in Mexico were imported and sold in the republic at excessively high prices. Now petroleum, benzine, kerosene, paraffine wax, asphalt and many by-products are manufactured in the country; and native oil has become an important factor in the national life. Whole railway lines use oil burners on their engines and petroleum is employed for producing motive power in many kinds of industrial life. Yet but a very small percentage of the possible native oil sources has been exploited; for the oil belt extends all the way from Texas to Guatemala on the Gulf side and large deposits are known to exist on the Pacific Coast. The refining of crude petroleum has become a business of considerable importance in Mexico. The exploitation of the asphalt deposits has already influenced the pavement of the streets of the cities and larger towns of the republic.

Iron and Steel Products.—No other Mexican industry has grown so fast within the past dozen years as that of the great iron and steel foundries now turning out products equal to those of the steel-producing centres of the world. This output includes smaller agricultural implements, marketable iron and steel, and a constantly increasing number of finished products such as are turned out from the great American and European steel plants. The Monterey Iron and Steel Company, capital $10,000,000, with its great blast furnaces, produces 300 tons of steel per day. It makes steel rails and structural iron and steel in vast quantities and of excellent quality. Monterey is the most important centre of this new industry; and naturally there the business has reached the highest state of perfection in the republic. The steel and iron industries of Richard Honey, in Hidalgo and the Federal District, are next in importance to those of Monterey. Two other important iron foundries in Jalisco rely chiefly upon local trade. One of these at Zúñiga has 50,000 dollars worth of equipment. The other, at Tepatitlán, is the largest and most important, and does an important national business.

Paper.—Paper is made (though not exclusively for local consumption) by the San Rafael Company, situated near the capital. This institution, which is capitalized for $7,000,000, has two factories, a pulp mill and extensive forests from which it draws its raw material. Though the output of San Rafael ranks among the commoner grades of paper, including the quantities of newspaper print, yet it also makes high-grade paper of numerous styles and qualities of fineness, among these being cartas and the finer grades of half-tone paper.

Dynamite and Other Explosives.—The important gunpowder factories of Mexico; and the government has its own ammunition factory at Santa Fé, near the capital. The Mexican National Dynamite and Explosives Company, at Dinamita, Durango, produces from 5,000 to 7,000 pounds of explosives per month. It is capitalized at $4,000,000 and employs from 900 to 1,000 hands.

Flour Mills.—Large flour mills, modern in every respect, and others of smaller capacity and more primitive types, are to be found in Mexico from Monterey to Yucatán. Of the modern ones are: El Hermosillense, Hermosillo; the Chihuahua Flour Company, Chihuahua; the Goleta Mills, Saltillo and Monterrey; the Phoenix Mills, Saltillo; the Guadalajara Mills, Monterrey and Ramos Arizpe; Alliance Mills, Torreón; the Diamond Mills, Gómez Palacio; the Gulf Flour Company, Saltillo and Mexico; and the Manufacturers Association, Guadalajara; and La Perla Mills, Acapulco.

6. TRANSPORTATION AND COMMUNICATION. Before the white man had set foot in Mexico the various nations then occupying what is now the Mexican republic had built many well-paved roads and innumerable mountain trails, in all probability better than the roads of to-day, if we are to judge them by their still existing remains, and by the ruins of the great and populous cities whose arteries they were. Following the Conquests, and as Spain gradually extended her power over her trans-Atlantic domains and as peace became established upon a firm basis, bringing with it an extension of trade, the necessity for an extensive system of highways between the inland cities and the ports and between city and city became apparent. The Spanish government, ever alive to its own interests, undertook the construction of the caminos reales, or king's highways, which, a century after the Conquest, had already connected together all the centres of commercial importance in New Spain.

Transportation Facilities of the Republic. — Throughout the revolutionary period (1810-21) transportation facilities of every kind in Mexico were neglected, on account of the activity of the revolutionists and the exhausted condition of the Spanish treasury after the Napoleonic wars. From 1821 to 1876, the new republic formed upon the ruins of the government of New Spain was so occupied with its own local dissensions that it found little time to give to the building of highways and byways of communication. Yet it was toward the close of this period of unrest that the first railroad was built in the republic. In 1854 a line connecting Mexico City and Guadaloupe, a distance of three miles, had been constructed; and a year later Vera Cruz was connected with Tejera (12 miles). These were the two extreme ends of a railway by means of which it was proposed to give the capital an all-rail route to the first port of the republic. But so slow was the work of construction that it was not until 1873 that this comparatively short line (263 miles) was completed. Practically no other railroad construction was undertaken in Mexico until after the election of Porfirio Diaz as president in December 1876. In November of the following year, the Secretary of Public Works signed a contract with James Sullivan and his associates for the construction of a railroad line from the United States border to Mexico City, and from there to the Pacific Ocean. But Sullivan found difficulty in getting the capital necessary to build the proposed line. In 1880 a strongly-subsidized concession was granted to the Mexican Central Railway Company, organized to build a narrow-gauge railway from El Paso to the Mexican capital; and about the same time the Sullivan concession was extended and rearranged so as to empower the holders thereof to construct a narrow-gauge railway from Mexico City to Laredo, on the Texas border. Both these lines were eventually built. From 1880 to 1898 hundreds of railroad concessions were granted by the Mexican government, most of them accompanied with subventions in cash, government bonds and national lands. Such a very active railway era was inaugurated that, in 1890, the government found it necessary to create the new Department of Communications and Public Works, at the head of which was a minister of the Cabinet. In 1898 Finance Minister Limantour announced that, in the future, the government would give subventions only to roads of great political and financial importance. In the plan for railway extension laid down by Mr. Limantour were included a road to connect the centre of the republic with some Pacific Coast port, Guaymas or Topolobampo preferred: a line from the interior to Mazatlán; another from the interior to Manzanillo and a fourth to Acapulco. The plan also included lines to connect the capital with Acapulco and Tampico. The following year a new general railway law was issued in order to co-ordinate the work of the Minister of Finance and to govern the roads in existence and those being built. The most important railway lines of the country were constructed between 1880 and 1890: after which very little building was done until Mr. Limantour took matters in hand in 1898. By 1902 the following roads had been constructed: The Mexican Railway, connecting Mexico City with Vera Cruz; the Mexican Central, from El Paso to the Capital; the Mexican National, from Laredo to Mexico City; the Sonora Railway, from Nogales to Guaymas; the Inter-oceanic, from Mexico City to Tecate, and the Tehuantepec National, across the Isthmus of Tehuantepec, from Coatzacoalcos (Puerto Mexico) to Salina Cruz; the Mexican Southern, from Puebla to Oaxaca; the United Railways of Yucatan; and the Pan-American, from San Gerónimo, on the Tehuantepec road, to a point in Mexico close to the border of Guatemala. In 1906 the Mexican government succeeded in uniting the two great railway lines, the Mexican National and the Mexican Central, with the Mexican Railway of Mexico. By 1908 the Mexican International, the Pan-American, the Vera Cruz and Pacific, the Inter-oceanic and the Tehuantepec National had been brought under the control of the government and included under the foregoing title of the National Railways of Mexico. During the revolutionary period from 1910 to 1916 the railroads of Mexico suffered very greatly; much of the rolling stock was destroyed and bridges, stations and other buildings were burned or wrecked. In January 1915, according to the report of the Mexican Minister of Railways, the total monthly income of the Mexican National lines was only 647,000 pesos (paper currency). But in August 1916 the monthly income of these...
roads had risen to 25,000,000 pesos (paper currency). At the same time the transportation of freight had become almost normal, notwithstanding the fact that the loss of the National Railways for the fiscal year 1913-14 was $28,035,624, and for the following year $28,181,328. When the Carranza government undertook the management of the railways in June 1915, it had to face a deficit of $41,289,609 United States currency. Since then the railway income has steadily improved. In 1916 there were seven railways in operation in Mexico. During the fiscal year 1917-18 the total receipts of the Federal Railway was $72,000,000.

Postal Service.—In 1913 there were in Mexico 2,917 post offices, branch post offices and postal agencies. In the postal service of the republic about 15,260 miles of railroad, 300 miles of street railway and 10,000 miles of steamship routes were in use for the distribution of postal matter. During the year domestic postal orders to the same extent as in 1915, and foreign paid postal orders valued at $8,886,979 were issued. During the same period the other income of the postal service was $4,914,640. All the railroads of the country disposable were made use of in the postal service, and they were aided in their work of distribution by messengers, horses, mules and automobiles, on land; by river boats of the interior navigation service; and by some 23 steamship companies, among which were the Mexican Navigation Company, the Pacific Navigation Company, F. Leyland and Company. Limited; West Indian and Pacific; Imperial German Mail, the Harrison Line, the New York and Cuban Mail Steamship Company, the Munson Steamship Line, the Atlantic and Mexican Gulf, the Southern Steamship and Banana Company, the Canadian Mexican Atlantic Line, the Kosmos Line, the Chinese Imperial Steamship Company and the Toyo Kisin Kaisha. There were 150 traveling post offices, principally on trains. During the year 20 new post offices were opened to the public. The parcel post service, which was instituted a few years previous, has proved of great value and is year by year, receiving more patronage. The government proposes to extend the scope of this service and to make it of still greater utility. Consult Halsey, F. M., 'Railways of South and Central America' (New York 1914).

7. BANKING AND FINANCE. The Mexican people have long shown a capacity for finance. In pre-Columbian days, the financial arrangements of the Aztec Empire were complicated and extensive; and the keeping of the accounts of the tribute rolls was in itself a matter that required more than ordinary executive ability, in an age when the whole income of an empire was not larger than modern Germany, and densely populated, was paid in produce of various kinds. This required vast storehouses in Mexico City and substations for customs receipts in many parts of the land. The Spaniards, too, are keen financiers and the mingling of the two races has produced a blend and a nation which has made great financial advance during the past quarter of a century. The revolution of 1910 temporarily checked this financial expansion. The first financial arrangement is that by which the dignified name of bank, was founded, in 1776, in connection with the charitable organiza-
500,000,000 pesos at the rate of 10 cents United States currency for one peso. This value was to be maintained by the sale of gold drafts in Mexico. The rate of 10 cents was fixed for the new paper. It was to be received, at this rate, for duties, by the government. This was known as the Non-counterfeitable Issue, and was to be issued gradually in payment of salaries and other government expenses at the rate of not over 50,000,000 pesos per month. However, a very considerable part of the taxes imposed by the federal government had to be paid in silver. These included all export and import duties. The greater part of this went to swell the guarantee or reserve fund behind the new paper currency issue. At the same time that this new issue was being put into circulation steps were being taken to retire all the former issues authorized by the Constitutionalist party, whether state or federal. To this end all the bills over 50, 100, 100 pesos were declared (1 June 1916) no longer of compulsory acceptance and the holders thereof were notified to turn them in to the government, upon which they would get receipts promising redemption beginning on the 1st of the next month at the rate of five cents United States money (10 cents Mexican silver) for the peso. As the market value of this currency was only about two cents and as it had previously fallen as low as one-half a cent, the offer was a very liberal one and had the desired effect. In order to further facilitate the retirement of the old paper currency, all railway and telegraph dues were made payable in it up to 1 Jan. 1917. Owing to this clever campaigning on the part of the government, the metal currency, which had gone into hiding shortly after the outbreak of the revolution, began to reappear in 1916, with the increase in confidence in the stability of the Carranza government.

As Mexico had no national paper currency previous to the outbreak of the revolution of 1910, the bills in circulation being all bank issue, were kept at par value by a reserve of 50 per cent of the amount in circulation, exacted and guaranteed by law. During the revolution, however, all state and federal governments, in exchange for issuing notes far in excess of their reserve. The Carranza government, after an investigation, gave the offenders a certain time in which to make good the required deposits under pain of being closed. This caused the rapid decline of the value of banknotes throughout the republic, both state and federal. In order to further guarantee the stability of the Non-counterfeitable Issue, $5,000,000 gold was taken from the national treasury and an additional $5,000,000 gold was obtained from the Henquen Regulating Committee of Yucatán; and all bank issues of paper currency were ordered withdrawn from circulation, the government thus retaining, in conformity with the provisions of the constitution, a monopoly of the issuing of all money, whether paper or metal, in the republic (15 Sept. 1916). The income from national lands and forests was also added in gold; and this too went to back up the new paper issue. Gold was also obtained from uncultivated parts of great estates which had previously paid little or nothing in the way of either federal or state taxes. At the same time all the banks in the republic were placed under the strictest government supervision, and those which had not complied with the conditions laid down as to currency reserve were permitted to do business only through a government-appointed board of directors empowered to see to their liquidation. None of these banks could issue any specie without the consent of the government. At the same time the duties were divided into four classes; those payable in metal only; those payable in metal or the equivalent thereof in national paper currency of the new issue; those payable in the new paper issue; and those payable in the new issue or the equivalent thereof in the paper issues of Vera Cruz and the Constitutionalist Army. The new paper currency issue was distributed as follows: 80,000,000 one peso bills, 60,000,000 two peso bills, 75,000,000 five peso bills, 75,000,000 10 peso bills, 70,000,000 20 peso bills, 75,000,000 50 peso bills and 75,000,000 100 peso bills. This work of reorganization of the currency and finances of the country was placed in the hands of a commission of five members, all of whom had had considerable experience in monetary matters, and who were required to report to the Treasury Department, under whose direction they were to work. The banks of issue in Mexico had, 30 June 1911, the following paper currency in circulation: National Bank, $54,841,000; London and Mexico, $19,278,000; other banks, $42,535,000; total, $116,634,000. There were issued by the government, in 1910, 6,206,000 silver coins worth $2,927,000; 6,146,250 nickel coins valued at $307,312; and 19,450,000 bronze coins worth $194,500. In the fiscal year ending 30 June 1911 the consular fees were $1,163,341; the general stamp tax amounted to $15,271,000; the taxes on mining land to $1,934,000; on ores and metals, $2,365,000; tobacco, $2,760,000; alcohol, $870,000; cotton goods, $2,517,000; explosives, $3,334; direct taxes, $6,295,000; municipal taxes, $3,133,000; postal service, $4,775,000; telegraphs, $2,255,000; and lotteries, $1,255,000. During the same period the importations amounted to $47,500,000; the exports to $43,000, and the port duties to $1,985,000, making a total income from foreign commerce of $48,985,000, exclusive of gold, the United States took from Mexico, goods to the value of $140,800,000 and sent there goods to the value of $106,893,000, a total business of $247,694,000. Owing to the fact that the revolution of 1910 and succeeding years divided the country into several factions, each of which controlled its own section of country and was more interested in maintaining its ground than in furnishing statistics, such as the Mexican government put forth annually previous to 1912, definite information relative to the financial and other conditions of the country from 1913 to 1919 is not available, except in a general way; and even this covers only that part of the republic under the control of the Constitutionalist party, which was able, largely, to finance the administration through the sudden enormous increase of the oil interests of the republic and the rise in the price of oil itself on account of the European War. The finances of Mexico, which were in a deeply bad condition in 1876, when Gen. Porfirio Díaz assumed the presidency for the first time, continued to steadily improve throughout his seven terms of office until, on his re-election for the eighth time in 1910, they had reached such a
position that the Mexican government had secured a solid standing in the money markets of the world. According to the report of the internal revenue tax office for the fiscal year 1917-18 the total revenue collected was $75,490,360, distributed as follows: Mining, $2,203,353; exportation of metals, $10,003,225; alcohol and other liquors, $4,047,532; textile fabrics and thread, $2,304,050; importation of wines and other beverages, $2,330,584; electric light and power, $800,743; telephones, $201,055; bottled liquors, $300,164; matches, $286,642; advertising, $93,054; pulp, $479,265; petroleum, $7,955,113; patents, $23,449; inheritance tax, $357,577; loans, $92,301; federal taxes, $27,545,930; stamp document tax, $14,376,216. The public debt of Mexico, which has never been large for the potentialities of the nation, began with a 5 per cent loan of £2,200,000 contracted in England in 1824, which was increased by a like amount at 6 per cent the following year. The interest on these two loans was not paid from 1827 to 1831; and even after this latter date the interest was paid only intermittently and was therefore, the cause of many disagreeable complications which have become part of the history of the Mexican national debt, which itself became mixed up with political events of primary importance. In 1829 two of these two first foreign debits of the Mexican nation were consolidated with the national debt. Previous to this, however, they and other loans contracted in 1831 were consolidated into one national debt of £2,204,387, in 1837, and this agreement was again ratified in 1839. In 1846, the whole Mexican foreign debt, including interest due and unpaid, together with certain internal bonds and other unfunded liabilities, were again consolidated into one national debt of £10,241,650 in bonds of the 1846 issue, for the payment of which one-fifth of the customs receipts of the ports of Vera Cruz and Tampico, the duty on tobacco in all forms and the silver export duties on ore sent out by way of the Pacific ports were pledged. During the war with the United States, American forces seized and retained Vera Cruz and Tampico and the Mexican government was thus unable to meet its foreign obligations. In 1850 another attempt was made to meet the foreign obligations through its conversion into new bonds bearing 3 per cent and guaranteed by 25 per cent import duties and 5 per cent of the Gulf ports and 75 per cent of the Pacific ports duties, which were to be employed for the payment of interest on the bonds and their redemption. In 1867, by a decree of the imperial government of Maximilian, government stock to the amount of £4,864,800 was issued and was accepted by the original bondholders in payment of arrears of interest. The same year the imperial government secured a second loan of £12,365,000 in Paris and London; and this loan was practically all converted into the Mexican Imperial Lottery Loan with a face value of £20,000,000. Both these transactions were repudiated by the Republic of Mexico in 1867. In 1870 the export and import duties and all the direct taxes on industries and landed property and buildings in the Federal District being pledged to meet the obligation thus contracted. The following year the Tehuantepec 5 per cent railway loan of £2,700,000 was made in London and Berlin and a year later silver currency bonds to the amount of £6,000,000, bearing interest at 6 per cent, were subscribed of in London and Amsterdam to meet certain pressing obligations for railway concessions and construction; and the same year another loan of £6,000,000 was made in London, Berlin and Amsterdam for the same purpose. Three years later a 6 per cent loan of £3,000,000, secured by 12 per cent of the import and export duties, was contracted in London. In 1894 the government created the 5 per cent Interior Redeemable Debt, with a view to a single new issue in which all future subventions to railways should be paid. This debt consisted of five series of £20,000,000 each. In 1899 the 5 per cent Internal Consolidated Gold Loan of £22,700,000, redeemable not later than 4 years, was also issued. In 1888, 1889, 1893 6 per cent loans and 1889 5 per cent Railway Loan. In 1903 the federal government assumed obligation to the extent of £2,400,000 for the payment of the City of Mexico 5 per cent Standard Oil loan, to meet the expenses of the drainage of the capital. The following year a 4 per cent gold bond issue of £40,000,000 was made in London, New York and Amsterdam, partially through banks and partially privately, to meet various obligations of the government. In 1910 the final loan of the Diaz government was made at 4 per cent for £22,200,000, with a view to the conversion of the 5 per cent loan of 1899. Finally, in 1913, a loan of £200,000,000 was authorized, of which £60,000,000 was placed in France, with a guarantee of certain export and import duties. In June 1910, the public debt of Mexico was $300,524,996 (Mexican silver) payable in gold, and $137,850,133 payable in Mexican silver, and an additional amount in silver in the ratio of 27:50 (Mexican currency), making a total of $438,648,528 in Mexican silver. In 1918 the public debt was over 500,000,000 pesos gold (including interest of about 70,000,000 pesos), the peso gold being nominally worth about 10 cents. C. A., ‘The Banking System of Mexico’ (Washington 1910) and works under section on MANUFACTURES. On the same date there were in Mexico 33 banks, 25 of which were banks of issue, all of which were then doing business on a gold basis which had been introduced into Mexico in 1905 on the basis of a 50 cent dollar. For the fiscal year ending 30 June 1913 the revenue of the Mexican government was $130,958,902 Mexican currency against an expenditure of $110,781,891, a very considerable increase having taken place in five years, when the revenue was only $98,775,510 and the expenditure $92,967,393. It is worthy of note that, even with the revolutionary activities then prevailing the revenue of the government was in 1912-13 $15,755,816 over and above the preceding year. This income had reached over $150,000,000 (pesos) in 1917. This federal revenue is, for the most part, derived from stamp taxes, direct taxes and import and export duties. Although the federal government had improved consider-
ably in 1919, yet the disorganized condition of the country and of many of the banks, both state and federal, and the loss of credit brought about by the long revolutionary period, made the task of the Constitutionalist party of straightening out the financial affairs of the country very difficult. Money was badly needed; and this the great money centres statesmen and financiers, in search of opportunities for the exploitation of Mexico's natural resources were granted them. Working under this handicap, the government steadily pursued its ends with as much success as could be well expected under the circumstances.

8. GOVERNMENT. The constitution of Mexico is based upon that of the United States which it very much resembles. The republic is formed of free and sovereign states which, for administrative matters concerning the interests of the nation as a whole, are united under a federal government. In virtue of the constitution of 5 Feb. 1857 the national power resides in the people, who are the source of all public authority. The administration of the affairs of the country is carried on by the national government, and by each state government for its own state. But no state law may conflict with the general good as expressed by the laws of the federation. Slavery is prohibited by the constitution and all persons born in the republic are free and equal in the eyes of the law, and every one has a right to freedom of thought, profession and occupation. In so far as it is consistent with private rights and the exigencies of state, the press is free. In Mexico one may publish what he pleases, for there is no press censorship; but the citizen and the government are protected by libel laws. Newspaper, magazine and other presses cannot now, as formerly, be confiscated as instruments of crime. The right to associate together for any lawful undertaking, business or enterprise, and the complete individuality of every law-abiding citizen of the republic or resident therein are recognized and all may leave or enter the country without passport. Mexico being a republic, hereditary honors and titles of nobility are not recognized and no one is permitted to accept or wear them unless by special act of Congress. Arms may be carried for lawful personal defense in certain parts of the country, whereas in others a permit to do so must be obtained; for the law recognizes that in the camps, wild mountainous regions and unsettled parts of the republic, arms are necessary for self-protection, and here a permit is not exacted. Search without warrant is prohibited, and a policeman may not enter a private house without authorization from the police court, unless it be in pursuit of a well-known criminal or one caught in the act of breaking the law. Privileged tribunals such as were customary during the Spanish occupation of the country are strictly prohibited; and every man, be he priest or layman, citizen or administrative officer of the government, is ruled and governed by one common law. The passage of laws contrary to the interests of the nation is prohibited, and no treaties can be made with foreign countries for the extradition of persons. Accords to the constitution and the law of the land offenses against law and order are divided into two great classes, civil and criminal. No one may be imprisoned for offenses coming under the first of these heads. This provision includes debts and other monetary obligations; for in previous periods of the history of the country, are declared contrary to law. All punishments except those of a correctional nature must be administered by judges of the criminal courts. The death penalty is practically never exacted in Mexico in times of peace. It is stipulated in the constitution, however, that it may be applied in cases of high treason, premeditated murder, parricide and highway robberies; but never for political offenses, except in time of war. In practice, however, about the only cases in which it is exacted, in normal times, are those of offenses of a most serious nature against military authority. In all legal actions one may appeal from a lower to a higher court until the Supreme Court of the nation is reached and finally dispose of its decision, which is final. But in cases of the death penalty, an appeal may be made to the clemency of the President of the republic. Once a man has been tried and acquitted he cannot be tried again for the same offense. In conformity with the democratic government, no spying upon the privacy of the people of the land is permitted and, on the same principle, all private correspondence is declared inviolable. The quartering of soldiers upon private individuals in time of peace is prohibited, and even in time of war it can be done only in conformity with certain regulations of Congress and through special orders issued to fit the exigencies of the occasion. Patents may be issued for a certain stated time on inventions of use to mankind, although the constitution states that no monopolies shall exist in the country except such as the government may take to itself for the general good of the nation; as, for instance, the coinage of money and the control of the postal system. In the event of internal disorder of whatever character, which threatens the safety of state or government, the President has the right to suspend the constitutional guarantees; as he also has in the case of foreign invasion. But this can be done only with the consent of his cabinet and Congress, or of the congressional committee when the Congress is not in session.

All persons acquiring land in Mexico become by virtue of this acquisition Mexican citizens, unless they distinctly state in their deed of acquisition that they reserve their right to the citizenship of their native land. One of the radical changes of the Queretaro convention (31 Jan. 1917) is the provision that only Mexican citizens, by birth or naturalization, may acquire landed property; that only they may right or obtain concessions to exploit mines or combustibles; but the state may concede such right to foreigners who appear before the Secretary of Foreign Relations and agree to be considered as Mexicans, in so far as the titles involved are concerned and agree not to invoke, in regard to the same, the protection of their respective governments, under penalty, for violation of these provisions, of losing the titles
thus acquired, which automatically revert to the nation. All Mexican citizens, whether native born or naturalized, are liable to military service. All persons resident within the republic are guaranteed the protection of the laws of the land.

The state government is divided into three branches, executive, legislative and judicial. The chamber of deputies and the senate, constituting the Congress of the nation, are the legislative bodies, and by them alone can laws for the government of the country be enacted. Two sessions of Congress are held each year. The first, which begins on the first day of April, lasts from two to two and a half months, and its primary business is to audit all accounts of the previous year and to arrange the estimates for the incoming fiscal year. The second, which begins on 16 September, lasts for from three to four months. The law provides for the election of a President of the republic, who shall serve for a term of four years and shall not be re-elected, and a Cabinet composed of the following departments: Fomento (promotion), foreign affairs, interior, justice, finance, communications and public works and war and marine. This Constitutional provision recognizing that the constitution of 1857, with the various amendments thereto, was unsuited, in certain important respects, to the conditions under which the Mexican people live, decided to make such changes in it as seemed necessary for the welfare of the nation. To this end a convention was held in Queretaro (December 1916). After two months' deliberation it closed its labors on 31 Jan. 1917, having reformed, in a radical manner, a number of the most important sections of the basic constitution. According to these changes the office of Vice-President of the nation is done away with and the filling of that of President, in case of the death or absence of the chief executive of the nation, is left in the hands of Congress. The age of compulsory primary education is raised to 15 years and all parents or guardians are under obligation to see to it that their children or wards receive primary, secondary and military education. Instruction in all government schools and in all primary private schools must be laic, and no ministers, priests or officials of religious organizations or societies may establish or own schools or teach in Mexican schools. This abolishes the church schools which, before the revolution of 1910, ministered to fully two-fifths of the educational needs of the country. To make up the deficiencies in educational facilities thus caused the new reforms in the constitution declare it obligatory upon all agricultural, mining and industrial companies, resident outside of towns, to establish and maintain schools for the education of the children of the people in their employ or resident on their property. All schools, whether official or private, must submit to official inspection and follow the government program of studies.

The constitutional amendments of 31 Jan. 1917 provide for the subdivision of large landed estates, aiming in this way to solve the land problem, which formed one of the causes of the revolution of 1910. Each state or territory is empowered to fix the largest amount of land which any person or company may hold, and all landed properties in excess of this amount must be subdivided and sold off with a certain stated time, and in accordance with official regulations, otherwise they are subject to confiscation. One of these provisions provides that at least 20 years shall be allowed the purchaser in which to acquire proper rights by making stated yearly payments. During this time no mortgage can be placed on the property thus acquired and the interest charged, in case of default, is not to exceed 2% a year. In no case can a lien of any kind be placed upon homestead properties nor can they be seized for debts or other causes. In theory all land, mineral and other resources of the country are the property of the nation, and this position is maintained by the constitutional amendment of 1917, and the theory itself is put forward as a justification for the subdivision, by order of the legislature, of large landed estates and the national control of oil, mineral and water rights, with a view to the more equal distribution of the wealth of the nation and the encouragement of small landed proprietors to hold mining properties it is necessary to work them; and no company may acquire and retain possession of more land than is actually necessary for the successful conduct of the business of the concern, whether it be mining, agricultural or industrial.

As the Constitutionalist party, when it rose arms against the Diaz government, proclaimed the rights of the Mexican people to govern themselves in a direct and democratic manner and demanded the immediate solution of the agricultural questions facing the nation, proclaiming, at the same time, the rights of the masses, naturally these reforms find a prominent place in the changes made in the constitution by the convention of 1917. These are radical and far-reaching. The new labor laws provide for an eight-hour day with six days' rest a week; while night work is restricted to six hours and when it is of a dangerous and unhealthy character, it is altogether prohibited for women and children under 16 years of age, while children under 12 may not be employed in any contract work. Commercial establishments may not work their employees after 10 p.m.; and children between 12 and 16 must not be worked for more than eight hours a day. Women shall not be required to do hard labor for three months before childbirth, and they may not work for one month after but they shall be paid for this month and shall retain their positions and all the rights of their contracts. They shall also be allowed two rest periods each day during the time they are nursing. The minimum salary in every district of the country shall be such as to provide for the necessities of life, the education of children and hospital care for all farming, commercial, manufacturing and mining enterprises the employees have the right to participate in the profits of the business, and the percentage of such participation shall be fixed in each community, by a commission acting under the central commission of conciliation which, by law, is established in each state. There shall be no distinction in salary by reason of sex or nationality, for the same work. Farming, mining and timber companies are obliged to provide the cities of larger towns, proper sanitary dwelling markets, hospitals and other convenience
necessary to the life of the community, and
when the employees number 200 municipal
buildings and recreation grounds shall be
provided within which no intoxicating liquors
shall be kept, such employees shall be allowed
to form combinations to protect their interests and the right to strike
and to close down is recognized. The work-
men must, however, give 10 days' notice to the
Commission of Conciliation and Arbitration
before striking, and they are not allowed to
use violence of any kind in the attempt to
enforce their demands. An exception to this
rule is, however, made in the case of govern-
ment employees in ammunition factories, which
are under the authority of the army and thus
subject to military discipline. A complete
close-down shall be legal only when the excess
of production makes suspension of work neces-
sary to maintain prices at a reasonable rate,
but approval for such closings can only be obtained from the Committee on Conciliation
and Arbitration, which shall be formed of an
equal number of representatives of capital and
labor together with one additional member rep-
resenting the government. Any employer re-
fused approval is given a time limit, in which
the contract can be terminated and to abide by its decision forfeits all right to any
contracts already made with his employees and
becomes obligated to pay them three months' salary. Should the workmen refuse the offer
of the commission their contracts automatically
become void. An employer who discharges an
employee because he has joined a union or
taken part in a legal strike or without any just
cause shall be obliged, at the option of the
workman, to pay three months' salary or to
continue the contract. The law provides for
free municipal employment bureaus and stipu-
lates that, when a Mexican workman contracts
to go to work outside Mexico, the contract
thus made must be approved by the municipal
authorities and vised by the consul of the
country to which he is about to go, and one of
its provisions shall be that the employer
must provide the means for the return of the
workman to his native land. No part of a salary may be retained as a fine, as was formerly the case; no salaries may be paid in a
saloon or place of amusement, and no work-
man may renounce his rights to indemnity for accident. No labor contract can be for more
than one year, and in such contracts the laborer cannot renounce any of the rights guaranteed
by him by the law. The only redress for the viola-
tion of a contract on the part of the employer
or employee is a civil action.

ARMY AND NAVY. Owing to the many
revolutions and upheavals through which
Mexico has passed since it became an independ-
ent country in 1821, the armed forces of the
republic have been a constantly varying quan-
tity. At the time of the collapse of the Max-
imilian empire in 1867 there were four great
military centres, the north, the west, the centre,
and the southeast. When Porfirio Diaz took
the city of Mexico in 1876 his army had under
his command more men than he had in the whole
military force of the republic in 1910, when
he was faced with an uprising which was
destined, in less than a year, to send him into
exile from which he never returned. Juarez,
who, on the death of Maximilian, was acknow-
ledged everywhere as the legitimate ruler of
Mexico, found one of his greatest problems in
the reduction of the armed forces which he
had inherited from the prolonged conflict
against the French, the clericals and the Re-
actionary party. He proceeded to solve it by
discharging from service hundreds of soldiers
and officers, many of whom, being unfitted for
civic life and having no means of making a
living, became a constant threat to the already
troubled side of the executive. Bandits roamed
the country and made so bold as to even invade
the capital itself. Robbers, on a less pretens-
tious scale, were everywhere; and most of
them had either been formed from or organ-
ized by the disaffected or the forces of the
Reactionary party. Diaz faced the same condition of affairs when he came
into power in 1876. But he was wiser
in his day than Juarez had been in his, probably
because he was a thorough soldier and under-
stood the soldier's point of view. He saw, in
the very restless element that had given the
Indian President so much trouble, the raw
material out of which to create a rampart
against the lawlessness that had overrun the
land. In the course of a few years he had
organized out of this unpromising material the
rurales (rural guard), which became as famous
in Mexico as the Northwest Mounted Police is
in Canada. These guardians of the peace, which
were to be found in organized groups in the
towns, cities and villages throughout the coun-
try, were military in every sense except that
they were under the jurisdiction of the Depart-
ment of the Interior (Gobernación) instead of
that of War. However, in the last few months of the Diaz administration (1911),
they were placed under the jurisdiction of the War
Department, for strictly military considerations.
Throughout the trouble they remained, for the
most part, faithful to the government, but be-
coming later on disorganized through the many
political changes that followed one another in
rapid succession, they were finally disbanded.
Throughout his long term of office, which ex-
tended from 1876 to 1880 and from 1884 to
1911, General Diaz gradually reduced the mil-
itary force of the republic and aimed at increas-
ing its efficiency. In 1910 the standing army
of the republic consisted of less than 1,000
commissioned officers of all grades and less
than 25,000 non-commissioned officers and men.
Thus the government, which had been lulled
into fancied security, through the previous peace which had followed the assumption of the
presidency by Diaz, found itself unprepared
to deal with a revolution like that of Madero,
which affected the greater part of the country.
The peace standing army of the Mexican army
in 1914: Commissioned officers, 3,112; non-
commissioned officers and men, 26,431. The
expenses of the maintenance of the armed
forces of the republic, the garrisons, etc., was, in the fiscal year ending 30 June 1914, over $40,000,000 Mexican money, or more than one-third of the whole revenue of the republic. As this amount embraces only the forces of the de facto government, it is probable that nearly as much more was spent in the maintenance of the revolutionary forces then in the field against the former. On 30 June 1916, A. G. Garcia, Mexican inspector of consulates stationed in the United States, gave the strength of the Constitutionalist army as 175,000 officers and men, all of which he claimed were well armed and uniformed. Other authorities place the Constitutionalist forces at between 85,000 and 100,000. This is considerably above the authorized strength which is 43,967 commissioned officers, non-commissioned officers and men. During the Díaz régime many new barracks were built and many old ones were reorganized and made modern. A school of aspirantes (officers in training) was opened at Tlapacoyan in the State of Mexico. A short distance from the capital for the military instruction of men in all branches of the service who could not afford to go through the longer and more thorough course given in the National Military School in Chapultepec. Owing to the part the pupils of this Tlapacoyan school took in the uprising under Generals Mondragón, Félix Díaz and Reyes in February 1913, it was closed. The West Point of Mexico, however, is the Chapultepec school, which occupies a part of the famous Chapultepec building, the official residence of the President of Mexico. There are generally in attendance about 300 students all being trained for officers in the Mexican army at the government expense. The school also offers an excellent post-graduate course in advanced engineering, topography, military jurisprudence, ordnance, military history, advanced military tactics and an extensive course in the geography of the country which, from the military point of view, is extremely difficult. The present Constitutionalist government, following in the footsteps of the Díaz administration, is attempting to educate the illiterate soldiers in the ranks of the army, or at least to teach them to read and write. According to the recent amendments to the Mexican constitution, service in the army is obligatory for every citizen of the republic, and in time of war the conscription covers from three to five years; but as a matter of fact only the lower classes are forced into the army. In time of peace the Mexican army now consists of 34 battalions of infantry, 18 regiments of cavalry, one regiment of horse artillery, two regiments of field artillery, one regiment of mountain guns, two battalions of garrison artillery and one battalion of engineers, each battalion consisting of four batteries. On mobilization each four-company battalion (including the engineers) forms a regiment of two battalions while the four-battalion regiments are raised to six battalions and the cavalry regiments to six squads.

Owing to the difficulty which the Constitutionalist government has met with in securing arms, the armament of the forces is of different kinds, including various Mauser models for the infantry, and Remington rifles of a date as far back as 1893, the Mauser carbine for the cavalry, and other arms of German and Japanese make. The field and horse artillery have Q. F. guns on the Schneider-Canat system, while the coast defense consists, in so far as it is modern, principally of guns of French make.

The Mexican Navy.—The navy consists of: the gunboats Vera Cruz, Zaragoza, Bravo, General Guerrero and Morelos, and the transports Progreso and Oaxaca. The Zaragoza is 207 feet in length, has a displacement of 1,226 tons and a speed of 13 knots, is built of steel, and its armament consists of six 8-inch and six 6-inch guns. The Nordenfeldt rapid fire guns and two Hotchkiss revolving guns. The Vera Cruz is 200 feet in length, has a tonnage of 1,000 tons, a displacement of 1,600 tons, and a speed of 12 knots, is built of steel, has two 15-inch and two 12-inch guns in the bow and stern, and carries two 6-inch rapid fire guns and four Hotchkiss automatic rapid fire guns and one Whitehead torpedo gun. The Bravo and Morelos each have 252 feet in length, have 2,500 horse power and a speed of 16 knots. They are built of steel, and each carries two 16-inch rapid fire guns and six Schneiders. Each of the four Oaxaca class is 230 feet in length, has 1,585 tons displacement, a speed of 12 miles, is built of steel and will carry 250 tons of cargo and 400 men, with the usual complement of officers. The Progreso is 100 feet in length, its tonnage is 1,897, its speed 8 knots, and it is built of steel, has a tonnage of 250 tons of cargo, 200 cattle and 500 men. Reserves are provided for service in the army-in-case-of-war, which can, if needed, be made to swell the entire fighting force to about 50,000 men.

10. EDUCATION. The early history of education in Mexico is particularly interesting. In 1529, the College of San Juan de Letrán was established in the capital and three doors open to Spaniards and Indians alike. The first university was opened in 1553 by special permission of the King of Spain. In 1573 two colleges, San Gregorio and San Ildefonso, were opened; and two others, a divinity school was established a few years later. Thus seven institutions of higher education were in operation in Mexico before the close of the 16th century. It was not, however, until 1570 that the science of medicine was recognized as meriting a separate branch of higher education, the first course of medicine being established in that year. Twenty-one years later another medical professorship was founded, and in 1681 anatomy and surgery were added. The Royal College of Surgeons, established in the city of México in 1768, still exists as the National School of Medicine, a name adopted in 1845. Its home is the building made famous as the residence of the Spanish Inquisition. The Mining College or School of Engineering, which occupies an edifice built by the famous Spanish architect Manuel Tolsa, at a cost of $3,000,000 and is in a most flourishing condition. Although the Spanish conquerors of the Americas were largely inspired by avarice, cruelty, and brutality in their treatment of their subjects, they were sincerely devoted to the cause of higher education and contributed liberally from public revenues and private fortunes to its advancement. In the city of México there was founded in 1551 by the Spanish Crown, the first university in North America, 200 years before the independence of the United States. The Nation
Academy of Art occupies a building on the site of which was the home of the first European school of the new world, a school for Indians. The first normal school for males and its companion for females, established in 1648; the Jesuit College of San Ildefonso, erected in 1749 at a cost of $400,000, is now the home of the National Preparatory School (a part of the National University of Mexico). The National Library, with its more than 400,000 volumes, was formerly the Convent of San Augustine. The building in which is now located the National Museum dates back to 1731 and cost $1,000,000 and The College for Young Women now occupies a roomy structure completed in 1734 at a cost of $2,000,000. Thus are education and history closely intertwined in Mexico City. In 1824 Humboldt wrote: "No other city of the new continent, not excepting those of the United States, possesses scientific establishments so great and so solid as those of the capital of Mexico." In most of the states, schools for the care and instruction of orphans are maintained at the public expense; in these both sexes are given the same instruction, of which are quite extensive. Boys are taught the ordinary trades, and girls are instructed in the various occupations pertaining to the sex. In these, as well as throughout the entire educational machinery of the republic, methods have been adopted, and system, progress, and thoroughness prevail. Everywhere there is manifested the deepest interest in the uplifting of the masses through the most effective of all agencies—education. When Dr. Porfirio Diaz was first elected President in 1876 there were only about 4,000 public schools in the entire republic. From the coming of the Spaniards the chief interest in education had been confined to the higher branches, to the establishment of seminaries, colleges and universities, and the primary or fundamental branches were neglected. Under Diaz this resulted a noteworthy increase of schools and attendance. In the period between 1876 and 1891 schools of all classes had increased from 4,250 to more than 10,000 and the total attendance of more than 350,000, and from 16,000 to 235,000, and of Indians from about 8,000 to 170,000. In 1891 the entire cost of maintenance of the educational system was $4,068,200, which sum was paid by the federal and state governments, the average cost per capita being $5.63. In 1907, the number of primary schools supported by the federal or state governments was 9,710 and by municipalities, 2,220; total, 11,940; and the attendance was 776,622. There were 34 secondary and preparatory schools supported by the federal and state governments, with an attendance of 4,231; of which 3,793 were males and 438 females. The number of private schools during the same year was 2,499 with 152,917 pupils. In 1913-14, $13,920,000 was spent in the education of Indians and among the population of the state was 972,600 with a total enrolment of over 700,000, for the teaching of which there were over 22,000 teachers. The number of public libraries in 1913 was 151; number of museums has of which 72 are archaeological, seven scientific, eight natural history, one geological and metallurgical, five agricultural, one medical and anatomical, one industrial, two commercial and nine miscellaneous. There were 164 scientific and literary societies. A law was enacted in 1888, but not put into force until 1896, for the establishment of at least one public school for every 4,000 inhabitants. Under the provisions of this law the advance in education and educational methods throughout the republic was rapid. The National Library, which has a large and very convenient building and location in the capital, is a noteworthy institution. In its collection of more than 400,000 volumes are many rare books and manuscripts. Among these are works by early Spanish historians and scholars written before the art of printing was known. A very large proportion of the volumes in this library was originally the property of the church or of the priesthood and the books were confiscatated by the government during the progress of the war of reform. Naturally many of them deal with religion, literature, language or history. Of similar character are most of the state libraries. While there are some 45 public museums in the republic many of which are of quite extensive and are exceedingly interesting and instructive, far greater importance attaches to the National Museum in the city of Mexico, than to all others combined. Although it has occupied its present quarters in the National Palace only since 1865, it was established in 1831, with the collections previously belonging to the Conservatory of Antiquities founded by Emperor Iturbide in 1822, and to the Royal University, to which Viceroy Bucareli y Ursula had in 1775 transferred the remnants of a most valuable collection of maps, hieroglyphs on skins, manuscripts, etc. These were consolidated under the name of the National Museum. Here the student of archaeology, of ethnology or of any other department of the ancient history of the American continent, or of the peoples who at different periods dwelt upon it, may find greater wealth of material for investigation and study than exists in any similar institution in the western world. While there are also a number of very important museums, of which the principal state capitals, the National Gallery, in the city of Mexico, holds unquestioned preeminence. Of literary and scientific societies there are many in Mexico. Every considerable community is the home of one or more of these associations, some of which have been in existence many years. The Revolutionary party of 1910 was unreservedly committed to the education of the masses; but the burden was unloaded upon the individual states and communities over which the federal government retained supervisory rights but with no central control. The Constitutional party has shown itself strongly opposed to church control of schools of any kind, whether public or private. In Mexico the city schools are fairly large and all those in the towns and villages and the country districts are very elementary and poor. This is due to lack of funds for the maintenance of public schools and the difficulty of getting capable teachers for the salaries paid. The plan of organization of the Mexican schools is more French than American. Primary instruction covers four years and the high school course two. Four
years of preparatory school duties lead to the university, which is much more academic in form than in the United States; so much so, in fact, that the work covered by the National University, as it is now constituted, was known, previous to 1913, as the course of higher studies. But the Revolutionary party did away with the cabinet office of Minister of Public Instruction, giving to the arts department of the university its old name of the National Preparatory School and erecting the preparatory school into a university. Whereas previous to this all education had been without charge, the new educational law exacts a fee of $5 a month in both the preparatory school and the university, with all their affiliated schools, like those of medicine, law, dentistry, engineering, etc. (17 Jan. 1916). For some years past the tendency of Mexican public education has been toward the practical at the expense of the academic; and this tendency has been accentuated by the changes recently made. Military instruction is made obligatory; French and English have been reduced from a three to a two-year course and much attention is paid to manual training. To the General Direction of Public Instruction of the Department of the Interior, re-established in 1914, is entrusted all educational matters pertaining to the Federation, which were originally handled by the Department of Public Instruction and Fine Arts. The General Direction of Fine Arts of the Department of Fomento (Promotion) has charge of all public libraries, national monuments, historical, archeological, artistic and other remains; the National University, preparatory, normal and primary instruction, including the teaching of agriculture, commerce, industry, geology and manual training in the Federal District and in the territories. Rudimentary education and state colleges and schools are in the hands of the local authorities which have their own governing bodies for this purpose. All companies having charters, whether federal or state authorities are, by virtue of this concession, obligated to provide schools and teachers for the children of the people in their employ. The same law applies to plantations, ranches and agricultural enterprises in general. This new law has worked fairly well and has been instrumental in increasing largely the number of schools throughout the republic. In the state of Yucatán alone there were, in 1917, nearly as many school buildings as there were in all the republic in 1876. In others of the states under the control of the Constitutionalist party, the number had, in 1917, been doubled since 1910.

The National Preparatory School in Mexico City (the old arts department of the National University) is now, what its name indicates, purely a school to prepare pupils to enter upon the study of some of the professions. It is a little higher than an American college and considerably less than an American university. The National University, which includes the School of Higher Studies and the institutions of law, medicine, engineering and odontology. It is governed by a university council at the head of which is the rector. Owing to the unsettled condition of the country due to the revolution, definite educational statistics are not available for the past six years; but the general reports issued by the Constitutional government show a steady increase in the efficiency of the public school system and an encouraging decrease in illiteracy in about two-thirds of the states of the union. More and better trained teachers, however, are urgently needed to carry on the work of general national instruction and to fight against illiteracy now under way. Yet the battle is an uphill one; for the illiterates still amount to about 70 per cent of the total population of the country.

11. RELIGION. There is complete separation of church and state in Mexico (in 1876); and the reforms in 1917 reaffirm with great emphasis the fact that the church, of whatever creed or denomination, is constantly under the direct government inspection and that ecclesiastical buildings, lands and other property belonging to the nation which cease their use to the church. So, therefore, religious order or denomination can acquire land or other property or mortgages on the same. This prohibition extends to school, college buildings, asylums, charitable institutions and residences of ministers and priests and even to the property collected within the walls of the churches and other ecclesiastical buildings. Gifts of movable property may be made to the church; but even these automatically become the property of the nation. Every church or religious society operating property must elect an official head to represent it before the government and to be responsible for the national property in possession. All ministers of whatever creed must be Mexican by birth. In the same year the reforms made in the Constitution of 1857 were re-enacted, hundreds of French priests, employed principally in schools and colleges, and Protestant ministers, mostly American, who had established numerous churches and operated many schools throughout the land. While religious not inimical to the interests of the government and the laws of the land were allowed to exist and to exercise their functions in Mexico, yet all public religious observances and ceremonies must be carried on within the church property and are subject to official inspection and regulation. The law does recognize the personality of any sect but legislature of each state is empowered to regulate the maximum number of churches and ministers within the state. No minister shall have the right to vote, to hold any public office or to be voted for, nor is he permitted to partake in any way, in public affairs. The establishment of monasteries and nunneries and the taking of monastic vows are prohibited by the Constitution, which asserts that the state does not permit the fulfillment of any contract or agreement the object of which is the entailment, loss or irrevocable sacrifice of the possession of the property or work, education or religious vows. Marriage is a civil contract and no other marriage ceremony except the civil one is legal. There are generally two marriage ceremonies performed in Mexico, the civil one by a layman appointed for that purpose by the government, and a second by the priest of }
of the Church of which the contracting parties are adherents.

12. MYTHOLOGY. Prior to the European occupation Mexico and Central America were inhabited by races possessing a long history and a semi-historical mythology, manifest in its ramifications and rich in its internal development. Within this mythology was the very heart of those nations and peoples, for around it clustered their social and political institutions and their industrial life. Though it differed in different peoples, fundamentally it was everywhere similar. The same thing had taken place in Mexico that had happened to the mythologies of the Indo-European races in Europe. Different tribes of the same great linguistic family had separated from one another and, in their migrations from place to place, during the more or less nomadic stages of their existence, they had, later on, come together again. During these wanderings they had forgotten one another and when they met they did so as alien peoples. Yet in similar were their institutions, languages, religious beliefs and the general course of their existence that they frequently blended and became more or less one people. This happened to the remnants of the Toltecs left on the upland plateau of Mexico after the overthrow of their empire; to the Chichimecas and to the various other tribes forming the Aztec Empire at the time of the Conquest.

After their long migrations from their primitive home, migrations which covered centuries, the NahuaTL races met as strangers in the valley of Mexico and surrounding country. The blending to which we have just referred was imperfect. Thus among the Toltecs we find the deity to whom most deference was paid was Quetzalcoatl; among the Aztecs it was Huitzilopochtli, god of war; among the Tzeczocans, Tezcatlipoca, god of the air; among the Tlaxcalans, Camaxtli; among the Otomis, Mixcoatl, god of the chase. Like the Romans, the Greeks and many other civilized peoples of pre-Christian times, the Mexicans were accustomed to adopt the gods of other races with whom they came into contact, more especially if the mythology of these races was closely related to their own. The natural result was the very curious mongrelizing of mythologies. Huitzilopochtli, Quetzalcoatl and Tezcatlipoca were all gods of the air, and they have so many characteristics in common there is little doubt they were originally one tribal divinity common to all the people who spoke the NahuaTL tongue at a time prior to the separation of the tribes. In fact, in Mexican mythology, these three gods are represented as brothers, and in every part of the Aztec Empire where NahuaTL was spoken they were the foremost divinities. In Tenochtitlan (Mexico City), where Huitzilopochtli was all powerful, in his great temple, a statue and an altar had been erected to Quetzalcoatl. At Cholula, the heart of the Aztec empire, stood the greatest of the pyramids of Mexico, with its famous shrine, built erected to the worship of the Feathered Serpent god of the Toltecs. But its worshipers were not confined to the remnants of the Toltecs who had become incorporated into the Mexican nation. Peoples of various races, Aztecs, Colhuas, Zapotecas, Mixtecas, traveled from the furthest confines of the empire and from beyond it to pay their devotions at the shrine of this once powerful divinity.

At Cholula, where the cult of Quetzalcoatl was all powerful, Huitzilopochtli also held a place by the side of the Toltec god himself.

In Texcoco, the reputed centre of the advanced culture of the Mexican Empire, while Tezcatlipoca occupied the place of most importance in the native pantheon, just below him stood Quetzalcoatl and Huitzilopochtli. As the superior culture, refinement and intelligence of the Mexican gradually came to exert an all-powerful influence over the rest of the Aztec Empire, their chief divinity, little by little, gained more importance in the NahuaTL pantheon, until at last he secured recognition which gave him, among the nobles and cultured class at least, a standing above that of the other tribal gods.

Gods of the Air.—To understand the curious relationship of these Mexican divinities it is necessary to remember that they were all gods of the air and that they had, in general, common functions, attributes and names. Camaxtli, the war god of the Tlaxcalans, was recognized by the Mexicans as being the equivalent of their own Huitzilopochtli, while the Tlaxcalans held that he was identical with Mixcoatl, the Otomi god of the chase. Among these three peoples this deity was designated by more or less the same significance. But he also wore upon his face and body the colors of the morning star, as did also Quetzalcoatl; he carried the lightning dart, which proclaimed him god of war, and at the same time connected him with the divinities of the wind, the lightning and the thunder. Mixcoatl, who had two temples in Tenochtitlan, also wore the symbols of the god of the air.

The same fate befell the mythology of Yucatan. Ixamán, the older culture god of the peninsula, was the popular culture hero of the Itzaes, the first of the historical races who overran Yucatan and the adjacent territory; while Kukulcán was the tribal god of the Mayas. Yet both divinities were recognized by the Mayas and the Itzaes; the divinities of the wind, the lightning and the thunder were to be found in the centres of the religious cult of the peninsula and to them came pilgrims from Chiapas, Guatemala and all southern Mexico, generally on well-paved stone roads which now lie buried in impene-

trable forests.

The Kiches of Guatemala called their culture divinity Gucumatz, a name indicative of divine intelligence; and the Mixtecas, hundreds of miles away on the west coast of Mexico, named theirs Yucano, the "Bright Light," a term having practically the same significance. But everywhere in the south, as among the Toltecs and the Aztecs, the traditions and offices of this great intertribal divinity were the same. He was the god of the winds, the thunder and the lightning, of the morning star, of fire and of light, the apostle of culture, the patron of merchants, the inventor of language, literature and art, the special divinity of athletes and sportsmen, artisans and thieves. To him, under one name or other, was erected all that was beautiful in the builder's art. He was the terrestrial representative of the great sun sent to teach the people of the earth the arts and
sciences. He was the originator of the Toltèc, Aztec, Kiche, Maya, Zapoteca and Mixteca calendars and systems of hieroglyphic writing, and is credited with having given names to animals, plants, minerals, places and geographical divisions. He was the great physician and the inventor of medicine; music and poetry, too, were his gifts to humanity. In short, he was the universal culture-god whose power and benefactions were bounded only by the advancement in civilization and the breadth of imagination of each of the many tribes and nations unto whom tradition represents him as ministering.

Creation Myth.—The Nahuaits believed that before the creation of the universe there existed a region inhabited by the creator, Tonacatecutli (Ometeuctli), and his consort, Tonacacihuatl (Omechihuatl), who had four sons, Tetzcatlipoca, Huiztilpochtli, Quetzalcoatl and Yaquauqui. When the youngest of these was 600 years old the gods appointed Quetzalcoatl and Huiztilpochtli as their representatives. The two executors created a fire and a deluge, and then two human beings: Oxomoc and his wife, Gipactonal. To the man they gave the art of cultivating the ground and to the woman those of spinning, weaving and prophecy. They then created Mictlán Tectuhi and his wife, Mictlán Cihuatli, Lord and Lady of Mictlán. They divided time into days, months and years; and below the shining residence of Tonaca Tecuhtli, in the 13th region, they created eight heavens, the first of which was inhabited by two stars, male and female; the second by Tetzcatlipoca Cihuatli (woman skeletons), whose business is said to have been to devour humanity at the end of the world. In the third heaven were men of all colors; in the fourth birds which descended to the earth. The fifth was the home and birthplace of fiery serpents, comets and falling stars; the sixth the dwelling place of the wind; the seventh that of dust, and the eighth that of the gods. Tlaloc and his consort, Chalchiuhli-cue, were also created as masters of the waters in the heavens above and upon the earth below. Tlaloc, in turn, created a great number of little servants, all of whom were known as Tlalocs, while he himself bore the title of Tlalocatecutli, "Lord of the Tlalocs." His pigmy servants distributed the water wherever Tlaloc ordered them to, and sent it down upon the earth in the shape of rain, where it was again taken in charge by other little Tlalocs. Whenever one of these was unfortunate enough to break the jar in which he carried the water the crash of the fall produced thunder, and when a flying fragment hit some mortal, men said he had been struck by lightning.

The sun created by the gods went half way across the heavens and then returned upon its tracks or, according to another version, it rose only a short distance above the horizon and stopped there, and its rays were very feeble, consequently the earth was dimly lighted. Both it and the moon were accustomed to wander about the heavens; so Tetzcatlipoca, created to crush and destroy all life, followed an era of sun-creation resulting in the making of four separate luminaries.

The Deluge.—There are different accounts of the creation of these suns and even the order in which they were created is disputed; but that their periods of existence represent four separate ages of the world is agreed by all. When the first sun, Atzcatl ("water-sun"), was created, the deluge descended upon the earth; when Ehecatonatiuh ("wind-sun"), met with a like fate, an all-devastating wind was created; and when Tlotonatiuh ("fire-sun") ceased to exist, everything upon earth was destroyed by a conflagration. Then followed Tlatonatiuh ("earth-sun"), who created all things as they now exist. Thus, according to Nahua tradition, the human race was swept from the earth three separate times, and people were in constant fear that a fourth destruction was to come, for they believed the four elements, earth, air, fire and water, were in constant conflict, and that, for this reason they had already caused previous destructions of the world. After each of these destructions the earth had been reaped by those who escaped. After the first inhabitants of the earth had disappeared, Cozcox and his wife, Teocipactli, escaped in a boat and landed on Mount Colhuacan. They were the progenitors of many children who in turn, on the first day a bird, from the top of a green tautly stretched to speak. They all spoke different languages, however. Hence the diversity of tongues.

Origin of Mankind.—According to one myth, after the destruction of the earth by fire, by Tetzcatlipoca, Camaxtitlán-Huitzilopochli sat upon a rock and, striking it with his wand, caused the first race—the Chichimeca-Otomi—to come forth and people the earth. According to an Aztec myth, the first men emerged from a place called Chicomoztoc (Seven-Caves); and this mythological starting-point figures in all accounts of their wanderings. It was probably the place from which the seven tribes set out on their migrations southward, and at the end of which they arrived at the valley of Mexico.

Mexican Religion.—The Mexican had over 300 deities, some of whom had been borrowed from neighboring tribes and all of whom may properly be classed as nature gods. In addition to these they acknowledged a supreme being, whom they represented as the Lifegiver, Itzpapalotl, "He who gives us life," and Tlquenahuauque, the "All-embracing." This supreme being was never represented by picture or image and no sacrifices of any kind were offered to him. He was called "Teotl," the god, and seems to have been identified with the Sun, and at times with Tcertacihuatl, the hieroglyphic by which he is represented is the same as that of the Sun Tlacatecoreli, "Reasoning Owl." The enemy of the human race, seems to have been, in a sense, the force of evil opposed to Teotl.

The Aztecs and Nahua in general believed in a life hereafter and that the souls of the dead went to one of three regions, the home of the Sun; Tlalocan, the residence of Tlaloc, the god of waters; and the dreary underworld called Mictlán, ruled over by Mictlantecutli and his consort, Mictlanchihuatl. Soldiers killed in battle, prisoners sacrificed by the enemy and women of a new sun, and the family of the home of the Sun, the men to wait upon him and to accompany him upon his daily journey to the zenith, where he was met by the women who formed his escort for the rest of the way. Those killed by drowning, lightning or any
One of the peculiar devices by which the ancient Mexicans computed time
of the diseases sent upon earth by Tlaloc or his consort, such as tumors and dropsy, and children suffering from malnutrition, were transported, after death, to Tlalocan, a delightful region of mountains, shady trees and running streams. All those not qualified to go to the home of the Sun or the pleasure regions of Tlaloc were sent to Mictlan, situated, according to one story, in the earth; according to others, in the gloomy "navel of the earth," where they were forced to lead an aimless existence.

By the Nahuas every phase of nature was personified and had its representative guardian spirit to whom offerings and sacrifices of some kind were made daily or periodically. Among these were household duties, of which every home had several, according to its class, condition and position in society. The sacrifices to the national and tribal gods were attended to by a numerous and opulent priesthood, who ruled in an autocratic manner and exacted heavy contributions for the maintenance of religious institutions and schools, the latter being called Tolochnowalli. These sacrifices, generally slaves or captives taken in war, were offered up upon the stone altars of the temples, the victims being thrown upon their backs and held down by attendants while the officiating priest ripped open the breast and tore out the heart of each and offered it, first to the Sun, and then to the particular divinity to whom the sacrifice had been made. The presentation of fruits, flowers, grain, animals and birds to the family gods was generally made by the head of the family and the community house, when a number of families lived in one large building, as was often the case in Mexico; while sacrifices were made by individuals to those divinities who were believed to work in the interest of individuals. Texcaltitoca, a purely tribal divinity of the Tzacans, the most civilized and cultured of the Nahuas, had continued to gather to himself the powers of most of the other divinities, until, at the time of the Conquest, he was looked upon as a great divine ruler and creator and had become identified with the Toltec supreme divinity, the "Teotl." But he never ceased to be the tribal deity of the Texcancans. Huizilopochtli, the tribal deity of the Aztecs, had become in the New World a universal god of all the Nahuas because the military successes of the Aztecs had imposed him upon the other nations forming the confederacy. The large bodies of Toltecs who remained in Mexico after the fall of the Toltec empire formed communities, the principal of which was at Cholula, where the presiding deity was Quetzalcoatl, also the foremost divinity of the Zapotecs and, under the name of Yucano, that of the Mixtecs. The Toltecs who went southward carried the worship of this deity into Yucatan and parts of Chiapas, Tabasco and Campeche, where he disputed sovereignty with the older deities of the native races. In the long ages of mythology, hundreds of races surged to and fro across Middle America, leaving behind them remnants of their languages, tribal customs and mythologies. Thus we have a mingling of tongues, creeds and customs which has sorely puzzled the antiquarian, the linguist and the student of mythology. The destruction of the native codices and the indecipherable character of the remaining records in stone of the Mayas, Kiches and other highly civilized peoples of the eastern Mexico and Guatemala add greatly to the difficulties of understanding mythologies of the various races of Mexico.

Roughly speaking, the Nahua, Maya and Kiche deities may be classed as gods of the air, to whom belong the winds, rain, lightning, the thunder and the storm gods; the sun, the moon and the planet Venus (the Evening Star) and the Supreme Creator; gods of rain, mist, moisture and the running waters of the earth; grain and other plant deities; special patrons of trades, occupations, games, sports, learning of all kinds, including astronomy, astrology, witchcraft, luck in gaming, medicine and the healing art. The functions of many of these seem to be inextricably mingled and confused. This is due partly to our inexact knowledge of the past institutions, history and mythology of the various races who mingled and blended on this great bridge of the continents throughout unknown centuries before history began. There have been left to show the complicated nature of the religious system of the Nahua and the other cognate races and to prove that they had advanced to a stage wherein ethical considerations played a very considerable part. The prayers addressed to their gods, the speeches to the sovereign and other officials about to take office, the advice of a father to his son and a mother to her daughter; the poetical effusions of the royal poet of Texcoco, Nezahualcoyotl, and many other like documents which have come down to us, are filled with evidence of the high ethical plane of Nahua religious thought at the time of the Conquest; for every occupation of society, all reasoning, every movement of life had their separate being within the shadow of the Nahua religion.

**MYTHOLOGICAL CHARACTERS.**

In the following account of the more important mythological characters most frequently met with in literature relating to Mexico, the territory in which each plays his part is, unless otherwise stated, the land of the Nahua.

**Bacabs.**—In the mythology of Yucatan the Bacabs, the upholders of the heavens, were supposed to have their stand at the four cardinal points. They were called Muluc, Cauac, Kan and Ix, North, South, East and West. They were probably related to the four wind deities and to the four rain Toltecs. The Bacabs were frequently represented in Maya sculpture.

**Bat-God.**—The Bat-God, Zotzilaha Chimalman, the "Dweller in the Bat's House"; a primitive divinity of the Mayas, the Zapotecs and the Mixtecs is met with in the Popol-Vuh under the name of Camazotz, where he plays a prominent part in the adventures of the hero gods of the underworld. He seems to have been a god of volcanic fire and to have been closely associated with earthquakes and the lower regions.

**Centeotl.**—A family name given to the maize gods. The female divinity, called Chicomocohuatl, "Seven-serpent," represented water as a fertilizer and was assisted by Chalchiuhlicue, the consort of Tlaloc, in fertilizing
of Serpents, was the Aztec goddess of flowers and probably identical with the fabled mother of the god of war of the Aztecs. She was also the personification of the period called Tonacahuitznahua, of which the name was also given as a special title to both male and female deities. A summer festival lasting 18 days was held when the maize had attained its full growth. Ceremonial dances formed a part of this celebration at which a female called Xalaquia, who represented Chiquemecuhuatl, danced with the rest. Her face was painted yellow and red to represent the ripe corn. On the last night of the festival all the women and the head men of the community joined in the "dance of death"; after which the Xalaquia was offered up as a sacrifice to Chicomocuhuatl. Not till the conclusion of this festival and its significant closing ceremony was it lawful to partake of the new corn.

Huehueteotl was also the god of maize. He is represented with a long spirer-like snout through which it was believed he blew the rain out over the earth. He corresponds to the Tzol of the Mexicans.

Chichihuitlicue, the rain goddess, wore a dress of nebulous green, a blue crown decorated with green feathers and a collar of precious stones to which was attached a golden pendant, all emblematic of the varying colors of the water. In her left hand she bore a conventional water-plant, and in her right a vase surmounted by a cross, the sign of the four directions or points from which the wind drove the rain.

Chihuapipiltin, honored-women, the spirits of women who died in childbirth, were closely related to the Moon Goddess. The moon had two tendencies, one actively beneficent, the other actively malevolent. The Chihuapipiltin partook of this latter tendency. They afflicted infants with certain diseases and they entered the bodies of weakly people, more especially the insane who were popularly supposed to be governed constantly by their influence. Their temples were built at the cross-roads where they were said to haunt.

Cihuapazol, the Great Star (Venus), was the Lord of the Dawn, Tlauizcalpaz Tecutli. This astral deity was thought to influence the events of life very greatly, so whenever the planet was due to rise, the people stopped up their chimneys to prevent the entrance of its harmful-bearing light; whenever it reappeared on its circuit, captives were sacrificed to its image or its representation painted upon a column called Ilhuiacatlán, Place in the Sky, erected in the courtyard of the great temple of Tenochtitlán. Owing to the very special importance attached to the movements of this planet by both Mexicans and Mayas, its periods of revolution were carefully watched and recorded with great accuracy. As the evening star, this deity was said to follow the sun on his journey to the west. He is represented as having a white body, symbolical of light, which was frequently covered with long, narrow, red stripes and over his eyes was a black mask, sometimes bordered with small white circles.

Coatllicue (Coatlalotan), She with Dress
where, as a tribal deity, he ruled as the god of lightning, of thunder and of terrifying winds.

Huiztilohuatz was the protecting goddess of salt and water. This deity was often represented as a deer or a rabbit. He carried a sheaf of arrows to typify his office. On the site of a famous ancient shrine of Mixcoatl stands Mixcoac, the "city of gardens," one of the most popular suburbs of the Mexican capital.

Nanahuan, "Lord of lepers and those afflicted with skin diseases," is always connected with the moon, and diseased persons under his protection were believed to be sacrifices peculiarly acceptable to her, for whose service they were set apart. The moon goddess was intimately connected with the art of healing and she also took a special interest in lepers.

Napapetcutli, "Four-times-lord,\(^\text{3}\) protector of mat-makers, one of the numerous rain gods, was one of the ministers of Tlaloc. He presided over the low, swampy lands where the reeds grow from which mats are still extensively made in Mexico.

Omatli, "Two-reeds.\(^\text{4}\) Nahua god of festivities and rejoicing, whose image always presided over the feasts of the well-to-do, was ceremonially eaten in the form of a great bone of Indian corn meal at every festival. The idol had a recess in the region of the stomach into which provisions were put. The image wore a paper coronet and a cloak fringed with flowers and carried a sword.

Opochti, "Left-handed,\(^\text{5}\) Aztec god of fishing, also called, in Chalco, Aixmapil, was said to be the inventor of the fish-hook, line and spear and other means of catching fish. The similarity of his name with that of the Aztec god of war would seem to connect him with the latter, especially when it is remembered that Huiztilohuatz was the tribal god of the Aztecs when they were mainly fishers.

Sun-god, the supreme deity of the Toltecs, played an important part in the mythologies of the Nahua, Itzaes, Mayas, Zapotecas, Mixtecas and other races of Mexico and Central America. He was called Ipalnemohuani, "He-brought-forth-by-three," as the sun was held by priests and nobles claimed descent from him. His golden image was hung upon the wall of his court where the first rays of the rising sun fell directly upon it. Human sacrifices were offered to the Sun, whose strength was sustained by the blood of these victims, otherwise he would not be able to continue his journey through the sky. Even the hearts of the captives offered to Huiztilohuatz and Texcatlilo were first presented to the sun. Some of the most magnificent temples of Mexico, Central America and Peru were erected to the Sun-god.

Tepetlollotl, "Heart-of-the-hills," personification of the echo of the mountains, was one of the nine attendants of the night and lord of the 13 days following the flood, in which no sacrifices were good, and during which the feast of the jaguar was held. He was a southern deity highly honored among the Zapotecas and the Mixtecas and bordering tribes.

Texcatlilo, "Fiery-mirror," the tribal deity of the Colhuas, was a god of the winds and the tempest and the giver of breath and hence of life. In the Nahua legend he is the
opponent of Quetzalcoatl whom he deceived and induced to give up his work upon earth and return to the home of the Sun. In the capacity of doomsayer he was called Yaotzin, "The enemy," and Nezahual pilli, "Hungry-chief." As the spirit of the ever-youthful tempest, he was addressed as Telpochli, "Youthful-warrior"; and as the spirit of the night, he was called Yoalli Ehecatl, "Night-wind." Benches were placed along the highway for him to rest on after his exertions of the night. He was a god of fortune and of fate. As the deity to whom worship was obligatory, he was known as Monenque, "Claimer-of-prayer" and as such he had special power over plague, famine and threatened danger to the people, the state and the human race. He had dominion over life and death. He carried a whistle, symbolical of the noise of the wind; as a warrior god he was armed with dart and shield. To his legs were fastened small bells and in his left hand he held a golden mirror, in which he saw reflected all that passed upon the earth.

Tlalocuani, the Mexican deity whose province it was to forgive or eradicate sin possessed a dual nature. She was the patroness of desire and luxury; and the confessions made to her were restricted to sins against morality. She was mediator between the penitent and Texcatlipoca, the "Most Powerful God," the "Protector of All" and the "Searcher-out-of-evil." The penitent, in the presence of the officiating priest, lighted a sacrificial fire and burned incense to the deity to whom he confessed his sins and addressed his prayers for forgiveness.

Tlahloc.—The Tlahloc were masters of the liquid element in all its forms. In the dwelling place of the Tlahocatecuhtli and Chalchihtlicue, Lord and Mistress of the Tlahoc, there were four ponds of water, the first of which aided germination, the second of which withered the seed, the third of which froze it and the fourth of which ripened it. These two deities were, according to the myth, created after the appearance of the last sun. Tlahocatecuhtli was called the "Fertilizer of the earth," and the "Protector of Temporal Gods." He and his consort lived on a high mountain among the eternal clouds; and from there he sent his visitsations of fire, mist and thunder. Hence his images were erected on high elevations such as hill tops and mountain summits. The characteristic sign of Tlahoc was the cross, which represented the four points of the heavens from which the winds move the rains. The representation of Tlahoc in the Mexican manuscripts, is painted green and azure to depict the different shades of water; and he carries a spiral-shaped wand of gold, typical of the lightning.

Tlalocuizque, the Aztec goddess of healing and the discoverer of turpentine as the base of certain native ointments, popular at the time of the Conquest, is credited with having originated most of the medicines in use throughout the Aztec Empire.

Yaotzin, "He by whom the Year is Poisoned," was the Maya deity who presided over the five unlucky days at the end of the year. His image was carried out of every village and town and left outside during the days of his influence in order that he might not poison the year.

Votán, the fabled civiliwer of the ancient people of Chiapas, was closely related to the culture gods of the other races of Mexico and Central America.

Xipe was the god of vegetation and the sowing time and his general characteristics are those of the culture deities. He was considered a tribal equivalent of Tezcatlipoca and, under somewhat varying forms, he was worshipped throughout the Aztec Empire and among the nations bordering upon it to the south. He was connected with the Moon, and the gold and silversmiths regarded him as their tutelar god. He was called the "flayed-one," because at his festival the skin was taken from a human victim sacrificed to him and worn for 20 days by the devotee furnishing the sacrifice. In Tenochtitlán, where his festival was one of the important religious events of the year, he appears to have been looked upon as the god of human sacrifices. The monarchs and chief warriors of the Aztec Empire, when actively engaged in war, frequently donned the classical costume of Xipe.

Xolotl was a southern deity of lightning; and in the Aztec calendar he occurred the 15th week and the 17th day sign; but as the Mexican calendar was borrowed from southern nations, and as the nature of this exotic deity was not understood by the Aztecs, he always remained to them a strange, mysterious figure. He was the Lightning Beast of the Mayan cognate tribes, among whom he was a deity of the air and the cardinal points or the four directions of the winds.

Xiplyacoec and Knucane, Father-and-Mother gods, are the Maya-Kiche equivalent of the Nahuatl generators of Omecihuatl. They were endowed with creative power.

Yacatecutli, "He-who-guides," was the Mexican god of commerce and trade; and the Aztec merchants held in his honor, twice a year, great festivities during which elaborate banquets were held and sacrifices were offered to the god. The traveler's staff was his particular symbol, and to it prayers were made and particular offerings of flowers and incense proferred.

13. ART. Pre-Columbian Art.—When Cortes, first visited the shores of Mexico in 1519, he was surprised at the skill displayed by the Indian artists, who rapidly drew excellent sketches of his ships, his men, with their clothing, their arms and their horses, and forwarded them, by rapid courier service, to Montezuma in Tenochtitlan. This was the first contact of European and Mexican civilizations which was destined, in the near future, to produce the greatest and most characteristic of all the colonial art in the lands under the domination of Spain, during the 16th, 17th and 18th centuries. The art was neither native American nor Spanish, but a mingling and blending of both in a way that has made it truly Mexican.

Mexican Indian art before the Spanish Conquest was mechanical, industrial, commercial and graphic. It was pictorial in the sense that all hieroglyphs and pictographs are pictorial; but it had not advanced beyond that stage in which it was still almost altogether a useful art. Mexican paintings, drawings and sculpture were the handmaidens of religion, commerce, trade, history, geography, literature and science; and so intimating were they all connected with one another that it is impossible to understand one without comprehending the others. Yet all had their influence upon the new art that sprung from the meeting of the two currents of thought, from the Old World and from the New.

The pre-Columbian inhabitants of Mexico were artistic in varying degrees; and the artistic sense still shows itself strongly in their descendants. Poets, orators, decorators, musicians, literary men, artists, penmen, all bring to their work a depth of feeling, a strong sensitiveness, often a strange vagueness, indicative of the artistic mind. The untutored, un­cultured Mexican peasant produces pottery, artistic in form and decorated in pleasing colors and designs. He readily imitates the furniture imported from the best art centres of Europe and the United States; in many parts of the republic his weaving, his designs on woven wraps and blankets and his pictures of feather work are the delight of art collectors. This art sense creeps out in the most unexpected places. The rude Indian from the hills surprises us with the artistic way in which he has arranged the flowers he offers us for a few cents; he delights us with the baskets of his own manufacture on which he has depicted, in a really graphic manner, scenes from the national customs; with figures modeled in clay and painted in natural colors, depicting, in a most rapid manner, local types, customs, dress, trades, occupations, sports and pastimes. Generally the humble, difiident, barefooted, brown­faced figure, dressed in wide-cut, cotton pantaloons and shirt of the same material, who offers his wares for sale, is their creator; for there is little retail business among the Indian population of Mexico outside the towns and villages. All this points to an artistic past; for the condition of a given race at a given time is the result of Magallanes, Cortes, and the Conquest.

Indian Feather-work.—The most characteristic of the pre-Columbian Mexican arts was the native feather-work, which called forth the admiration of the art lovers of Europe. The Mexican artists produced wonderful pictures by matching, with infinite patience and consummate skill, small particles of feathers, which they gummed to a background of woven fabric. An enthusiastic witness, bearing testimony shortly after the Conquest, says: 'They (the Aztecs) painted in feathers, producing the living colors of nature'; and one can well believe this statement; for the untutored, ignorant Mexican Indian still hanging down the traditions of his fathers imitates in feather mosaics national scenes, customs, occupations and sports, in so realistic a manner that, at a short distance, his work seems painted.

These feather artists were in all their glory at the time of the Conquest and they continued to flourish in Mexico for almost a century afterward. Their art was known to all the Nahua or Mexican peoples; and centuries after the Norman Conquest of England, the Toltecs had developed it to such an extent that immense pieces of feather draperies representing mytho­logical and other scenes were used as hangings with which to cover up completely the walls of certain apartments of the great temple at their capital, Tula, dedicated to Quetzalcoatl, god of the winds. Three different sections of the temple were decorated in this way, in each of which a distinctly different color effect had been produced. Feather tapestries were used as hangings for the palaces of the Aztec emperors and nobles; and they were, competent witnesses assert, the equal of the best woven or painted wall hangings made in Europe during the 16th century. With the boldness born of long practice and acquired skill, Mexican feather artists attempted successfully to produce in feathers the works of the most famous Italian artists of the 16th century. The crowded Indians "painted" in feather mosaics the favorite saints of the Catholic Church; and their work, which was forbidden by the papal authorities at Rome, became immensely popular in Europe.

The most brilliant plumage of the birds of the tropics were sought out with which to imitate the colors of nature. Shortly after the Conquest a great Christian-Pagan feather mosaic was sent to Pope Paul III; and so excellent was its workmanship that his Holiness would not believe it had not been painted in oil until he had tested it by examining it closely and carefully. This wonderful work that he expended a bull, in 1537, rehabilitating the Indian races of Mexico, the greater part of whom had already been reduced to slavery in the 16 years that had elapsed since the Conquest.

Feather-work mosaics and other forms of ornamentation and decorative feather art entered into the very life of the Mexican people prior to the Conquest. All the land of the Aztecs was searched for artists who showed
special talent in this difficult and exacting kind of work. Children were trained from childhood in special schools of art and their masters were themselves the most skilled artists of the land. Picture-making was, however, but a part of their instruction. They were schooled in the art of making ornamental garments for the emperors, the princes, the nobles and the priests and the noble ladies of the court: so highly was the art esteemed that the sovereigns themselves considered it high honor to be classed as even passably good feather artists. Clazonal, king of Michoacan, next to Texcoco, the greatest centre of feather-work, enjoyed the distinction of being the best artist in his kingdom; and he was inordinately proud of his skill, probably more so than of his royal honors.

The Feather Market.—The work of the feather artists developed a great commercial business for the Aztec merchants. The most highly appreciated feathers were bought and sold daily in the market, where they were so esteemed that they brought literally several times their weight in gold. They passed as currency among the Aztecs and neighboring nations; and nothing more valuable with which to pay the ransom of captured princes or conquered kingdoms existed than they. Captives who were good feather artists brought high prices in the market and, for this reason, their lives were spared from the sacrificial altar. Merchants devoted themselves especially to the buying and selling of art feathers; and the chief purchaser for the court held the title of purveyor of feathers to the sovereign. Merchants were trained to sort feathers and to arrange them into classes according to their color, fineness, merit and market value. They held office under the government and were highly paid officials.

Throughout the Aztec Empire, very stringent laws protected the birds from which the most esteemed feathers were obtained for the work of the artists; and the quetzal, the most highly valued of these favored ones, grew into a sacred bird, and as such his feathers could be worn only by the king and the high priest, both of whom represented their gods upon earth. The Aztec monarchs maintained great aviaries in the capital where birds of rare plumage were reared with the greatest care; and the stealing of feathers from these royal aviaries was punished with death.

Centuries of training in art worked of such an exacting nature as feather mosaic developed the artistic sense strongly in the artist caste of the Mexican people; and it is not at all strange that this ability began to show itself in a new way shortly after the Conquest, when Spanish friars and missionaries, many of them no mean artists themselves, began to teach the principles of European art to the pupils of the Mexican convents and schools, nearly all of whom being nobility or to families dedicated to trade, to the arts, the crafts or to literature and music, all of which were held just a little lower than noble rank. The merchants who brought the precious feathers to the capital and distributed the manufactured product to the furthermost confines of the empire and to the countries beyond formed a guild unto themselves, over which presided Quetzalcotl, the first half of whose name is formed from the "quetzal," the sacred bird and the symbol of divinity. It was preserved upon the coat of arms of Guatemo. But the very enthusiasm with which the new learned art for the restraining hand of Spain, which naturally garments for the them almost every selle endeavor except that of painting, or so controlled the workmen that the Spaniards exacted profits and the glory from every accomplishment.

Hispano-Indian School.—Echoes have gone down of a school of Indian painters, who flourished during the first 50 years following fall of Tenochtitlan, in Texcoco and Cuautitlan, both towns near the capital. Under the Spanish masters they had learned to paint saints and to represent graphically biblical religious legendary subjects. They painted pieces of scenario necessary for the production of the miracle plays and the dramatic representations by means of which Christian Church attempted to teach the masses, unlettered, the truth. The fairest of, or none of the art of this period has survived with the exception of one picture of national fame which, on account of the manner in which it is painted and the artist's element of his subject, almost certainly belongs to this early Ibero-Indian school. This is a famous picture of Our Lady of Guadalupe, which made its appearance within eight years after the fall of the City of Mexico, or 1539. The religious legend asserts that the picture of the patronness of Mexico was miraculously made by the tilma or shroud covering of a poor Indian named Juan Diego. Historical investigation has shown that it was painted for a miracle play given in one of the new convent schools in the City of Mexico shortly after the Conquest. This picture shows very considerable artistic talent, it is neither Spanish nor Indian, but a blend of the two. The drawing is bold and free and coloring anticipates, by three-quarters of a century, the soft, pleasing tone of the arts of the first Great Mexican school.

The demands of the ever-tireless, ever-changing church upon the Spanish-born and Indian artists alike were insistent and persistent, and many hundreds of canvases belonging to the first three-quarters of a century following Conquest were produced at the wave of miraculous wand, for the churches, convents, monasteries and episcopal palaces that sprang up, phantom-like, throughout the land. Spanish artists of note were here from old Spain to superintend the work of the native artists in New Spain; and this attested the wonderful aptitude of their pupils.

Early Spanish Masters.—One of the greatest of these masters was Rodrigo de Cirujano, who arrived in Mexico shortly after the Conquest, native nobility to have presented his services to the conqueror, Cortes, of whom he painted several portraits. The picture of the Lady Magdalena in the church of San Francisco, Tlaxcala, is said to be his work. He painted the portraits of the first audiences also of Dona Maria, the Indian queen Cortes, about 1530.

Andrés de Concha, who arrived in Mexico during the time of the first viceroy...
Indian pupils enjoyed a high reputation as interior decorators of churches and convents and they were often called to interior cities to do decorative work. The group of paintings over the high altar of Santo Domingo Church in Yanhuitlán, Oaxaca, is the work of Concha, whom Padre Burgoque calls the Apelles of the New World.

Arteaga, another master painter, is said to have reached Mexico City three years after the Conquest and to have been very active in building up the Indian school. There was one of his pictures, 'The Visitation of the Virgin,' in the old church of Santa Teresa about the middle of the 18th century; and it is probably still in existence.

Simón Pereyns, a Flemish artist, painted the pictures for the main altar of La Merced Church, and a 'Virgin with a Child' in the National Academy is supposed to be his work. Francisco Zumaya and Francisco Morales were his contemporaries. Alonzo Vázquez, who was somewhat younger than Pereyns, was also active in the 18th century. 'The Assumption' and the 'Redemption,' in the National Academy are credited to him. Juan de Rua, one of Vázquez' pupils, has left a fairly good series of scenes from the life of the Virgin, in the church of San Francisco, Cuautitlán, Puebla.

Pupils of these masters, also famous in their day, have come down to us. Bernal Díaz del Castillo, the first historian of the Conquest and one of the soldiers who took part in it, praises highly three Indian painters and artists, Andrés de Aquino, Juan de la Cruz and El Crespillo whom he likens to the best artists of Italy and Spain in his day. Alonzo Vázquez and his pupil Juan de Rua, already mentioned, are credited with having introduced correct European methods of art into Mexico; and they and their school undoubtedly paved the way for the flourishing and excellent school of artists of the 17th century. In fact we know, by the results already obtained, that the reports that have come down to us, that there had been a wonderful quickening of life in all the arts between 1521 and 1600. This was but a re-echo of the animation in art in Spain herself, in Italy, in the Netherlands and throughout the Spanish empire in America. Industries, arts, trades, commerce, mining, agriculture took on a new existence, and Mexico City became the first metropolis of the New World, and the centre of this new-born progress in America. The genius of the Spaniard for organization aided its hand upon the immense domains of the Moctezumas and that hand was never lifted for 400 years, during all of which time the artistic life of the luxurious capital of New Spain was in touch with that of the mother country. With the coming of the first viceroy in 1535, his activity of the favorite colony increased.

A year later printing was introduced into Mexico City; and the court of Spain began to take a peculiar interest in the educational and artistic level of its means of study and to this interest and the strong encouragement which accompanied it is due, in part at least, the agerness with which the native artists worked. The hundreds of Spanish and Flemish paintings not the thousands of art prints that flooded the and, afford means of study and to this interest and the strong encouragement which accompanied it is due, in part at least, the activity of the favorite colony increased.

The discovery of America and the sudden vast treasures that poured into Spain from over seas, the long struggle with the Moors, of Christianity against Mohammedanism, the rise of the Catholic Church and the birth of the temporal power of the popes and the consequent wars necessary for the maintenance of the powers and conditions thereby engendered, were forces that worked inexorably to the shaping of all Spanish art, which had its origin in the Church and received its inspiration and encouragement constantly from the same source. Italy was the great mistress of Latin art and the teacher of Spain, when she came to lay by her Gothic traditions, but Spanish art traveled a road distinctly different from that of Italy. In Spain art was very largely influenced by the traditions and dogma of the Christian Church, which continued to shape it to its ends and control its execution. In Italy it was classical and it run according to the views that existed at that time. In Italy art was free, unrestrained, licentious the more orthodox Christians contended. It was bound by the canons of Church law, by the restrictions of ecclesiastical councils and by an intense fanaticism and a devotion to the Christian doctrine and legendary lore unknown in other countries. Upon it rested the heavy hand of asceticism and the sombre shadow of the Inquisition, a peculiarly Spanish institution. Yet the artists of Italy exercised an all-powerful influence upon those of Spain, for more than two centuries of changes varying always within a certain defined and restricted area of activity. The ascetic Spanish taste did not change its Gothic attitude, when under Italic influence it changed its fashion in painting. While the Italian gloried in the nude of Greek and Roman art, the asceticism of Spain covered up the parts of the human body, wrapping them about with draperies, too often much less artistic than the freer treatment of Italy. While the Italian artist boldly attempted to depict the human anatomy in all its nude or semi-nude and almost wholly Pagan attitudes, the Spanish artist was forced to resort to suggestion to convey lasting impressions of what his asceticism had foreseen and desired. Thus, while the Italian artist, by his free and unconventional use of the nude, obtained brilliant sculptural effects, the Spanish artist, in his efforts to reach the same ends, while draping his figures, became insensibly a colorist. So Murillo, the greatest of all Spanish colorists, has always been Spain's most popular artist.

It was therefore natural that, of all the Italian schools, the Venetian suited Spanish taste best; and of all the Venetian artists, Titian appealed most to the Spanish attitude of mind toward art. The brilliant coloring of the Venetians, their indistinct drawing and their neglect of the antique appealed to the religious ideas of the Spanish artists. So Titian became the motive spirit in the movement in Spanish art. A powerful but secondary influence was exercised by the Hollanders, Antoine More, who, as a portrait painter, was little inferior to Titian. Van Dyck also contributed to the making of Spanish art traditions. But the atmosphere of Spanish life...
and the fervid religious spirit of the land twisted all the foreign traditions of art and of schools to their own way of thinking and of viewing life and of acknowledging its obligations, with the result that Spanish art grew to be a thing apart from its own Gothic traditions, from the classical style which it imported from Italy and the rigid Venetian school to which it very strongly inclined. The sombre, ardent, fanatical Spanish mind worked over all these materials and from the working sprang a new art which was peculiarly Spanish. For more than two centuries this strange semi-artistic, semi-asetic spirit brooded over Spain, producing the magnificent creations of Vargas, Morales, Sanchez, Coello, Joannés, Becerra (the great teacher), Fernández el Mudo (the "Titian of Spain"), Coitán, Zúñzarán, Pereda, Velázquez (the incomparable portrait painter) and Murillo, the superb master of color. And they all had, through their art which found its way across the Atlantic, their influence upon the artists of the continent. Yet we look in vain in treatises on art for any adequate presentation of the work of the American artists or of the vast output of excellent painting by the Spanish colonies in America, all of whom followed the traditions of the mother country, redifying them as they went, but quite to their several environments and local influences. Yet for more than two centuries, the followers of the Spanish masters in America, enthusiastic students of their creations, tireless workers, covered the two continents from San Francisco to Buenos Aires, from Cuba to Chile. In every provincial capital industrious schools of art existed; and all followed the traditions of Spain. At the exhortation of the Church and the insatiable demands of the dealers who made a business of shipping pictures over seas to the colonies, the Spanish artists at home redoubled their efforts; and a constant stream of canvasses poured forth from their hives of art industry. No church, convent, college or university in the vast domains of Spain beyond the seas was so poor as not to possess at least one treasure from the art centres of the mother land. When the ecclesiastical dignitaries of Spain wished to show honor to some institution of the colonies, they forwarded to it a painting or other work of some revered master. The king, the emperor and the nobles showed their favors in the same manner. New Spain, the favorite namesake of the mother land, became thus a storehouse of Spanish art. These treasures were to the Mexican artists what the pictures of Italy and Holland were to the artists of Spain. They copied them, they imitated them and they built upon them a Mexican art which, while it followed the traditions of the Spanish school, was yet, in many respects, distinctly Mexican, as the character of the Mexican people and their environments are distinct from those of Spain.

For more than 200 years the Spanish artist attended to only one of the manifestations of nature, that is, man and his relation to the deity and to heavenly manifestations. Mountains, streams, oceans, the sun, the moon, the beauty of the night and the glory of the day meant nothing to him except when they helped him to depict his deity, his saints, his religious traditions, his dogmas and his miracles. In all this the Mexican artist followed his masters, faithfully, conscientiously, devoutly. But the spirit with which he executed his tasks was noticeably different from that of his teachers. The stern, harsh character of the Spaniard is depicted in the hard lines of the best of his artists up to the time he leant to leave behind him the vivid memory of the terrific religious wars against the Moors. When the "heathen" of the New World had been conquered and placed beneath his heel and he had filled with churches, altars and colored statuary his vast domain; when he had lifted from his shoulders the burden of useless and selfish earthly labor, the Spaniard began to cover up the hard lines of Gothic and early Venetian art traditions and feelings, thus engendering an attitude of art that made possible the wonderful naked representations of Velázquez and the brilliant coloring and softening effects of Murillo. But as the Indian character was different from that of the Spaniard, so long before Spanish contact America. Yet we look in vain in treatises on art for any adequate presentation of the work of the American artists or of the vast output of excellent painting by the Spanish colonies in America, all of whom followed the traditions of the mother country, redifying them as they went, but quite to their several environments and local influences. Yet for more than two centuries, the followers of the Spanish masters in America, enthusiastic students of their creations, tireless workers, covered the two continents from San Francisco to Buenos Aires, from Cuba to Chile. In every provincial capital industrious schools of art existed; and all followed the traditions of Spain. At the exhortation of the Church and the insatiable demands of the dealers who made a business of shipping pictures over seas to the colonies, the Spanish artists at home redoubled their efforts; and a constant stream of canvasses poured forth from their hives of art industry. No church, convent, college or university in the vast domains of Spain beyond the seas was so poor as not to possess at least one treasure from the art centres of the mother land. When the ecclesiastical dignitaries of Spain wished to show honor to some institution of the colonies, they forwarded to it a painting or other work of some revered master. The king, the emperor and the nobles showed their favors in the same manner. New Spain, the favorite namesake of the mother land, became thus a storehouse of Spanish art. These treasures were to the Mexican artists what the pictures of Italy and Holland were to the artists of Spain. They copied them, they imitated them and they built upon them a Mexican art which, while it followed the traditions of the Spanish school, was yet, in many respects, distinctly Mexican, as the character of the Mexican people and their environments are distinct from those of Spain.

For more than 200 years the Spanish artist attended to only one of the manifestations of nature, that is, man and his relation to the deity and to heavenly manifestations. Mountains, streams, oceans, the sun, the moon, the beauty of the night and the glory of the day meant nothing to him except when they helped him to depict his deity, his saints, his religious traditions, his dogmas and his miracles. In all this the Mexican artist followed
to become worm-eaten. Guardians of the treasures of the church, tempted by cupidity, or for other motives, have not infrequently passed to foreign lands there to cease to be Mexican in name at least.

And yet no other country on the American continent continues to possess anything like the amount of really artistic pictures of its ancient artists as that still retained by Mexico. Lovers of art in Mexico have begun to recognize the high standard of excellence attained by their best masters of the 17th and 18th centuries; and the market value of these pictures has risen rapidly during the present century. But this is an added danger to the retention of the native art at home.

The School of Echave.—The founder of the first Mexican school was Belisáar de Echave, the elder, whose first existing picture dates back to 1601. He had already become a famous artist by 1609, years before Velázquez and Murillo flourished in Spain. His drawing and conceptions are very much better than anything produced by his contemporaries; his figures are graceful in nature and his style is devoid of affectionation and conceits. Other Mexican painters have surpassed Echave in execution, in perfection of style, in the observation of the technical laws of art, but none have approached him in fertility of invention and depth of thought. In fact he was a philologist, critic and writer as well as artist. His wife, La Sumaya, who was also an artist of no mean merit, is said to have been his teacher in the art of painting; and a meritorious picture of San Sebastian in the cathedral is said to be from her brush. Echave and his wife both belonged to the Spanish school of Joaquin, the best artist of his day and superior to all who preceded him in Spain. The work of Echave is unequal, but the best of it shows a genius superior even to that of his master, whose praise all Spain sang in his day. Though his style was finished and somewhat labored, like that of the artists of his epoch, yet his industry and application were so great that he left very many pictures varying from huge canvases to small tablets, which, before the amortization of church property, were to be found in many of the churches of the capital and in many of those in the interior. Among the most remarkable are these: ‘San Cristóbal’ (1601), which stood over the great door of the Franciscan monastery, ‘San Ignacio’ (1610), and the ‘Martyrdom of the Virgin of Colonia,’ both of which were also in the same edifice, ‘San Francisco de Paula,’ in Guadalupe church; ‘Martyrdom of Santa Catarina’ (1640), in Santo Domingo, and ‘Santa Cecilia,’ one of his best, in the Profesa. In 1608 he painted 15 tablets for the altar of the old church of Santiago, Tlaltelolco.

Luis Juárez, a contemporary of Echave, shows, in all his works, strong individuality. His figures are excellent, his exposition strong and true, but his execution is frequently unequal. Many of the heads of his figures, to whom he paid much attention, were superior to anything produced by the Spanish masters of his day. Juárez's style is free and less labored than that of his master, Echave, to whom he is but slightly inferior. He was very prolific and this, coupled with his popularity, made his execution, like that of Echave, very unequal. However, his conception is always bold and his coloring good. His work is more realistic than that of Echave. Many of his best pictures are in the Mexican National Academy.

José Juárez, who was active from 1642 to 1698, followed the traditions of Echave and came the nearest of all the Mexican painters to attaining to the excellencies of his master, to whom he was but slightly inferior in expression and the depicting of religious feeling. He had exceptional talent but, owing to the speed with which he was forced to do the vast amount of work that came to him, he often became careless. Rafael Lucio, an excellent critic, says of Juárez: “I have seen angels of his that seemed to belong to the very best period of Italian art.” His style is elevated and even more realistic than that of Luis Juárez; his drawing and execution are good, and in his grave and harmonious coloring there is a noble severity. His figures are free and flexible and show strong individuality, while his canvases are generally lit with the animation of life, partially due to his deftly grouped figures, his excellent coloring and his decided tendency toward that softness and simplicity which distinguishes the school of Echave. There is a noted depth and contrast in his coloring. A number of his best pictures are in the Mexican National Academy.

Sebastián de Arteaga, a priest and notary for the Inquisition, was another excellent artist belonging to the school of Echave. He displays vigor, power, freedom of movement and a boldness unknown up to this time in the Mexican school. His style is less finished than that of his great contemporaries and his coloring is not so good; but his figures of the Virgin are graceful and beautiful. He is content, too often with carefully executing his central figures and leaving his accessories but poorly done. His style is truer to nature than that of the elder Echave but he lacks the grace of the old master and that simplicity which distinguishes the early Mexican painters. In his work there is a dash and a freedom with the brush that might have made of him a really great artist had he given his whole attention to art; but he had too many other occupations to permit him to work out his own salvation. In the Mexican National Academy there are some notable pictures of his: the ‘Benediction of the Virgin,’ the ‘Saint Thomas Putting his Hand into the Wound of the Christ’ and his ‘Adoration of the Wise Men.’

Belisáar de Echave (1632-82) the younger, son of the elder artist of the same name, developed a style very different from that of his father. He was bold and vigorous but too impatient to finish his work well. His drawing is frequently faulty and his execution reminds one of Arteaga, of whom he was a contemporary. His compositions, however, show plenty of life and a strong sense of the dramatic. Although he was a follower of Arteaga, he foreshadows the new school which distinguished the following century. His ‘Entombment’ is one of the finest pieces of the old Mexican school. Two other notable pictures of his, the ‘Triumph of the Church’ and ‘The Triumph of Faith,’ are both in the Puebla Cathedral, which also possesses several other pictures of his: ’The Sorrow,’ the ‘Martyrdom of Saint Peter of Verónica,’ ‘The Four
Evangelists) in the Mexican National Academy are also good pictures.

The latter part of the 17th century, which America and Mexico, the work of the school influenced strongly, was very active in art. Juan Correa, whose drawing and coloring are excellent, painted much. His work shows freedom of execution, a firm handling of the subject and an easy swing of the brush, but his tone is often oppressive. Six great paintings of his are in the cathedral. With Correa begins a period of decadence in Mexican art. But he was a great teacher and he introduced new ideas into Mexican art which were destined to become the most noticeable motive power of the new school made famous by Ibarra and Cabrera, his two most noted pupils. He was lavish in his employment of figures, loved immense canvases and aimed at grand and imposing scenes. His grouping is artistic and the general tone of his pictures shows sincerity and there is a general air of devotionness about his more deeply religious canvases. He has been rather under than over estimated by modern critics. His boldness of conception, freedom of execution and an inspiration to greater attainments are his two great pupils. His 'Coronation of the Virgin,' the 'Triumph of Saint Michael' and the 'Entrance of Jesus into Jerusalem' all contain multitudes of figures, but the tone is gloomy and the coloring is generally opaque.

Nicolás Becerra, who also belongs to the latter half of the 17th century, anticipates the characteristics of the painters of the first half of the 18th century, excellent coloring, boldness of conception and rapidity of execution. Another, Diego de Becerra, a Franciscan monk, of the same period, devoted his energies to depicting scenes and events in the history of the order. Many of his pictures were in the convents of the Franciscans in Mexico City and Puebla. Another priest, Nicolás Rodríguez Juárez, shows good coloring, simplicity of style and studied and well-executed drapery, all characteristically foreshadowing the coming school. He was the best portrait painter of his day. His 'Saint Francis' is found in the Convent of the Crucified Christ (1699) is in the Mexican National Academy. Other pictures of his are in the Profesa and other churches of the capital.

Juan Rodríguez Juárez (1675-1728), nephew of José and brother of Nicolás, enjoyed a very high reputation in his day; and he had a strong influence over the younger artists, who were destined to later establish a new school. He was very prolific and many of his works survive. He is noted for his series of the Virgin of Tepeozotlán, of which the most realistic and best executed represents the flight into Egypt, 'San Antonio,' 'San Francisco de Querétaro,' 'San Juan de Dios' are in Querétaro; an autoportrait is in the National Academy. His are the decorative pictures for the altar of Los Reyes in the cathedral. Three paintings in the Profesa suggest Murillo. A colossal San Cristóbal and the 'Vision of Santa Inés,' as in San Agustín Church, The 'Judgement of Saint Lawrence' (1702) is a notable picture. In the Carmelites churches are a number of his pictures and four large canvases are in the National Academy. He has a vision of the loveliness of color that reminds one of Murillo in no uncertain manner. He preached the doctrine of freedom from restraint and he revolted against the careful work of the school of El Echevar. His touch is light, his color brilliant; but his light and shade are weakly defined. It may be said to have been the father of a school that produced much brilliant work in Mexican art.

Among the other artists of this period are José Torres, Manuel Orellano, Diego Casasola, Juan de la Plaza (extravagant in coloring and execution) and Manuel Luna (coloring and drawing good). So brilliant is the color of the latter's work that much of it has been passed off as that of Murillo and his pictures have been gathered up and shipped to Europe where they have been sold as works of a great Spanish master.

Cristóbal Villalpando painted from 1683 to 1710 and played a very unequal manner. Few if any Mexican artists have had freer and bolder imagination than he or greater power of execution. In his imagination there was much of the poet, but he was affected with the 18th century mania for elegance. The multiplicity mark his best work. His coloring is weak and his larger canvases are in poor taste, yet some of his decorative work is excellent.

'Pícaro Manuel,' a Jesuit priest, has been called the Murillo of Mexico on account of the brilliancy of his coloring; but his drawing is careless. His simplicity, boldness and self-consciousness of coloring leave no doubt that he had studied Murillo.

José Ibarra (1683-1756), one of the best painters of the 18th century, followed by Rodriguez Juárez to exaggeration. His fine perspective and drawing are good and the general tone of his work is pleasing and effective; but he shows strongly the mannerisms of his school. He is prodigal of reds and blues, etc., in masses, in the style of Murillo. He was a finished artist, a tired worker and possessed of great natural talent. Many of his pictures exist in Mexico though many have been sold abroad. Nicholas Enriquez, an ardent admirer of Ibarra, has been following his example. Miguel Cabrera, the close friend and colleague of Ibarra, has maintained, for considerably over a century, his position in the estimation as the greatest Mexican artist of the 18th century. He was a most fast worker. Even to-day, after dealers have been collecting his pictures for three-quarters of a century and sending them abroad, there are scores of Cabreras in Mexico. He lived in his art and he painted pictures as Lopez Vega wrote scenes of the Virgin of Tepeozotlán, of which the most realistic and best executed represents the flight into Egypt, 'San Antonio,' 'San Francisco de Querétaro,' 'San Juan de Dios' are in Querétaro; an autoportrait is in the National Academy. His are the decorative pictures for the altar of Los Reyes in the cathedral. Three paintings in the Profesa suggest Murillo. A colossal San Cristóbal and the 'Vision of Santa Inés,' as in San Agustín Church, The 'Judgement of Saint Lawrence' (1702) is a notable picture. In the Carmelites churches are a number of his pictures and four large canvases are in the National Academy. He has a vision of the loveliness of color that reminds one of Murillo in no uncertain manner. He preached the doctrine of freedom from restraint and he revolted against the careful work of the school of El Echevar. His touch is light, his color brilliant; but his light and shade are weakly defined. It may be said to have been the father of a school that produced much brilliant work in Mexican art.

Among the other artists of this period are José Torres, Manuel Orellano, Diego Casasola, Juan de la Plaza (extravagant in coloring and execution) and Manuel Luna (coloring and drawing good). So brilliant is the color of the latter's work that much of it has been passed off as that of Murillo and his pictures have been gathered up and shipped to Europe where they have been sold as works of a great Spanish master.

Cristóbal Villalpando painted from 1683 to 1710 and played a very unequal manner. Few if any Mexican artists have had freer and bolder imagination than he or greater power of execution. He preached the doctrine of freedom from restraint and he revolted against the careful work of the school of El Echevar. His touch is light, his color brilliant; but his light and shade are weakly defined. It may be said to have been the father of a school that produced much brilliant work in Mexican art.
average of his artistic qualities and the tenderness, devotion and mysticism displayed in his characterizations, easily place him in the forefront of Mexican artists. His style is easy, light and comparatively free from mannerisms; and his brilliant coloring lacks the solidity of the previous school. Like Shakespeare he laid tribute upon all who preceded him, but upon all he made use of he placed the stamp of his own individuality, in grouping, painting and coloring and idealization. As he was the official painter of the Jesuits, their institutions were filled with his works. So great was his fame in his day that churches, convents, schools, the university and individuals overwhelmed him with orders and forced him to work to the limit of his capacity. With fame all kinds of honors came to him both at home and abroad. He was made official painter to the archbishop of Mexico and the archiepiscopal palace possessed many of his works. Rich churches paid him large sums to paint series of pictures for them. The mining town of Taxco engaged him to do all the decoration of the new church in that rich district and the church remains untouched to this day.

The 18th century witnessed the most active period in Mexican art, and more than 200 artists are said to have flourished during this comparatively short span of time. Francisco Antonio Vallejo, Francisco León, Juan Patricio Morlet, José Paez, Nicolás Enríquez and José Alcibar, all followers of Cabrera, reflect the characteristics of his style. Alcibar carried to exaggeration the softness of style of the school. He enjoyed a reputation equal to Cabrera, to whom he was really much inferior in talent, imagination and execution.

After Cabrera no passably good artist appeared for almost 50 years; for the enthusiasm that had built up the power of the Church in Spain declined rapidly even before the close of the 18th century; and with this decline, the erection and adorning of sacred edifices ceased, and good artists became scarce.

The Academy Artists.—For 50 years after the French Revolution the only artists in Mexico were Spanish professors sent over from Spain to the San Carlos Academy of Art and their pupils. Aguirre, one of these professors, painted the vaulting of the parochial baptistery of San Gabriel Arcángel. The work is very suggestive decorating. His mural work is good but his oil paintings are poor. The "Assumption of the Virgin" in the dome of the cathedral is by his hand. It is highly imaginative and full of action and possesses the true aerial quality necessary for ceiling decorations. Juan Saens and José M. Vásques, two of his pupils, helped him constantly in his work. Saens took part in the decoration of the cathedral dome and Vásques painted the "Annunciation" in Loreto church, and "Saint Anthony Sustained by the Angels" in the chapel of the Sagrario. José M. Castro, another pupil, has left some fairly good pictures, one of which is in the National Academy. He exhibits a real love of beauty.

Francisco Eduardo Tresguerras, a Querétaro artist and architect of note, did considerable interior decoration in which he shows creative power that just falls short of being great.

In the following year the following followed Echever the elder, and in general it reflects the influences at work in Mexico City. Its artists are inferior to those of the capital. García Ferrer painted the "Creation of Adam," and decorated the altar of Los Reyes in the Puebla Cathedral of which he was the architect. Diego Becerra executed a series of pictures for San Francisco Church, Puebla, "Saint Francis in the Desert," "Saint Francis Accompanied by Angels," and "Saint Francis in a Charriot of Fire," all of which are strong, realistic and well executed. José del Castillo and Miguel de Mendoza, an Indian prince, are two other well-known Puebla artists. Joaquín Magón painted the large mural pictures in the Puebla Cathedral, Puebla, "The Last Supper," "The Washing of the Feet," "The Protection of the Virgin," and also a series of the 'Passion' in the Carmelite convent and another series on the same subject in the sacristy of Ocotlán, Taxco. His coloring is too vivid and his work has an unfinished appearance. Miguel Jerónimo Zendejas (1724-1816) was exceedingly popular. His technique is faulty but his work is pleasing. His best picture is "Christ Praying in the Garden," in the Puebla Cathedral. José Rodriguez Alendo, an artist of much talent, a sculptor and a botanist, expelled to Spain for revolutionary intrigue in 1808, acquired there great facility in pastel, which he introduced into Mexico. Two of his Virgins are in the Puebla Cathedral and two fine portraits are in the Puebla Academy, one of himself and the other of a Spanish lady.

Later Academy School.—Among the painters of the latter half of the last century whose works are represented in the National Academy are José Obregón, whose large painting "Queen Xochitl," the discoverer of pulque, the national drink of Mexico, is one of the most popular and best known in Mexico. Xochitl is represented as offering her discovery to King Tecpancaltzin, who is enthroned upon his seat of honor in the midst of his royal attendants. "Hagar and Ishmael" is perhaps a better picture, though on account of the subject of which it treats it is not so well or popularly known. Rodriguez Gutiérrez' very striking "Senate of Taxco" represents that body deliberating on the course to be pursued toward the invader Cortés. The invention and grouping are better than the coloring. Pelegrin Clave's "Isabel the Catholic Attending the Religious Services" is perhaps the best and most attractive pictures of his epoch. The coloring is rich and harmonious, the drawing good and the scene depicted is spirited. Juan Cordero has two pictures in the Academy, one representing "Columbus and his Little Son at the Gate of Rábida Convent" and the other "Columbus after the Discovery of America." Juan Ortega's "Meeting of Cortés and Montezuma" is full of imagination and fine coloring and is indicative of what the author might have continued to do. Salomé Pina enjoyed considerable reputation among his fellow-artists. Two of his pictures in the Academy, "Abraham and Isaac" and "Saint Charles Borromeo" are spirited in conception and execution. Luis Munroy's work, "Charity," represents a Roman girl conveying food to her imprisoned father. This and the "Prodigal Son" and the "Last Moments of Atala" are good pictures. Manuel Ocaranza has in the Academy two fairly good pictures in the characteristic style of the middle of last century: "Love's
MEXICO — ARCHITECTURE (14)

Wiles* and 'The Faded Flower,* Juan Urruchurt reverses to the religious school of art of the 18th century in style and subject in 'Let the Little ones come unto Me,' 'Sor Juana Inés de la Cruz' and 'San Sebastian.' Gonzalo Carrazco is represented by two pictures, 'Job' and 'San Luis Gonzaga.' The latter scene is during the.plague in Rome. Francisco de Mendivil has created two fairly good pictures in 'A Miracle of Saint Peter' and the 'Good Samaritan.'

Modern Painters.— There is no school of modern painters in Mexico though there are good artists. This is because the artists have, for the most part, been educated abroad under different influences and environment, and have become neither Mexican nor foreign in sentiment.

José María Velasco, an excellent landscape artist, painted with great care and detail, producing canvases that won for him renown in Europe. His coloring is delicate and true to nature and his cloud effects are especially happy. Many of his best pictures have found their way into his pictures. France, the 19th century, upon him the cross of the Legion of Honor and Austria that of Francis Joseph; and other countries have rendered like tribute to his genius.

F. Parra, best known of modern Mexican painters, does his work with loving care and in good taste. He shows invention, boldness of imagination and excellent grouping. His coloring, too, is good. Three of his pictures, 'Las Casas,' 'Galileo' and the 'Massacre of Chihuahua,' have been photographed without number and copies of them may be found in every curio store in Mexico. They are all striking pictures of sterling worth, in which the drawing is good, the conception vivid and the coloring in good taste. A smaller picture, the 'Flower Market,' is of greater artistic worth, but it is almost unknown, because it has always been in private possession. The comparatively small canvas is crowded with figures, all different and all true to life.

Herman Gedövius, who received his art education in Germany and who reflects German influence, is probably the best portrait painter Mexico has produced. His early work was labored but his latter shows freedom of movement, richness of color which reminds one of the old Flemish masters. His auto-portrait in the Academy is excellent.

Leandro Izaguirre, who spent 10 years in study in Europe, is the best known of modern Mexican portrait painters, but his imagination, execution and coloring are inferior to those of Gedövius. Izaguirre once showed signs of possessing daring and inventiveness in his earlier works, especially in his great canvas the 'Torture of Guadalmhcolm,' now in the Academy; but his European residence weaned him of things Mexican to the loss of native art.

Gerardo Murillo is perhaps the most characteristic of the younger Mexican artists, especially in Mexican landscape effects, which, on account of the high elevation of the valley of Mexico, are very difficult to analyze and depict. Very often his work is more sketchy than solid and he gains his effects in paint through the methods of the sketch artist. Yet he is generally strikingly effective.

Andrés Rios delights in painting scenes filled with figures. He inclines to historical char-
sovereigns of Michoacán, of Yucatan of the Zapotecs and the Mixtecas. For untold years Mexican artisans had been accustomed to depend very greatly upon themselves in working out the plans and ornaments of buildings, all of which were controlled by partially conventionalized mythological ideas and Church policy. The European architects who arrived in Mexico from Spain almost immediately after the Conquest found these native artisans wonderfully skilled in their line of work; but they soon realized that the surest way to get the best results was to allow them to work out ideas not from a detailed plan but from rough sketches. The result was that, while Mexico adopted Spanish architecture, it did so with modifications introduced, consciously or unconsciously, by the native workmen who brought to their task traditions that, from time immemorial, had governed their plans and the manner of executing them.

Iberian Transition Period.—The Spanish conquerors were in spirit much like the Crusaders. They fought the races of America in the name of the cross, and they smote the heathen for the greater glory of God. They demolished temples; they smashed idols and idols worshippers; they burned cities, and they leveled gigantic pyramids that had required centuries for their erection. The priests and monks who followed the soldiers continued the demolition of all evidence of the historic past of the native races. So fierce was the force of destruction that it was necessary for the Spaniards to erect excessively heavy walls to support massive roofs and high ornamental façades, and the builders brought to their work, during the Spanish régime, an ingrained belief in the necessity for massiveness in the construction of walls and façades, a belief which continued throughout the 300 years of Spanish domination. Mexico has always been subject to heavy earthquakes, and these have helped to accentuate this belief in the necessity of massiveness in the construction of the main walls of buildings. The monumen- tal edifices of the country are often more massive in character than those of Spain. The walls of some of the Maya buildings still standing are from 6 to 10 feet thick and these are equalled in massiveness by the walls of the cathedral and other great edifices of the capital.

Building Material.—The more durable building material of Mexico was in no way inferior to that of Spain. A score of different kinds of excellent stone, all well suited for the purpose of it handsome and some of it, like the native tezontli (lava-rock), of a character to give a distinctive appearance to edifices constructed of it; marble of a dozen different varieties; and onyx as handsome and as varied as any in the world, were all at the command of the Mexican builder. There was in Mexico for dwellings, no light, durable earthquake-resisting building material such as existed in the forests of the United States and Canada in the early years of colonization and expansion. Adobe (sun-dried earthen bricks) took the place of lumber in the construction of the houses of the lower and middle classes of the upland plateau; and it has kept its place to the present in the public favor. Owing to the fragile nature of this material, walls constructed of it are necessarily very thick. In country places even churches are frequently constructed of adobe, which, covered with stucco, presents a very pleasing appearance. There are towns of considerable size in the interior of the table lands where practically all the buildings are constructed of adobe, and the plain mud walls of the Indian pueblos are familiar and picturesque parts of the landscape. These are constructed probably as in pre-Columbian days, and villages
themselves, with their irregular, lane-like streets, are like their Aztec progenitors.

But as adobe is not suitable for the lowlands with their torrential rains, it is replaced there by uncut stone, for the town houses; and in the villages and country by primitive thatched huts with walls of bamboo or other poles, through which the air makes its way at will. Owing to the prevailing mildness of climate all the year and the excessive heat in the hot season, these Indian huts, on the whole, meet the requirements of their occupants, who lead lives very near to nature’s heart.

The Dome and the façade.—The architecture of Spain was influenced by the Romans, Goths and Arabs throughout the periods of Romanesque, Gothic and Renaissance supremacy. The Greeks, Phoenicians and Carthaginians, too, have left their impress upon it. It does not, therefore, belong wholly to any one of the recognized styles; but it is, for this reason, none the less interesting. Mexico followed Spanish models more or less closely; but the Indian mind, and the Spanish, by their ornamentation, her architecture departed, in matter of detail, of execution and of adornment, from that of Spain. The Moorish dome, with its striking appearance, its handsome tiles and its frequently elaborate adornment, appealed to the Indian mind more, related to their elaborately adorned aboriginal façades, towering often from one to two stories above the habitable part of the building. The dome is seen everywhere in Mexico. It peeps out from amid the branches of trees sheltering the little Indian village; it crowns the summit of a commanding hill; it retreats, almost hidden from sight, to some little valley amid mountain fastnesses. Everywhere majestic, it lends a touch of Orientalism to a landscape for which it is eminently fitted.

Early Spanish colonial architecture in Mexico was largely influenced by the Gothic and the Moorish; but the buildings erected after the close of the 16th century followed some of the various phases of the Spanish Renaissance. The Spanish mind alike understood the value of contrast and concentration in decoration. In the Maya buildings the elaborate ornamentation which they lavished upon their monumental edifices was confined, for the most part, to the upper stories; the lower having a plain surface of cut stone or stucco. This disposition threw into relief and thus made more effective the ornate superstructure. The Spaniard confined his ornamentation to parts of the façades, to the doors and windows and the parts of the towers above the level of the roof. This had a splendid cumulative effect, which can be seen in the illustration) the façades of the Sagrario and the cathedral of Mexico City. This ornate style of decoration was especially fortunate in its mass for its column a column a column of the other, are evidences of the many-faced traditions of the native dynasties and the influences of Spain. The free hand of the native workman is best seen in the earlier buildings of colonial Spain, for later on he conforms generally to the standards set by the exacting and better trained architects and master-builders. But this conformation is outward. In the spirit of execution the attitude of the Indian mind is still strong. He has taken instinctively to the Spanish idea of cumulative effect, which, in another form, was his own; and his inclination in this direction often displays itself in florid ornamentation frequently approaching the uncouth but always effective. In its adherence to Spanish forms, Mexican art is as notorious a disregard of convention as the Spaniard himself is in his adoption of the Renaissance, in building, painting, sculpture and all the arts. It is this respect that Mexican architecture differs from that of Spain; and it is this very difference that makes it so interesting; for it seen within the activity of the highly-developed native races of America, these artist artisans, stone-cutters, wood-carvers, metal-workers, floridly ornament their buildings of all kinds, essentially thinkers, creators, builders in love with their work of creation.

Styles of Mexican Colonial Architecture.—Of the early colonial edifices of Mexico, more middle-age than Renaissance, one of the best examples is the church of San Francisco at Cholula, about which there still clings the mysterious atmosphere that the Indian workman lent to all he touched in the years following the Conquest, while his ancient traditions were still in force. The Renaissance soon made itself felt in Mexico as it had already done in Spain. The Moorish dome was its inseparable attendant; and New Spain, in a few years, became the centre of tireless building activity which was to cease only when the Spaniards withdrew from the country. This movement was at its height when the cathedrals of Mexico and Puebla were begun, in the latter half of the 16th century, when Mexico was under the Baroque influence; and before they were finished the Churriguersque had supplanted them. The Puebla edifice was built more in accordance with the original Spanish Renaissance ideas of its architect; but the cathedral of Mexico, especially in its interior decoration, was strongly under the influence of the two ornate styles, both of which are characterized by the interruption of straight lines, the breaking of entablatures and pediments, an inclination toward unexpected arches or curves. The Baroque retains the original column of the Renaissance, but it takes itself with it by twisting it out of its primitive shape and running it into panels and stories and decorat ing it in an unorthodox way.

The Churriguersque, child of the Baro que, can to extravagance in its love of the ornate; It made such its column a column of the other, are evidences of the many-faced traditions of the native dynasties and the influences of Spain. The free hand of the native workman is best seen in the earlier buildings of colonial Spain, for later on he conforms generally to the standards set by the exacting and better trained architects and master-builders. But this conformation is outward. In the spirit of execution the attitude of the Indian mind is still strong. He has taken instinctively to the Spanish idea of cumulative effect, which, in another form, was his own; and his inclination in this direction often displays itself in florid ornamentation frequently approaching the uncouth but always effective. This movement was at its height when the cathedrals of Mexico and Puebla were begun, in the latter half of the 16th century, when Mexico was under the Baroque influence; and before they were finished the Churriguersque had supplanted them. The Puebla edifice was built more in accordance with the original Spanish Renaissance ideas of its architect; but the cathedral of Mexico, especially in its interior decoration, was strongly under the influence of the two ornate styles, both of which are characterized by the interruption of straight lines, the breaking of entablatures and pediments, an inclination toward unexpected arches or curves. The Baroque retains the original column of the Renaissance, but it takes itself with it by twisting it out of its primitive shape and running it into panels and stories and decorat ing it in an unorthodox way.

The Churriguersque, child of the Baro que, can to extravagance in its love of the ornate; It made such its column a column of the other, are evidences of the many-faced traditions of the native dynasties and the influences of Spain. The free hand of the native work-
acteristic styles of architecture, developments of the Renaissance, influenced by Moorish and other ideas dominant in Spain at that time on its introduction. Both are splendid in their general effects, in their monumental façades and in their elaborate stone carving which, at a distance, gives to the façades the appearance of one huge piece carved from the living stone itself. The impression is that the great Maya buildings give. The Baroque in Spain was stamped with a strongly individualistic character; and the Churrigueraques, a very ornate development of it, became in Mexico the most truly expressive medium of the native mind. In the 18th century Mexico went mad over Churrigueraques, and all the invention, all the grotesqueness, all the fertility of imagination, all the originality of the native mind, were exercised in creating new forms of ornament and intricate adornments for church façades and interiors, which became masses of gold and silver, of richly-adorned columns and pilasters reaching to the lofty ceilings, of elaborate altars, splendid in their intricate carving, their painting and gilding, and the use of the precious metals. Intricate scroll work, fruits and shells proclaimed the influence of the native Mexican workman, while strange mythological designs showed that there still reached him echoes of the creed of his ancestors and of his pre-Columbian art. Yet the sense of proportion is ever there, and this strange mingling of various systems of art gives one the impression of a magnificent and unified ensemble. The touch of the artist is ever perceived in the best of these old colonial buildings; for Catholicism and the native Indian mysticism seem to feel the bond that binds all mystics together.

Influence of Tolosa.—Manuel Tolosa, a noted Spanish artist and architect, who came to Mexico as a teacher in the National Academy of Arts, the last part of the 18th century had been trained in a school that disliked intensely the Churrigueraques and he set about reconstructing the interiors of many of the public buildings of the capital of Puebla and of others. He helped to extend her Moorish influence. Even in the capital this influence is seen in existing buildings and many others of the same style have disappeared. The famous Jockey Club of Mexico City, completely covered with bluish tile, reflects strongly this Puebla style. Some of the Churrigueraques churches, whose ornate exteriors are set against a background of Puebla tile, present a gorgeous and fascinating appearance; but in many others the employment of the Mexican Moresque is so not fortunate, for it was not always applied in good taste. JOHN HUBERT CORNYN, National University of Mexico.

15. ETHNOLOGY. Ethnologically Mexico is one of the most interesting of the countries of the Western world. Within her boundaries are represented all the really great cultured races of North America. Her territory forms the bridge of the continents over which surged backward and forward for uncouunted
centuries untold races, many of whom have disappeared forever, leaving behind them buried remains of their arts, their industries, their tribal customs and remnants of their various languages engrafted upon those of the races who succeeded them.

The historic races of Mexico belong to a score or more of families, which future intense study and investigation may or may not show to be united. Many of the languages are divided into sub-families and these into dialects, some of which are quite separate, while others blend into one another so that it is hard to determine where one begins and the other ends. But all are indicative of the presence in Mexico of many races of distinct customs, habits and religious beliefs for a long period of time, and of the changes in the distribution of these people which had already taken place, and which were continuing to take place at the time of the Conquest. Mexico, as we see it in the first quarter of the 16th century, presents but one of the many ethnological phases of her kaleidoscopic existence.

Origin of Races.—Beside tradition, there is no guide pointing the way to the penetration of the cloud that hangs over the past of the enigmatic races, other than such aids as are lent by linguistic studies, comparative ethnological investigations, archeological remains and such echoes of the past as have come down to us in the complicated mythologies of the various families inhabiting the western hemisphere.

Two great racial traditions in Mexico point to distinctly different origins for the two leading races of the country. Nahua tradition would seem to indicate that they came into Mexico from the north by way of the Pacific coast, while Maya tradition as invariably points to the east and more specifically to the coast of the Gulf of Mexico, as the direction from which they worked southward into their present habitat. And yet, when the great Nahua culture god, Quetzalcoatl, arrived in Mexico, it was by way of the Gulf of Mexico, and when he departed from the scene of his labors, for the unknown land from which he had come, it was by way of Coatzacoalcos (Puerto Mexico) on the Gulf side of the Isthmus of Tehuantepec. His and similar traditions have been used to prove that the Nahua tribes must have come from the east. Much is made of the fact that, while the Nahua are represented, in their traditions, as coming from the north and west, Quetzalcoatl is as invariably represented as coming from the east, and that, as mythology is always older than tradition, the Nahua must have come originally from the east and have afterward wandered north and come south again. There is nothing to support this hypothesis. It must be kept in mind that, in these traditions of race migration and in that of the movements of the culture god, there are wrapped up two distinctly different events, which, in all probability, have no relation to one another. Quetzalcoatl's office as messenger of the sun god who sent him on his mission of culture to Mexico necessarily forced him to begin his journey from the direction of the home of the sun which, according to Nahua tradition, was in the east; and the same reason made him sail away again toward the east when his mission on earth had been accomplished. The great prophet who came into the sun and the races that arrived from west and north are, therefore, distinct in origin, the others bid us listen to the echoes of migration through several centuries of its semi-historic existence.

The origin of the Mexican people has been traced, by over-zealous investigators, to almost every corner of the earth. Greeks, Parsees, Egyptians, Africans, have been successively put forth with elaborate arguments as the original fathers of the Mexican people. But it is within the past half century that serious investigation along scientific lines has been undertaken by properly trained workers. The result of this investigation shows conclusively that, whatever may have been the origin of the races of the American continent, it is to be sought for so far back in the past that races, customs, mythologies and tongues have had time to blend and to create a number of sub-tongues and dialects with the complex and many-colored nations that also shows that Mexico must have been originally populated before the domestication of wild animals, and even before many of the animals of the present day came into use in the Eastern Hemisphere. The horse, the cow, the sheep, the goat, the elephant, the camel, had become an integral part of the civilization of the Old World, were unknown in America prior to the Columbian discovery. In general the animal life of the Western Hemisphere so different from that of the eastern that separation of many centuries is necessary to account for this diversity. The differences in the plant life of the Eastern and Western Worlds is even more noteworthy.

The uses to which the pyramidal structures were put are different for those to which they were put in Egypt and neighboring civilized nations. If the builders of Mexico and Central America had any affinity with those of the Old World it is clearly not with those of the Mediterranean. So, after reviewing the evidence which would derive the original races of Mexico from European or African civilizations we are forced to come back to the native traditions, which offer us the only glimmer of light in the darkness. As has already been stated, these traditions point to the north as the original home of the Nahua people; and investigators have taken this to mean somewhere in Arizona, New Mexico, Colorado or California.

All these conjectures may be partially true; it is probable the Nahua were, at various stages of their exodus, in these several places. But it is still more probable that they came from much farther north and that, in their migrations southward, they followed the Pacific coast for a considerable portion of the way. There is a very suggestive similarity between the customs, culture and mythologies of the Nahua and those of Kwakiutl people of British Columbia; and between those of the Aztecs and those of the races of northeastern North America, to whom they resemble in appearance. But though these similarities are, they...
show, by their several stages of development, that a very considerable space of time must have elapsed since these widely-separated races were in contact with one another.

The similarity of the myths and customs of other western and northern tribes would seem to connect them with the Nahua and with the people of northeastern Asia. As the Nahua and the Maya show affinities in culture, customs and traditions sufficient to suggest that they had a common origin, and as the more recent linguistic and ethnological investigations would seem to confirm this suggestion, the latter probably came from the same original habitat as the Nahua; but in their journey southward, instead of keeping to the coast, they made their migration eastward across the continent.

There are, in Mexico, races much older than the Nahua and the Maya, races that have, undoubtedly, been profoundly influenced by these latter arrivals, but have retained certain characteristics and still proclaim their earlier origin. Of these the Otomi, jointly with the Chichimeca, are credited, in Nahua mythology, with being the first races created by Camaxtli, the Tlaxcalteca creator. Primitive though these peoples were, it is almost certain, however, that they were not the first races in Mexico; for in places we meet with strange tongues, curious wrecks upon the strand of time, that seem to have no affinity with those of the races dominant in the days of Moctezuma.

Distribution of Races.—A glance at an ethnological map of Mexico shows that the country is divided into a great number of race areas. One of these, comprising Lower California and a part of Sonora on the Pacific side, was populated, in historical times, by races of a low culture, who had undoubtedly been driven to these confines by the conquering Nahua and other races who swept over the great upland plateaux. Along the Rio Grande, in parts of Sonora, Chihuahua and Coahuila; and along the Rio Grande in the north, and driving the Tamaulipesco and the uncivilized tribes of southern Coahuila, Nuevo Leon and Tamaulipas also in the direction of the Rio Grande and toward the coast of the Gulf of Mexico. Encountering highly civilized peoples in the mountainous and east-central part of Guanajuato, Queretaro, Hidalgo and Michoacan, they skirted the latter on the west, making their way through Guerrerio, and, pouring over the mountains to the east, overran Morelos, Mexico, Tlaxcala, Puebla, most of Vera Cruz and a part of Tabasco. A wing of the migration, coasting further south along the Pacific, left a strong colony on the southern shore of Guatemala, another in the interior and a third in Salvador, while a few settlements upon islands in Lake Nicaragua and occupied all the land between that body of water and the southwestern coast. A fifth crossed the isthmus and took possession of territory on the northwestern shore of Panama, near the Costarican boundary line. The latter, headed by the Aztecs, extended its territorial dominion, though not successful in forcing its language on the conquered races or in assimilating them to the customs, the culture, or even to the political system of the Nahua; so that the people over whom it gained its sway remain ethnically distinct to-day.

All these separate ethnic divisions show decidedly distinctive racial characteristics. Their languages, industrial arts and mythologies present such variations and dissimilarities as could only come from distinct races or from families separated from one another in the early stages of their tribal life. Therefore Mexican ethnology has to deal with these races as such, and also with their relation to one another and the general influence they have had upon one another ethnically; for the mixing and the blending of the races which have successively appeared in Mexico, have been going on for ages, just as they are going on to-day, with added European and other elements.

But though the native ethnic elements are gradually losing their distinctiveness, or have already lost it, as in Tamaulipas, San Luis Potosi, Nuevo Leon, Coahuila and northern Chihuahua, yet there are many states, like Michoacan, Guerrero, Oaxaca, Chiapas and Yucatan, where the native languages are still spoken with comparative purity. These parts of the country racial characteristics persist.

The Nahua is the most important of all the races of Mexico, on account of the vast extent of territory it covered, stretching as it did from the Rio Grandal race of northern Mexico, forcing the Seri to the mountainous parts of the state of Sonora on the west and splitting apart the Apache and Toboso and crowding them back to the Rio Grande on the north, and driving the Tamaulipicos and the uncivilized tribes of southern Coahuila, Nuevo Leon and Tamaulipas also in the direction of the Rio Grande and toward the coast of the Gulf of Mexico. Encountering highly civilized peoples in the mountainous and east-central part of Guanajuato, Queretaro, Hidalgo and Michoacan, they skirted the latter on the west, making their way through Guerrerio, and, pouring over the mountains to the east, overran Morelos, Mexico, Tlaxcala, Puebla, most of Vera Cruz and a part of Tabasco. A wing of the migration, coasting further south along the Pacific, left a strong colony on the southern shore of Guatemala, another in the interior and a third in Salvador, while a few settlements upon islands in Lake Nicaragua and occupied all the land between that body of water and the southwestern coast. A fifth crossed the isthmus and took possession of territory on the northwestern shore of Panama, near the Costarican boundary line. The latter, headed by the Aztecs, extended its territorial dominion, though not successful in forcing its language on the conquered races or in assimilating them to the customs, the culture, or even to the political system of the Nahua; so that the people over whom it gained its sway remain ethnically distinct to-day.
Linguistically the Nahua are divided into a score or more of distinct tribes, all speaking, with variations, the Nahua tongue. The Toltecs, who had disappeared as a political entity several centuries before the Conquest, were the most noted of the Nahua. They occupied a considerable part of the territory afterward held by the Aztecs at the time of the Conquest. The following tribes are now recognized as belonging to the Nahua race:

The Acahui, speaking four closely-related dialects, inhabited the mountainous regions of Durango, between the Tepehuán and the Aztecs. The Aztecs or Mexicans (including Tlaxcalans) were spread over a vast extent of territory from Tabasco, through southern Vera Cruz and across the state of Puebla, Morelos, Mexico and Guerrero, to the Pacific, and thence up the coast, through Jalisco and Sinaloa, past the southern end of the Gulf of California. Another group of considerable extent occupies the shores of the Gulf of Tehuantepec. The Yaqui, also known as Hiaqui, Cahita, Cinaloa and Sinaloa, who were divided into three-tribes speaking distinct dialects, Yaqui, Mayo and Tehueco, are closely allied to the Aztecs, with whom they have been classed. At one time they occupied considerably more territory than they do to-day. They extended over the middle and lower Yaqui, the Mayo and the Fierro districts of Sonora. Now, so far as language is concerned at least, they are confined to the Yaqui River district. All the Yaqui tribes were energetic, patriotic and intelligent and they were one of the foremost factors in building up the civilization of Mexico. The Cacazcanes occupied the mountainous districts of Jalisco about midway between Guadalajara and Zacatecas. The Conchos, now extinct, but at one time an important tribe, occupied a considerable extent of territory, lying between that of the Tarahumare on the west, the Apache on the east, the Tepehuán on the south and the Rio Grande or the north, their habitat being almost entirely within the boundaries of Chihuahua. The Cora, belonging to the northern or Sonora group of Nahua-speaking tribes, live along the Jesus Mariá River in the state of Jalisco. The Huicholes (Guachichiles, Guachichiles), according to Orozco y Berra, occupied parts of Cochila, Nuevo León, San Luis Potosí and Zacatecas. They were between the Laguneros on the north, the Otomi to the southeast and south and the Zapotecs to the west. Catholic missions were early established among them; they were brought under the domination of the Spaniards and their language finally disappeared as a tribal institution. In the heart of the Yaqui country were the Nio, who lived south of the Fuerte River. The Niquirán, one of the Nahua settlements furthest south, form a small community occupying the land between Lake Nicaragua and the Pacific Ocean and also the neighboring islands in the lake. About the headwaters of the Hermosillo and Yaqui rivers, between the Seri on the west, the Apache on the northeast, the Pima on the northwest and south, was the important Opata tribe, which consisted of two sub-tribes speaking distinct dialects, Enderé (Hove, Dohera) and Joval (Ova). The most northern Nahua family, the Pima, was divided into the following scattered groups: Pima Alta (Upper Pima), situated principally in the United States, but occupies a small part of northern Sonora; Pima Bajo (Lower Pima), who lived around the middle part of the Yaqui River, between the Tarahumare to the east, the Yaqui to the south, the Seri to the west and the Opata to the north. A small extension of the Opata country, Pima de Bamosa (Salikan) and around Bamosa, on the lower Sinaloa river south of the Mayo; Tepehuán Pima, a scattered group in the western part of the Tepehuán country. In southwestern Salvador are the settlements of Nahua known as Pinol and related to the Aztecs, while the Sigua (San Xicaguia, Shelaba, Chicaguia, Chicachaguia) are Aztec colony on the northwestern side of Pama, marks the southernmost limit of the Nahua extension. South of the Apache, east of the Concho and north of the Tepehuán, lived the Tarahumare, an extensive division of the Nahua family, covering parts of the states of Sonora, Chihuahua and Durango. They spoke a number of distinct dialects and their territory was divided into three districts: La Baja, or the Tarahumare proper was spoken in the upper country while the tongue of the lower land was known as Chinipá. The Tepehuán closely related to the Tepehuán, occupied territory between that of the Cacazcan and the Guachichil in modern Tepic. The Apache, living principally in the state of Durango, south of the Tarahumare, where they are considered for the most part, to the mountainous region for a distance of about 250 miles.

The Olive (Olivean) is a race of hokicolored people than the tribes surrounding the occupy territory southeast of the Pico de Janambre, in the state of Tamaulipas. Tradition says they came from Florida, which is mean only the Gulf coast. They were skilled in culture to their neighbors, but, nevertheless, their language has become extinct.

The Pakawán or Coahuiltecas is the name given to a number of cognate tribes of southern Texas and northern Mexico. They covered considerable territory east of that occupied by the Tepehuán. This included, in Mexico, the coast side of Coahuila, most of Nuevo León and northern part of Tamaulipas. As these were inclined to be nomadic and were partially civilized, they rapidly lost their language after their conquest by the Spanish.

The Otomi (Hia-hti) is the word Otomi also in two senses. It signifies the race of speaking the Otomi language; and it is also tended to include, in a general way, those who from time to time formed loose alliance with the Otomi for war or defense. They have been confounded with the so-called Chichimeca, and some authorities claim that they were one of the ethnic divisions of the latter indefinite tribal designation. The Otomies had distinct customs and a complicated mythology, but were less civilized than the Jicarillas occupied a large, somewhat irregular, yet compact portion of central Mexico, where most of their descendants may be found today speaking their ancient tongue. Their territory extended over part of San Luis Potosi, Queretaro, and most of Guanajuato, reaching into the state of Mexico, a short distance south of Mexico City, and from there westward to Michoacán. On the east were the Huastecs.
the southeast the Tarascans and along the northwest of the Nahua. They were divided into four tribes: Otomi proper, Pirianda, Pame (northwest of the Otomi) and the Mazahua (east of the Tarascan, in the southwestern part of the state of Mexico). In the time of the later Aztec empire the Mazahua occupied the province of Mazatlan situated in the western mountains of the valley of Mexico. They were subject to Tacuba. The Pirianda territory was principally in the valley of Toluca, and some descendants still live in villages in the land of the Mexica, others in Tarascan territory. The Otomi were a numerous, industrious and fairly intelligent race.

Under the heading of "Rio Grande tribes," Orozco y Berra groups a number of native communities occupying territory in the state of Tamaulipas at or near the mouth of the Rio Grande River; but he furnishes no further data respecting them with which to classify them; but as the Indians of this district no longer retain their tribal organizations, and as their languages have also disappeared, little is known of the Rio Grande Indian culture.

The Seri, who occupied a considerable extent of territory on the mainland opposite the peninsula of Lower California, where their language is still spoken to some extent, are classed among the least civilized of the Mexican races. Their territory stretches inland from the mountain region for 150 miles or more from the coast, and includes the island of Tiburón (shark) in the gulf.

Under the head of Tamaulipeco, Orozco y Berra, who has paid more attention than any other investigator to the races of Tamaulipas, where the native languages have all practically disappeared, gives the following tribes: Tamaulipeco proper, Canayes, Quinicuanes, Borrados, Texexenos, Pasitas, Taguilllos, Carbayes, Mariguanes, Panguayes, Anacana, Cadina, Guixolotes, Pintos, Comerodunos, Malcheninos, Ancasiguais and Artines.

The Tarascos (Michoacanos), occupying approximately the state of Michoacan, speaking a distinct language and having customs, myths and traditions different from those of the other races of Mexico, form one of the important racial divisions of the republic. They are a highly cultured people and, in the time of the Aztec empire, they maintained a separate, independent government.

From the city of Vera Cruz northward to the Huasteca and inland to Tlaxcala, lie the Totonoaca, almost completely surrounded by the Nahua. They were a cultured race at the time of the Conquest, and it was among them that the conqueror, Cortés, established the first Spanish government and colony on the mainland of the American continent.

Two cognate tribes, the Wacihuir and the Pericu, occupy the southern end of the Isthmus of Lower California. Their languages, which are still spoken, are very badly corrupted.

The Yuma family is represented in Mexico by the Cocopa (Cucapa) and the Cuchim, who occupied the southern one-fourth of Lower California. The native tongue is already badly corrupted and is fast disappearing.

The Zoque, stretching over four and one-half degrees of longitude, across the Isthmus of Tehuantepec, from east to west, and occupying parts of the states of Oaxaca, Chiapas and Tabasco, are surrounded by Zapotecs, Chicantecas, Maya and others. The Zoque family is divided into four branches. Mixte, to the north and west of the main territory, Zoque proper, to the south and east, Tapachula, in the southeastern corner of the state of Chiapas, on the Guatemala boundary line, and the Popoloco in the state of Puebla.

The great Athapascan family is represented in Mexico by the Tohono and the Apache. The area and location of land occupied by these two nomad, warlike tribes changed from time to time; but, roughly speaking, the Apache occupied an irregular territory, stretching southward from the Rio Grande and the American boundary line for a distance of five degrees of latitude, from about 105° westward, covering parts of Chihuahua and Sonora. But they often raided over the northern part of the latter state far into the interior. The Tohono also occupied territory stretching from the Rio Grande southward, but their general habitat reached eastward from the western boundary line of Coahuila, within which they still reside in normal times. They often joined hands with the Apache in raids on the more civilized parts of the surrounding country; and they frequently gave the United States and the Mexican governments considerable trouble.

Sometimes the depredators took refuge on the American side after a raid on Mexican citizens and vice-versa when they had raided American territory.

In an area around the town of Chinantla, south of Vera Cruz, occupying territory about 100 miles in extent, are the Chinantecos, who are probably a survival of one of the ancient races who populated the country before the arrival of the Nahua. The Huave (Huabi, Guavi, Juave, Wabi), another primitive race, occupy the marshes around the great lagoon which forms the northern inlet of the Gulf of Tehuantepec. Tradition says they once possessed all the isthmus country and that they came from the south. The Yanambé, a third primitive tribe, of a very warlike disposition, who occupied the rugged southwest of Tamaulipas, from a short distance north of Victoria to the southern boundary of the state, about 100 miles, gave the Spaniards much trouble before they were finally conquered toward the close of the 18th century.

To the south and east of the southern Nahua and stretching from Guerrero to the Isthmus of Tehuantepec was the home of the great Mixteca-Zapoteca family, which in culture, intelligence, enterprise and achievement was scarcely inferior to the Nahua and the Maya, between whom they seem to have been the medium of communication and of the distribution of the arts and sciences. They possessed a culture which, while it resembled that of the Maya and Nahua, was nevertheless distinct. The Mixteca whose territory extended into parts of Puebla, Guerrero and a considerable portion of Oaxaca, were surrounded on the north and west by the Nahua, while the Mixtecas were their neighbors on the east. They had an outlet on the Pacific Ocean to the southwest, which they may have possessed for a long time, since it is the boast of one of their oldest legends, that their great culture hero, Yucano, defied the Sun, engaged him in combat and drove him into the ocean. The Mixteca lan-
language is still spoken over most of the Mixteca country. The traditions of the Mixteca make them an alien race fighting desperately for years for their existence, in the mountains, a part of which they were forced to abandon.

The rugged nature of the country in which they lived created, in time, numerous dialects of the Mixteca. To the east and partly to the south of the Mixteca country lay that of the Zapoteca, stretching for a considerable distance along the Pacific Coast and occupying the southern tip of the Isthmus of Tehuantepec, reaching north and west of the city of Oaxaca and including the famous valley of Oaxaca, in the mountainous districts of which the native tongue is still spoken with comparative purity. The pottery and the metal work of the Mixteca and the Zapoteca were sought by the Mexican merchants, who distributed them over a wide area of country.

The Maya family, the most highly civilized of all the aboriginal races of America, is divided into two great groups, the Maya and the Kiche, to which may be added the Huasteca. The Maya proper, within whose territory were contained most of the semi-historical cities of the more advanced culture of Mexico, were spread over all the peninsula of Yucatán, east of Tabasco, British Honduras and the island of Carmen. They were divided into Lacandón, Mopán and Iztae or Petén, three tribes speaking slightly different dialects. The Lacandón still inhabit a region near the headwaters of the Usumacinta River, in eastern Chiapas and northern Guatemala. They were once a very extensive and important people; but their ancient greatness has disappeared. They still speak their native tongue. The territory of the Iztae occupied a part of northern Guatemala and eastern Yucatán stretching westward probably to Campeche and southward to Chiapas. The Mopán occupied an undefined territory partially in southern British Honduras, Guatemala and Chiapas. To the south of them were the Chol, also a Maya tribe, to the west the Lacandón and to the east and north the Iztae.

The Huasteca, a tribe situated far from the port of Tampico, and extending from Tampico southward and westward is wedged in between the Otomi on the west, the Nahua, Totonac and Tamaulipas tribes on the north. It was once a powerful nation and the people of to-day still bear all the racial characteristics of the Maya.

16. LITERATURE. All the culture and most of the semi-cultured races of America are included under this name. The Spanish conquest brought with it a passion for oratory and story-telling. But the literary men of the Aztecs in Mexico and other civilized nations of Mexico had, years before the Conquest, evolved literatures which had already begun to break down the barriers of conventionality. The Aztec literatures were noble in sentiment, passionate in utterance and beautiful in form. Fragments that have come down to us, principally in the shape of translations or transcriptions into some one of the native languages, leave no doubt. Mistrust has been cast as to the legitimacy of these fragments by some critics; but the fact that, after 400 years, they represent, in their utterance, form and spirit, the survival of the soul of the Aztec mind to-day, is so different from the Latin and the Saxon, that upon them the stamp of genuineness. Alas, rano, the greatest, the most passionate, the subtly poetical, the most oratorical of Mexican literary men, was a full-blooded Indian. How we see reproduced, in the heroic type, the prototype of his Indian forebears, who were literary glory of the courts of Netzahualcoyotl and Montezuma II, where oratory and other literary efforts were sedulously cultivated as a successf ull career cluster master leg end and story. Early Spanish writer
Mexican subject and native Indian literary men represent him as a great and inspired poet, and that, at such a time as his, the gift of the Mexican people and the stories and legends still current among the ignorant Indians are of strikingly imaginative, poetical and beautiful. The literary men of Indian race who learned Spanish after the Conquest and wrote in it, owe much of the information we possess of the culture and history of the native races of pre-Columbian days. The best of these Indian writers was a direct descendant of the famous Netzahualcóyotl. These Indian literary men of the early days of New Spain formed a promising literary school; but the policy of Spain, which had already led her to destroy the pre-Conquest literature and records of the native races, soon began to show itself in the oppression of the Indians, their nobles and their princes; and the most active and aggressive members of the native literary school, on account of the prestige they had won and the influence they reaped before or during the most fiercely persecuted. Broken in spirit, they soon ceased to be active figures in the national life.

Of the post-Conquest literature of the 16th century but a very small part has come down to us; and of this, principally in the form of letters, grammars of the native tongues, chronicles of the religious orders and information of a like nature. The letters of Cortés, the 'History of the Conquest of New Spain' by Bernal Díaz del Castillo, the works of Las Casas and de Sahagún are invaluable on account of the information they furnish and the light they shed on the customs, habits, government, industries, religion and superstitions of the native races prior to the Conquest. Fernández de Alva Ixtlilxóchitl, a liason descendant of the royal house of Texoco, in his 'History of the Chichimeca', gives a most intimate picture of the life of the court of Netzahualcóyotl and extensive and interesting information concerning the Nahua tribes and the history of its glory. Acosta's 'History of the Indies' furnishes valuable data about the Spanish colonies at a time when the writer was still in touch with men who had known intimately Cortés, the conquistadors and many of the Indian leaders and the Spanish conquerors. Gerónimo de Mendieta, Agustín Dávila Padilla, Francisco de Aguilar, Juan B. Pomar, Gil González de Ávila, Alonzo de Zurita, Francisco Cervantes de Salazar, Francisco López de Gomara, Fernando Alvarado Tezozómoc, Beltazar Dorantes de Carranza, Juan de Cárdenas, Pietro Martire d'Anghiera, Pedro de Alvarado, Diego de Godoy, Juan de Zumárraga, Antonio de Mendoza, Fernando Alarcón and Antonio Villa-Señor have left us full or partial pictures of life before, during or immediately after the Conquest, or throughout the 16th century, which make our knowledge of early Mexican history more complete than that of any other part of the American continents during this period.

The enthusiasm for literature and, more especially, for poetry in the majority of the 16th century was one of the distinguishing features of the life of New Spain. For the most part the writers were native-born Mexicans, some of Spanish, others of Mestizo or Indian blood. Balbuena, the religious chronicler, tells us that, during the last quarter of the 16th century, there were numerous literary contests held under different auspices and that, at such times as those, the candidates were the contestants, 300 contestants entered for poetic honors alone. He also asserts that as poets they might have compared with the most flowery in the world. It is more than probable that the first Mexican critic of his day was mistaken in his estimate of the literary excellence of these contestants, the very names of most of whom have disappeared.

Good poetical form, correct language and the sparing use of rhetoric are the characteristics of this period which is, however, inclined to prosiness and the imitation of Spanish literature. Yet it shows originality enough to redeem it from being the work of mere imitators. Tones of expression, development of subject and the handling of the matters treated of distinguish the Mexican literature of this period, in an interesting manner, from that of Spain. This is all that could be reasonably expected of it in an age when the whole American world, south of Virginia, rotated about the Spanish court.

Among the Mexican literary men of the latter part of the 16th century who have been praised by Lope de Vega and other noted Spanish writers of the period is the Mexican poet de Saavedra Guzmán, author of 'El Peregrino' (1599), a 20-canto poem, in which a bold attempt is made to sing the deeds of Cortés and his conquistadores. This poem is true to historical fact, displays careful investigation and reveals a wide knowledge of the subject and close intimacy with Aztec customs; but it is monotonous and prosy. Guzmán was a mestizo whose father was one of the conquistadores and his mother an Indian princess of the royal house of Mexico. He spent seven years in collecting the material for the 'Peregrino' whose dominant characteristics are simplicity and naturalness.

Of the writers of this period, a portion of whose works have come down to us, Fernán González de Eslava is one of the most interesting. He was wonderfully popular in his day as a writer of autos sacramentales, a kind of religious drama in high favor for over a century in New Spain. He was so notable a poet as to attract attention in Spain itself. His dramas were long performed and read and they have been presented to appreciative audiences in Mexico within the past 50 years. Francisco Terrazas, who belongs to the same period as Eslava, had the honor of being warmly praised by the great European Juán Arista, Pedro Flores, Bernardo Llanos, Francisco Plácido, Eugenio Salazar, Carlos Sámano and Juan Pérez Ramirez, were all poets highly esteemed by their contemporaries. To these we must add the name of Bernardo Balbuena, to whom we are indebted for our information concerning the literary activity of the latter part of the 16th century. Balbuena was a great lover of Mexico whose praises he constantly sings. He branched out into all kinds of literary endeavor and produced some of the most interesting. He wrote with great facility and elegance in both Spanish and Latin and is said to have been a master of Aztec. 'Mexican Greatness,' 'The Golden Age in Erilfe' and the 'Bernardo' are his best-known works. Juan Pérez Ramirez was a poet of
international reputation and wonderful popularity in his own day, and he, and Alarcon, another Mexican writer, have been much written about and praised in Spain. Plácido was a full-blooded Indian of noble Mexican family who first sang the praises of the Virgin of Guadalupe, the patroness of Mexico, who, her critics say, had the Aztec gods transformed into a Christian saint. However that may be, the Indians of Mexico have shown a wonderful devotion to her; and it was fitting that Plácido, a lineal descendant of the Aztec goddess, should have been the first to sing her praises. As the cult of this saint grew in popularity and spread to the ends of the republic, numerous Mexican poets, from time to time, recounted her glories, in richly fair and indistinct verse.

This cult of the Virgin of Guadalupe by Mexican literary men during the latter part of the 16th and all of the 17th centuries presents two interesting phases. In Guadalupe there was, in pre-Columbian days, one of the most powerful of native shrines. This shrine, a few years after the Conquest, was suddenly changed into a Christian sanctuary, on account of the reputed miraculous appearance, near the sacred well of the Aztecs, of the Virgin herself, to Juan Diego, an Indian, whom she commissioned to bear a message to the archbishop of Mexico, stating that she desired erected, on the hill top, above the well, a chapel dedicated to her worship. This chapel was duly built; and, since that day, the thousands of Indians who flock to it annually have made of it a most interesting depository of the mingled faiths of the aboriginal races and their Spanish conquerors. The literature that grew up around this historic shrine was, therefore, further removed from form, spirit and execution from that of Spain than any other class of writing emanating from Mexican sources. Yet whatever may have been the spirit and the influence of this distinctly national literature, its expression and the peculiar form it assumed were directly dependent upon the usos y costumbres, and the encouragement given to them by both church and state and by people otherwise exercising authority throughout the land, all of whom were encouraged to extend their patronage to the court of Spain itself and by the home church.

The autos were performed in the presence of vast multitudes, in the day time. They began as a species of miracle play intended to teach the natives what it was considered necessary they should know of the dogmas and history of the Catholic Church. Naturally the priests were the first writers of autos; and they continued to be their most prolific producers. But the call for new autos daily and their immense popularity with all classes, from courtier to peasant, made the demand much greater than the Church could satisfy; so lay writers soon found a paying field for their literary activities in the production of these primitive religious dramas. Thus the Church became the patron of literature as she became that of art in Mexico. The simple primitive autos, intended for the edification of the Indians, with a small admixture of mestizos, were often written in Aztec, and were almost always performed by Indians. Occasionally one may still come across one of these curious old dramas presented by Indians in some country, Mexico is known for her enthusiasm at the beginning of the present century were still features of the celebration of the festival in many parts of the republic. But the Church authorities set their stamp of disapproval upon them and they rapidly disappeared. The mother of the Aztec gods transformed into a Christian saint. However that may be, the Indians of Mexico have shown a wonderful devotion to her; and it was fitting that Plácido, a lineal descendant of the Aztec goddess, should have been the first to sing her praises. As the cult of this saint grew in popularity and spread to the ends of the republic, numerous Mexican poets, from time to time, recounted her glories, in richly fair and indistinct verse.

This cult of the Virgin of Guadalupe by Mexican literary men during the latter part of the 16th and all of the 17th centuries presents two interesting phases. In Guadalupe there was, in pre-Columbian days, one of the most powerful of native shrines. This shrine, a few years after the Conquest, was suddenly changed into a Christian sanctuary, on account of the reputed miraculous appearance, near the sacred well of the Aztecs, of the Virgin herself, to Juan Diego, an Indian, whom she commissioned to bear a message to the archbishop of Mexico, stating that she desired erected, on the hill top, above the well, a chapel dedicated to her worship. This chapel was duly built; and, since that day, the thousands of Indians who flock to it annually have made of it a most interesting depository of the mingled faiths of the aboriginal races and their Spanish conquerors. The literature that grew up around this historic shrine was, therefore, further removed from form, spirit and execution from that of Spain than any other class of writing emanating from Mexican sources. Yet whatever may have been the spirit and the influence of this distinctly national literature, its expression and the peculiar form it assumed were directly dependent upon the usos y costumbres, and the encouragement given to them by both church and state and by people otherwise exercising authority throughout the land, all of whom were encouraged to extend their patronage to the court of Spain itself and by the home church.

The autos were performed in the presence of vast multitudes, in the day time. They began as a species of miracle play intended to teach the natives what it was considered necessary they should know of the dogmas and history of the Catholic Church. Naturally the priests were the first writers of autos; and they continued to be their most prolific producers. But the call for new autos daily and their immense popularity with all classes, from courtier to peasant, made the demand much greater than the Church could satisfy; so lay writers soon found a paying field for their literary activities in the production of these primitive religious dramas. Thus the Church became the patron of literature as she became that of art in Mexico. The simple primitive autos, intended for the edification of the Indians, with a small admixture of mestizos, were often written in Aztec, and were almost always performed by Indians. Occasionally one may still come across one of these curious
more than 100 writers who, in a century and a half of activity, attained to more or less literary prominence, there are very few who rise above mediocrity. They all worship at the shrine of Gongorism and lay upon its altar involved, obscure constructions and ornate devices overloaded with classical references. The literary spirit was all-pervading, far-reaching, yet the age has produced comparatively little that is worthy of preservation for its literary merits alone. *Poets were as plentiful as dirt,* one of the critics of that day tells us; they treated every subject in very much the same way, religious poetry, lyrical, heroic, amatory, dramatic, epic. Even the prose works, which are the best of the period, are marred by Gongorism.

Among the poets of this period who, following in the footsteps of Plácido, made a literary cult of the Virgin of Guadalupe, were Carlos de Seguínza y Gongora, who published three volumes of poems devoted to singing the glories of the Indian saint in the cultus verse and lyrical metre; Francisco Bramón, *Songs of the Virgin* (1620); Luis Sandoval y Zapata, many high-sounding devotional poems in a decidedly Gongoristic vein; José López Áviles, retaining the glory of Our Lady of Guadalupe; and Antonio Morales Pastrina, fervid religious poems in praise of the patroness of the Mexican people. All these poems, a small part of a somewhat extensive literature, are touched with the strange, passionate longing of the Indian for his vanished past; and one feels in them, at times, the presence of that ancient mother of the gods whose spirit, for the Mexican Indian at least, still hovers over the rocky heights of Guadalupe.

Most of the Mexican poetry of the 17th and 18th centuries is touched with the religious spirit of the age and many poets were exclusively devoutly religious. To this class belong Pedro Muñoz de Castro, Juan de Guevara, who wrote *Religious Poems and Lamentations* wonderfully popular; Francisco Ayerra, Juana Inez de la Cruz and Francisco Cochero Carreño. During the 17th century, however, the drama, which, as we have seen, was purely religious, turned to profane subjects, without deserting the autos and miracle plays. Agustín Salazar, who died at the age of 33, had already won for himself the foremost place in Mexico as a dramatist and writer of comedies and autos. Eusebio Vela, a very prolific writer, was considered the equal of most of the Spanish writers of his day in conception, execution and management of his plots and characters. Alonso Ramirez Vargas also wrote a number of excellent dramas, the best of which is *The Triumph of Diana.*

A favorite occupation of the poets of the 17th century was the writing of history in verse. Of these historical poets Gaspar Villagrán and Pedro Arias Villalobos are the most worthy of note. The former wrote *The History of New Mexico* and the latter *History of Mexico,* both of which are proxy and tinsel-like.

Of the prose writers of this period one of the most noted is Pedro Avendaño, who was one of the first of a long line of illustrious priests to take up the cause of the criollos (people of white blood born in Mexico). In 1692 he preached several sermons in Mexico City in which he warmly expressed the feelings of the oppressed criollos and criticized the pro-Spanish attitude and addresses from the pulpit of the archdeacon of the capital. For this and other similar acts he was expelled from the Jesuit order; but this only increased his popularity with the masses to whom he continued to preach and over whom he exercised a strong influence. He possessed a withering sarcasm, powerful inventive and a great facility of expression and these qualities and his talent for interesting powers and his command of imagery make his writings and sermons always vivid and effective.

The 18th Century continued to manifest the same strong interest in literature that distinguished the two preceding centuries, but certain changes had taken place that showed the old influences were passing away. José Abad (1727-79) was the last of the great Latin scholars of Mexico who made a pastime of growing the crops of the cultivated land; and Francisco Ruiz de León goes back to the age of the Conquest for his inspiration in his *La Hernandía,* a long poem containing many excellent passages and pictures of the various characters who play their several parts therein. Although falling below the level of the great epic, the *Hernandía* is superior to all previous attempts made to evolve a great poem out of the events of the conquest.

Of the many religious writers of the period José Manuel Sartorio and Francisco Soria are the best, Sartorio, a priest, strongly in favor of the independence of Mexico, was one of the most noted orators of his time; and, like Avendaño, he wielded a powerful influence over all classes. He was a tireless and prolific writer and has left 23 volumes of miscellaneous and devotional works and sermons and seven volumes of sacred and profane poetry. His religious poems, which constitute his best work, are often animated, natural, easy in style and filled with fine imagery. The most popular dramatist of the 18th century was Arriola, whose best play is *There's nothing Worse than Jealousy*; but Cayetano Cabrera Quintero was more prolific and possessed of more talent than Arriola. Among his comedies are *The Disappointed Hope* and *Iris of Salamanca.* *A Study of the Coat of Arms of Mexico* is his most noted work. Manuel Soria disputed with Arriola the claim to be the most popular dramatist of the century. One of the best writers of the Coledoron school he has left, among others, the following dramas: *William Duke of Aquitaine,* *Mexican Magic,* *The Genoese* and *Love and Jealousy.* Though strongly Gongoristic, his dramatic situations are excellent, his verse free and natural, the development of his plots always interesting and he is never at a loss to express passion and sentiment in a pleasing and effective manner. Manuel Zumaya was the author of *Partenópe,* a very successful opera, and *El Hidalgo,* a popular drama first produced in 1708. He translated into Spanish a number of the most popular Italian operas of his time for the Spanish stage. Another translator of note was José Rafael Larraga, who was the first to turn the works of Virgil into excellent Spanish. This translation
MEXICO—LITERATURE (16)

is faithful to the text and the spirit of the original.

The greatest poetical genius of the 17th century in Mexico was Sister Juana Inez de la Cruz (1651–94), whose name is a household word in her native land, where every Mexican holds her up as the perfection of literary art. She plays upon all the passions of the human heart and she wanders into many bypaths of literature. Lyrical, amatory and descriptive poetry and the drama she manages with equal skill and facility. In her own day she was looked upon as a tragedian of great power and was credited with such superior poetic genius that she was and is still called the 10th muse. Yet she had the defects of her age; and modern literary standards, while admitting her superior talent, find her guilty of Gongorism.

The next most important figure in the literary life of Mexico, after Sister Juana Inez de la Cruz, is Manuel Navarrete (1768–1800), who may be said to have restored lyric and descriptive poetry to his native land. Naturalness and simplicity of the best in literature distinguish his work, which is dominated by deep philosophic thought and pitched in an elevated style uncommon in his day. His verse is strong and sonorous and his subjects are presented in a masterly manner. The religious feeling of primitive peoples is strong in him. His god is the god of the storms and winds, the all-powerful, the maker and unmaker of men and nations, who wipes from the earth, when He wills, the mightiest of the works of men. He is the Divine Providence of the world, and all that He does is good because He does it. Through and behind Navarrete's undoubtedly Christian faith there appears the ever-present glory of his strong conception of ancient paganism. His god is the divinity of the ancient Greeks, Romans and Hebrews who rides upon the clouds and plants His footsteps on the storm. His faith is the simple faith of a primitive age; and his poetry, true to this attitude, creeps ever closer to the heart of nature. His language is always simple, clear and correct, his lines harmonious, his taste good and his moderation in the use of poetical and oratorical adornment noticeable in his age. He rose above the prosiness and mediocrity of his time. Gorostiza, the Spanish poet, has said of him: "The defects of his work are those of his age; their beauty and excellence are his own." Navarrete was a close student and a great lover of Greek and Roman mythology; yet such was his natural genius that he was able to hold a steady midway course between the excesses of Gongorism and the barrenness of prosim in an age when both were rampant in Spain and Mexico. His odes and religious poems are his best work. Of the latter his 'Divine Providence' is one of his most characteristic compositions.

Mexican literature has always been noted for the number and excellence of its historians, and three, Gama, Veytia and Clavijero, add lustre to the 18th century. To their industry, clearness of thought, the perspicuity of style we owe much of our knowledge of the history of New Spain.

Nineteenth Century.—José Joaquín Fernández de Lizardi (1771-1817) forms the bridge between the last of the schools that grew up, flourished and declined under the patronage of the Spanish Crown and the new school which came into being with the successful revolution which made of Mexico an independent nation. He is the most pronounced herald of independence and the keenest thinker of his day. For this reason he is universally known wherever the Spanish language is spoken as "El Pensador Mexicano" (The Mexico Thinker). 'El Periquillo Sarniento,' his most famous work, is as well known in Spain as in Mexico. It has been published many times and is now looked upon as a classic in the Spanish tongue and was credited with many faults in style, its Mexicanisms and careless use of words. It is so true to nature, so full of compassion and understanding, yet withal so humorous, so sprightly, so convincing, that it appeals directly to the universal human heart. The 'Periquillo' analyzes character and actions and presents the reader with immortal charming pictures which he instinctively feels are true. Lizardi was a publicist in the broad sense of the word, and he has left in his voluminous works an example of a great variety of subjects. Next to 'Periquillo' his most popular works are his 'Fables' and his 'Sad Nights.'

Among the successors of Lizardi are Manuel Carpio (1791–1860) and Manuel Eduardo de Gorostiza (1789–1851), who have shed lustre on Mexican literature. Carpio displays a wide range of sympathies; and his descriptive poetry is considered the equal of any written in Mexico. He is the first and best epic poet of his country and his lyrics have the true lyrical swing. Gorostiza led the way to the production of modern drama in Mexico. He was the first to enter the field which was successfully filled, later on, by the many dramatists who have won laurels for Mexican literature since the overthrow of Spanish domination in 1821. His subjects are always full of interest and wide in range; his plots are skilfully constructed and his dramas have the broad human sympathy which ever appeals to mankind, simple, sincere and correct in style with depth of thought and keen analysis. Three other dramatists belong to the period, Juan Mencescal Barquera (1779–1840), Anastasio Ochoa (1783–1833) and Francisco Ortega (1825–1849). Of these, Ortega is the best. Both he and Barquera were journalists of note and saw many sides of life, which the both reflect in their dramas. Being journalists they were also naturally political writers, but of great power and influence. Ortega wrote heroic odes, love poems, sacred sonnets, fables, epigrams and stories of a political cast. His dramatic works are 'Camatzin,' a drama; 'The Mysteries of the Print-shop,' a comedy; and 'Freedom of Mexico,' a melodrama. Among Barquera's successful dramas, all of which were produced in the capital, are 'The Baker,' 'The Seducer,' 'Triumph of Education,' 'The Proxy's Love,' 'The Orphan Girl of Tlalnepantla,' and 'Don Alfonso.'

Manuel Sánchez de Tagle (1772–1848) shared the misfortune of forming the connecting link between Mexican literary activity under Spanish rule and the revolutionary literature that followed. He is noted for naturalness, simplicity and regularity of metre forms. He is fond of the ideal, the mystical, he is poetically religious and he looks upon
actions of men and the deity alike as ruled by an inexorable destiny, which recalls the Latin fates. His plots are simple in construction and development and he is free from astringency and the excessive poetic adornment which distin-

guishes works of Pedro Pescado (1801-61), José M. Heredia (1803-39) and Manual Alpuche (1804-41), contemporaries of Tagle, and very active during the stirring years that followed the establishment of the re-
publican power of the singers of a more distinctive Mexican sentiment and thought and treatment. Of these the greatest is Pescado, who, in his day, enjoyed, in the mother country, the reputation of being "a new star on the horizon of Mexican literature." Among his admirers were the Spanish poets Zorrilla, Martinez de la Rosa and Herreiras. Purity of language, care-

eful choice of words and expressions, vividness of thought and classical restraint are characteristics of Pescado's work. But it is with Jesus Hidalgo (1753-1811) and Guadalupe (1769-45) that the real spirit of Mexico, as a new na-
tion, begins to manifest itself. To Calderón is due the honor of creating for Mexico a na-
tional drama. He often went afield for his subjects when he might have found better at home; yet, inasmuch as he comprehended the way which others subsequently followed, his work is of great importance in any review of Mexican literature. Among his dramas are 'Reinaldo and Elisa,' 'Zadig-Zelita,' 'Arman-
dina,' 'Modern Politics,' 'Ramiro Count of Lu-
cena,' 'Infuego,' 'Hersilia and Virginia,' 'None of the Three,' 'The Tournament,' 'Anne Boyley' and 'Herman.' Ignacio Rodríguez Galván (1816-42), a lyric and dramatic poet of great power, imagination and passion-
ate utterance, has left two dramas distinctly Mexican, 'Muñoz' and 'The Private Secretary to the Vicerey.'

From the days of the revolution against Spain to the present, the literary life of Mex-

ico has been wonderfully active and varied. To the vanguard who breathed the breath of life into this national literary activity belong José M. Esteva (1818-98), Ignacio Ramirez (1818-

79), Guillermo Prieto (1818-94), Manuel Payno (1820-92), and Ignacio Altimirano (1834-93). Eduardo Ruiz (1832-1913), Joaquín García Icaz-
balceta (1825-94), Antonio García Cubas (1832-96), José M. Vigil (1829-1908), José M. Roa Bácena (1827-1906), Isabel Prieto de Landazuri (1831-76), Ramón Aldama (1832-92), Ignacio M. Altimirano (1834-93), Vicente Riva Palacio (1832-96), Luis G. Ortiz (1835-94), Melisio Morales (1838-83) and Rosas Moreno (1838-83). Es-
teva gave a distinctly national note to his work and was an almost universal humorist, a poet and with considerable humor, pathos and vividness, the cus-
toms, habits and peculiarities of the Mexican people, with whom he was very popular. Ramirez and Prieto, though very far apart in many respects, may be classed together on ac-

count of the unity of their aims and the strong influence they had over the Republic and democratic Mexico. They were both fire-

brands of the revolution that finally swept away all the privileges of the Catholic Church, and by their zealous and unremitting efforts to drive the French out of Mexico. Both were noted orators and their poetry takes a decidedly oratorical cast. Ramirez plays so successfully

upon all the strings of the human heart that his admiring countrymen call him "The Necro-
mancer." Prieto is the master spirit of re-

publicanism in Mexico. His is the loudest, sur-
est, most-compelling voice crying out in be-
half of the people of Mexico against privileges, entrenched abuses and foreign inter-
vention. He had a way of going right to the hearts of the people of the idol he was; and for whom he was the first to form tradi-
tions of national glory. He summoned them out of the darkness of their national glo-
gle and bade them listen to the voice of their mother-land. He called up the Mexican heroes of the past and crowned those of his own age with laurels of glory. Possessed of the true poetical fires, he set the nation aflame in an age when the passions of men were easily stirred. He was lyrical poet, roman
ci, political writer and chronicler. His best-known work is 'El Romaneco Nacional.' Payno was a political writer, biog-

rapher and historian and novelist. He was very prolific. His best novel is 'The Devil's Scarf Pin' and his history of the war between Mexico and the United States is a good presentation of the Mexican side of the question. Cuellar, an excellent comedy writer and novelist, was very successful on the stage. Among his dramatic pieces are 'The Art of Love,' 'Old Man Chacón,' 'Poor Boys,' 'Griefs and Sacrifices' and 'Natural and Figura.' Among his novels and stories are 'Salad and Chicken,' 'Chuchu,' 'Gobina,' 'Old Maids,' 'People who are Just so' and 'Gabriel the Locksmith.' Many of his most successful stories appeared in the 'Magic Lantern Series.' Isabel Prieto and Aldema were also successful and popular dramatists. The latter, who was poet, journalist and political writer, and in-
clined strongly to the melodramatic, has left numerous dramas, of which the most popular are 'A Noble Heart,' 'Pledged to Vengeance' and 'Head and Heart.' Isabel Prieto is the most noted woman dramatist of Mexico; she is also an excellent lyrical poet. Among her dramas are 'Both are the Worst,' 'Two Flowers,' 'Abnegation,' 'A School for Sisters-in-

law,' 'Gold and Tinsel,' 'A Type of the Day,' 'Thorns of Sin,' 'A Woman's Fate and Seraphim,' 'Carnival Night,' 'Sin and Penitence,' 'A Lily Among Thorns' and 'The Angel of the Hearth.'

José M. Roa Bácena is the best short-story writer of Mexico and much of his work has been translated into French, Italian and Eng-

lish. He also wrote several novels. His 'Leg-

ends of Mexico' and his 'Recollection of the American Invasion' are well and carefully written. His short stories display a saving sense of humor, keen analysis of character and excellent constructive ability.

Altamirano and Riva Palacio stood beside Prieto and Ramirez in their glorification of re-
publican Mexico. The most popular work of the former, who was a full-blooded Indian, is 'Landscapes and Legends.' Palacio, who was a noted republican general, filled many high public offices. He was a successful dramatist, poet, novelist, critic and writer of short stories, legends and political articles. With Palacio and Altamirano may be men who dug deeply into the rich mine of national life and re-
counted the glories of Mexico. Novels, lyrics,
narrative poems, dramas poured from the pen of Peón y Contreras as if by magic; for several years he held the centre of the stage in the national capital where his dramas were wonderfully popular; while at the same time his metric romances were read with avidity throughout the length and breadth of the land. 'Umb Heaven,' a drama produced in 1876, may be said to have made him famous over night. This was followed by many other dramas, which were produced in the capital as fast as they were written. Several of these were also successfully presented on the Madrid stage. Mateos, who has strong imagination, intensely oratorical, form and wonderful facility of expression, naturally turned to the drama; and the capital welcomed him as it had already welcomed Peón y Contreras; and he was bidding at the bidding of the public drama after drama, most of which were successful. Ireneo Paz also wrote successful dramas and there was little room for more of the Mexican capital to welcome them too; and when Chavez came along and repeated the act, he also was received with open arms. Thus Mexico City became the centre of a strong dramatic movement, in some ways superior to the great dramatic movement that produced the music and in other ways. These 19th century Mexican dramatists were all men of many parts. Mateos was his country's greatest romancer and historical novelist, Chavez was an archaeologist, epic poet, historian and critic of the first rank, while Paz was a journalist, political writer, novelist, historian and humorist. Meliseo Morales wrote good lyrical dramas which were staged in Italy; and he translated popular Italian operas into Spanish for Spanish playhouses. Izazalcaeta and Pimentel worked together. The former dug into the countless records of the past of America hidden in the many libraries of the republic and gave to light a long list of valuable documents for the history of Mexico. He also wrote much good original matter along the same line, a 'Political History of the Indies,' 'Mexico in 1554,' 'Mexican Biography of the Sixteenth Century,' 'Zumarraga,' a 'Dictionary of Mexican Provincialisms' and 'Mexican Physicians of the Sixteenth Century.' Pimentel worked in the same library and produced, among other works, the best 'History of Mexican Literature' extant.

Rosas Moreno disputes with Lizarditi the honor of being the most successful Mexican writer of fables. His work has become a classic in Spain. Ruiz, an excellent raconteur of legends; Ortiz, a fine poet and novelist, and Rivera, a voluminous historian, may be said to complete the period, though the latter lived on into the 20th century and was the nation's honored guest at the opening of the National University in 1910. His long life of tireless and ceaseless literary activity enabled Rivera to produce over 100 histories, critical works and booklets. Ruiz is best known by his 'Legends of Michoacan' and 'Traditions and Legends.' The connecting link between the literary activity of the Diaz régime (1876-1910) and that of the preceding years of the life of the republic and Acosta (1849-73) who, notwithstanding his short life and tragic death, exercised a wonderful influence upon the poets who followed him. He was endowed with vivid imagination and a strong literary and poetic sense which reminds one somewhat of Poe. Ignacio Montes de Oca (1840—), Manuel Gutierrez Najara (1850-95), Salvador Duran Miranda (1853—), Juan de Dios Perez (1855-1900), Jose A. Ortiz (1851-1900), G. Urbina (1868—) and Justo Sierra (1848-1911) are all names that shed lustre on Mexican literature. Flores is an epic bard with strong histrionic and dramatic talent. Gutiérrez, Najara and Sierra are among the best writers and poets in the field of tall and other field and Othon and Urbina are among the most popular singers of the present century in Mexico. But of the writers of the Diaz régime, Perez is by far the best and most popular. He published three dramas, 'A Love Affair,' 'A Real Home' and 'Columbus' which became popular. But it is his simple, heartfelt, almost homely poems that made him the literary lion of the Mexican capital. Among these are 'Songs of the Mexican Field', 'The Hymn to Our National Land' and 'Legends of the Streets of Mexico.' Mandigaviea, who is called the poet of poetry, has great breadth of imagination, a deep sense of the beauty of rhythm and imagery and a decided lyrical talent. Carlos H. Seran made comedy and native vaudeville popular in Mexico. Modern Literature. - The period of the Diaz administration was prolific in writers of talent in every line of literary endeavor, to such an extent that even a cursory review of their activities would far overpass the limits of this article. Antonio Zaragoza is the author of several volumes of fervid lyrical poetry. Francisco I. Icaza, whose work is chaste and classical in form, has been welcomed in Spain as at home. Jose M. Bustillos has taken up the song of the glory of the Mexican race and has gone back to the days of the Indian empires for many of his subjects, plots and characters. 'Rocks of the Lake' is his best work. Zayas Enriquez, biographer, historian, poet and essayist, is a talented but not over-conscientious writer. Enrique Fernandez Granados, correct in style, ardent and enthusiastic in aims, has published two volumes of excellent poetry, 'Myltes' and 'Daisies' and made excellent translations of Italian poetry into Spanish. Joaquin D. Casasus (1858-1916) and Julio Guerrero are distinguished writers on political and social subjects. Casasus also did other good literary work and translated Longfellow's 'Evangeline' and Horace's 'Odes' into Spanish verse. Guerrero's 'Genesis of Crime in Mexico' is an illuminating analysis of that character, condition, customs and tendencies. Juan Jose Tablado, Oriental in the richness of his imagination and the depth of coloring he imparts to his images, has the true lyric gift. He and Jesus Valenzuela and Amado Nero form a trio of brilliant young newspaper men who have found warm welcome in all Latin American countries and in Spain herself. Babinio Dvalos has published a book of poems and made excellent translations into Spanish from English and French; his workless imagination than that of the two above mentioned.

Francisco Bulnes and Luis Gonzalez Obre
gón are both historical investigators of note and brilliancy. Bulnes is oratorical, passionate, picturesque, vivid. Obrógen is cool, collected and severely impartial. He lacks the warmth of imagination. Bulnes and the passion which produces highly-colored pictures; but he sees clearly and illuminatingly into the past and lays it before us in all its nakedness. His published works make a long list, the best known of which is 'Old Mexico.' Bulnes The True Judges,' convincing though it is, raises a storm of protest from Mexicans all over the land.

The Ishmael of Mexican literature is Antonio Plaza. He has been damned by the educated as vulgar and unchaste; the Church has accused him of paganism and blasphemy, and the critics have taken delight in stabbing him; yet, next to Juan de Dios Peza, he has long been the most popular poet of the Mexican middle class. Plaza is a soul in revolt against the world as he found it. He has a wonderful power of the language to fittingly express it; and yet, at times, he reveals a tenderness through which shows the tortured soul behind all his railings.

Among the talented women writers of Mexico are Badillo Dolores Guerreiro and Teresa Vera and Josefa Leetchopia, who have covered practically the whole field of Mexican literature.

Historical investigation has always attracted Mexican literary men. This is due to the romantic interest of the country and its great wealth of material relating to the native races, to the Conquest and to the period of Spanish occupation immediately following. The most noted historical writers of the 17th century are Francisco de Burgos, 'Account of the Dominicans' (1597); Alonso Franco and Ortiga, Fernando de Alva Ixtlilxochitl, Augustín de Vetancur, 'Teatro Mexican'; Antonio Tello, 'History of New Galicia' (1650); Antonio de Solís (1610-86), 'History of Mexico'; and J. Villagómez Soto-Mayor, 'History of the Conquest of the Mayas.'

The historians of the 18th century have left more pretentious, better arranged and more philosophical histories and pictures of Mexican life than their predecessors. Of these historians the most trustworthy are Javier Alegre (1729-88), 'History of the Jesuits in New Spain'; Lorenzo Boturini Benaducci (1702-50), 'General History'; Andrés Cavo, 'Spanish Government in Mexico' (1766); Francisco Saverio Castellanos (1731-89), 'Ancient History of Mexico'; Granado y Gálvez, 'Indian History'; Antonio Lorenzana, 'History of New Spain' (1770); José Beristain (1756-1817), 'Biographies' and Mariano Vey- tia (1718-79), 'Ancient History of Mexico.'

The 19th and 20th centuries of Mexican historians include Lucas Alamán, Marco Aroniz, Carlos M. de Bustamante (1774-1848), Antonio García Cubas (1832-96), Luis González Obregón, Ignacio M. Altamirano, Diego de Landá, Nicolás León, Joaquín García Icazábal, Canela, Manuel Orozco y Berra (1816-81), Carlos Pereyra, Anselmo de la Portilla (1816-79), Pantaleón Tovar, Eufemio Mendoza, Eduardo Gallo, José María Vigil, Augustín Rivera (1913), Hernández Rivera, Combate Francisco Sosa (1848-). Justo Sierra, Niceto de Zama-cois, Manuel Payno (1810-94), Genaro García, Victorio Salado Álvarez, Eduarz Roa, Manuel Sanitibañez, José María Iglesias, Fernando Iglesias Calderón, Vicente García Torres, Antonio de León y Gama, Manuel Revilla and José Víctor Martínez (1810-61).

National University of Mexico.

17. HISTORY. Pre-Conquest Period.—The history of Mexico divides itself into three parts: aboriginal Mexico under the domination of its native Indian rulers, from the border land of prehistoric times to 1521; Spanish occupation from 1521 to 1821 and independent Mexico from 1821 to the present.

A score of distinct aboriginal tongues and more than 100 dialects still spoken within the confines of the Mexican Republic are evidence of the presence of numerous races that ranged the country at various periods during its prehistoric existence. These early races seem to have had considerable influence upon the traditions, mythology and customs of the people who followed them in the country. From the confused movement of the shadowy peoples of the past stand forth the forms of several more or less distinctly cultured races whose written and traditional records, legends and folklore reach back to the dim border land beyond which all is myth. The Seminole, the Seminole of the southern part of this period the great Nahe race, beginning its many years wandering from the north, crossed the Mexican boundary in the 6th century and continued southward. These migrations were participated in by numerous tribes or nations. The first of these, the Toltecs, came from the semi-mythical land of Old Tapallan under the leadership of their high priest and chief, Heumatan, he of the big hands, and arrived at Tulancingo (a short distance north of Mexico City) in 720, after 176 years of wandering. Soon afterward they established populous centres at Tula, San Juan, Teotihuacan, Cholula and numerous other places and extended their power over a wide reach of country. They are said to have been a highly civilized race, to have been builders of great and handsome cities and to have extended organized commerce for hundreds of miles beyond their own territory which, at the height of their power and prosperity, stretched from the Gulf of Mexico southward to the border of the domains of the Maya of Yucatan, Chiapas and Campeche. They had a settled form of government and
complicated, far-reaching codes of law which included military, political, social and religious regulations; and these, in their turn, were supported by racial customs and dogmas. See **MÉXICO — Mythology; MÉXICO — Literature**.

While the Nahua held the central portion of what is modern México, the Maya and other kindred races occupied the south, stretching from Campeche, Yucatán and Chiapas south and west to the Pacific and into Guatemala, where they established a civilization rivaling that of the Toltecs. Between the Maya on the south and the Toltecs on the north lay the Zapoteca and the Mixteca, almost as far advanced as they in the arts and sciences and the principles of government. All four peoples were skilled workers in metals and excellent makers of pottery and woven fabrics. They recorded their histories, traditions, religious formulas, tribute rolls and important events in complicated hieroglyphics which varied with the different races. They were good agriculturists, excellent builders and organizers and there were maintained extensive and well-affecting armies and systems of public instruction. All education was in the hands of the priests and administered from the temples, thousands of which, rising from high, truncated, pyramidal structures, covered the land. These temples were specially numerous and of notable magnificence in the Aztec land and Yucatán. See **MÉXICO — Architecture; MÉXICO — Art**.

Civil wars, internal dissensions, famine and plague are given as the causes of the disruption of the Toltec empire which came to an end in 1116, after nearly 400 years of existence. A part of the Toltec population is said to have migrated southward and to have entered the land of the Maya. It is certain, however, that many remained behind and lost their identity in the Chichimeca and other less cultured races who occupied the valley of Mexico and surrounding country. From this union sprang the famous Texcocans, whose capital, Texcoco, on the lake of the same name, preserved the civil institutions of the early Nahua and finally became the most noted centre of culture in the Mexican empire.

The Aztecs, Texcocans, Tepanecas, Chalcos and Tlaxcalans are the most notable of the Nahua tribes who took possession of the country deserted by the Toltecs. Of these the most important are the Aztecs, who began their wanderings from Aztlan, their old home in the north, about a century after the Toltecs. Six hundred years later they arrived in the valley of Mexico, where they eventually, after many struggles and privations, established themselves on two little islands in Lake Texcoco, and founded their capital, Tenochtitlán, the Place of Tenoch, their priestly leader and mighty warrior, or Mexico, the Place of Mexihli, their war god.

The Aztecs prospered, grew in numbers and extended their power over the Chalcos and other tribes bordering on the lakes of the valley of Mexico and, forming an alliance with the Texcocans and the Tepanecas, carried their conquering arms from the Gulf of Mexico to the Pacific and, from some distance north of Mexico City, southward past the Isthmus of Tehuantepec almost to the border of modern Guatemala, where they were repulsed by the Maya. The creation of this vast empire which, in extent and power, outrivalled that of the Toltecs, was due to the skill in intelligence, executive ability and warlike prowess of a line of kings which began with Acamapichtli, Prince of the Reeds (1370–1404), 30 years after the founding of Tenochtitlán. The other Aztec rulers in succession, up to the time of Cortés, were Huitzilohuaztil, Humunrugtli, Feathers (1404–17), Chimalpopoca, Smiling Shield (1417–27), Izcoatl, Obsidian Knife (1427–40), Moctezuma I, Whathy Chief (1446–69), Axayacatl, The Fly (1469–81), Taxcoatl, Lame Leg (1481–86), Ahuizotl, Water-Eagle (1486–1502) and Moctezuma II (1502–20), all of whom worked zealously for the upbuilding of the Aztec empire and the beautifying and extension of their capital.

From the beginning of the reign of Moctezuma II, Spanish navigators had been exploring the neighborhood of the Mexican coast and several had touched on the mainland of Yucatán and Campeche. In 1519 Hernán Cortés, inspired by the dream of conquering a great and powerful land with which he was brought to Cuba, set out with a small military force on his daring expedition to the lands of Mexico. On the way he defeated the Tlaxcalans, an independent nation, and the Chololans, who formed a semi-dependent province of the Aztec empire. From these he recruited a considerable native army, with which he continued his march to Mexico City, where he was reluctantly received by Moctezuma II and quartered in one of the royal palaces. He finally succeeded in making a prisoner of the Aztec ruler, who was killed a short time afterward (30 June 1520) either by the Spaniards or by the Mexicans themselves. The presence of the Spaniards in the city, the death of the emperor and the profanation of the shrines of their deities enraged the Aztecs to such an extent that they rose against Cortés and were forced to leave the city by night. In the retreat he lost his cavalry, artillery and most of his infantry. After recruiting a new army and obtaining additional war equipment, Cortés turned and laid siege to the City of Mexico which he captured (13 Aug. 1521) and afterward continued the conquest of the domains of the Moctezumas.

**UPPosOPASH Rule.**—Immediately after the surrender of Tenochtitlán the government of Mexico fell into the hands of the conquistadores who, being purely military governors, administered the affairs of the land by means of military law. Gradually the large cities were granted local governments similar to that of Spain and the province was divided into districts controlled by the central government of Mexico City. In 1528 auditors (osdorex) were introduced to keep a check on the captain-general, Cortés. They soon succeeded him and continued to govern the country until 1535 when Antonio de Mendoza became the viceroy. He was a very earnest and capable man and at once proceeded to replace the disorderly and settled form of government with the haphazard methods of the oidores and military leaders.

Spain monopolized the trade of Mexico or "New Spain." Commerce to and from the colony could be carried only in Spanish bottoms: nothing was permitted to be grown in Mexico that might in any way come into commerce.
petition with products from Spain. Only native-born Spaniards could hold office under the government in New Spain. The establishment of manufactures of all kinds was discouraged or prohibited. Yet Spain gave her colonists a strong government and one that was thoroughly under the control of the class of Indians and mestizos who composed the greater part of the population of Mexico, for it was much like the kind they had been accustomed to for centuries under their native rulers. The encouragement of literature and art, beautifying the cities and towns, the extension of great highways of commerce, the improvement of harbors, the establishment of high schools, colleges and a provincial university and the practical eradication of the native religion with its human sacrifices were far-reaching benefits which Spain bestowed upon Mexico. But the evils of her administration outran the good. The establishment of peonage and the concentration of the Indians in centres, towns, camps or haciendas under the protection of the encomenderos or which they were assigned to, both the religious and the secular, the Christianizing them soon destroyed all the machinery of the native civilization. The masses of the population, their aboriginal laws and codes of morality gone by the board, soon lost the respect and fear with which they had regarded the institution of slavery bringing with it debauchery, a loss of interest in life and a consequent loss of ambition. These and scores of other abuses created discontent throughout the viceroyalty, which was destined to show itself in vigorous protests and insurrection against Spanish authority. An unsuccessful revolutionary plot in the capital in 1808 was followed by the uprising of Hidalgo, the patriot priest of Dolores, on 16 Sept. 1810. Hidalgo, after a wonderfully successful initial campaign which brought him, with an army of 100,000, almost to the gates of the capital, was finally defeated, captured and executed the following year. The war of liberation dragged on with varying success until 1821, when the life of independent Mexico began.

Independent Mexico.—The first government of independent Mexico consisted of a council of six, with Gen. Augustin Iturbide, the commander of the revolutionary army, as president and the other members proclaiming the empire, and on 21 July he and his wife were crowned in the cathedral of the capital. But dissensions soon set in and Iturbide was forced to abdicate and to leave the country. On returning to Mexico in 1824 he was arrested, tried and shot as a traitor. Then followed many kaleidoscopic political changes in which the personal ambition of military leaders played the foremost part.

Santa Anna, who became President in 1833, and who was looked upon as a good soldier, took the field against the Texas revolutionists with an army of 6,000 trained men. Successful at first, he was defeated in 1836, captured and taken to the United States, but was allowed to return to Mexico the following year. For more than a generation, from the first days of the republic to the middle of the 19th century, the figure of Santa Anna appears ever in the foreground of the political life of Mexico guiding the destinies of the nation or watching political moves from either voluntary or forced retirement. Shortly after his return from the United States the French government sent a squadron to Vera Cruz to enforce the payment of claims against Mexico held by French citizens. Santa Anna, who had gone into one of his periodical retirements, came forth and placed himself at the head of a force to oppose the French, who finally withdrew. Santa Anna claimed the honor of having driven them from the country. This claim and the fact that he lost a leg in the encounter made him once more a national figure and a popular hero, although Mexico had been forced to comply with the French demands. But the struggle between ambitious military leaders became more intense. Santa Anna, Faredes, Bustamante, Farias, Herrera, Nicolas Bravo and others played their several parts on the constantly changing stage. The admission of Texas to the American Union as a State, 29 Dec. 1845, roused the resentment of Mexico against the United States to a high pitch. James K. Polk and Christianizing them soon destroyed all the machinery of the native civilization. The masses of the population, their aboriginal laws and codes of morality gone by the board, soon lost the respect and fear with which they had regarded the institution of slavery bringing with it debauchery, a loss of interest in life and a consequent loss of ambition. These and scores of other abuses created discontent throughout the viceroyalty, which was destined to show itself in vigorous protests and insurrection against Spanish authority. An unsuccessful revolutionary plot in the capital in 1808 was followed by the uprising of Hidalgo, the patriot priest of Dolores, on 16 Sept. 1810. Hidalgo, after a wonderfully successful initial campaign which brought him, with an army of 100,000, almost to the gates of the capital, was finally defeated, captured and executed the following year. The war of liberation dragged on with varying success until 1821, when the life of independent Mexico began.

Independent Mexico.—The first government of independent Mexico consisted of a council of six, with Gen. Augustin Iturbide, the commander of the revolutionary army, as president and the other members proclaiming the empire, and on 21 July he and his wife were crowned in the cathedral of the capital. But dissensions soon set in and Iturbide was forced to abdicate and to leave the country. On returning to Mexico in 1824 he was arrested, tried and shot as a traitor. Then followed many kaleidoscopic political changes in which the personal ambition of military leaders played the foremost part.

Santa Anna, who became President in 1833, and who was looked upon as a good soldier, took the field against the Texas revolutionists with an army of 6,000 trained men. Successful at first, he was defeated in 1836, captured and taken to the United States, but was allowed to return to Mexico the following year. For more than a generation, from the first days of the republic to the middle of the 19th century, the figure of Santa Anna appears ever in the foreground of the political life of Mexico guiding the destinies of the nation or watching political moves from either voluntary or forced retirement. Shortly after his return from the United States the French government sent a squadron to Vera Cruz to enforce the payment of claims against Mexico held by French citizens. Santa Anna, who had gone into one of his periodical retirements, came forth and placed himself at the head of a force to oppose the French, who finally withdrew. Santa Anna claimed the honor of having driven them from the country. This claim and the fact that he lost a leg in the encounter made him once more a national figure and a popular hero, although Mexico had been forced to comply with the French demands. But the struggle between ambitious military leaders became more intense. Santa Anna, Faredes, Bustamante, Farias, Herrera, Nicolas Bravo and others played their several parts on the constantly changing stage. The admission of Texas to the American Union as a State, 29 Dec. 1845, roused the resentment of Mexico against the United States to a high pitch. James K. Polk and
became law on 5 Feb. 1857 figured in every Mexican conflict during more than half a century. President Comonfort was forced to resign, thus estranging his own followers without gaining the support of his opponents. He was forced to flee the country, and his departure gave rise to internal dissensions not finally settled for years. Benito Juárez, president of the Supreme Court, claiming the presidency in accordance with the provisions of the Constitution. War divided the people and devastated the land and the reactionary party forced Juárez from the capital. In the midst of all this civil trouble, a real danger threatened the republic from without. In 1861 England, France and Spain entered into an agreement known as the Treaty of London, by which they were to send a three-fold fleet to Vera Cruz to demand of Mexico guarantees for the payment of her foreign debt and for the safety of her subjects in Mexican territory. This fleet, which appeared at Vera Cruz on 8 Dec. 1861, captured the port and proceeded to Orizaba, where a conference was held with Juárez, who agreed to comply with the demands of the powers. England and Spain at once withdrew their troops from the country. But the French, who had a secret understanding with the Mexican reactionary party, at the head of whom was Miramón, who had disputed the presidency with Juárez, remained in Mexico with the avowed purpose of subduing the country and political difficulties. The French army soon began its march toward the uplands, but it was defeated before the walls of Puebla and forced to retreat to Orizaba (1862).

The Archduke, Maximilian of Austria, and his consort, who had been selected by Napoleon III as emperor and empress of Mexico, arrived in Vera Cruz 24 May 1864. In the capital they were welcomed and crowned with great ceremony. The protest of the United States forced the French troops from Mexico, and Maximilian, left to his fate, was compelled to surrender at Queretaro in 1867. He was tried, found guilty of treason to the Mexican people and shot on the Hill of the Bells near Queretaro, together with his two guards, Miramón and Mejía, 19 June 1867.

The concerted action of the Army of the North under Escobedo and the Army of the East under Porfirio Díaz defeated the Imperialists; Mexico City surrendered to Díaz 21 June, two days after the execution of Maximilian; and on 15 July Juárez returned to the capital amid rejoicing of the populace. But opposition to the Juárez government soon developed and his administration was troubled by constant uprisings and disaffection. Juárez died suddenly 19 July 1872, shortly after he had been re-elected President. He was succeeded by Sebastián Lerdo de Tejada, who served one term and was forced out of office shortly after his re-election by Gen. Porfirio Díaz who defeated the Lerdist party at the battle of Tecocac, marched upon the capital and was there proclaimed provisional President, 24 Nov. 1876, and later constitutional President. At the expiration of his term of office, 30 Nov. 1880, he was succeeded by Gen. Manuel González, who continued the Díaz policy of encouraging the construction of railways and increasing the efficiency of the rural police charged with the protection of the country from revolutionary and robber bands.

In the winter of 1884, and for more than a quarter of a century, he continued to be the one great power in Mexico. He found the country in debt and the income of the administration inadequate to meet the demands on it. He increased the revenue of the nation over 400 per cent; he built railways, highways, roads and harbors; he drained the valley of Mexico and made the pest-ridden coast towns places of resort. He encouraged foreigners to settle in or invest in the country and to contribute their part to the program of expansion and development, and he created a credit for the nation and steadily increased and improved it. He introduced a system and encouraged honesty in the public service and prevented, to a very great extent, the misappropriation of public funds, which had been noticeable during previous administrations. He introduced a rigid and modern system of accounting and by holding the heads of the departments accountable for the funds passing through their hands With the aid of the mestizo elements, constituting fully 85 per cent of the population, began to come into its own. Thus a new social life was created under his régime, and in it the mestizo for the first time, began to play a prominent part.

Díaz found public instruction neglected and practically non-existent and he set to work to remedy this defect. Training schools for teachers were established and the higher schools and colleges were increased and improved with a view to supplying, through them, the teaching body for new primary and secondary schools. Though lack of funds hampered the work, the results achieved bore fruit in the rapid increase of the standard of intelligence in the larger towns and cities. Under Díaz the resources of the country were developed; commerce threw off its provincialism and began national and international, and new industries sprang up throughout the land. But, with government which had absolute control of all affairs of the country so long as that of Díaz, abuses were bound to creep in. About the President had grown up a strong personal party of the members of which, while professing admiration for him and his work, succeeded in enriching themselves, and friends through concessions and contracts secured their close connection with the administration. The spread of public instruction and the rise of the Indian east extent, enabled a new and restless element of the population to compete with the President, who had constantly, throughout his régime, had to curb, control and discipline. The discontent increased; Mexican exiles in the United States used every means in their power to overthrow the man they characterized as autocratic and tyrannical. Ramón Corral, the Vice-President, who was looked upon by the leader of the senatorial influence at work in the party was elected President, 24 Nov. 1880, and later constitutional President. At the expiration of his term of office, 30 Nov. 1880, he was succeeded by Gen. Manuel González, who continued the Díaz policy of encouraging the construction of railways and increasing the efficiency of the rural police charged with the
throughout the republic with great pomp and ceremony and special representatives of foreign nations gathered in the capital to lend dignity to the occasion. But scarcely had the month of national rejoicing ended when political unrest showed renewed activity. Francisco I. Madero, who had presented himself as a candidate for the presidency in opposition to Diaz and had been arrested on the charge of sedition and finally released from prison and ordered to leave the country after the elections had been held, furnished the necessary leader to the Liberals in the United States and their many sympathizers in Mexico. The active revolutionary propaganda already begun was intensified, and agents of the insurgent party spread their doctrines throughout Mexico and induced uprisings in Vera Cruz, Puebla, Chihuahua, Durango and other cities and towns of the republic; and, as Madero crossed the border to head the insurgents, similar outbreaks took place south of Mexico City, while revolutionary bands gathered in force in the north near Torreón, Gómez Palacio and Parral. The inauguration of Diaz as President (1 Dec. 1910) increased the revolutionary centres and quickened their activities, thus compelling the government to concentrate its forces over a large and constantly increasing area of territory. Radical changes were effected in the Diaz Cabinet and attempts were made to meet the demands of the revolutionaries as American troops were ordered concentrated along the Mexican border; for this move was taken in Mexico to mean a threat of intervention. The government offered to enter into peace negotiations with the insurgents, but attempts made to this end proved abortive and were suspended 6 May. Juárez fell to the insurgents 10 May, and Diaz, urged to save the country from further bloodshed and the danger of intervention, resigned, 25 May, and was succeeded in office by Francisco de la Barra, Secretary of Foreign Affairs, as President-elect pending election. Two weeks later Madero entered the capital where he was enthusiastically received. So powerful was his influence that the de la Barra administration was forced to consult him in every important matter. On 15 October he was unanimously elected President of Mexico; but scarcely had he assumed office when opposition began to develop and revolutionary intrigue to show itself within his own party. Zapata revolted in Morelos and Gen. Bernardo Reyes attempted an unsuccessful insurrection. Gen. Pascual Orozco, one of the foremost revolutionary leaders, rebelled and captured Juárez 12 Feb. 1912. Gen. Félix Díaz took Vera Cruz, but was himself captured, tried and condemned to be shot—a sentence which was commuted to confinement in the penitentiary near Mexico City. In the meantime Madero found himself unable to control those who surrounded him, to establish a stable government or to carry out the promised reforms. Military courts were established, his own troops and the students of the Military Training School at Tlapan, a suburb of the capital, rose against the government, 9 Feb. 1913, marched to the military prison and set free General Reyes, and from there to the penitentiary and liberated Gen. Félix Díaz. Practically unsupported the three generals entered the capital, where Reyes was killed in an attack on the National Palace. The revolutionists seized The Citadel, a strong fortress and ammunition depository, while the Madero forces took possession of the National Palace and the Treasury, and other points in and around the city. Both factions bombarded one another almost continuously for 10 days, when Gen. Victoriano Huerta, commander-in-chief of the government forces, brought the conflict to a dramatic close by the seizure of President Madero and Pino Suárez, the Vice-President, who were forced to resign their respective offices. Pedro Lascurain, Minister of Foreign Relations succeeded to the presidency. He appointed Huerta his minister of foreign relations and resigned in his favor. Thus, in one day Mexico had three Presidents. On the morning of 23 February Madero and Pino Suárez were murdered, presumably by agents of the Huerta government. For this act, Venustiano Carranza, governor of Coahuila, disavowed the new government and issued the Plan of Guadalupe which called for reforms in the administration, equitable taxation, extension of the educational system and the solution of the land problem (March 26). President Wilson dispatched John Lind to Mexico City to try to establish a representative with a view to bringing the opposing parties together; but Huerta's refusal to be eliminated as a presidential candidate and his arrest and imprisonment of 110 Congressional deputies and the forcible dissolution of Congress (10 and 11 October) made any compromise impossible. A new election held on 26 October, under pressure, resulted in the election of Huerta as President. The new Congress, which met on 15 November, in view of a protest from Washington, declared void the election of the President and Vice-President but confirmed Huerta in the office of provisional President. The Constitutionalists determined to make no compromise with Huerta, and the war went on. Villa took Juárez 15 November; other important places fell and early in 1914 Villa captured Ojinaga, after the Federal garrison of 4,600 had retreated across the American border. Then turning southward he took Torreón in April. While Mazatlán and Madero was unanimously elected President of Mexico; but scarcely had he assumed office when opposition began to develop and revolutionary intrigue to show itself within his own party. Zapata revolted in Morelos and Gen. Bernardo Reyes attempted an unsuccessful insurrection. Gen. Pascual Orozco, one of the foremost revolutionary leaders, rebelled and captured Juárez 12 Feb. 1912. Gen. Félix Díaz took Vera Cruz, but was himself captured, tried and condemned to be shot—a sentence which was commuted to confinement in the penitentiary near Mexico City. In the meantime Madero found himself unable to control those who surrounded him, to establish a stable government or to carry out the promised reforms. Military courts were established, his own troops and the students of the Military Training School at Tlapan, a suburb of the capital, rose against the government, 9 Feb. 1913, marched to the military prison and set free General Reyes, and from there to the penitentiary and liberated Gen. Félix Díaz. Practically unsupported the three generals entered the
May 24 June, without being able to find a solution for the troubled conditions in Mexico. On the day they adjourned González took Zacatecas and, two weeks later, Obregón entered Guadalajara; and in July, San Luis Potosí, Manzanillo and several smaller places fell to the Constitutionalists. Huerta, forced to resign, 15 July, was succeeded by Francisco Carabajal, Minister of Foreign Relations, who at once entered into communication with the Constitutionalists and resigned in favor of Carranza, 13 August. Two days later Obregón took possession of the capital, where Carranza arrived on 20 Aug. 1914.

With the elimination of Huerta and the success of the Constitutionalists, bitter dissensions appeared in the heterogeneous elements composing the party. A convention of generals called to meet in Mexico City on 1 October served only to intensify the trouble and the convention was moved to Aguascalientes, where, dominated by Villa, it disallowed the claims of Carranza and elected General Gutiérrez provisional President. This was also decided upon Mexico City and, compel Carranza to yield to the will of the Convention. In the face of this threatened danger, the latter went to Puebla and, from there, to Vera Cruz on the withdrawal of the American forces from Mexico 23 November. Zapata and Villa at once occupied the capital and Gutiérrez set up his government there (3 December). In January 1915 the Convention, disowning Gutiérrez, proceeded to govern Mexico City in its own name; but the approach of Obregón with a strong force compelled it to abandon the capital, which was occupied (26 January) by the Carranza commander, who, in turn, was forced to retreat before a Zapataist horde, 10 March. Two weeks later Villa recognized as convention provisional President Gen. Roque González Garza.

One of the dramatic incidents of the year was the siege of Naco, Sonora, by General Mayortena. Five Americans were killed and 30 or more wounded by shots coming across the border. Washington warned both the contending parties to refrain from firing into American territory. Early in January General Scott, representing the American government, and Villa had a conference at which, it was agreed to withdraw the contending forces from Naco. In the meantime the Convention, party was faring badly in the north. Guadalajara fell to Carranza and Villa was defeated at Celaya in March. Other disasters followed and finally Washington notified the Constitutional and Convention parties, 2 June, that unless peace was restored soon, the United States would be compelled to support some man or group of men capable of bringing order out of chaos. Meanwhile raids were being frequently made across the Texas border by bands from Mexico instigated from without Mexico by certain predatory interests, and finally, on the night of 9 March 1916, an armed band of Villistas attacked Columbus, N. M., killing eight soldiers and wounding several others, and then went into Washington. At one time 17, March, and sent into Mexico 12,000 troops under General Pershing with orders to take Villa dead or alive. Carranza refused a request from the American government for permission to ship, over the Northwestern Railway, supplies to Pershing's forces which were finally compelled to come to a halt at Parral, where several American soldiers were killed and others wounded in a surprise attack.

In April General Scott, chief of staff, was sent to the Mexican border to report to Washington on the situation, held a conference with General Furst, commissary of the American forces of the frontier, and General Obregón, Mexican Minister of War. The latter insisted on the withdrawal of the punitive expedition from Mexico, and this was conditionally agreed to, 2 May. Carranza, charging the American government with faith and asserting that the presence of United States troops in Mexico proved a constant source of irritation and weakened the hands of the Mexican authorities, refused to ratify the agreement Washington replied by renewing the course of events in Mexico and charged that the Mexican government apparently did not wish to see the border raiders captured. On 18 June the American militiam was ordered to the Mexican border two days after General Pershing had been ordered to prevent the movement of the Pershing expedition in any direction except homeward and to oppose the entrance of further American troops into Mexico. In pursuance of this order an American force of some 900 troops attacked at Carrizal and a number of officers and troopers killed and 17 taken prisoners. On a peremptory demand from Washington the latter were released, 22 June 1916. Carranza began to show a more friendly front, and proposed the naming of commissioners by the American and Mexican governments to consider the issue between them, 12 July. The proposition was accepted and Luis Cabrera, Minister of Finance, Ignacio Bonillas, Minister of Communications and Alberto Pani, head of the National Railways, representing Mexico; met in New London, Conn., with Franklin Lane, Secretary of the Interior, Judge George Gray and Dr. J. R. Mott. After many subjects had been discussed Carranza declared that he approved the agreement, and finally the troops of the United States were withdrawn from Mexico without having accomplished an definite result.

A constituent assembly whose members were chosen at elections supervised by the Carranza army met at Querétaro. That assembly made radical changes in the constitution of 1857 which were promulgated on 5 Feb. 1917 and went into operation 1 May 1917. This provided for the democratization of the judicial system, collective bargaining, a minimum wage, compulsory profit-sharing, a free labor bureau and protection against trusts. It also provided for confiscation by the government of churches, schools and hospitals in the possession of religious bodies; and that all clerics be native born. A congress was elected and began its sessions on 15 April 1917, on which occasion President Carranza declared that the nation would continue to be neutral in the European War. Many Germans fled from the United States to Mexico, and these were accused of fomenting trouble for the Entente. General charges were made in the United States and in Britain usually by capitalists interested in Mexican mines or their agents, that Mexico, notw
standing her proclaimed neutrality, was secretly encouraging the Germans. However, the connection of the Mexican government, if it ever existed, with that movement, has never been proved. From 1917 to 1919 there was friction between the Mexican government and the foreigners resident in the country over taxes and restrictions placed on mining and oil properties in the Republic, both of which national assets the government rightly aims at nationalizing and protecting from exploitation by predatory foreign corporations. In 1916 the national currency was rehabilitated so as to give it a recognized and regular standard of valuation. In 1919 President Carranza issued a public statement that, in conformity with the provision of the constitution which prohibits re-election for second term of the chief official of the Republic, he would not again be a presidential candidate.

18. DIPLOMATIC RELATIONS OF THE UNITED STATES WITH MEXICO.

Early relations were largely determined first by the Mississippi question and later by the failure to define the western limits of Louisiana in the treaty of 1803 and consequent friction with Spain after 1805. The American government viewed with sympathy the Mexican revolutions, beginning in 1810, and later accorded belligerent rights to the revolutionary government which was aided by filibustering expeditions from the United States; but it endeavored to maintain neutrality until 1822 when, after the final ratification of the Florida Treaty with Spain, it recognized Mexico as an independent nation. The government promptly opened Texas to American immigration.

At the close of 1822 José M. Zozaya was accredited first Mexican Minister at Washington, but the real beginning of the Mexican legation dates from the arrival of Balboa in Oregon in November 1824. In March 1825, the American government sent Joel R. Poinsett as Minister to Mexico to recover the prestige lost by delay, but his methods aroused increasing distrust and suspicion which postponed the completion of treaty negotiations and finally led to his recall. After successfully opposing the plans of Mexico to unite with Colombia for the liberation of Cuba, he negotiated a Treaty of Commerce of July 1826 and another treaty of February 1828, both of which failed in the Mexican Congress after ratification by the American Senate. He hastily concluded a Boundary Treaty of January 1828 which was lost by delay in the Mexican Congress, but was revived in 1832 and ratified following the ratification of the new Treaty of Amity and Commerce negotiated in April 1831 by Anthony Butler, the successor to Poinsett. Meanwhile there arose new sources of friction which produced strained relations after 1829, temporary severance of relations in 1836 and finally (a decade later) resulted in war. In Texas, which the United States unsuccessfully attempted to purchase in 1825, 1827 and 1829, internal troubles arising from differences between the Mexican government and the American colonists, and increasing after the Mexican attempt to prohibit American immigration in 1829 and the Mexican establishment of military posts in 1831, finally resulted in a successful revolution of 1835, in which many Americans participated and also won American recognition (in 1837) of Texan independence—which, together with other grievances, aroused the hostility of Mexico. Relations temporarily severed in 1836 were again seriously threatened in 1837 by the withdrawal of the Mexican Minister who was not replaced by a successor at Washington until 1842. In 1835 President Jackson, renewing proposals to Mexico for purchase of Texas, authorized negotiations for a boundary on the parallel of 39° westward from the Nueve Granda to the Pacific, but in 1837 he declined Texan offers of annexation.

Relations were also endangered by Amer-
ican claims (against Mexico) which in 1837 brought the American government to the verge of reprisals by force. Attempts at adjustment were made by the Convention of 1838 which was ratified by both parties in April 1839 and made effective by acts of Congress approved on 12 June 1840 and on 1 Sept. 1841. These claims, allowed by a later Convention of 1843, were only partially paid, and later negotiations for another Convention were prevented by war.

Following the American annexation of Texas by joint resolution in March 1845 (after failure of the Senate to ratify an American-Texan Treaty of Annexation), Mexico again severed relations and later refused to receive John Slidell whom President Polk sent to Mexico to re-establish relations and to negotiate for adjustment of the American government, and by another Convention which was ratified by both parties in April 1839 and made effective by acts of Congress approved on 12 June 1840 and on 1 Sept. 1841. These claims, allowed by a later Convention of 1843, were only partially paid, and later negotiations for another Convention were prevented by war.

These claims, allowed by a later Convention of 1843, were only partially paid, and later negotiations for another Convention were prevented by war.

Peace negotiations following the war were begun by the American government in April 1847 after important victories at Buena Vista and Vera Cruz. Nicholas P. Trist was sent as confidential agent with instructions similar to those of Slidell and with full powers to conclude a treaty of peace at a propitious moment. In November 1847, however, he received instructions to return. Unexpectedly detained, he finally determined to remain; and without the authority of his government, he negotiated the Treaty of Guadalupe Hidalgo of 2 Feb. 1848, by which the Mexican government ceded New Mexico and Upper California for $15,000,000 and the American assumption of all Mexican claims against the United States. This treaty, including all Polk's sine qua non except the right of transit over Tehuantepec (which had become less important by the recent acquisition of rights over a better route by the Treaty with New Granada), on its arrival at Washington was hastily accepted by Polk, who, although he refused to pay the salary of the "impudent" clerk, was anxious for peace.

For over a quarter-century after 1848, relations were disturbed by border turbulence, filibustering expeditions, Mexican internal troubles, questions of new claims and of protection of transit routes and apprehension of European designs or of foreign intervention.

In compliance with a demand for additional territory, James Gadsden concluded with Mexico in Treaty of 30 Dec 1853, by which the United States for $10,000,000 obtained south of the Gila River a strip of territory including the Mesilla Valley, and also a right of transit across the Isthmus of Tehuantepec where conflicting interests complicated later negotiations and relations.

The Mexican problem, which thrice had been adjusted by change of boundaries, still persisted after the Gadsden Purchase. Complicated with Southern interests, and largely under the influence of Spanish claimants, it was remedy most persistently proposed for its solution, in connection with an American transit

route across Mexico, was an additional relation of Mexican territory by a new cession to the United States, or, if that should fail, the establishment of an American protectorate which would be dependent on the United States for annexation to the stronger country. The problem, only partially solved by the Pierce administration, was inherited by the Buchanan administration, which continued to negotiate for a treaty. First, Convention of 1859 and then, in 1861, a later Convention of 1843, were only partially paid, and later negotiations for another Convention were prevented by war.
For a decade after the withdrawal of the French, Mexico was disturbed by domestic contention and by the presence of foreign forces and by lawlessness which at times impaired good relations and gave rise to troublesome questions and difficulties reaching an acute stage after November 1876, when the constitutional order of Mexico, which the United States had continually recognized for 17 years (since 1859), was overthrown by the successful military revolution of Gen. Porfirio Diaz. The cattle raids from Tamaulipas on the Lower Rio Grande, which had caused trouble since 1848 and had become prominent in the remarkable incident known as the Cortina war in 1859–60, but had declined during the Civil War, were renewed at the close of the campaign against Maximilian, and culminated in the Corpus Christi Raid of 1875 which attracted the attention of the American government to the precarious position of Americans along the border. These raids and depredations were intimately connected with the collateral question of the condition of the free zone along the Mexican side of the Rio Grande and the subject of extradition. Meantime the American government continued a temporizing neglectful policy, but in 1875, it sent additional troops to the border and finally on 1 June 1877, authorized Federal forces to cross the border in hot pursuit.

The dangerous breach in relations of amity was for a time widened by the delay of the American government under President Hayes to recognize the government of Diaz. Finally the American Minister (John W. Foster), who had advised against the withholding of recognition, received authority by which he promptly placed himself in official relations with the Diaz government on 11 April 1878, nearly a year after it had been recognized by the other powers. Meanwhile, in December 1877, the House of Representatives adopted resolutions looking toward a consideration of the best means of removing the existing and impending causes of difference and of confirming and enlarging commercial relations.

The friendly feeling manifested following recognition of Diaz was of brief duration. Negotiations, which encountered delays, were rendered more difficult by complications resulting from internal disorders and from the excesses of the American forces again crossed the border in hot pursuit of marauders in the spring and summer of 1878. Diaz, induced by Mexican clamor, demanded the withdrawal of the American forces; for a border in March 1879, the American government in 1880 withdrew the order for crossing the border.

At the same time by the steady growth of centralized power in Mexico, relations had become increasingly friendly. The danger from Mexican internal disorders had largely disappeared in 1880, when Diaz retired and acquiesced in the election of his lieutenant whom he succeeded by re-election four years later. Border conditions rapidly improved. A reciprocity treaty was signed in 1882 and troublesome questions of the "free zone" and extradition were settled by convention (May 1906) for the equitable distribution of the waters of the Rio Grande for irrigation purposes and the negotiation of an arbitration treaty in 1908. It was especially illustrated by the American-Mexican cooperation in the 1907 plans tacitly initiated by the United States to maintain order in Central America.

The growing intimacy of relations during the long presidency of Diaz, indicated by many international agreements, culminated in a general treaty of arbitration and the meeting of Taft and Diaz in 1910.

Relations again became strained after 1911 in connection with the collapse of the Diaz government and by conditions of the Maderista revolution, both in Mexico and along the border, which were a source of much concern to the United States.

The American government under President Taft, although it mobilized troops on the frontier, declined to intervene, and with difficulty maintained neutrality—both before and after
it recognized the new government of Madero, which was finally overthrown in February 1913 by Felix Díaz and General Huerta. In 1912 the rumor of Japanese plans to secure a harbor at Magdalena Bay caused the Senate to pass an opposing resolution which, however, was not accepted by President Taft.

President Wilson’s new policy of using non-recognition as a means of discouraging the establishment of governments based on force and violence, the American government refused to recognize Huerta, unsuccessfully urged an early free election in Mexico, warned Americans to leave that country and vigorously demanded both the de facto government of Huerta and insurrectionists to respect lives and property of Americans.

In April 1914, after a series of irritations and insults it sought separation by a naval and military force which occupied Vera Cruz; but, with certain restrictions, it promptly accepted friendly mediation of the A B C powers of South America (Argentine, Brazil and Chile), which in May 1914 considered plans for settlement of the internal and external difficulties of Mexico.

Finally, after the failure of an appeal (by a Latin-American conference at Washington) to the rival factions to settle their differences, the American government, on 19 Oct. 1915, recognized the Carranza government as the de facto government of Mexico.

In March 1916 a new trouble arose from an attack of Villistas on the American town of Columbus, N. Mex., instigating the American government to send a punitive American force under General Pershing into Mexico in hot pursuit. Carranza protested and insisted upon withdrawal while the United States, refusing to rescind from a settled determination to maintain its national right and its duty to remove the peril, called 150,000 militia to the border. The situation during a period of negotiations was complicated by a new raid of Mexican bandits into Texas. An encounter with Mexican troops, resulting in casualties on both sides and capture of 17 Americans as prisoners, threatened to produce a final crisis which was averted only by Mexican acquiescence in the American demand for immediate release of the prisoners. The strain of the situation continued until complications were solved by agreement upon a joint commission of six members, who, however, could not reach an acceptable plan of action. Early in 1917, the American government, after gradually withdrawing American troops, sent an ambassador to the Mexican government of Carranza under whose auspices preparations for better conditions were begun by the adoption of a new national Constitution.

Later relations were affected by conditions relating to the World War. In February 1917 when the American government was becoming more determined in its resistance to Germany’s piratical acts against American rights upon the seas, Mexico proposed to neutrals to invite the European belligerents to terminate the conflict, or, in case of failure, to reduce the congestion by refusing any kind of implements and by suspending commercial relations. In reply the American government, declaring the proposal a recently discovered plot of the German government to induce Mexico to negotiate an alliance with Japan for war against the United States by offering Mexico at the price her submission to Germany, and the recovery of territory ceded to the United States in 1848. Although the Mexican government denied any participation in the plot, German influence in Mexico continued inimical to the United States.

West Virginia University.

MEXICO, a state of the United States of Mexico, in the southeast; bounded by the size of Hidalgo on the north, on the east by Calca and Puebla, on the south by Morelos and Guerrero, and on the west by Michoacan and Queretaro. Adjoining the state of Morelos is the federal district enclosed by the state of Mexico but outside of its limits. The area of the state of Mexico is 9,247 square miles and its population about 1,000,900. The capital is Toluca. Several railroad traverse the size and centre in Mexico City.

MEXICO, Mo., city, county-seat of Adrain County, on Salt River and on the Wabash, Chicago and Alton and the Burlington roads; about 115 miles northwest of St. Louis. Mexico was settled in 1833 and in 1858 was incorporated. It is in an agricultural section, the chief products of which are wheat and corn. The manufactures are dressed nubile, flour, shoes, cigars, stove lining, fire-brick products. Mexico is the centre of the saddle-horse producing section of the West. It has also in mules and livestock and has recently completed 18 miles of electric railway used to Santa Fe, Mo. and corn, hemp and beets are principal products. Mexico is the seat of the Missouri Military Academy and of the Marlin College for Women, founded in 1873. The charter under which the government is administered was adopted in 1866, and provides for a mayor who holds office two years and a council. Pop. 5039.
